Ma, Qi, and Wang (2008) also examined the impact of some key contextual factors that affect

knowledge sharing within project teams in the Chinese construction sector. They found that trust is positively related to knowledge sharing. In their study, Dhanaraj, Lyles, Steensam, and Tihany (2004) also found that tie strength, trust and shared values are important in tacit knowledge transfer in international joint-ventures. Some other studies also showed that knowledge sharing, communication, and learning in organizations are strongly influenced by cultural values of individual employees (Hutchings and Michailova, 2004; Ardichvili, Maurer, Li, Wentling, and Stuedemann, 2006).

King (2008) focused on the various levels of culture in terms of how they can affect knowledge management practices and outcomes. He developed a conceptual framework that can be used by a firm to address culture-knowledge management relationship issues. Ang and Massingham (2007) examined the affect of national culture on knowledge management for multinational companies and proposed a framework for standardization and adaptation of knowledge management processes based on differences in national culture. They found that the level and nature of impact will vary by knowledge management's processes or sub-processes. Pauleen *et al*. (2007) developed a model to explain the influence of national culture on organizational knowledge management processes. Their model proposes that national culture affects organizational knowledge management processes both directly and indirectly.

Marshall, Prusak, & Shpilberg (1996) indicate that it is not easy to encourage voluntary sharing of knowledge by employees, particularly in financial trading firms where competition is fierce. Davenport and Pursak (1997); Kluge, Stein and Licht (2001); Kankanhalli, Tan and Wei (2002); Keong and Al-Hawamdeh (2002), all refer to the 'knowledge is power syndrome'. If the view of employees is that knowledge is power this will make sharing of knowledge 'an unnatural act in most organizations', and if knowledge is seen as a valuable resource then any situation that may allow knowledge to become public could be seen as threatening (Keong and Al-Hawamdeh 2002). Kluge, Stein and Licht (2001) refer to the 'not invented here' syndrome which they explain as 'the tendency to neglect, ignore or, worse still, disparage knowledge that is not created within your own department' and say the situation can arise through a mistrust of external knowledge. Keong and Al-Hawamdeh (2002) also make reference to the 'not invented here' attitude saying that this attitude can have a detrimental impact when striving to promote knowledge sharing.

Concern about job security is another aspect of sharing that brings a strong resistance to sharing of knowledge (Darling 1997). Darling continues, 'A knowledge culture devotes itself to increasing and sharing knowledge and involves every person in those vital tasks' Resistance to knowledge sharing is evident in comment referred to by Darling, 'this stuff about knowledge sharing is nothing more than me dumping what I know in a pool so I will become dispensable' It may be that if their employment is threatened people will not be inclined to share their knowledge and may even leave the organization taking with them the very knowledge that could have given value to it. The ageing population of many industrial countries is a further aspect of knowledge sharing that needs to be addressed and is raised by Keong and Al-Hawamdeh (2002). So often the knowledge accumulated over many working years is not captured so that the considerable pool of knowledge and experience possessed by such employees is lost to the younger generation. They also indicate the detrimental effect on the organization of the loss of knowledge when resignations, and promotions occur. However, for those who are made redundant there is perhaps a more difficult situation to deal with—they frequently feelings of resentment and asking them to share their knowledge before leaving is likely to be a difficult task.

Resistance or lack of interest in sharing knowledge deprives others of the opportunity to gain knowledge and can in fact rebound on those who are not very willing to share. Many organizations have intranets to enable employees to share, exchange, and access knowledge, but if a non-sharing culture exists there will be little benefit for the organization or its employees. It is possible that employees may not find the intranets user friendly, therefore, there is likely to be resistance to sharing knowledge through that system, or for some it may simply be too much of a hassle to try to find what is being sought (Mitchell 2003). Where resistance to sharing knowledge attitudes exist, organizations need to consider undertaking an approach to implementing behavioral patterns amongst staff that are conducive to knowledge sharing. Regular meetings for the purpose of discussing work-related experiences provide an avenue for sharing knowledge that generates a collaborative environment and one through which everyone benefits.

3. PREVIOUS STUDIES

Previous studies and experiences in the construction industry showed that cultural have an impact on knowledge sharing, either negative or positive of construction enterprises working. However, exactly how culture affects management is still a difficult question to answer (Shore and Cross 2005).

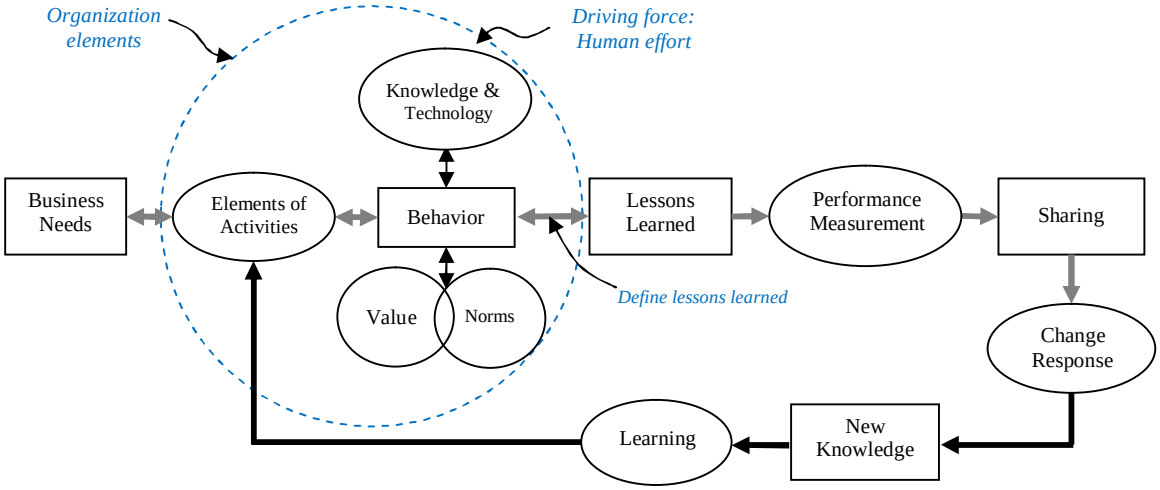

Figure 1 : An Overview of Organization Elements Driven Successful lessons

4. UNDERSTANDING THE KEY DRIVERS FOR SUCCESSFUL LESSONS LEARNED

By understanding how culture influences knowledge sharing in their organizations, can be illustrated specific actions for adapting the organization's culture to support the behaviors needed as overview figure 1:

4.1 Business Needs

Define the activities of business: Coming up with new ideas; Improving implementation and processes. Identify the business needs e.g. reduce project time and cost, improve quality. Finding the gap between the status quo and these activities; Tie the needs to strategic objectives.

Determine what the organization wants to be able to do. e.g. improve efficiency, provide a better quality service. Identify who could provide the requirement; consider potential options for meeting the need.

4.2 Elements of Activities

Element of activities or practices are the formal or informal routines used in the organization to accomplish work. Practices include project implementation processes, key activities, team meetings, time sheets, career paths, compensation plans, etc. Each practice – formal or informal – has specific roles and rules (often unspoken) guiding how they are carried out (Trice and J.M. Beyer, Cliffs, 1993). Work processes: include encourage people to work together more effectively, to collaborate and to share - ultimately to make organizational knowledge

more productive (David Gurteen, 1999). But we need to remember a few things.

4.3 Knowledge and Technology

The ultimate goal of knowledge management is the sharing of knowledge (Tserng and Lin, 2005). The majority of the managers also highlighted the importance of knowledge sharing and pointed out the direct relationship between knowledge sharing and culture. Previous studies and experiences in the construction industry showed that cultural differences have an impact on daily businesses, either negative or positive, of construction enterprises working nationally or internationally. However, exactly how culture affects management is still a difficult question to answer (Shore and Cross 2005).

Gurteen(1999) state that Knowledge Management is fundamentally about people – not technology. But absolutely no way that you can share knowledge effectively within an organization without using technology. The role of IT in a KM system is as a facilitator as previous attempts to capture personal experiences proved unsuccessful (Carrillo *et al.* 2004). There is a need to incorporate technologies that augment existing work practices, with the development of an IT strategy being important in improving its effectiveness (Egbu and Botterill 2002). *"IT systems don't manage knowledge; they manage data and information (Prusak, 2006)."*

The Knowledge content generation tools include various authoring tools (Bergeron, 2003) – word processing editors, multimedia editors, graphics programs, image and sound editors, video editing systems, as the focus is put on time-saving and efforts-saving technologies facilitating the process of creation of relevant high-quality content. Another technology allowing the generation of knowledge from data is knowledge discovery, defined in (O'Leary, 1998) as "nontrivial extraction of implicit, previously unknown, and potentially useful information from data."
Knowledge discovery is a method that includes different tools and approaches to analyze both text and numeric data. As an example of a class of technologies for knowledge discovery could be mentioned data mining tools or the process of extracting meaningful relationships from usually very large quantities of seemingly unrelated data. Specialized data mining tools allow managers to perform competitive analysis, market segmentation, trend analysis, sensitivity analysis, and predictions based on information in the corporate database (Bergeron, 2003).

4.4 Elements of Organization Culture

Schein (1985) defines organizational culture as a set of implicit assumptions held by members of a group that determines how the group behaves and responds to its environment.
These tacit values and beliefs determine the more observable organizational norms and practices that consist of rules, expectations, rituals and routines, stories and myths, symbols, power structures, organizational structures, and control systems (Bloor & Dawson, 1994; Johnson, 1992). In turn, these norms and practices drive subsequent behaviors by providing the social context through which people communicate and act (DeLong & Fahey, 2000). Putting this into the context of knowledge management, organizational culture determines the social context (consisting of norms and practices) that determines "who is expected to control what knowledge, as well as who must share it, and who can hoard it" (Delong & Fahey, 2000). Figure 1 illustrates this conceptual linkage between culture and knowledge management behavior.

Culture exists at different levels of the organization. Values are deeply embedded, tacit assumptions that are difficult to talk about and even more difficult to change. Norms and practices, on the other hand, are more directly observable and easier for employees to identify. Thus, norms and practices around knowledge use are more amenable to change. In fact, practices are the most visible symbol of culture, and they provide the most direct levers for changing behaviors needed to support knowledge management objectives. Changing behaviors around knowledge use is the most direct way to alter organizational norms, which will reinforce the necessary behaviors over time.

Values

Values indicate what an organization's members believe is worth doing or having. They indicate preferences for specific outcomes or behaviors, or what the organization aspires to achieve. It is important to differentiate espoused values, which are talked about but that don't influence behavior, from values that truly motivate behavior in a firm (Trice and J.M. Beyer, Cliffs, 1993). Schein (1992) state that value can be understood as the stated and unstated preferences and principles shared by members of an organization. Examples include loyalty, customer satisfaction, innovation,

diversity, and teamwork. Schein's rationale can be summarized thus: once the (a) espoused values become (b) employees' shared values and beliefs, they can turn into (c) expected behaviors and attitudes. After they do so, those behaviors and attitudes develop into (d) shared assumptions or basic underlying assumptions. Around the entire process there are artifacts, which are helpful illustrations of values. Values are beliefs on how people should behave with regard to such matters as care and consideration for colleagues, customer service, the achievement of high performance and quality, and innovation (Handy, 1993). Green. S (2005) state that there are three attributes to a core competence: it adds value to customers, it is not easily imitated and it opens up new possibilities in the future (Youker, 2006).

Newcombe (1997) defined a project's culture as: 'the shared values, beliefs and assumptions of the stakeholders involved in a project'. Its positive consequences include: enhanced project effectiveness; reduced parochialism and rivalry; and ability to reconcile conflicting project strategies. Its negative consequences include difficulty to introduce change and innovation.

Norms

Norms are the shared beliefs about how people in the organization should behave, or what they should do to accomplish their work. Norms represent the *expected* patterns of behavior. For example, they describe how employees *actually* create, share, and use knowledge in their work (Trice and J.M. Beyer, Cliffs, 1993). Norms are unwritten but accepted rules which tell people in organizations how they are expected to behave. They may be concerned with such things as how managers deal with their staff (management style), how people work together, how hard people should work or the extent to which relationships should be formal or informal (Handy, 1993).
A norm is a behavior (way of doing things, custom) that the group practices on an ongoing basis. A norm serves as a "ground rule" for the group's behavior. Through a process of consciously creating norms for the group, positive norms can be selected (Rochelle Kopp, 2005; http://www.japanlink.com/en/business/pdf/hybrid.pdf).

The following are some general examples of the types of topics that can be addressed when creating norms for a hybrid culture. However, the specific issues that should be addressed for a given team will depend on its situation and challenges.

- What language should be used when?
- How should documents and correspondence be handled?
- How should information be reported? To whom? How often? In what format (oral, written, meeting?)
- What should be the frequency and type of regularly scheduled meetings?
- How to ensure that meetings and conversations are readily understandable for non-native speakers of English?
- How to ensure that all participants contribute equally to the discussion, and that the discussion is not dominated by individuals who are more vocal or fluent in English
- What degree of *nemawashi* (consensus-building pre-meetings) should be conducted prior to meetings? Will decision-making be done by consensus, majority rule, or determination of the senior individual present?

What then does it mean to create a Knowledge Sharing Culture?" Well it's about making knowledge sharing the norm. To create a knowledge sharing culture you need to encourage people to work together more effectively, to collaborate and to share - ultimately to make organizational knowledge more productive David Gurteen (1999). But we need to remember a few things:

- We are talking about sharing knowledge and information – not just information.
- The purpose of knowledge sharing is to help an organization as a whole to meet its business objectives. We are not doing it for its own sake.
- Learning to make knowledge productive is as important if not more important than sharing knowledge. Michael Schrage in a recent interview said that he thinks, "knowledge management is a bullshit issue" as "most people in most organizations do not have the ability to act on the knowledge they possess".

Changing a culture is tough. Not only does it mean change – which has always been tough – it means seeing the world in a different way. It means revealing our hidden paradigms like the tacit acceptance that "knowledge is power".

4.5 Lessons Learned

The aim of lessons learned is to convey knowledge gained through experience, in some specific field of action, as means to enhance future performance. Few studies provide a definition of the lessons they present or explore the concept of lessons learned. The *PMBOK® Guide* defines Lessons Learned as "The learning gained from performing the project. Lessons Learned may be identified at any point." Learning can come from successes where we did something creative or imaginative and we would like to see it repeated on future projects and learning can come from our failures where something failed to meet our expectations and we would like to improve and not make the same mistake again. It would be nice to say most of the learning comes from our successes, but the reality is that most of the learning comes from our failures. Cowles (2004) state that a lessons learned is knowledge or understanding gained by experience contain negative experience and positive experience. A lesson must be significant, valid, applicable, and could describe a problem or issue that the organization will investigate. "*A lesson learned is knowledge or understanding gained by experience. The experience may be positive, as in a successful test or mission, or negative, as in a mishap or failure…A lesson must be significant in that it has a real or assumed impact on operations; valid in that is factually and technically correct; and applicable in that it identifies a specific design, process, or decision that reduces or eliminates the potential for failures and mishaps, or reinforces a positive result* (Secchi, 1999 in Weber 2001)*.*"

Lessons learned is forms of knowledge artifacts. *A knowledge artifact is a defined piece of recorded knowledge that exists in a format that can be retrieved to be used by others. A process drawn on a napkin at lunch can become a knowledge artifact if it can be recorded for someone else to use. Typically artifacts are something more tangible – i.e. a document, a picture or graphic, a video, an audio, a project plan, a presentation, a template … to name several (Seiner, Robert S., 2001).* What one user may consider a valuable lesson learned another may consider inconsequential or non-relevant information. It is critical to establish a common understanding as to what type of information (i.e., knowledge artifact) is a candidate for sharing using this system.
"The lack of leadership involvement in and commitment to the learning process is the most critical barrier." (Dressler, 2007) An effective Lessons Learned process means having a disciplined procedure that people are held accountable to follow. It means encouraging openness about making mistakes or errors in judgment. It often means cultural or organizational change, which does not come easy in most organizations. It means leading by example. If management is unwilling to learn from their mistakes, it is unlikely that the rest of the organization will be willing to admit to mistakes. In fact, management must reward people for being open and admitting to making mistakes, bad decisions, judgment errors, etc. This, of course, flies in the face of many corporate cultures.

Lessons Learned captured on a project seldom benefit that project. They benefit future projects. Often, a project manager sees capturing Lessons Learned as simply another chore that provides his or her project with little value, especially if the Lessons Learned procedure is complex, takes a fair amount of resources and time to implement, and management has not provided adequate resources to perform the work. The solution here is to have a simple procedure, ensure projects have the resources and time to implement the procedure, and hold project managers accountable for following the procedure. The "lack of value to my project" problem can be alleviated by proving to people the value of Lessons Learned to the organization and by ensuring that projects in the planning stages incorporate Lessons Learned from prior projects.

4.6 Performance Measurement

In an attempt to address successful lessons learned, characteristics of emerging performance indicators have been proposed by different researchers (Kaplan and Norton, 1992; Lynch and Cross, 1995; Neely, 1999; Love and Holt, 2000; Neely and Adams, 2001). It is of agreement that the formation of indicators should start with analysis of both the organizational complexity and the operating environment characteristics. Common issues that are used to describe these include:

- The changing nature of work;
- Increasing global competition;
- Specific improvement initiatives;
- National and international quality awards;
- Changing organizational roles;
- Changing external demands; and
- The power of IT.

Further, the indicators should have the following essential characteristics:

- Measures should be able to identify causes of problems;
- Measures should be able to address all possible performance drivers (in broad, complex and dynamic nature of the construction industry business environment);
- Measures should be able to identify potential opportunities for improvement; and

Information they provide should arrive in time to take actions. Characteristics of emerging performance measurement systems.

4.7 Sharing

One approach to defining knowledge-sharing success focuses on the degree to which the knowledge is re-created in the recipient. Consistent with the innovation literature but on more micro basis, knowledge can be seen as knowledge packages embedded in different structural elements of an organization, such as in the people and their skills, the technical tools, and the routines and systems used by the organization, as well as in the networks formed between and among these elements (Argote & Ingram, 2000; Leonard-Barton, 1992). Successful knowledge sharing results in firms mastering and getting into practice product designs, manufacturing processes, and organizational designs that are new to them (Nelson, 1993).

The concept of knowledge management has narrowed the definition of knowledge sharing as being essentially a process of capturing a person and organization's expertise wherever it resides and distribute it to wherever it can help produce the biggest returns for the individual and organization (Krogh, 2000). According to Wang (1999), knowledge sharing is the conversion between tacit knowledge to explicit knowledge and vice versa while the knowledge 'oscillates' from individuals to the organizations and back. When, employees shared tacit and explicit knowledge through their daily interaction and activities, the original knowledge spread out.

4.8 Change Response

After the knowledge has been acquired or "sourced," it normally cannot be used in its raw form and must be transformed in order to become a valuable knowledge asset and to facilitate its further application and re-use (Liebowitz, 1999). Knowledge can be transformed in many ways, specifically to conform to the format of the target repository. Traditionally, knowledge has been collected, compiled, verified, validated, and organized by an "end user", who embeds it into intermediate products, new customer products, or educational programs.

4.9 New Knowledge

New knowledge is a result of sharing and change response among project employees and stakeholders

4.10 Learning

America's Construction Industry Institute conducted a large-scale investigation of lessons learned processes, carried out by its Modeling Lessons Learned Research Team (Fisher,, Deshpande and Livingston, 1998). Out of the 2400 organizations surveyed, they found strong evidence that most organizations were using insufficient dissemination processes. Such lessons learned system has grown through popular concepts such as the "learning organization" (Senge, 1990), through developments in knowledge management (Davenport and Prusak, 1998), and through technological advancements that hold the promise of wider, more efficient distribution of lessons within an organization. Lessons learned systems supported by knowledge management and organizational learning approaches can be used to develop validated experiential lessons (Fong & Yip, 2006)

Knowledge Sharing is not about giving people something, or getting something from them. That is only valid for information sharing and occurs when people are genuinely interested in helping one another develop new capacities for action; it is about creating learning processes (Peter Senge, 1990). Knowledge sharing is seen as occurring through a dynamic learning process where organizations continually interact with customers and suppliers to innovate or creatively imitate. Lessons learned can be shared amongst parties that have a vested interest in ensuring that positive experiences are repeated and while avoiding the recurrence of negative experiences (Kim & Nelson, 2000).

Furthermore, to create a true learning culture, learning must not be for the sake of the individual alone, but for the team and the wider organization, as Fifth Discipline Field Book points out: *Learning in organizations means the continuous testing of experience, and the transformation of that experience into knowledge*

– accessible to the whole organisation, *and relevant to its core purpose*
Creating a climate in which staff naturally share their learning is a significant part of building a learning culture.

5. DISCUSSION

After identifying the factors expected to influence knowledge-sharing culture, we then proceed to detail the key people management practices that, according to theory and research, should be most effective in fostering knowledge sharing in construction organizations to gain successful lessons learned.

The conceptual frameworks knowledge sharing culture for successful lessons learned, namely:

1. Cultures which driven knowledge sharing behavior are:
   - Norms produce behavior which strongly influence works climate, management style and how people work together.
   - Core values are the basic beliefs about what is good or best for organization, and about what management thinks is important, what should or should not happen.
   - Practices are the formal or informal routines used in the organization to accomplish work.
2. Knowledge sharing base on behavior will create a good or best lessons learned.
3. Effectiveness lessons learned must be measured to make matching with business objective
4. Sharing lessons learned knowledge include of mistake and successful to all project employees
5. There are response of audience to increase performance through improvement value, norms and practices. Ultimately to create a new knowledge
6. Transfer knowledge and skill individually to organization will change element of activities
7. All of organization elements driving force by human effort

A cultural and behavioral shift in the mind-set of all participants in the construction process especially top or senior management is necessary if the construction industry is to improve its performance

6. CONCLUSION

This paper firstly deals with the conceptual framework of knowledge sharing culture for successful lessons learned and its critical success factors. It also examines the preferred practices of knowledge sharing as illustrated in the Figure 1. At the end, the factors that promote the development of knowledge sharing culture will be identified, which can be followed by element of organization culture to change their employees behavior driven successful lessons learned within the organization.

ACKNOWLEDGMENT

Many thanks go to Mr. Mohammed Ali Berawi, PhD my supervisor who giving supported to accomplish this paper and beloved my family who motivated me.

ABSTRACT

Jakarta is a complex city, a city of conflicts and a city of differences: the traditional and modern, the informal and formal, the unplanned and planned, the rich and poor, and the sacred and the worldly, often standing side by side. It presents as a complex of kampungs and, at the same time, a kota. This paper responds to the question: Why do people want to continue living in kampungs despite the tensions and conflicts they experience, seemingly caused by excessive and ever-encroaching development of kota? The question will be addressed through exploring the lived experiences of people in kampungs. This paper discusses Jakarta, view of both kampung and kota, from the perspective of kampungs. Images that Jakarta inhabitants have of their own kampungs, which reported not only the views of the residents and the informal sector workers, but also the views of the NGOs who work in the kampungs of Jakarta.

Key words: kota, kampung, and images of Jakarta.

1. INTRODUCTION

An article in *Kompas* on 19 February 2000 titled '*Kampung Kagak Kampungan'* (*kampung* is not *kampungan*) reminded us of the meaning of *kampung* by distinguishing it from *kampungan*. A *kampung* is simply a traditional, spontaneous and diverse settlement in an urban area. *Kampungan* has two meanings: primitive, and bad mannered. This article was a critique of the Government of the Province of *DKI* (Special Region of Capital City) Jakarta, which tends to view *kampungs* only as ugly, poor and informal settlements; they are seen as weakening the attractiveness of Jakarta, just as they are also interrupting the urban development of Jakarta towards a modern metropolitan city.

Jakarta is indeed, at one level, a *kampung* and at the same time a *kota*. It is a complex city or city of contrasts: the traditional and the modern, the rich and the poor, the sacred and the worldly, often standing side by side in a bustling metropolis. Jakarta is a big city and, as well, a big *kampung* [1]. Leaf makes this point:

> …Jakarta is also *perkampungan yang besar*, the big village, and [this is] a reference to both its physical forms as a multitude of small *kampung* settlements or villages grown together as well as its social role as a receptor of immigrants from throughout the country.

2. KOTA

2.1. A Bulldozer

The image of the bulldozer is not unfamiliar to *kampung*[1] residents, particularly those who have faced the threat of having their *kampungs* demolished. They view the government and developers as a bulldozer or destructive machine, which has flattered their houses in the *kampungs*. It is an image of power on one side and of powerlessness on the other. The image of the inability of *kampungs* to fight against the bulldozer is the image of their weakness against *kota*. Rosello tells a similar story of the *bidonvilles* (in France, which are similar to *kampungs* in Jakarta), when residents cannot stay to defend themselves from the power of 'bulldozers'[2]. He stressed that:

> There was nothing more important than the complete erasure of *bidonvilles*. This included making them less visible, hiding them behind

1 K*ampung* is an unstructured, unorganized and informal settlement in relation to the broader socio-economic system. It can also be realized as a settlement in an urban area without infrastructure, planning or urban economic networking. Poverty and poor of quality of life are the features of *kampungs*.

ISSN 114-1284

> smokescreens of words and physical barriers: fences and walls were built, bulldozers piled up earth to create artificial hills [high-rise buildings or new developments in Jakarta] that compounded the inhabitants' serious drainage problems but successfully hid unsightly *bidonvilles* from richer neighbourhoods (p. 249).

From the perspective of *kampung* residents, *kota* is a bulldozer that has excessive power over *kampungs*. According to Urban Poor Consortium (UPC) the government has removed 200,000 families from river banks because of their alleged contribution to flooding in Jakarta.

2.2. Expensive and Restricted Space, but Place for Working

Large numbers of people from *desas*[2] or other cities have moved to Jakarta to improve their income and seek a better future. To reduce their costs (of both transport and housing) and also minimize the time to get to their office places, they live in *kampungs* close to the city or even in the city centre. In this sense, Han argued that *kampung* is 'a settlement "in" or "around" a city where…urban characteristic is noticeable, and high density [and] low servicing account for some general environmental and housing problems'[3].

The informal sector in *kota* must pay an 'informal daily tax', which is collected by *premans*.[3] If they do not pay this 'tax' to the *premans*, they will not be safe working in the area, or may even lose their jobs. The *premans* are employed by a mafia or godfather[4] who illegally controls particular areas in *kota*.

Kota is high-cost space and every square metre is costly, so people from middle to low income groups cannot afford to live there. *Kota* is also seen as modern (high-tech, sophisticated, and the centre of information), and is the locus of the new culture of modernity. *Kampung* inhabitants cannot gain access to these matters, which are alien to them. People struggle for work and for the right to live.

Another sign of the exclusiveness of *kota* is when government includes in the master plan the idea of privatization of large areas, roads and recreation places. Fenced, gated settlements and a divided city are exclusive space and place, and express another characteristic of *kota*. Toll-road developments in Jakarta become exclusive, while the government is reluctant to revitalize the public transport system and its facilities, which are needed for most Jakartans. *Kampungs*, the informal and poor settlements, feel that *kota* is restricted space and place. From the perspective of *kampungs*, *kota* is also impermeable or exclusive for them.

The trend to separate *kota* from *kampungs* is another form of exclusiveness. These separations can occur through demolishing *kampungs* and relocating the inhabitants to the outskirts of the city, or putting them into low cost flats. However, most *kampung* residents choose to live 'on earth' or 'on land' because earth or land is the symbol of power, prosperity, and harmony. And they sense that flats are enclosed (walled and rigid) settlements. Thus both of these separations—out of the city or into the flats—are problematical.

In line with the view of *kota* as a place for working, *kampung* inhabitants, particularly those working in the informal sector, feel that *kota* is a restricted zone for them. The government has issued many *Perdas* (urban regulations) to restrict the operation of the informal sector such as those on *becaks* and *PKL* (*pedagang kaki lima*) or pedestrian vendors mentioned earlier.

Jakarta as a restricted city, for example for *becak* and *PKL*, is in some sense a contradiction of the people's freedom to come, move, or live in Jakarta from different *desas* or cities, at various socio-economic levels, and from various socio-cultural backgrounds. Every year after *Idul Fitrie*[5] Jakarta gets an additional population (1–2%) of people coming to work in the informal sector. In anticipation of this migration, *Pemprov DKI* Jakarta established a new *Perda* to sort out people migrating to Jakarta. Thus, besides a restricted space being established for the

---

2 *Desa* is a traditional settlement in the rural area.

3 *Preman* comes from the phrase 'free man'. The word '*preman*' is a term used in Medan (North Sumatera) to indicate the local mafia.

4 Prof Sahetapy, a member of parliament, suggests (*Kompas*, 13 March 2003) that there are 'untouchable godfathers' found in this country, particularly in Jakarta, who control the city, and the police are unable to arrest them.

5 *Idul Fitrie* is Islamic Great Celebration

ISSN 114-1284

informal sector, the *Perda* also designates Jakarta as a 'forbidden city' for people from other Indonesian *desas* and cities, through checking the identity cards of migrants during this season (after *Idul Fitrie*) in train stations and bus terminals.

As a result of centralization of socio-economic activities in *kota*, the opportunity to find jobs is greater in *kota* than in *kampung*s themselves. *Kota* is a place where elites run their businesses, generating a lot of jobs in both the formal and the informal sectors. Many *kota* employees, particularly the young and single, who work in formal jobs (secretaries, middle management, junior professionals, etc) choose to live in the *kampungs* behind *kota*. Some of them are from *kampungs* who have succeeded in moving up the socio-economic ladder.

However, many *kampung* inhabitants are from uneducated and unskilled backgrounds, so they find it difficult to get formal jobs in *kota*. The informal sector enables them to solve this problem, because they do not need a large amount of capital and training to do these jobs. They can work in the informal sector to serve *kota* activity as supporting staff, drivers, servants, pedestrian vendors, etc. (Figure 1). For example, Wati from *kampung* Anyer (Central Jakarta) protested against the Jakarta government, because in her view: 'government has never understood the people, we would not stay on illegal land (close to or along the railway) if we had the money to buy houses in permitted settlements'.

Ordinary people want to live in the city centre close to their work place, but the government has removed many of them to the outskirts of the city, for example to *Perumnas* (National Housing Agency) estates or peripheral settlements. However, as a result of poor planning of these new settlements in the outer city they have difficulty in getting to work in *kota*. Because of inadequate public transport they need more time to get to their work in the morning and to get home in the evening. Johan Silas (*Kompas*, 22 Juni 1996) criticized the inefficiency of Jakarta. He argued that people need two hours to get to work places (offices) in *kota* and another two hours to get home. They have to get up early in the dark (at about four or five a.m.) to catch public transport and arrive at work on time, and they arrive home in the dark.

2.3. Center of Power and Basis of Conflicts

Non Government Organizations (NGOs) suspect that the implementation of *RTRW* in city developments does not take the side of the public. Elites can design the results of public opinion surveys according to their own wishes, just as if that opinion had come from Jakarta's citizens, the majority of whom live in *kampungs*. NGOs view *kota* as the centre of power to control the whole city through city planning and design. This view was also stressed by Michel Foucault when he described architecture (including planning and design) as an intermediary of 'the relationship of power and space' and 'as a political "technology" for working out the concerns of government through the spatial "canalization" of everyday life' [4]. So planning and design are tools of government or elites to maintain power over *kampungs*, as Low and Lawrence–Zuniga quote from Rabinow (1982) and Foucault (1975) [5]:

ISSN 114-1284

> …architecture and planning function as spatial tactics contributing to the maintenance of power of one group over another at a level that includes the control of the movement and surveillance of the body in space as well as the transformation of spatial ideologies. They do not focus, however, on individuals' everyday resistance to spatial forms of social control.

When the elites use excessive power over the city, particularly over *kampungs*, by manipulating city planning and design, *kota* becomes a basis of conflicts between the formal and the informal sector or *kota* and *kampungs*, consistent with the suspicions of the 36 NGOs.

The central and provincial governments, supported by the private sector, practise such social, economic and political power on the people of Jakarta. Socio-economically, elites manage most of the markets and the formal economy of the city, control most strategic spaces in the city, and also try to persuade government to change public space to private. And hence they also effectively manage the constraints within which the informal economy also must function.

Socio-politically, elites use their power by exploiting Jakarta's citizens for their personal interests, or for the interests of their group or party. As Ward [6] argues, 'the crime is political or economic gain from the exploitation of the ignorance or hardship of others'. It is now widely believed that many social conflicts that have occurred in Jakarta have been provoked by the elites. For example, in the Manggarai elites (developers) established their power in the business area. Moreover, Ward stressed that 'the criminal is usually the promoter or developer' [7]. As well, in Kebon Kosong, members of the Kemayoran delegation and the NGO activists alleged to me that elites paid *premans* to intimidate and build fear among people to cause them to accept relocation from this *kampung* more easily. Building the *Masjid* Akbar in Kebon Kosong is also a kind of 'soft' persuasion from developers, by using their power (money and intelligence) to persuade inhabitants to accept the plan. Furthermore, religion is an easy tool with which to persuade people. Elites often use this to create horizontal social conflicts between different groups. Social harmony between religions had been building in Indonesia for a long time, but is now deteriorating. Destroying churches, banning Christian services in communities, and banning the building of new Christian churches are examples of the abuse of power by elites over citizens to promote their own (invariably economic) ends.

Social conflicts have occurred often between one *kampung* and another and between *kampungs* and *kota*. According to Low and Lawrence–Zuniga [8], such 'contested spaces' are generated by political struggles, conflicts of characteristics between elites and residents, and bringing together race, poverty, and place in urban communities. Low and Lawrence–Zuniga [9] quote Kuper's experience of Swazi sites:

> … some sites have more power and significance than others; "these qualities need have no fixed relationship to a physical, empirical dimension," although "political influence may manifest itself in bestowing these qualities through the manipulating of forms"… sites are social spaces that function in politicized dramas as a condensed symbol operating within complex social and ideational structures (p. 19).

Kota seems more powerful than *kampungs*, even though there are more residents in *kampungs* than in *kota*. Socio-culturally, *kampungs* are more powerful than *kota*, but politically and economically, *kota* is more powerful than *kampungs*. Thus, *kampungs* and *kota* not only influence each other, but also come into conflict based on their power.

3. KAMPUNG

3.1. Tiny and Unfenced Space but Public and Recognizable

For *kampung* residents their homes, even though small, have the real value of settling or dwelling beyond their walls. Nugroho [10][6] argued that for *kampung* residents the psychological value of living or settling in *kampungs* is greater than for people living in *kota*:

> …something beyond the walls of a house in *kampungs*, which cannot be seen by the eye, has a psychological value contributing to the real value of the house or settlement. The value of the house or settlement for the people in a *kampung* might be higher than for the people from middle-to-up classes in the *kota* (p. 43)

6 This is translated from a paper by R. P. Nugroho (1997), Sebuah Rumahkah Rumah Kumuh? Suatu Study Tentang Arti Sebuah Rumah, *Kilas*, Jurnal Arsitektur FTUI, Jakarta, Indonesia

ISSN 114-1284

Reflecting the middle to low income status of residents, *kampungs* are low-rise settlements with an effective and tight use of space. These characteristics, along with the kinship tradition in *kampungs*, encourage openness and friendly relationships among inhabitants. As a consequence of limited space in *kampung*s, all spaces outside houses such as lanes, streets, *warungs*[7], *masjid* (mosque), and tiny open spaces between the houses become public spaces. Hilda Kuper in Low and Lawrence-Zuniga [11] notes that these kinds of spaces can be accepted as 'social spaces'. Even though the public and organic spaces in *kampungs* are tiny and poor, they are social spaces because, according to Kuper, social spaces are experiential, 'whereby individuals attach values to space through social and personal experiences, and culturally as a conceptual model'.

In *kampungs*, the public and social spaces on lanes or streets are produced by the connection between socio-cultural activities and relationships, and the built environment itself. This is somewhat similar to social spaces in *desa*, which are naturally established by kinship (socio-cultural relationship) and also the built environment, but which are of lower density and larger in area than in *kampungs*. This in part happens because most *kampung* residents originally practised a traditional way of life, often from the *desa*s of rural areas (many of which have in fact been transformed into urban areas, e.g. in old Jakarta, and in my present *kampung* in Pondok Labu). Additionally, as a result of the tiny space in their houses and also the tropical climate, the residents often socialize and even work outside their houses (Figure 2).

Kampungs are unplanned and 'no barrier' settlements. They originally did not consider boundaries and fences. As a consequence of the fluidity of the functioning of space, *kampungs* have no fixed land-use, so it is difficult to identify particular functions, sizes and forms. Even though *kampungs* are not on the formal (city) map and have no planned land-use, nevertheless we have seen in the cognitive maps of residents that they do identify their land, area, or even the territory of their community or neighbourhood. From my experiences and the surveys in *kampungs*, the residents recognize each other well in a community. They do know who their neighbours are, and even their names, the number of family members, and their jobs.

Figure 2: Public space on the lane: walking trader with children

7 *Warung* is a traditional local shop/kiosk in a *kampung*, which usually provides the daily needs of people in the *kampung*.

3.2. Unprotected but Secure

Legally, *kampungs* have no protection. The system of land rights in Indonesia is based on the Basic Agrarian Law (BAL) of 1960 [12]. According to MacAndrews, the two types of land system in Indonesia are informal registration of *hukum adat* (traditional law) and written land titles and land registrations. The first originated from traditional law and the second, which was created by the colonial government, has remained mainly in urban areas up to the present. Thus the written land rights system is dominant in urban areas. The implementation of this system does not cover the *kampung* areas of Jakarta, however, but focuses much more on *kota*.

Because ownership certificates give evidence of their rights, land owners, developers, or users have security to develop and commercialize their areas. All activities and buildings in *kota* are developed and built on legal land with land certificates and building certificates. These certificates also give an assurance of protection of urban regulation and future city planning, including essential city services of infrastructure and public facilities.

From my investigations in *kampungs*, most of the people in *kampungs* own their own houses. However, the majority of them have no right-of-ownership (*hak milik*) certification (Figure 4). This indicates that most people in *kampungs* live on illegal land. This uncertainty of right to the land creates land conflicts in *kampungs*, between people and people, people and the formal private sector, and people and government. In these conflicts, ordinary people always lose either by force or by law in court [13].

Most buildings in *kampungs* are also built without building certificates, because a building certificate cannot be applied for by people while they have no ownership certificate for their land. Thus, legally, people are insecure; and their buildings or even whole *kampungs* can be demolished easily by *kota* development. Conversely, however, the government allows *kampungs* as part of city administration by establishing *RT*s and *RW*s in *kampungs*. In view of this form of municipal administration, residents in areas with this status feel that they have some legal security in their *kampungs*.

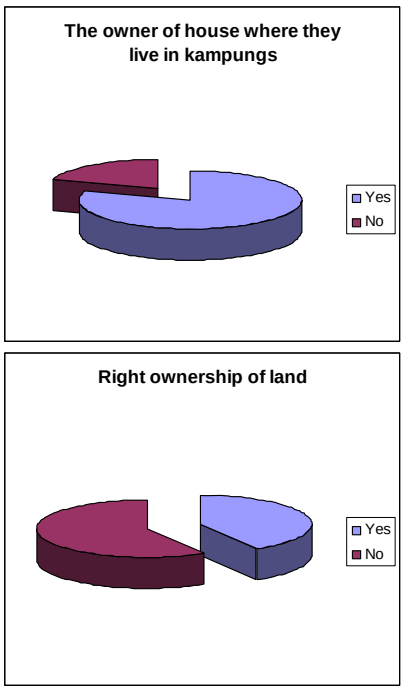

Figure 4: Ownership of houses (top left); of land rights (top right) in *kampungs*

Source: Survey by author

In reality, *kampungs* are unprotected by law and government. Fires, floods, social conflicts, and demolition of *kampungs* occur because of poor protection by government. The government is reluctant to construct better infrastructure and facilities in *kampungs* which are going to be demolished. As a result of poor public facilities and lack of infrastructure, *kampungs* are not only insecure; they are also uncomfortable.

However, in another important sense, *kampungs* are secure for the residents, because socially they are recognized by and are friendly with each other. They manage their own local or community security system, *hansip* (*pertahanan sipil* or civil defence) and *ronda kampung* (*kampung* guarding), supported by security posts and *RW* posts. This system is based on the mutual self-help tradition among communities or neighbourhoods, *gotong royong*[8] and *rukun*[9], in which people are not paid for any tasks in

8 Gotong royong is the custom of cooperation, mutual self-help, the sharing of burdens, or solidarity in *kampung* communities

9 *Rukun* is understood as 'good' and 'peace' in connection with relationships. It also means 'one mind' or 'one interest', or unanimous.

ISSN 114-1284

guarding their community. From my own lived experience in *kampungs* and from my survey, I found another reason why the community residents feel secure living in *kampungs*: they are close to their relatives or friends; thus, socio-economically, they can survive living in the city.

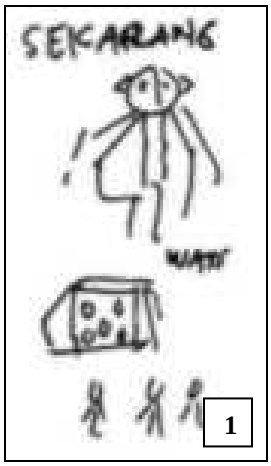
3.3. Self-Sufficient

A community is a place and space where a group of people live together, consequent on two needs: interests and territories. *Kampung* as community of interest practises *gotong royong*, *rukun*, democracy, and friendship among inhabitants, establishing adaptability among residents. *Kampung* as community of territory covers informal, unregulated, and uncontrolled space, and place is flexible. The remarkable system of social relationships in *kampung*s, built on the concepts of *gotong royong*, *rukun*, *arisan*, and *koperasi*[10], is also the basis of self-sufficiency in *kampungs.*

Kampung residents do not find it too difficult to change their jobs because they do not need special skills for the jobs that they seek, whether those are in the *kampung* or even in the formal sector represented by *kota*. Thus in a crisis they are likely to be able change their jobs more easily than the residents of *kota*, to adapt to a new situation. For example: Wati was a nurse in a hospital, but now she works together with her husband in *warung makanan* (meals) (Figure 5, no 1); Iyah was a garment labourer, but now she works as a car-park attendant; etc. (Figure 5, no.2).

Through this characteristic of adaptability to different situations, it seems that *kampungs* are able to manage their problems or crises better than *kota*.

As a result of irregular and unpredictable earnings, many people in *kampungs* have multiple jobs, because they need extra revenue from the second job. A teacher can run a *warung* in his house; a labourer working in a market in the morning can be a *satpam* (security) in *kota* in the evening; an office boy in *kota* in the day time can be a *bakso* vendor in the evening, etc. Another example is the 'three in one job': one person can work in three different places and at three different times in the day (morning, afternoon and evening) in one particular job: formal and informal, such as *satpam*, teacher, car-park attendant, etc.



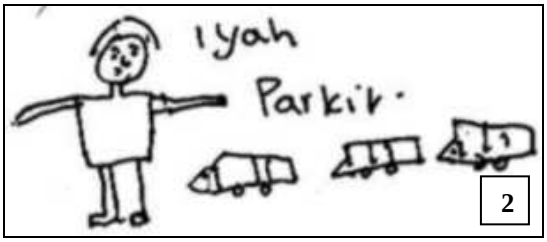


Figure 5: Adaptability of *kampung* residents

Note: (1) From nursing to *warung*, (2) From garment worker to car park attendant.

3.4. Behind Kota

Socio-economically, *kampungs* are settlements for middle to low socio-economic classes. The main reason why most ordinary people choose to live in *kampungs* close to *kota* is because they want to be close to their workplaces. As argued in previous discussion, in the everyday life of Jakarta, *kampung*s support *kota* lives 'from behind'. For instance, behind *Jalan* Thamrin, Sudirman and other grand avenues can be found *kampungs* that contain many *warungs* and much low-cost rental housing to support *kota* lives Another form of dependency of *kota* on *kampung*s is from *kampung* residents with portable shops who walk to *kota* to sell various kinds of fresh food (Figure 6). The dependency

2

10 *Koperasi* is Indonesian traditional banking; and *arisan* is the local and traditional banking system in a community.

of *kota* on the *kampungs* has increased since the Indonesian economic crisis. The ability of people (including formal workers in *kota*) to afford to buy things through the formal sector is decreasing, while their daily needs remain the same.

Figure 6: The informal sector supports *kota* life: portable shops in Menteng (bottom) move from *kampung* Manggarai (top)

4. CONCLUSIONS: JAKARTA AS A KOTA KAMPUNG

This was demonstrated that from the perspective of *kampung* there were different and often conflicting images between *kampung* and *kota*: private and public, formal and informal, restricted and open space, or the power of elites and mutual self-help.

The image of Jakarta from the *kampung* perspective is also one of contrast, as it was from the perspective of *kota*. It seems like white and black or good and bad. Nevertheless, it is clear that *kota* provides job opportunities for many *kampung* residents, in both the formal and the informal sector, while the *kampungs* provide cheap and accessible labour. Thus in reality the relationship between *kampung* and *kota* is to a large extent symbiotic—it is arguable that neither could exist without the other (though the *kampungs* might indeed survive, albeit transformed). Therefore, people want to continue living in *kampungs* despite the tensions and conflicts they experience, seemingly caused by excessive and ever-encroaching development of kota.

ABSTRACT

In order to save the earth from global warming, USGBC (United State Green Building Council) uses LEED (Leadership in Energy and Environmental Design) as a green building standard rating system for sustainable design. LEED for Existing Building maximizes operational efficiency while minimizing environmental impacts. To achieve LEED certification, buildings must meet all Perquisites in the Rating System and a minimum of 32 points. In this research, we study how a Computer Science Building (CSB) operation relates to LEED USGBC Values. How far implementation of green building standard. This study concentrates on perquisites for existing building criteria version 2.0. CSB is one of the best buildings in technology facilities for the University of Indonesia. It has a chance to have a good rating score. The data collection method includes surveying, interviewing, and obtaining literature related to LEED. Standards Research methods include a qualitative description for CSB and quantitative measurement.

Keywords

LEED, USGBC, Green Building

1. INTRODUCTION

In green building design, LEED USGBC become one of standard to evaluate the quality of building using energy efficient performances and controlling environmental impacts. LEED for Existing Buildings (LEED EB) maximizes operational efficiency while minimizing environmental impacts. As a leading-edge, consensus-based system for certifying green building performance, operation, and maintenance. LEED for Existing Buildings addresses exterior building site maintenance programs, efficient/optimized use of water and energy, purchasing of environmentally preferred products, waste stream management and ongoing indoor environmental quality (IEQ). In addition, LEED for Existing Buildings provides sustainable guidelines for whole-building cleaning/maintenance, recycling programs and systems upgrades to improve building energy, water, IEQ and materials use.

This study focuses on 6 (six) LEED USGBC values related to CSB building operations. The six values are Sustainable Site, Water Efficiency, Energy & Atmosphere, Material Resources, Indoor Environmental Quality and Innovation in Upgrades, Operation & Maintenance. The results of the study can be used as a parameter to improve building interior and exterior quality for peoples and environment.

2. LEED REQUIREMENT

In favor of the sustainable site aspect, there are 14 possible points for green building sub criteria. The subcriterias are Erosion and Sedimentation Control, Age of Building, Plan for Green Site and Building Exterior Management, High

ISSN 114-1284

Development Density Building and Area, Alternative Transportation: Public Transportation Access, Bicycle Storage & Changing Rooms, Alternative Fuel Vehicles and Car Pooling & Telecommuting, Reduced Site Disturbance: Protect or restore Open Space, Storm water Management: Rate and Quantity Reduction, Heat Island Reduction, Light Pollution Reduction. Each sub criteria has LEED-EB standard point. The two earlier sub criteria have to be required to evaluate other sub criteria.

Water Efficiency aspect have 5 possible points standard. Sub criteria in water efficiency aspect are Minimum Water Efficiency, Discharge Water Compliance, and Water Efficient Landscaping: Reduce Water Use, Innovative Wastewater Technologies, and Water Use Reduction. The first and second sub criteria have to be required before evaluate others.

For Energy & Atmosphere aspect, green building has to get minimum 23 possible points. It has 12 sub criteria, they are Existing building Commissioning, Minimum energy performance, Ozone Protection, Optimize energy performance, On-site and off-site renewable energy, Building Operation and Maintenance: Staff education, Building System Maintenance & Monitor, Performance Measurement: Enhanced Metering & Emission Reduction Reporting, Documenting Sustainable Building Cost Impacts. The first three sub criteria have to be required.

In Material Resources aspect, building have to get minimum possible 16 points in Source Reduction and Waste Management: Waste Management Policy and Waste Stream Audit, Storage & Collection of Recyclables, Toxic Material Source Reduction: Reduced Mercury in Light Bulbs, Construction, Demolition and Renovation Waste Management, Optimize Use of Alternative Materials, Optimize Use of IAQ Compliant Products, Sustainable Cleaning Products and Materials, Occupant Recycling, Additional Toxic Material Source Reduction: Reduced Mercury in Light Bulbs. The first three sub criteria have to be required to continue other sub criteria evaluation.

Indoor Environmental Quality aspect have 22 possible points. It consists of Outside Air Introduction and Exhaust System, Environmental Tobacco Smoke (ETS) Control, Asbestos Removal or Encapsulation, Polychlorinated Biphenyl (PCB) Removal, Outside Air Delivery Monitoring, Increased Ventilation, Construction IAQ Management Plan, Documenting Productivity Impacts : Absenteeism and Healthcare Cost Impacts & other impacts, Indoor Chemical and Pollutant Source Control : Non-Cleaning-Reduce Particulates in Air Distribution & Non-Cleaning-High Volume Copying/Print Room/Fax Stations, Controllability of System : Lighting & Temperature & Ventilation, Thermal Comfort : Compliance & Permanent Monitoring System, Day lighting and Views : Day lighting & Views, Contemporary IAQ Practice, Green Cleaning : Entryway System, Isolation of Janitorial Closets, Low Environmental Impact Cleaning Policy, Low Environmental Impact Pest Management Policy & Low Environmental Impact Cleaning Equipment Policy. The first four sub criteria have to be required.

Innovation in Upgrades, Operations and Maintenance aspect has minimum 4 possible points and 1 point for LEED Accredited Professional.

3. IMPLEMENTATION RESULT

The result study shows that CSB has lower score than LEED certified point. In design, CSB has good quality planning even though some materials has lower quality than other Campus buildings. CSB has been already designed with energy efficiency building standard in Indonesia. LEED has higher and more detail standard than building regulation in Indonesia.

For sustainable aspect, CSB has meet almost all points required, except one on Alternative Transportation: Car Pooling & Telecommuting. For the other sub criteria, CSB still doesn't get full point so for this aspect; CSB gets 9 points than 14 standard points or 64% value.

Table 1. CSB Points Result for Sustainable Sites

CRITERIA	STANDARD POINTS	RESULT
Erosion and Sedimentation Control	Required	√
Age of Building	Required	√
Plan for Green Site and Building Exterior Management	2	1
High Development Density Building and Area	1	1
Alternative Transportation: Public Transportation Access	1	1

Alternative Transportation: Alternative Fuel Vehicles	1	1
Alternative Transportation: Car Pooling & Telecommuting	1	-
Reduced Site Disturbance: Protect or Restore Open Space	2	1*
Storm water Management: Rate and Quantity Reduction	2	1*
Heat Island Reduction: Non-Roof	1	1
Heat Island Reduction: Roof	1	1
Light Pollution Reduction	1	1
Total Point	**14 points**	**9 points**

Notation * shows that data is not complete

For water efficiency aspect, CSB get only one points of 5 standard points or 20%. In CSB operation, it has used water equipment as Indonesian National Standard (SNI) but not propose for water efficiency yet.

Table 2. CSB Points Result for Water Efficiency

CRITERIA	STANDARD POINTS	RESULT
Minimum Water Efficiency	Required	√
Discharge Water Compliance	Required	√
Water Efficient Landscaping: Reduce Water Use	2	1*
Innovative Wastewater Technologies	1	-
Water Use Reduction	2	-
Total Point	**5 points**	**1 points**

Notation * shows that data is not complete

Energy & Atmosphere aspect is the most important aspect for green building standard. CSB acquires only 4 points of 23 standard points (16,7%). It hapens cause in Energy & Atmosphere aspect requires measurement control in building operation. CSB doesnot has this requirement.

Table 3. CSB Points Result for Energy & Atmosphere

CRITERIA	STANDARD POINTS	RESULT
Existing building Commissioning	Required	√
Minimum energy performance	Required	√*
Ozone Protection	Required	-
Optimize energy performance	1-10	-

Total Point	**22 points**	**12,5 points**

Notation * shows that data is not complete

For the last aspect, Innovation in Upgrades, Operations and Maintanance, CSB has not done improvement yet and It has not submitted for LEED sertificatification yet. So for this aspect CSB doesnot get point.

Table 6.CSB Points Result for Innovation in Upgrades, Operation And Maintenance

CRITERIA	STANDARD POINTS	RESULT
Innovation in Upgrades, Operations and Maintenance	4	-
LEED Accredited Professional	1	-
Total Points	**5 points**	**0 point**

Finally, In favor of all criteria, the summary is represented in table below. CSB gets better point for aspects: sustainable sites and Indoor Environmental Quality. CSB meet very lower value for the other aspects. This result indicates that CSB has been good in physical design but has to improve energy efficiency planning.

Tabel 7.CSB Complete Points Result

CRITERIA	STANDARD POINTS	RESULT	Persen t points
Sustainable Sites	14	9	64 %
Water Efficiency	5	1	20 %
Energy & Atmosphere	23	4	16,7 %
Materials & Resources	16	2	12,5 5
Indoor Environmental Quality	22	12,5	57 %
Innovation In Upgrades, Operations & Maintenances	5	0	0
Total Point	**85 points**	**28,5 points**	**100 %**

4. CONCLUSION

Based on the analysis, there are some conclusions of LEED EB implementation on CSB:

1. Design based on building regulation and SNI is not meet LEED standard points yet.
2. Limitation of CSB Documentation causes the research cannot measure others important data that possibly effecting the total point.
3. This LEED certified points can improve Indonesian building quality in energy efficiency, but It needs government support to implement green bulding that can save environment.
4. There are some contraimplementation between design and operation in CSB, so they cannot get along. Building operation have to be improved to get first aim design bulding so energy efficiency can be reached.
5. LEED EB 2.0 version doesnot intent yet to firesafety as energy efficiency in green building concept. We think that firesafety is very important aspect in building design completeness.

ACKNOWLEDGMENT

We say thank to CSB management faculty that has given completely documentation and lecturers who has supported for this study.

ABSTRACT

Shading device, window to wall ratio, window height, and glazing are important factors in determining building energy consumption in the tropics. This study employed the four factors in designing energy-efficient window for classroom to reduce the energy consumption for supplemented lighting and mechanical ventilation. The main parameter is classroom's cooling load or heat transfer through the building skins (< 10 watt/m^2) incorporated with secondary parameters, i.e. indoor illuminance level (200-400 lux) or daylight factor (2-3%), and horizontal illuminance distribution. Relationship among window to wall ratio, window to floor ratio, height of clerestory, clerestory to wall height ratio, and classroom's orientation, width and length are examined using Ecotect simulation program to establish a concept for energy-efficient classroom's window. Window with projected clerestory is the most energy efficient. It transfers minimum solar radiation and creates the most even horizontal illuminance distribution with sufficient level. Small difference in energy performance but lower cost can be achieved by window with glass-block clerestory or with lightshelf. Three kinds of clerestory should be applied on classroom with considering the window to wall ratio (20%), the clerestory head height to room height ratio (11%), the head height clerestory to room width ratio (around 5%).

Keywords: *clerestory, cooling load, daylight factor, illuminance distribution, window.*

1. INTRODUCTION

Three main issues in window design for warm tropical area are uneven horizontal illuminance distribution, glare and high solar heat gain. Window design is one of the factors, which affects the building energy consumption for lamps and air conditioning [1]. An energy-efficient window, then, should be able to distribute horizontal illuminance more evenly, avoid glare and reduce solar heat gain.

A determinant factor of window design in the transmission of solar radiation into indoor space is window to wall ratio (WWR). Proper shading devices and/or replacing the window glazing property with the lower solar admittance can modify WWR in order to achieve low thermal transmission and sufficient indoor illuminance. Shading devices function as effective shields for solar radiation, but in some cases they cannot create even horizontal illumination distribution and even block occupant's view to outside.

To maintain the view through the window, while at the same time let daylight penetrate into the deepest side of the room, side window is divided into two parts. The lower window functions as view window with shading device surrounding the window to shade the indoor space from direct sunlight, rainfall, and glare. The upper window which called as clerestory allows daylight to penetrate into the deepest side of the room.

Lightshelf introduces internal shelf upper the view window to bounce daylight more deeply by reflecting the light up to the ceiling and to avoid direct glare to occupants. Many studies proved the advantages of lightshelf in creating even daylight distribution and reduce penetration of solar heat gain [10][8][3].

Special glass for the clerestory can replace the internal shelf to avoid glare and creates uniform indoor illuminance [9]. The glass should have low thermal transmission, but high or medium visible transmittance.

Projected clerestory is another idea to allow daylight coming into the deeper side of the room and functions as solar shading for the lower window.

In this study the three possibilities would be examined by using Ecotect simulations to find optimum model/form, dimension, and position with suitable glazing properties. The aim is to generate a concept of energy-efficient window, that can be applied on classrooms with varied dimension in Yogyakarta.

This paper reports results of two experiments. The first experiment examined 48 models of classroom with 3 variations in window design. These models have similar (not the same) window to wall ratio (WWR) and window to floor ratio (WFR). Fifty six models with the same WWR and WFR were constructed in the second experiment to improve the first experiment results. As the results of models with projected clerestory in the second experiment seem

unreasonable, disscussion will combine results of the two experiments.

2. METHOD

Energy-efficient window will be designed on classroom models with variation in capacity. It was assumed that classrooms rely on mechanical ventilation to achieve the indoor thermal comfort. Models are located in Yogyakarta, which is renowned as a student city with many educational buildings. Located on 8^0 south latitude and 110^0 east longitude, the city belongs to a tropical region with very bright sky and abundant solar radiation.

Ecotect simulation program were used to examine their thermal and visual performances. Comprehensive facilities provided by Ecotect offer possibility to analyze the solar, thermal and daylight aspects in relative short time without reconstruction of the model. The same procedure was applied in the first and the second experiments.

2.1 Define Classrooms with Variation in Capacity

Classroom models with three variations in capacity were designed by following principles of classroom design requirements. Calculation of the classroom area was based on National Standard of classroom area, i.e. 2 m^2/person [7]. Classroom length must be no more than six times of screen height to maintain its visual comfort for learning. The width should be more than the screen width. The screen sill height is between 1.22-1.83 m'. The minimum ceiling height is 3.05 m' [4].

Table 1: Area of classroom models

CAPACITY (p)	MIN. CLASSROOM AREA (m^2)	CLASSROOM AREA (m' x m')
The first experiment		
25	50	6.1 x 8.4
50	100	8.5 x 12
75	150	9.5 x 16.5
The second experiment		
25	60.2	7.0 x 8.6
40	82.0	9.3 x 9.0
60	123.0	11.7 x 10.5
75	154.0	11.0 x 14.0

2.2 Define Classrooms and the Height of Clerestory

The classroom height was determined by the minimum standard of air flow rate for classroom and the minimum height of clerestory. A classroom should have 4-12 times of Air Change per Hour and provide 15 cfm per person of air-flow rate [2]. In order to illuminate the deepest side of the classroom, clerestory head height must have 1.5 times in height of the classroom width for window without internal shelf and 2.5 times for window with internal shelf [12]. Considering net (occupancy) area of classroom, in the the second experiment clerestory head height became 1/3 times of the classroom width.

Table 2: Height of classroom models

CAPACITY (p)	CLASSROOM AREA (m' x m')	CLASSROOM HEIGHT (m')	CLERESTORY HEAD HEIGHT (m')
The first experiment			
25	6.1 x 8.4	3.2	6.1/2.5 ≤ 3.1
50	8.5 x 12	3.5	8.5/2.5 ≤ 3.4
75	9.5 x 16.5	4	9.5/2.5 ≤ 3.9
The second experiment			
25	7.0 x 8.6	3.0	8.6/3 ≤ 2.9
40	9.3 x 9.0	3.2	9.0/3 ≤ 3.0
60	11.7 x 10.5	3.6	10.5/3 ≤ 3.5
75	11.0 x 14.0	3.8	14.0/3 ≤ 3.7

2.3 Designing Energy-efficient Windows

Window affects the building energy consumption in two ways.

First, it can transfer heat energy into the building. Energy flows through window in a building by three physical effects, i.e. (1) conductive and convective heat transfer between the outer window surface and the adjacent air due to temperature difference, (2) net long-wave radiative heat exchange between outer window surface and the sky, ground, or adjacent objects; and (3) short-wave radiative heat exchange incident on the window [1]. Window to wall ratio (WWR) can determine the rate of conductive, convective and radiative heat transfer through the window and the wall. Design of the shading device (width, form, and thermal properties) can reduce radiative heat transfer rate. Whilst, glazing properties affect conductive and radiative heat transfer rate through the window.

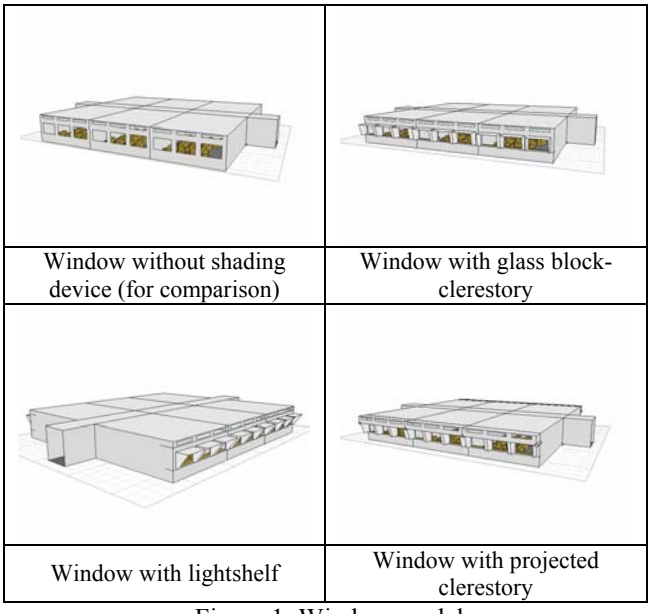

Figure 1: Window models

The second, daylight incoming through the window can reduce electrical energy demand for artificial lighting during sunshine. Window area, form (including shading device), position, and the optical properties of window materials (visible transmittance) are important factors in creating proper illuminance level and even horizontal distribution.

This study proposed three window models. First model is window with 1 m'-lightshelf. Second model is view window with clerestory made of glass block. This kind of glass is considered as affordable material with low thermal transmitance (U_v = 2.9 W/m^2.K) and medium visible transmitance (0.55). The third is view window with projected clerestory. Shading devices on view windows were designed by "shading design wizard" tool in Ecotect. The calculation was based on the sun path diagram. Material properties of each model remain constant except glass-block clerestory.

2.4 Heat flows through the building fabrics

Ecotect's "Thermal Analysis" provides "Losses and Gains" as a facility to simulate relative contribution of different heat flow paths. Actual hourly fabric gains distribution can show the amount of heat flows through the external surface of each zone. The calculation is based on Admittance method. This method is based on the concept of cyclic variation. It is not as physically accurate as the response factor or finite difference methods. However, it can be very helpful in desicion making of building design process in conditions where the temperature swing and energy inputs are changing steadily. This method is suitable to the models condition, where mechanical cooling is applied to achieve indoor thermal comfort. Simulation of fabric gains can describe relative accurate results, because the simulation calculates incident solar radiation passing through an aperture as part of space load and fabric load based on internal admittance values.

2.5 Illuminance Level and Daylight Factor

Ecotect analyzes illuminance level and daylight factor based on Building Research Establishment (BRE) Split-Flux method. Standard overcast sky illuminance distribution is used to calculate the illuminance level and daylight factor in order to represent a worst-case scenario to be designed for. Therefore, values will not change with different dates or times and not be affected by changing model orientation. Ecotect also provides link to Radiance for physically accurate and comprehensive lighting analysis.

3. RESULTS AND DISCUSSIONS

3.1 Projected Clerestory for Low Heat Transfer

At the first time total glass area had 34-39% of the exposed wall area and height of clerestories are between 25% and 34% of the classroom height. Only window with projected clerestory can reach the standard of thermal transfer. Windows with lightshelf transfer solar radiation relative low, but still above 45 W/m^2.

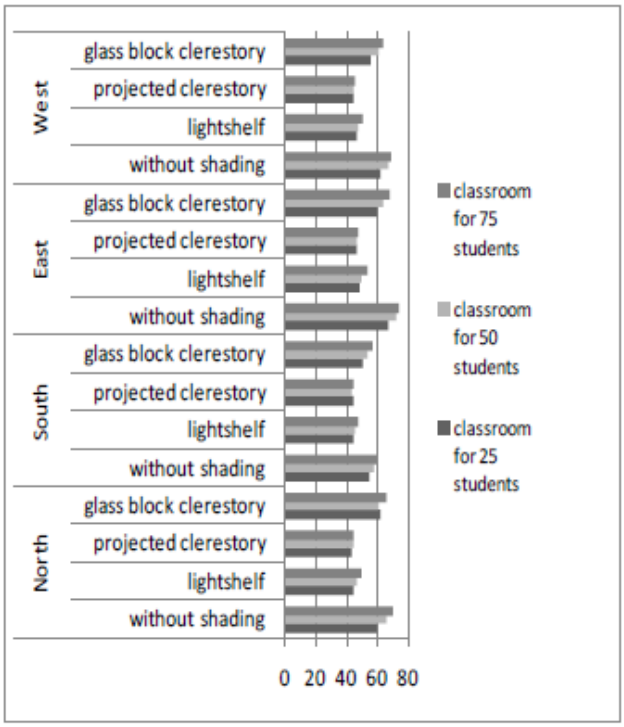

Figure 2: Hourly thermal transfer value (W/m^2) of window with 34-39% WWR (the first experiment)

Results of daylight factor simulations show very high value. Windows with projected clerestory create daylight factor above 5%. Windows with lightshelf have higher value (more than 6.5%). These results are too high for classroom which the standard of DF is 2-3.5% [5]. Low daylight factor is considered as more comfortable, because the calculation of daylight factor is under the worst-case (overcast sky condition).

Table 3: Dimension of Windows

CLASSROOM CAPACITY (persons)	VIEW WINDOW (m' x m')	CLERESTORY HEIGHT (m')
The first experiment		
25	3 @ 1.3x1.0	0.35
50	3 @ 2.0x1.0	0.40
75	3 @ 3.0x1.0	0.45
The second experiment		
25	3 @ 1.75 x1.10	0.250
40	4 @ 1.75 x1.10	0.305
60	5 @ 1.75 x1.10	0.410
75	6 @ 1.75 x1.10	0.465

In order to reduce thermal transfer value and daylight factor, window areas are decreased into 20% of exposed wall areas. This value was also applied in the the second experiment. All models in the the second experiment have 20% WWR and 20% WFR. The height of view window remain constant in 1.10 m' with 1'm sill height.

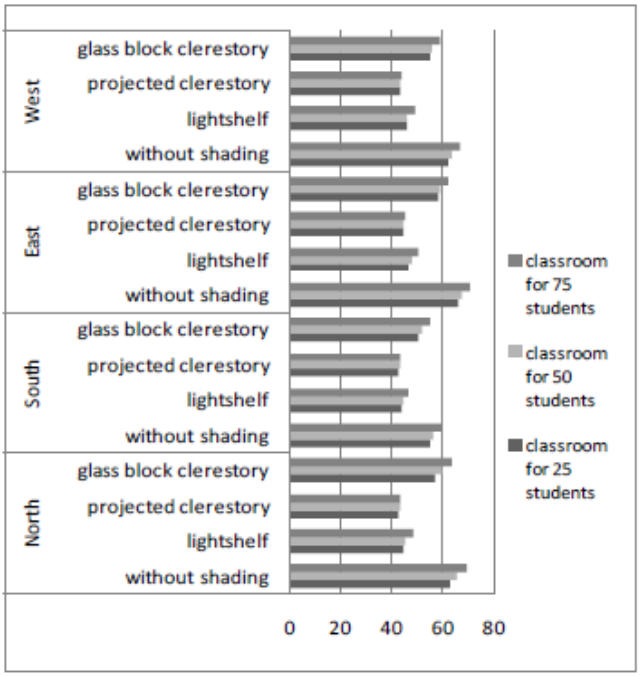

Figure 3: Hourly thermal transfer value (W/m^2) of window with 20% WWR (the first experiment)

New dimensions reduce the rate of heat transfer insignificantly (< 10%), but can create acceptable daylight factors. Only windows with projected clerestory transfer solar heat below the standard. Some windows with lightshelf facing to North or South can raise the standard of thermal transfer value. Others are still above 45 W/m^2.

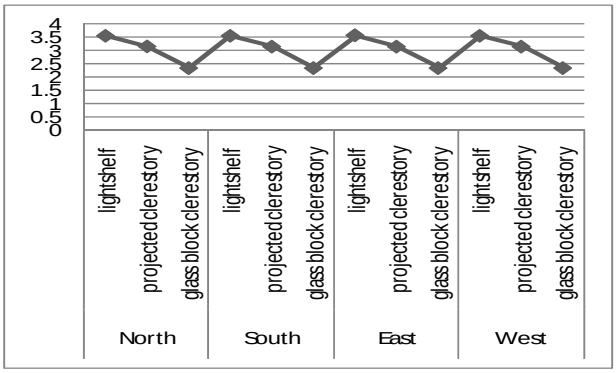

Figure 4: Average daylight factor (%) of windows for 25-students classroom (the first experiment)

Uneven daylight distribution potentially creates glare in area with high level illuminance or needs more electrical lighting to supplement daylighting in area with low illuminance level. Daylight distribution can be considered as uniform if the distribution value is not less than 80% [11]. Some windows with projected clerestory facing to north and south have more uniform daylight distribution (76%). Daylight factor distributions of windows facing to west and east are still difficult to handle.

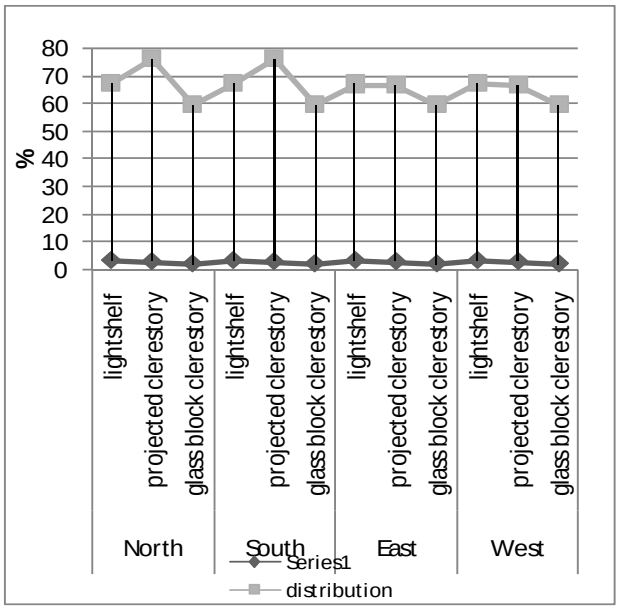

Figure 5: Distribution of daylight factor of window for 25-students classroom (the first experiment)

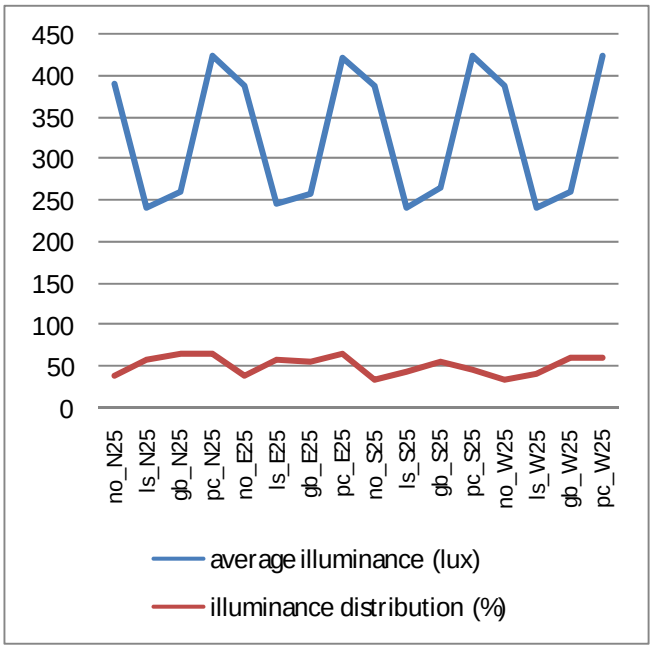

Figure 6: Average illuminance and illuminance distribution of windows for 25-students classroom (the second experiment)

Daylight performances of windows simulated in the second experiment show regular patterns. Windows with lightshelf create the most comfortable illuminance level. The average illuminance levels of windows with glass-block clerestory are still acceptable/comfortable. Similar patterns in illuminance distribution indicate there is insignificant improvement in classrooms with shading device. The best improvement occurs in small-capacity classrooms. Results of window with projected clerestory, however, seem unreasonable. Window with any shading device should have lower average illuminance level than window without shading device. There may be an error in the model construction.

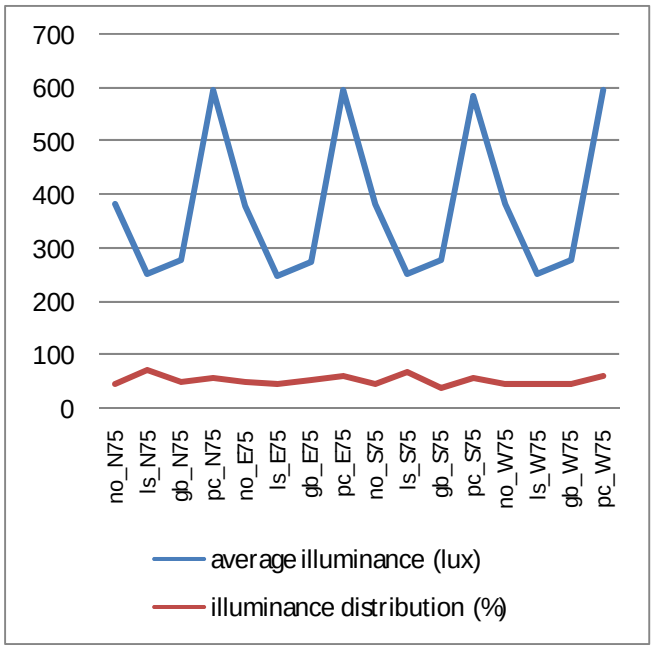

Figure 7: Average illuminance and illuminance distribution of windows for 75 students classroom (the second experiment).

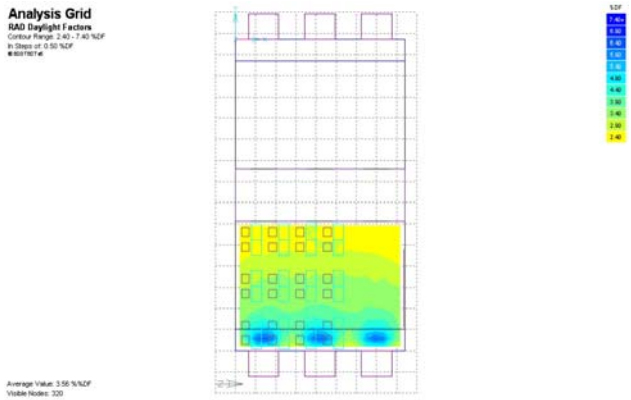

Figure 8: Daylight Factor in a classroom for 25 students with lightshelf facing to East (the first experiment)

Figure 8 and figure 9 show that high daylight factors (> 7%) or illuminance level (> 600 lux) are located on the area near the windows, because large amount sunlight passed through view windows directly. Two alternatives to improve daylight distribution without reducing window area in order to maintain comfortable view angles:

- Enlarge the shading device. This alternative seems to be unrealistic, as the recent shading devices are large enough.
- Change glass of view window with low visible transmittance glass, such as: tinted glass.

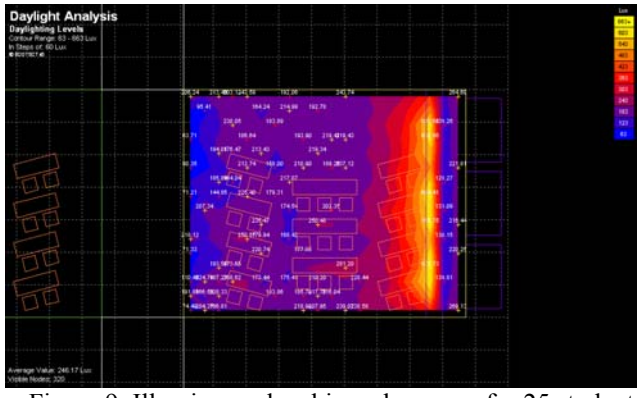

Figure 9: Illuminance level in a classroom for 25 students with lightshelf facing to East (the second experiment)

3.2 Heat gains through the building fabrics

Simulation results of hourly heat flowing through the building fabrics (figure 10) show similar conclusion. Window with projected clerestory is the most energy-efficient. Windows with glass block-clerestory perform better in heat gains comparing to windows with lightshelf. This is opposite to results produced by simulations of thermal transfer value through exposed wall surfaces.

Interesting results were shown by comparing results of classroom for 50 students to those of classroom for 25 students. Three window models have the same pattern. Heat energy flowing through classroom models for 25 students has higher rate than those for 50 students if window models applied are glass block clerestory, lightshelf and without shading. These make sense, because classrooms for 25 students have bigger WWR, window to floor area ratio, window to wall height ratio, clerestory height to room width ratio, and smaller room width to window height ratio.

Classrooms with projected clerestory show opposite results. Higher value of classroom for 50 students than its classroom for 25 students may be related to the ratio of the room width to the room length. The ratio of classroom for 25 students is 0.73 (0.02 higher than the ratio of classroom for 50 students). Relative narrow space allows higher penetration of solar radiation. Ratio of room width to room height seems to work in a room with projected clerestory.

A classroom having 10 W/m^2 heat loads through the building fabrics with adequate daylight level can be considered as energy-efficient if it is compared with 15 W/m^2 for energy standard of lighting for classroom [5].

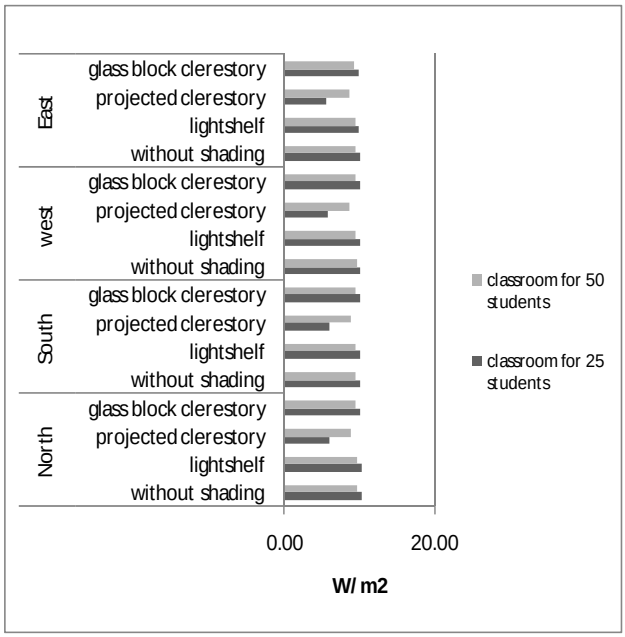

Figure 10: Hourly heat flows through the building fabrics (the first experiment)

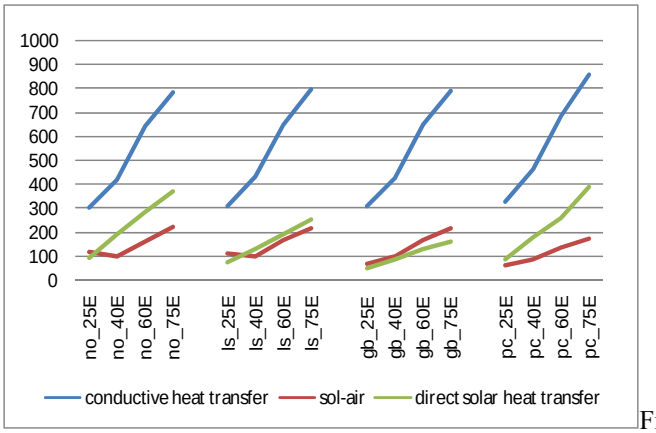

Figure 11: Heat Transfer Through The Building Skins of Classrooms Facing to East (in Watt)

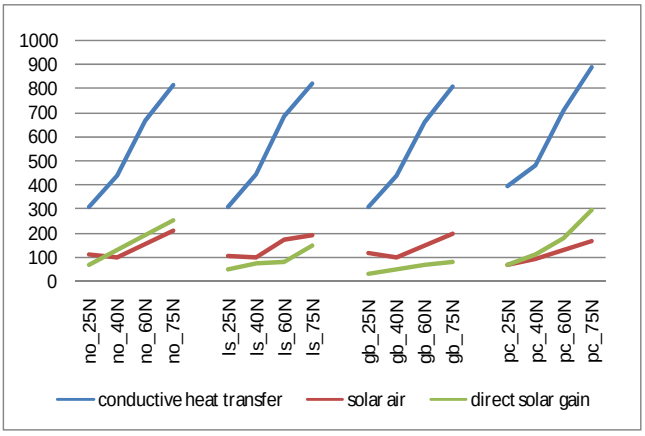

Figure 12: Heat Transfer Through The Building Skins of Classrooms Facing to North (in Watt)

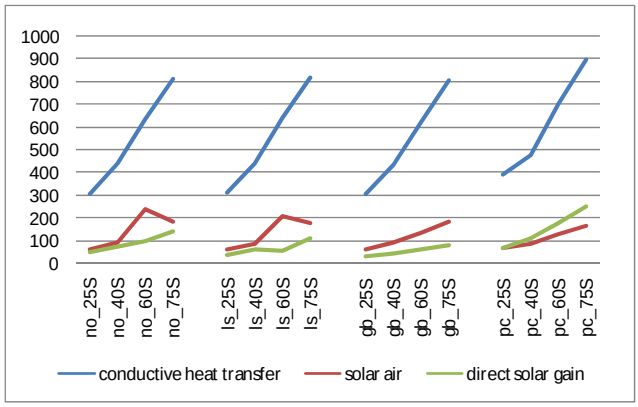

Figure 13: Heat Transfer Through The Building Skins of Classrooms Facing to South (in Watt)

Results of the second experiment show the effect of shading device on the heat transfer. The present of shading device reduces direct solar gain of the classrooms. Window with glass-block clerestory reduces the greatest direct solar gain. Lightshelf can decrease the direct solar gain. Window facing to south admits the lowest direct solar gain, but the greatest effect occurs on windows facing to east. Projected clerestory gives unreasonable results again. Its energy performance is worse than without shading device.

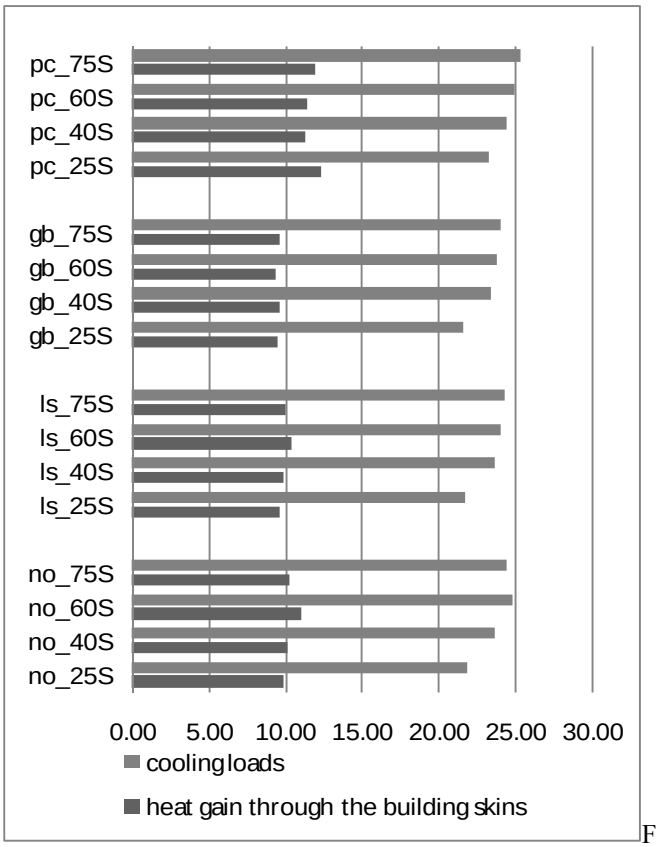

Figure 14: Energy profile of classrooms facing to South (W/m2)

Calculations of classrooms cooling load in the the second experiment show similar pattern. Window with glass-block clerestory or lightshelf has the best energy performance.

Glass-block clerestory can reduce solar heat gain until below 10 W/m^2 for the window facing to south. Relative high energy performance of classroom can be reached by applying lightshelf on its windows. Lightshelf can reduce cooling load a little bit lower than glass-block clerestory. However, it can distribute daylight more evenly, especially in classrooms with big capacity. Application of glass block on clerestory has an advantage in construction cost. Lightshelf and more even projected clerestory are still much more expensive. However, the internal shading device which presents on lightshelf and projected clerestory can prevent annoying glare that may appear on its clerestory.

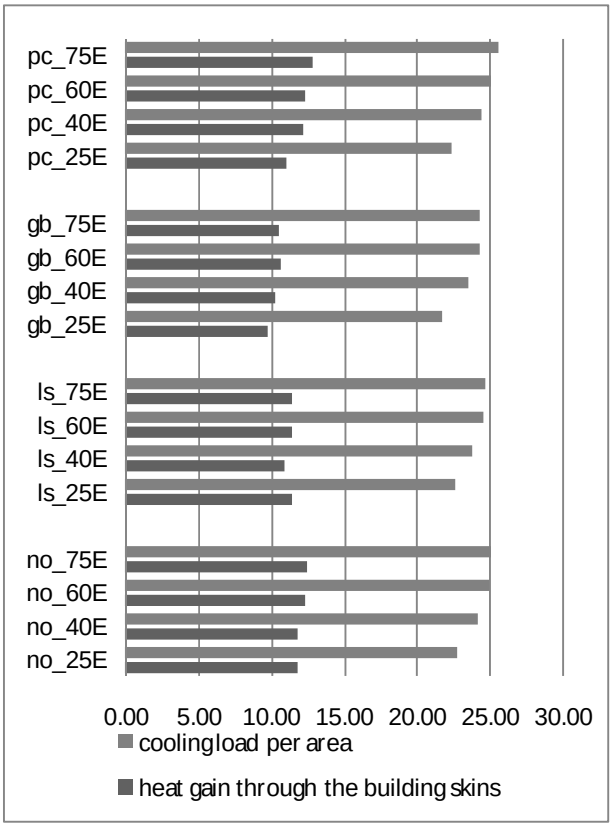

Figure 15: Energy profile of classrooms facing to East (W/m2)

3.3 Window glazing

Low-e double glass replaced clear glass on view windows in order to achieve the most energy efficient window. However, low-e double glass on view windows cannot improve their thermal performances. The amount of solar radiation transmitted through building envelope remains the same as those of view windows with clear glass. Low emittance glass cannot work effectively if there is only small temperature difference between the indoor and the outdoor (naturally ventilated room), but it work effectively in mechanically ventilated room.

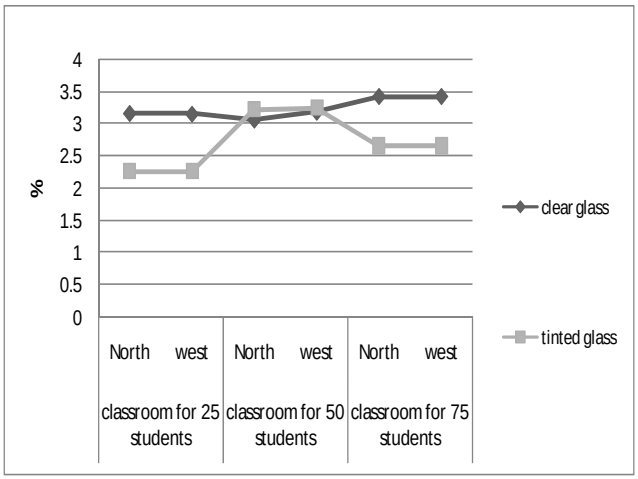

Figure 16: Comparison of average daylight factor between projected clerestory window with clear glass and with tinted glass (the first experiment)

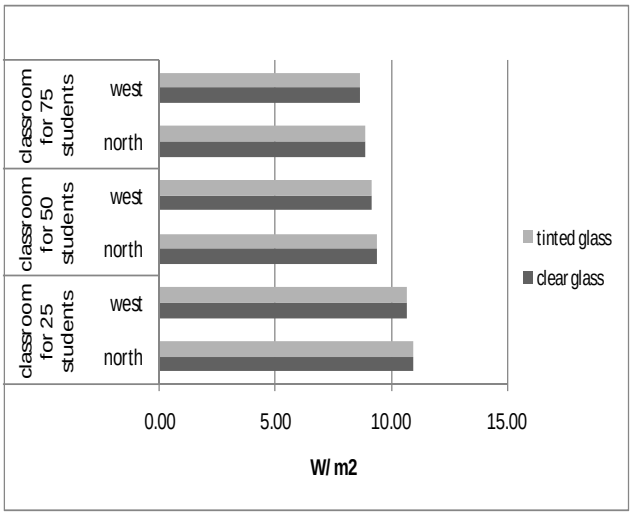

Figure 17: Comparison of hourly heat gains through the building fabrics between projected clerestory window with clear glass and with tinted glass (the first experiment)

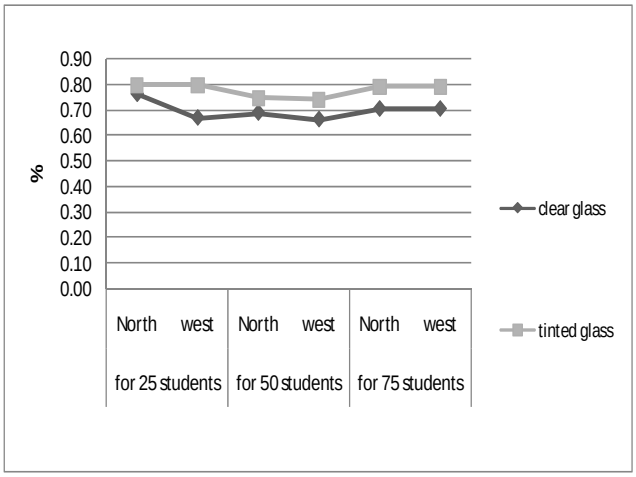

Figure 18: Comparison of daylight distribution between projected clerestory window with clear glass and with tinted glass (the first experiment).

Figure 19: Three dimensional picture of a classroom for 25 students with projected clerestory is resulted by Radiance (link to Ecotect) simulation.

Replacing clear glass with tinted glass on view window can improve the average and the distribution of daylight factor. All windows with projected clerestory and tinted glass on their view windows produce uniform daylight distribution (> 75%) and suitable daylight factors for learning activity (reading and writing). However, different interior illumination levels created by placing clear and tinted glass on the same wall plane cause a feeling of gloom.

4. CONCLUSION

Projected clerestory can protect the indoor area from direct solar radiation. Horizontal surface of the projected clerestory also functions as horizontal shading for view window below the clerestory. Its horizontal surface reflects sunlight into the deep side of the room depending on the ratio of clerestory height to room width. Less expensive alternatives are lightshelf and glass-block clerestory.

A window with 20% WWR can be considered as an optimal window area for classroom with reflectances 0.95 for the ceiling, 0.85 for the internal wall, 0.7 for the floor, 0.85 for the desks and 1.0 for the shading device; both for energy-efficiency and to maintain proper view to outside. Lower average classroom reflectance needs higher WWR, clerestory height, and window to floor area.

Comparing the results of the first and the second experiment, for classroom's window without obstruction from adjacent wall or building, the clerestory head height should be around 0.4 of the room width to achieve low energy classroom. One meter height view window with around 11% of clerestory head height to room height and 5% of clerestory head height to room width can distribute daylight evenly. Higher view window creates hotspot on area near the window. View window glazing with low visible tranmittance can improve the horizontal illuminance distribution.

ACKNOWLEDGMENT

The author wishes to thank Univ. of Atma Jaya Yogyakarta for financial support to conduct this research.

ABSTRACT

For most people live in small walk-up flat units in Indonesia, aspect of thermal comfort and food safety is not considered as a quality of life element. Nonetheless, satisfaction with their thermal environment and food safety has a place to influence the expectation about what their "dream" house is. The quality-of-life issues discussed in this paper were limited to thermal comfort and food safety and conducted in two multi-storey public housings in Semarang. This study assesses the inhabitant perception to their thermal environment, level of food safety knowledge including how appropriates the food hygienic practices applied in their daily life and propose some recommendations to improve it to advance their quality of life. Houses of each typical flat unit (27 m², 36 m², 54 m²) will be assessed through observation and interview using questionnaire. Thermal comfort was measured using method of Field Studies of Thermal Comfort (FSTC). The level of food safety knowledge was measured based on USDA/Partnership for Food Safety Education. The findings of study indicate lower satisfaction of thermal comfort and lower level of food safety knowledge among occupants who live in smaller flat units, while was lower.

Keywords*: thermal comfort, food safety, satisfaction, quality of life, public housing*

1. INTRODUCTION

According to the Indonesia Central Statistic Bureau [1] 45.6% of total 206 million populations in Indonesia are living in urban area. Almost 70% of those urban populations are the middle low and low income groups [2]. With the urban population growth rate 4.2% per annum during 1990-2000; urban development in Indonesia is characterized by rapid land-use changes in its urban center as well as by the conversion of prime agricultural lands to residential areas and other urban land use to the peripheries [3]. It follows that the need of new houses in urban area is raised about 800.000 units per year, not included the backlog of house units from the years before. Simultaneously, the increase of urban population growth in Indonesia have created seriously implications on the need of land for living space and shelters as the result of market forces because lands especially those in inner-city areas became scarce and more expansive.

Since the development of housings in urban area in line with population growth is not fit with the provided lands, the vertical-housing development has been promoted by Indonesian government as one of appropriate alternatives. For middle-low income groups, *Rumah Susun (Rusun)* has been built-up intensively in some major cities in Indonesia such as Semarang.

Unfortunately, Indonesia has not come close yet to solve neither its quantitative nor qualitative housing problems after three decades of development. Those quantitative problems may actually be influenced by the qualitative problems since the most Indonesians have miss-perception with respect to live in public residential buildings like *Rusun*. For many people, built-up for low income community means sometimes low cost construction (unsecured), low environmental quality (unhealthy) and low design quality (uncomfortable) [4].

1.1 QOL indicators

With respect to healthy city concept, housing conditions are part of the most general quality of life (QOL) indicators [5]. Nonetheless, in Asian developing countries such as Indonesia, studies on QOL especially in housings have been scarce and infrequent. Seik [6] mentioned that research efforts in this field are mainly focused on urban QOL originated from scholars in Western world who were from various disciplines such as sociology and psychology.

Eight essential indicators of housing quality components is identified by Lawrence [5] i.e. (1) site characteristics, (2) residential buildings as a shelter, (3) safe supply of water, sewage and solid waste disposal, (4) neighborhood ambient atmospheric conditions and indoor air quality, (5) household occupancy conditions which avoid transmission of infections and the occurrences of injuries (6) access to community facilities and services, (7) food safety and (8) control of vectors of disease that can propagate in the building structure.

To measure those indicators, researchers usually conduct the form of either objective or subjective measurements. The first is employed to assess the level of various basic needs of life as Maslow stated such as food and shelter. These needs are common human needs to all cultures, which indicated by objective conditions and settings (such as physical, social, and economics settings). On the contrary, Morris & Coombes argue subjective indicators are more at individual´s level of satisfaction indicated by psychological state [6]. Although both types of measurement assess QOL differently, they are interrelated. With regard to Maslow and Lawrence [6, 5] theory mentioned above, this research assesses thermal comfort

using subjective measurement while for level of food safety knowledge using objective measurement.

1.1.1 Thermal Comfort

ASHRAE Standard 55-2004 describes thermal comfort as "that condition of mind which expresses satisfaction with thermal environment" [7]. This standard aims to identify the combinations of indoor space environment (temperature, thermal radiation, humidity and air speed) and personal factors (activity and clothing) that will produce thermal environmental conditions acceptable to 80% or more of the occupants within a space [8]. In like manner, Fountain *et al* [9] suggest an alternative theory of thermal perception i.e. the adaptive model. It states that the match between one's expectations about indoor climate in a particular context and what actually exist will convince thermal sensation, satisfaction and acceptability. In terms of QOL, Malkina-Pykh and Pykh [10] mentioned that subjective satisfaction is usually described in strongly relation to one's expectations of it. One's satisfaction level of thermal environment explains one's expectation of a better condition than he/se feels at the moment.

A method so called Field Studies of Thermal Comfort (FSTC) is expounded by Nicol and Roaf [7] as an appropriate approach to evaluate thermal comfort environment in building. The focus of this method is more concerned with the responses to a building of its occupants. In the FSTC, the occupant is asked to express his/her own feeling at the time such as "how do you feel about temperature now?"

1.1.2 Food Safety

Obtaining safe food is everyone's right. Winarno [11] emphasized that food safety is the ultimate, first and most important prerequisite aspect must be fulfilled before other requirements of food. It means if food is no longer safe to be consumed so its nutritional content, deliciousness, appearance and quality have no meaning anymore, in fact that kind of food have to be destroyed. In addition to that, Act of The Republic Indonesia Number 7 of 1996 on Food [12] stated that food safety is included as one of QOL's elements. It stated that sufficient availability of safe, nutritious and quality food is a main pre-requisite, which must be met in the effort to arrange a system, which provides protection for the purpose of health, and to play a larger role in increasing the prosperity and welfare of the people. Food safety itself is defined as food safety is the condition and efforts required to prevent food from possible biological, chemical-contamination and contamination by other objects which may disturb, harm, and endanger the human health.

Human population consists of different age, living experience, healthiness, cultural knowledge, sex, political view, nutritional need, family states, type of work, and educational background. This condition will result in different perception on food safety [13]. Bappenas [14] reported that the first cause of food poisoning insidents in Indonesia during 2004-2005 comes from household food (food processed at household scale), see Table 1. One of the reasons of this occurrence is because of insufficient food safety knowledge of the food preparer in the household, as one of stakeholder in the food supply chain.

Table 1. Causes of Food Poisoning in Indonesia in 2004-2005

Cause	Number (%)	
	2004	2005
Household food	53,7	42,4
Processed food	15,2	15,2
Catered food	15,2	21,2
Snack food	12,2	17,9
Not reported	3,7	-
Miscellaneous	-	3,3

Source: Bappenas (2007)

This study assesses the inhabitant perception to their thermal environment, level of food safety knowledge including how appropriates the food hygienic practices applied in their daily life and propose some recommendations to improve it to advance their quality of life.

2. METHODOLOGY

The study described was conducted in two multi-storey public housings in Semarang. The buildings were built under different initiative programs and concepts since the problem of housing for low and middle income groups in Semarang was issued to be solved.

1. The first was *Rusun* Pekunden was built in 1996 using "top down" design approach in which the population has no experience on participatory decision-making to plan their environment. Situated on a central district of city, it comprises 92 flat units disposed in five blocks which have 4-storey height.
2. The second was *Rusun* Bandarharjo, which is located in an urban fringe of Semarang nearby the national harbor Tanjungmas, about 2 kilometers to the north from city centre, and orientated at 22 degrees to the true north. Around the housing some villages called kampongs are exist which has high density of land occupancy. It comprises 210 flat units disposed in three blocks, which has 4-storey heights.

Figure 1 : Building facades of *Rusun* Pekunden & Bandarharjo

This study is conducted in "different period", which is during April – May 2006 for thermal comfort measurement and during May – July 2009 for the level food safety knowledge measurement. The second part of this study is an extension of the first, since QOL assessment need to be measured in more aspects to attain more complete QOL status. This research was done in

three steps, which are observation, development of questionnaire and interview of respondents using the questionnaire.

Climatic condition

Questionnaire surveys on thermal comfort were conducted in a season characterized by hot and humid days and nights. The daily average temperature recorded during that "period" fell within 25.6-29.1°C and the maximum RH was higher than 60%, occasionally reaching 90%. As recorded by Semarang climatology station, hot winds blow from Southeast direction to Northwest direction during that "period". The monthly wind magnitude is only up to 3.6 m/s with the average value 2.3 m/s at the height of 10.0 m above ground level

Sampling

To asses thermal comfort aspects, a total of 165 respondents from two multi storey low income housings were asked to participate in a questionnaire survey. More than 50% of them involve in all observation seasons. The objective is to investigate the degree of thermal comfort based on the occupant's perception.

Table 2. Demographic data of respondents for thermal comfort

.

Housing	Flat Unit	Gender	Age groups					Sub total	Total
			<20	21-30	31-40	41-50	>50		
Pekunden	27	M	3	17	7	7	9	43	
		F	9	15	13	6	6	49	
	54	M	5	0	1	3	4	13	
		F	1	0	3	2	1	7	112
Bandarharjo	27	M	1	5	5	4	1	16	
		F	4	5	5	0	1	15	
	36	M	0	1	2	1	3	7	
		F	1	9	1	2	2	15	53

Table 3: Sampling distribution

	Hot season
Number of subjects	165
House type (number of subjects)	27(31) 36(22) 54(33)
Date of survey	1 April 2006 – 22 May 2006
Time of survey (number of subjects)*	M(105) A(87) E(94)

**) M = morning (07.00 -11.00 am), A = afternoon (13.00 -16.00), E = evening (18.00 -22.00)*

Simultaneously, questionnaires about the level of food safety knowledge were also conducted to housewives as respondent samples. The housewives were chosen since they have important role in food supply for their family. The number of respondents used from *Rusun* Bandarharjo are 49 respondents (type 27) and 16 respondents (type 36); whereas from *Rusun* Pekunden are 68 (type 27) and 9 (type 54.)

The key questions in food safety knowledge questionnaire are divided into three parts, which are background; basic information related to food safety; food safety knowledge and food handling practices. This knowledge questions was developed based on the 4 elements (separate, cook, chill, and clean) of food safety identified in the USDA/Partnership for Food Safety Education, Fight Bac!® program [15]. The response for basic food safety knowledge and food handling practices questions was agree, disagree or don't know. Knowledge based questions were graded as right or wrong. For purposes of statistical assessment, "don't know" was considered as an incorrect answer. Whereas for food handling practices 1 – point is given for the proper handling practice (right answer) and 0 – point is given for improper practice (wrong and don't know answer.)

In addition to that, there was a close observation conducted during data collection using questionnaires, which acquire information about typical flat unit plan. This information is needed to find out the use of existing rooms related to food hygiene practices.

3. RESULTS AND DISCUSSION

3.1 Thermal Comfort Aspect

3.1.1 Comparison between seasons

Fig. 2 shows that for all seasons, the thermal acceptability is below to 80%. Surprisingly, it is not like what expected, with mean thermal sensation (ASHRAE/Tsv) vote of 0.434, the evening session can satisfy only 44% of people.

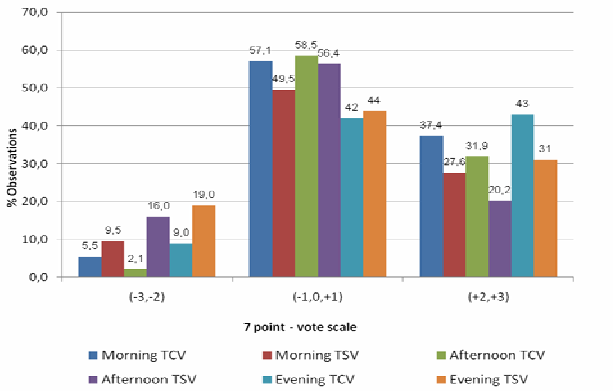

Figure 2 : Thermal comfort acceptability for different sessions indentified on ASHRAE scale and Bedford scale [N (M) = 105, (A) = 87, (E)= 94)]

Distribution of those thermal sensation votes is seen have a correlation with wind sensation scale as shown in Fig. 3. It describes a high 29.8% of occupants have a feeling that the air movement for evening season was in motionless condition.

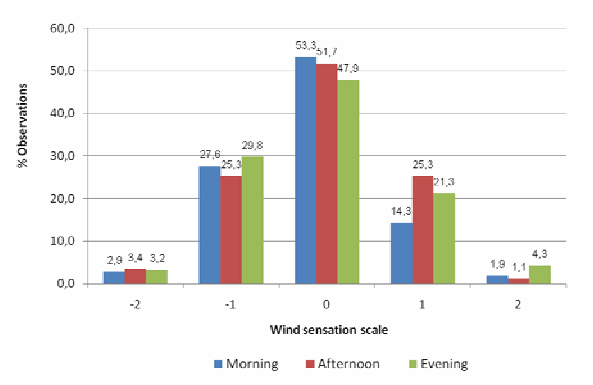

Figure 3 : Wind sensations for different sessions
[N (M) = 105, (A) = 87, (E)= 94)]

3.1.2 Comparison between flat types

Based on the ASHRAE scale, none of occupants in all flat types is able to achieve an acceptable thermal condition with 80%, whereas with Bedford scale, only they who live in flat type 54 (83.3%) expressed satisfaction with their indoor thermal environment. It confirms that a comfortable condition of a house is usually described in relation to type, size and location.

Inspection to a correlation between thermal sensations with wind sensation, occupants living in flat type 27 units seem to experience an extreme condition. A high percentage of respondents (76.7%) in left categories (-2,-1) feel the low wind speed in their indoor environment.

During the visit of the field survey, evidence was found dealing with the unused bedroom in the bedtime. By a deeply interview**,** the occupants mentioned that this bedroom occupied by 5 people was uncomfortable for sleeping due to the high temperature and lack of fresh air inside. It follows that they prefer to sleep in living room at the floor.

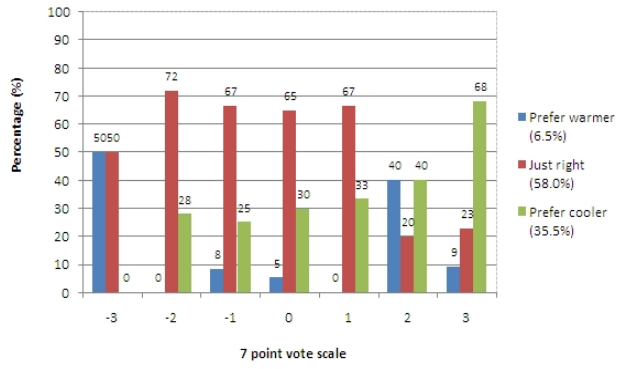

Figure 4: Thermal comfort preference (N=165)

From Fig. 4 we can see that there is a tendency for occupants to perceive coolness or cold sensation as comfortable condition. It is reflected that occupants wanted to be cooler is relatively higher compared to the percentage of occupants wanted to be warmer by 35.5%. Hence, occupants who voted cool (-2), slightly cool (-1) and neutral (0) said that those conditions are just right for their bodies. It might indicate that people living under tropical hot humid region wish a cooler environment since they have expectation about the better condition in cool level.

Evaluating human response to their real environment in building, some complex factors of human being such as culture, gender, economic status, preference and expectation may be not included in human heat balance method [8]. Accordingly, currently approaches are more suggested to view human as active subjects who can modify their environment and behavior for attaining a state of comfort.

Fig. 5 illustrates various adaptive actions which are commonly employed by the occupants when they feel uncomfortable inside. Going out from indoor rooms to outdoor space is highly preferred by occupants with the percentage of 39%. Other favored action in this case is the usage of fan with the percentage of 33%.

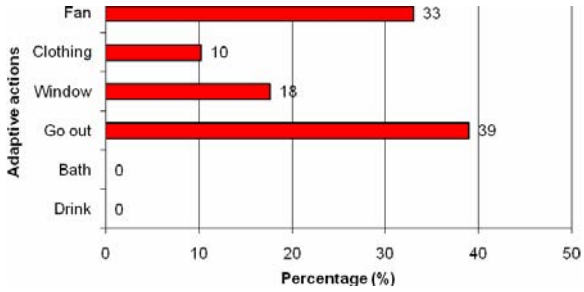

Figure 5: Adaptive behavior (N=138)

Interestingly, the environmental control by opening window is less favorable for occupants with the percentage of only 18%. Compared to finding results from previous natural ventilation studies conducted in tropical hot humid region such as Wong & Huang [16]; Feriadi [17] & Wong [18], this different phenomenon can be explained with these following arguments. Firstly, the low percentage of window indicates a real problem that the current available window is insufficient for improving the uncomfortable condition inside as mentioned in earlier discussion. Secondly, the unique characteristic of observed buildings should be considered where the sheltered skywalks can facilitate not only social engagement for low-middle income groups but also provide open and airy feeling.

On the other hand, relatively higher preference for the use of fan can signify that in facts occupants also want to experience comfort sensation due to wind or air movement inside their flat units. Also, this result shows a good agreement with the common phenomenon in Indonesia where the most homes has at least one fan unit to control their environmental thermal comfort.

A significant correlation between the favorable action and the most comfortable space is found where occupants prefer to go to terrace for obtaining more comfortable condition at outdoor space compared to indoor environment such as at living room or bedroom by

percentage of 51%. This condition may be due to the following reasons. Firstly, natural ventilation cannot work well within small flat units due to inappropriate design in which the cross ventilation pattern was changed to be single-sided ventilation pattern. In other
word, there is insufficient air contact due to inappropriate room organization. Secondly, dense occupant with high activity in afternoon, for instance, creates heat accumulation that cannot be transferred well to outside due to the lack of air movement. Thirdly, terraced corridor provides airy spaces for various forms of activities.

3.2 Food Safety Aspect

3.2.1 Floorplan observation

From the conducted observation on typical flat unit plan, it is revealed that all three types of flat unit have kitchen that is relatively near the toilet and not good enough air circulation within (see Fig. 6) One of the consequences of having limited area of living is higher risk of cross contamination of microorganism among the existing rooms. In the case of toilet, there is high possibility to leave unoccupied toilet open, which will lead to microbial spreading inside the flat. Activities in the kitchen influent the introduction or removal of air, such as cooking drives off oxygen, while stirring, mixing, and beating foods introduce oxygen. Some bacteria grow rapidly only in the presence of free oxygen; others require the absence of oxygen; some grow in both atmospheres and even others may have special atmospheric requirements [19]. Nonetheless, the occurrence of cross contamination via hands was already prevented through washing-before produce-food behavior practiced by more than 75% inhabitants.

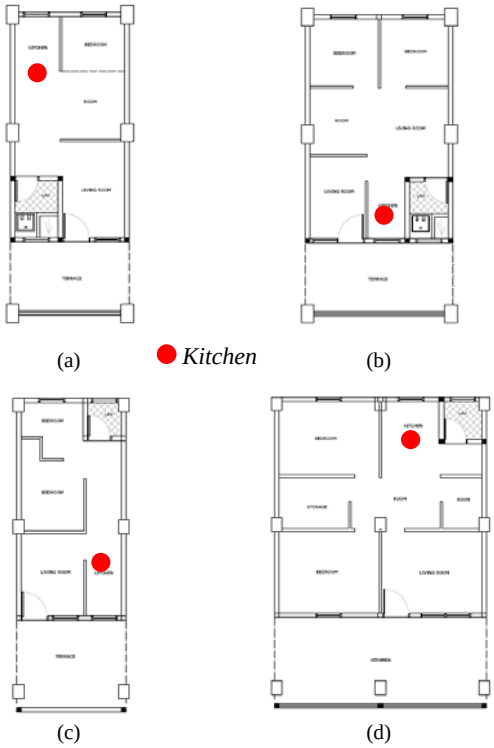

Figure 6: Typical Floorplan of four existing flat unit in *Rusun* Bandarharjo (a) type 27 (b) type 36 and Pekunden (c) type 27, (d) type 54.

3.2.2 Food Safety Knowledge

Housewives represent a family member which is mainly involved in preparing and providing meal in their family. Thus, level of food safety knowledge of housewives is crucial. Housewives assumed as home food preparer is a critical link in the food production to consumption to prevent food-borne illness [20].

Studies have estimated that between 50% and 87% of reported food borne disease outbreaks have been associated with the home. Identified common mistakes identified include serving contaminated raw food, cooking/heating food inadequately, having infected persons handle implicated food and practice poor hygiene. However it is known that a part of food borne illnesses in the home result from eating raw foods of animal origin or engaging in unsafe food preparation practices in the home [21]. Therefore, home food preparer need to know how to minimize the presence of pathogens or other risky contaminants in food.

Table 4 . Distribution of the right answers given by respondents from different multi storey housings to questions related with general food safety knowledge

Questions	The percentage of true answers (%)			
	B-27	**B-36**	**P-27**	**P-54**
• All harmful bacteria are destroyed by thorough and complete cooking	**93.9**	**81.3**	**83.8**	**100**
• Moldy food is safe to eat if you scratch the mold off the surface of the food	**93.9**	68.8	**94.1**	**88.9**
• It can take only a small number of harmful bacteria to make the person sick	**81.6**	**75.0**	60.3	44.4
• Unsafe foods can be identified by the way they look and smell	*4.1*	*0.00*	*4.4*	*0.00*
• In the kitchen, food can be contaminated with harmful bacteria during handling and storage	*69.4*	*68.8*	*69.1*	*66.7*
• Bacteria can grow and survive in refrigerated food	**77.6**	56.3	52.9	44.4
• It is safe to eat raw cookie dough or cake batter that contains raw eggs	*44.9*	*25.0*	*45.6*	*66.7*
• Meat that has been handled and/or prepared properly can be kept in the freezer for 6 months and still be safe to eat	**87.8**	0.00	61.8	**88.9**
• It is safe to place cooked meat on the same unwashed plate you used for the uncooked food	**95.9**	**75.0**	**97.1**	**100**
• It is safe to thaw meat in the room temperature	*28.6*	*25.0*	*19.1*	*44.4*
• The color changes of meat indicate meat quality deterioration	**98.0**	**87.5**	**88.2**	**77.8**
• It is safe to consume half-cooked meat	**83.7**	**87.5**	**86.8**	66.7
• It does not necessary to wash vegetable or fruit before we consume it	**95.9**	**87.5**	**98.5**	**88.9**

Note: B = Bandarharjo (B-27: type 27; B-36: type 36)
P = Pekunden (P-27: type 27; P-54: type 54)

Table 4 presents the right answers given by respondents to the questions about general food safety knowledge of housewives from *Rusun* Bandarharjo and *Rusun* Pekunden. The result shows that most of respondents have no sufficient basic knowledge on food safety. Only respondents from B-27 showed adequacy in food safety. It is indicated with the percentage of correct answers that reached 75% of 9 out of 13 given questions. While, other respondents from B-36, P-27, and P-54 only can answer 5 - 6 out of 13 questions with 75% correct answers (the limit of subject proficiency.) The result implies that people with low income, which is associated with *rusun* inhabitants, not always has lack of food safety knowledge.

Almost all of respondents agreed that harmful bacteria could be eliminated by thorough complete cooking (81.3-100%.) However, many of them stated that it is safe to consume raw food that contains raw eggs. Microbial hazards include food poisoning bacteria such as *Salmonella*, *E.coli*, *B. cereus*, *S. aureus* and many others can spread from raw foods such as meat, poultry and unwashed vegetables either directly or via food preparers, work surfaces and equipment [22]. Eggs can carry harmful bacteria inside and on their shells. Salmonella is often found as a threatening contaminant in eggs. Salmonella – positive eggs present another risk of which many food preparers are unaware – cross contamination. Cracking, separating, or beating an egg can spread Salmonella over a wide area in the kitchen, contaminating work surfaces, utensils, mixing bowls, and hands. Moreover, the numbers of live Salmonella in a contaminated egg can become dangerously elevated if the egg has been mishandled – high enough that traditional cooking methods may not kill all of the Salmonella organisms [23]. Therefore, egg or food contained with egg should not be consumed raw. These raw foods can be made safe by cooking which kill bacteria [20].

Most of respondents also believed that it is not safe to place cooked food on the same unwashed plate, which has been used for the uncooked food (75 – 100%.) However, the respondents seem do not have good understanding on cross contamination. Most of them do not aware that harmful bacteria contamination can occur during food handling and storage in the kitchen. The presence of pathogens in raw meat, poultry and eggs places the burden of ensuring food safety on the shoulders of food preparers. Insufficient and improper storage conditions can cause the growth of microbial contamination. Clearly the home kitchen can be a dangerous place. Cross contamination of the pathogen microorganisms from storage places to production area can occur if food preparers pay less attention on hygiene practices. Poor attention to hand washing, inadequate cleaning of utensils and work surfaces, and use of contaminates sponges can contribute to cross contamination [24, 23].

Moreover, most of them do not know that thawing meat in room temperature can cause bacterial the growth of microbial contaminant. Food poisoning bacteria can grow in food that is not defrosted properly. Food can be thawed at room temperature, but it should be done quickly as harmful bacteria could grow if the food gets too warm while thawing. Ideally thawing or defrosting is done in the fridge. Putting food in the fridge will keep food at a safe temperature while it is defrosting. Microwave or putting the food in a container with a lid and then place it under cold running water also can be alternatives [22].

Most respondents also stated the changes of food color denote the degradation of food quality (77.8 – 97.9%.) However, it seems that respondents only rely on the visual observation to detect the degradation of food. As a matter of fact, microbial contamination on food cannot be examined only by the way the food look and smell. The presence of pathogenic bacteria or toxin in food has to be found out through laboratory testing.

Table 5. Distribution of the right answers given by respondents from different multi storey housings to questions related with food handling practices

Questions	The percentage of true answers (%)			
	B-27	B-36	P-27	P-54
• When grocery shopping, you always choose good quality of food	**98.0**	**100**	**97.1**	**100**
• You always wash fruit or vegetable before further processing	**100**	**100**	**97.1**	**100**
• You always wash fruit and vegetable by soaking it in water	53.1	18.8	44.9	33.3
• You always wash raw meat and fish before further processing	**98.0**	**93.8**	**97.1**	**100**
• After cutting raw food, you wash the cutting board and knife first before cutting cooked food	**95.9**	**93.8**	**84.1**	**88.9**
• You separate raw meat and fish from ready-to-eat food	**93.9**	**93.8**	**97.1**	**100**
• It is important to wash your hand after cracking an egg	**85.7**	**81.3**	**88.4**	**100**
• You or your family consumes raw egg	46.9	12.5	28.9	33.3
• You cook egg and make sure that the egg yolk is well cooked	**93.9**	**87.5**	71.0	**88.9**
• You wash your hand with soap before processing foodstuff	**81.6**	**75.0**	**76.8**	**77.8**
• It is safe to eat snack while you preparing food	57.1	43.8	47.8	55.6
• It is safe to use the same spoon to taste then stir the food without washing it	**83.7**	**81.3**	7.3	11.1
• After handling raw meat, fish, and/or poultry, wiping hands on a paper towel is sufficient to clean hands	**93.9**	**81.3**	17.4	11.1
• It is safe to clean your hand using the same towel to clean kitchen utensils	**93.9**	**87.5**	17.4	11.
• You often wash towel that you use for hand cleaning	59.2	**75.0**	69.6	55.6
• It is safe to keep cooked rice in room temperature more than four hours	**77.6**	62.5	50.7	11.1
• It is safe for person who suffer from typhus, diarrhea, cough, influenza and dysentery to produce food	51.0	37.5	33.3	11.1
• It is important to have short and clean hand nails while produce food	**87.8**	**75.0**	**84.1**	**100**
• It is safe to consume food that is already keep for more than six hours in room temperature and reheating it	28.6	31.3	46.4	44.4

Note: B = Bandarharjo, P = Pekunden

In general, respondents only apply appropriate food handling practices for eight out of nineteen questions with

minimum 75% of true answers. The result reveals that respondents from smaller flat unit tend to aplly more food handling practices than the bigger one (See Table 5.)

We also can see from Table 5 that the respondents answer five out of nineteen questions with less than 75% correct answer. Most of them do not understand that cleaning fruits and vegetables by soaking will cross contaminate microorganism among the washed food and also the soaking water. Interestingly, more than 97% of the respondents surely choose good quality food and they also wash fruit and vegetable before they consume or process it. Meanwhile, eating raw eggs become the habit of less then half of the inhabitants (12.5 - 47%); this condition is risky to cause bacterial infection as it is explained earlier. Consuming snack during food production will increase risk of microbial contamination, since the preparer's hand sometimes touch his lips and may cross contaminate the food produce. Many bacteria and viruses found in the mouth can cause disease, especially if an employee is ill. For instance, the preparer who suffers from typhus, diarrhea, cough, influenza and dysentery produce food, the pathogenic microbes can be transported from the person to food via hand or air. During a sneeze, some bacteria from the mouth are released into the air. The microorganisms may infect other people or may land on food while it is being handled [26]. Citing Buckland and Tyrell (1964) in Lelieveld *et al.* [27], they reported that sneezing and blowing the nose were more than 1000 times more efficient than coughing in producing infectious aerosols from nasal secretions.

Some housewives assume that consuming food that is already keep for more than six hours in room temperature and reheating it is still safe (28.6 – 46.4%.) As a matter a fact, the number of microorganism within the food will increase exponentially during room temperature storage. Even after reheating the food, it should not be consumed since the food is already decayed. They do not understand that most foods spoil easily because they have the nutrients that microbes need to grow. One way to inhibit counts of microbes is by cold storage, which only allows facultative microorganisms and psychrotrophs to survive [26].

Although it is important for people to distinguish safe food and to develop food safety knowledge, behaviors, and practices; there are only a few studies conducted on food safety knowledge and perceptions of consumers in Indonesia. Hence, it is required to carry out further research on food safety literacy, especially focusing on people who act as food preparer. Later on, it is required to develop food safety education program for every element involved in food supply chain, including home food preparers.

4. CONCLUSIONS AND RECOMMENDATIONS

- Since the shortage of land inline with the growth of cities in developing countries like Indonesia will dictate the development of buildings vertically, it is worthy to enhance the design quality of multi-storey public housings with respect to local climate characteristics and room layout.
- From the subjective measurement results, it can be concluded that people who live in tropical hot humid regions have expectation to reach a better thermal condition in cooler environment. Nevertheless, they can accept slightly warmer condition by carrying out some adaptive behaviors. In terms of Quality-of-Life, this subjective satisfaction can enlighten one's expectation of a better condition. If building occupants are given opportunity to modify their environment, they will make themselves comfortable.
- Dealing with building design of multi storey public housings in Indonesia, it is important to be mentioned that providing flat units with small area i.e. type smaller than 27 m^2 is no longer suggested. In fact, it is a difficult task to create a comfortable environment in a small unit by utilizing natural ventilation optimally. It retains a retrograde image of uncomfortable building for living.
- Most of respondents have no sufficient basic knowledge on food safety, except for B-27 respondents. It implies that people with low income, which is associated with *rusun* inhabitants, not always has lack of food safety knowledge. Moreover, respondents from smaller flat unit tend to apply better food handling practices than the bigger one.
- It is suggested to conduct further research on microbial air quality and microbial density on food and kitchen utensils. The result will give more complete picture on food safety status as one of QoL indicators.
- It is required to carry out further research on food safety literacy, especially focusing on people who act as food preparer.

ACKNOWLEDGMENT

The authors would like to thank Sherly Ardiany Subarjo and Nancy Yustina for their valuable contribution in conducting the survey and data input of the level of food safety knowledge.

ABSTRACT

The uncontrolled growth of population has influenced some pressure to space and environment. As an effect, we must making serious efforts of the housing demand and its facilities. Meanwhile, good quality of the healthy housing is everyone's need. The land limitedness sometimes brings some quite bad impacts to the quality of the environment itself and eventually will cause the decrease of the quality of environmental housing and people's living quality.

This research is aimed to analyze some factors which influence the quality of housing environment. This research is implemented in a local/self-supporting and formal housing in district of North and South Cikarang.We obtain data from the survey result and questionnaires addressed to some samples of people around the location. We use descriptive and discriminated analysis to find out the significant factors of the housing quality and get discriminated equation to estimate the quality of the housing environment. The result of the research states that the quality of air/noise, reforestation/greening, road width, transportation and numbers of places worship are the main factors which determine the quality of the healthy housing whether it is good or not. Also we get the discriminated equation as follow:
Y = 0,601X1 + 0,165X2 + 0,1615X3 + 0,590X4 + 0,471X5 – 0,662X6 – 4,835

Cutoff point of group of housing environment health is -0.6. This means that the environment can be included in good health of environment if Y> 0.6. Classification accuracy is 67.8%.

1.INTRODUCTION

Housing area have been increasing about 50% during ten years ago, and most of them as formal housing at urban area. An Uncontrolled of housing growth cause the decreasing of environmental quality of residential

The growth of residential are not followed the development of infrastructure which to serve the residential for basic needs such as water, to maintain environmental sustainability and support the flow of goods and people between internal and external regions in the city can cause of degradation for quality environment of residential.

This research carried out at Cikarang District of North and South. The reason for choosing the location is as these districts are located in Bekasi Regency, which borders directly with Jakarta, so Bekasi obtain additional population of DKI Jakrta

The research focused on studying the factors influencing the quality of housing environment. The objectives of the research were: (1) to evaluated the residential quality based on standard guidelines by Department of Health (2) to identify the factor assosieted to quality of housing environment, (3) to make the descriminan formulation of housing environmental quality

1.1.Housing and Residential

Housing according to Decree of The Minister for Public Health of RI Number 829/MENKES/SK/VII/1999 is functioning house group as residence environment or dwelling provided with environmental facilities and basic facilities.

Residential according to Minister for Public Health of RI number 288/MENKES/SK/III/2003 is housing, hostel, dormitories, kondomonium / apartment, mansions and of a kind him.

According to SNI concerning Procedures Planning of residential defined that housing environment is a group of houses with environmental facility. Environmental facilities are road/street, drinking water channel, drainage,

solid waste disposal, electrics network. And the infrastucture at residential consists of educational facilities, healthy facilities, commercial, governance,public service, recreation, and culture.

1.2.Environmental Quality of Housing

Environmental Quality of Housing consists of physical and non physical component (social of economics). Direktorat Cipta Karya(1979) specified level of quality of housing environment use parameter such as . (1)furnerability of location against natural disasters; (2)quality of fresh water resource; (3)quality of air and noise pollution; (4)greening/penghijauan; and (6)facilities and infrastructure consisting of sanitation, waste management, drainage/sewerage system, condition of roads, transportation, education and worshipping facilities.

Identification of Housing Environmental Health Quality level of each type of residential areas was evaluted based on basic standard of Minister of Health Republic of Indonesia no:829/Menkes/VII/1999 regarding criteria of Housing Environmental Health Quality covering six aspects: critical areas, quality of air and noise pollution, reforestation/greening, disease vectors, and environmental facilities, and infrastructure such as transportation facility, school, worship facilities and vector of disease

2.METHODOLOGY

2.1.Stage sampling

Type of the research used is analytic descriptive research. Amount of Sample is taken pursuant to formula of Slovin, 1994 as follows:

$$n = \frac{N}{(1 + N e^2)}$$

in this case:
n = amount of sample every types housing
N= amount of populations every housing type in one segment
e = diffuseness of carelessness because of mistake of intake of sample which can be tolerated. To the amount of populations 500-2500, assess e gyrate 2 - 10%.

2.2 Phase of Identification and Classification of Health of Environment Housing

Factor Physical and non physical at indicator mount the quality of health of housing environment is given by score 1 to 5 at propagated questionnaire to resident in region of North and South Cikarang.

Classification analysis result of calculation of health of housing environment is based on the amount of variable scores health of housing environment and factor of scale is later; then calculated by highest and the lowest score. According To Direktorat Cipta Karya(1979), classes amount made by classification 4 class health of environment that is:
class 1 : very good,
class 2 : good,
class 3 : rather good,
class 4 : unfavorable.

Formula used in class interval is:
class interval =

$$\frac{\text{The highest score – The lowest score}}{\text{The amount of class}}$$

Class 1 : very good	(75 – 60)
Class 2 : good	(59 – 44)
Class 3 : rather good	(43 – 28)
Class 4 : unfavorable.	(27 – 15)

Hereinafter to discriminan, analysis to know variable having an effect on (variable of predictor) at forming of health of environment housing of dab obtained also equation of model of its discriminan.

Through analytical method will be identified and tested by variable data in each housing environment:

1. Variable which is enough significant statistically as predictor variable (with f value < 0.05) so automatically process of analysis will be discontinued
2. Model of Discriminan used is
   $Y= C + B_1X_1 + B_2X_2 + B_3X_3 + B_nX_n$

Where:

- Y is the level of quality of health of housing environment at selected housing
- C is number of Constanta of equation of discriminan
- B1, B2, B3 and of Bn is the level of function value from each predictor variable X1, X2, X3, and Xn 3. Critical point is boundary value determining what is type health of housing environment including very good classification, good, rather good, unfavorable, according to Santosa and Tjiptono (2004), and and determined based on the calculation formula:

$$Z_{cu} = (Nb.Za + Na.Zb)/ (Na + Nb)$$

3.DATA ANALISYS

The health of environment housing data obtained from propagated questionnaire to 182 houses in district of North and south Cikarang.

3.1.Health of Environment Housing

Measurement of health of housing environment is meant to know how condition of quality of environment which is in

district of North and South Cikarang. Measurement of health of housing environment is based on some physical variables and non-physical. Pursuant to field survey obtained data that without differentiating self-supporting housing and foral housing explained that counted 22 boxes of sample which in district of North South Cikarang and enter in criterion health of good housing environment (Class of II) and 2 boxes of sample enter in criterion health of rather good housing environment (class of III).

Meanwhile for the district of North Cikarang that counted 20 boxes of sample, existing enters in criterion health of good environment (class 2) and 5 boxes of sample enter in criterion health of rather good housing environment (class 3).

3.2.Analysis of Discriminan

Analysis of discriminan is aimed to know some phenomenon that is how relation of level the quality of health of housing environment with characteristic variable at housing area. What kind of variable of having an effect on or becoming variable of predictor at level of quality of health of housing environment.

Analysis Discriminan of Health of Environment Housing
Health of housing environment in North and South Cikarang reside in two conditions that is health of good housing environment (class 2) with score value range between 46 - 59 and health of rather good environment (class 3) with value 30 - 45.

Pursuant to analysis of discriminan for the health of housing environment, obtained data that from 13 variable found on health of housing environment, there are 6 most differentiating variables to class health of good housing environment (class 2) with class health of rather good housing (class 3). This matter can be seen at table 1.

Variable with value of significant F 0.05 meaning there is difference between environmental class 2 with environmental class 3. Variable differentiating is the quality of air / noise, tree protector of road, green space, wide environmental road, transportation medium and Places worship. Meanwhile variable which cannot differentiate between rather good and good environmental quality is location, quality of ground water, sanitary, solid waste disposal, drainage, condition of environmental road, amount of school and vector diseases

Table 1. Significancy Score
Health Of Environment Housing

Tests of equality of group means

	Wilks' Lambda	F	df 1	df 2	Sig.
Quality air, noise	,846	10,358	1	57	,002
Tree protector of road	,911	5,591	1	57	,021
Green Space	,865	8,898	1	57	,004
Wide of road	,901	6,294	1	57	,015
Transportation facility	,922	4,830	1	57	,032
Places worship	,900	6,351	1	57	,015

Process hereinafter is to look for equation of discriminan. It is approach model of calculation of class type of health of housing environment
table 2. Tables of discriminan function of health of housing environment.

Table 2. Canonical Discriminant Function Coefficients

	Function
	1
Air quality	
Noise, Vibration	,601
Tree protector of road	,165
Green Space	,615
Wide of road	,590
Transportasi	,471
Places worship	-,662
(Constant)	-4,835

Unstandardized coefficients

Pursuant to table 2 obtained by equation of discriminan for the health of housing environment shall be as follows:

$Y = 0{,}601\ X_1 + 0.165\ X_2 + 0{,}615\ X_3 + 0{,}590\ X_4 + 0{,}471\ X_5 - 0.662\ X_6 - 4{,}835$ (equation 1)

Where:
Y = Class of health of environment that is class 2 (good) or class 3 (rather good)
X1 = Quality of air, noise
X2 = Tree Protector road
X3 = Green Space
X4 = Wide of environmental road
X5 = Medium Transportation
X6 = Places worship

Explanation of distinguishing variable between qualities of health rather good and good environmental shall be as follows:

Noise at housing with good environmental quality relative peaceful with gyration < 50 dB, and air quality tends to cleaner of cause far from motor vehicle pollution and noise. Meanwhile the noise quality at housing with rather good quality is ranging from 51-60 dB. Analogical from fisrt equation obtained positive sign (+) at X1, this matter mean that good progressively air quality of housing hence will have good progressively also the quality of health of housing environment.

Protector tree road for good category have amount of above 50% from existing housing area, meanwhile for rather good category have 25-50% protector tree at housing area. Based on first equation obtained positive sign (+) at X2, matter this means more and more protector trees road of housing environment will compare diametrical with environmental quality of housing.

Green Space meant to improve the environmental quality, comfort, freshness and avoid environmental degradation for sustainable development. Green spaces at housing are with category health of good environment between 25 - 50% from housing area. Meanwhile Green spaces at housing with rather good environment class gyrate less than 25% from housing area. Based on first equation is obtained positive sign (+) for the X3, matter this means more and more green space at one particular housing environment hence will good progressively also the quality of health of housing environment.

Transportation medium at housing with quality health of good environment, more complete, generally they use ojek (rent motorcycle), private vehicle or made available by city transport residing in at elbow main road. Meanwhile at environmental quality of rather good housing is generally only one just city transport type to especial road/downtown. Equation 1 is obtained by positive sign (+) at X4, of matter this means complete progressively transportation medium which there is at one particular housing environment, hence will be good progressively also the quality of housing environment.

Wide for environmental road at housing with good quality tend to more wide and can passed by vehicle of wheel four and road of its environment has been concreted. Wide meanwhile environmental road at housing with environmental quality rather good 2- 4 meters and cannot passed by vehicle of wheel four. Based on first equation obtained positive sign (+) at X5, matter this means wide progressively environmental road of housing environment hence will good progressively also the quality of health of housing environment.

Places worship at housing with health of good environment has amount less than two places worship. Meanwhile the amount of places worship at housing with health of rather good environment generally has more than two places worship, Based on first equation where obtained negative sign (-)at X6 (amount of places of worship) which means the more places worship at one housing environment hence environmental quality of the housing is not yet good of course. Process hereinafter is to look for critical point (cut off Point) as constrain to determine a housing type come into environmental class 2 (good environmental class) or 3 (rather good). To calculate to search score boundary value or critical point follows formula of Santosa and of Ciptono, (2004), as follows:

$$Z\,cu = (Nb.\ Za + Na.Zb) \ / \ (Na + Nb)$$

Coefficient value center group (Z) obtained from value of centroid pursuant to calculation of SPSS. Assess Centroid for the health of housing environment can be seen at table 3.

Tabel 3. Cenntroid Score of Health Environment

Functions at Group Centroids

Class of Environment	Functions
	1
2,00	,408
3,00	-1,008

Unstandardized canonical discriminant functions evaluated at group means

As for detailed calculation to look for score boundary value or critical point shall be as follows:

$$Z\,cu = (Nb.\ Za + Na.Zb) \ / \ (Na + Nb)$$

Where:

Zcu= Critical point of level health of housing environment.
Na = Amount of sample which enter environmental class category 2 (good) = 42
Nb = Amount of sample which enter environmental categories 3 (rather good) = 17
Za= Function of Centroid environmental class 2= 0,408
Zb= Function of Centroid environmental class 3=-1,008.

$$Z\,cu = (Nb.\ Za + Na.Zb) \ / \ (Na + Nb)$$
$$= (17 . 0{,}408) + (42 . -1{,}0081) \ / \ (17 + 42)$$
$$= - 0{,}6$$

Tabel 4. Critical Value Boundary (Cuttoff Point) health of housing environment

health of housing environment	Number of group member	Core Coefisien of Group (Z)	Critical value boundary (Z_{cu})
Class 2 (good)	42	0,408	- 0,6
Class 3 (rather good)	17	-1,008	

Pursuant to table 4, hence critical value boundary (cutoff point) of group of health of housing environment is - 0.6,. Matter this means an environmental type of housing tends to come into class category 2 (good) if value of Y is - 0.6. Meanwhile an environmental type of housing tends to come into class category 3 (rather good) if value of Y is - 0.6.

After conducted cross validated like at table 5, hence accuracy of estimation equation of discriminan of class 2 (good) and class 3 (rather good) shows number 67.8%. This matter means that function of discriminan can classify 67.8% from existing variables.

Table 5. Result of Classification Health of Environment Housing

Classification Results[b,c]

		Environment Class	Predicted Group Membership		Total
			2.00	3.00	
Original	Count	2,00	28	14	42
		3,00	0	17	17
	%	2,00	66,7	33,3	100.0
		3,00	0	100,0	100.0
Cross-validated[a]	Count	2,00	28	14	42
		3,00	54	12	17
	%	2,00	66,7	33,3	100.0
		3,00	29,4,0	70,6	100.0

a.Cross validation is done only for those cases in the analysis. In cross validation, each case is classified by the function derived from all cases other than that case.
b.76,3 % of original grouped cases correctly classified.
c.67,8 % of cross-validated grouped cases correctly classified

CONCLUSION

Based on the research result in District of North and South Cikarang can be concluded that variable health of housing environment is divided into two classes, those are health of good environment (class 2) and health of rather good environment (class 3). Variable differentiating between class health of environment 2 and class 3 is the quality of air/noise, reforestation/greening,, green area, wide environmental road, transportation facility and amount of Places worships. Equation of discriminan obtained is:

$$Y = 0.601\ X_1 + 0{,}165\ X_2 + 0.615\ X_3 + 0.590\ X_4 + 0.471\ X_5 - 0662\ X_6 - 4.835$$

Meanwhile boundary assess score (cutoff point) for the health of housing environment is - 0.6. This matter means that an environmental type of housing comes into environmental class 2 (good) if value of Y is the same or bigger than - 0.6. Meanwhile an environmental type of housing tends to come into class 3 (rather good) if value of Y is less than 0.6. Accuracy of classification for the health of housing environment is 67.8% where analysis of its discriminan can classify existing variable counted 67.8%.

ABSTRACT

On the rapid process of urbanization in developing countries it is not surprising that many spots in urban areas could be found informal settlements particularly squatters on riverbank in most Indonesian cities, such as Jakarta, Surabaya, Palembang, Semarang, Yogyakarta, etc. The informal settlement is any residential activities in any areas that are conducted without formality aspect relating to the government, such as tax, regulation, location permit, license, etc. This paper will analyze the landscape of the informal settlement on the Code Riverbank in Yogyakarta to respond the urban heat island issue. Landscape is characterized by a broad area of common unique visual character based on physically landform, vegetation, waterfront, and land use pattern. Urban landscapes with a high content of vegetation elements in particular, have thus potentials to perform a variety of social functions and as such to establish or regain a role of healthy, desirable and restorative urban landscapes. However, on the Code Riverbank in the city of Yogyakarta, there are many informal settlements that dominate the land use pattern of the urban riverfront. The physical component of the high density of the informal housing represents a variety of social functions of urban land uses. The high density of the informal settlement on the Code riverfront has avoided the ecological function of the Code watershed. The high density of the informal housing is able to influence the urban temperature in Yogyakarta that support the issue of urban heat island issue as a part of global warming phenomena. "Urban Heat Island" (UHI) refers to the tendency for a city to remain hotter than its surroundings. The casual factors of the UHI are mainly building density, more paving, and less vegetation. The research suggests that the informal housing density in urban riverfront has visually represented a low content of natural landscape, particularly landform, vegetation and water and this visual has reduced the uniqueness of the natural potential of the Code Riverfront. This phenomenon has a contribution to the higher level of urban temperature as an aspect of the UHI effect. Another finding is that the proposed balance landscape development between natural and man-made construction on the river watershed of the Code Riverfront will support the cooler urban landscape.

Key Words: *Urban informal settlement, Code Riverfront*

1. INTRODUCTION

Landscape study has been practiced in the earliest time, when human pointed out where is the best location for agricultural field, trading center, or even residential uses. Historically, it was found that urban settlements or other development centers located close water resources, such as lakes, beaches or rivers. Ecologically, the river should be treated as a main water resource and played as a natural drainage system on continuous water cycle. Due to the population growth, urbanization, and technology inventions in many sectors including constructions, urban population need more housing, paved streets, and other built area. This growth has reduced vegetation and increased building density in urban areas. One of the basic urbanization problems in developing countries is illegal settlement. A slum is a house especially built on public or private land illegally. Due to the economic and social conditions, taking down of these slums owned by low income persons is very difficult. [1] In Indonesia, this phenomenon has been the way how people try to occupy more land that people can found in urban areas, including riverbanks that referred to be watershed and not permitted for construction.

The development created by current urbanism in Indonesian cities caused serious changes to the quality of the riverfront landscape. River Code, one of three main rivers in the city of Yogyakarta has been degraded with loosing its function as a water resource and watershed. This river has many houses occupy land on the riverbank and most buildings are informal settlements. Therefore, the quality of the Code riverfront landscape has formed a slum area that has more illegal housing constructions and not much vegetation. Any urban areas with many building construction and with little vegetation will be hotter compared with its surrounding areas.

2. ISSUE AND OBJECTIVE

The current development on the Code riverside in the city of Yogyakarta does not concern with ecological development. The Ecological development is respecting to the value of river as natural drainage system and as protected area on riverside. Intensive development on the riverside has created very high density of people and building houses, mostly informal settlements. This development pattern has reduced green areas of vegetation increased pavement along the Code riverfront in the city of Yogyakarta. This development phenomenon will support the issue of Urban Heat Island where the city of Yogyakarta is hotter compare with surrounding areas, particularly rural areas. Therefore, Yogyakarta needs some alternative of development model constructing any human settlements along the river, particularly on the Code River in Yogyakarta.

The objective of this paper is to (1) analysis the current development along the Code riverside by using a river as natural drainage system, (2) analysis the current development of informal settlements (on the Code riverfront in the Yogyakarta municipalities) relating to the casual factors of the urban heat island issue, (3) suggests a development model of informal settlements on the Code riverside that is likely able to reduce the problems of Urban Heat Island in urban areas. The method of analysis is using the qualitative approach. The analysis model consists of three concurrent flows of activities including data reduction, data display and conclusion drawing or verification. [2]

3. RIVERFRONT LANDSCAPE

Natural conditions of river landscape providing a proper drainage system and well-continuous water cycle. When rainfall occurs, the water is absorbed by vegetation that covering the soil surface (for itself and groundwater) and the others gently returned to surface water such as river or lake. By the river stream, the water journey continued to the sea, which a great evaporation take place, form a clouds, and thus become a rainfall again.

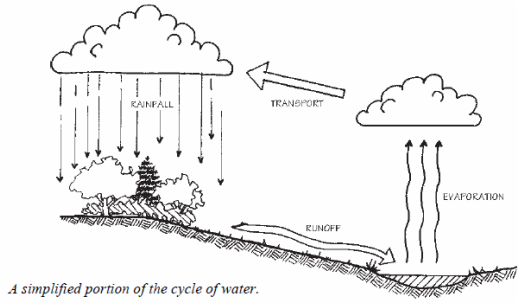

Figure 1. Natural Water Cycle

By the change of human development, the contours are smoothed and the landscape is comprised of hardened surfaces (rooftops, paved streets, etc.). These changes resulting in higher run off velocity that increased erosive potential. Hence, at a high concentration of rainfall, it can be resulting as floods or landslide [3]

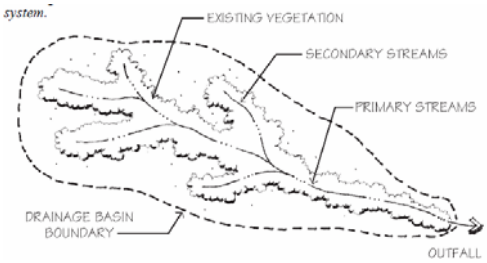

Figure 2. River as natural drainage system

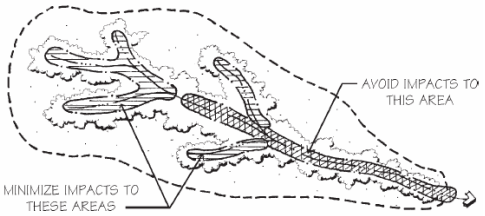

Figure 3. Areas must be protected along the riverside

The riverfront natural landscape gives the basic concept for analyzing the current Code riverside development, particularly the existence of informal settlements, based on the value of river as water cycle as natural drainage system, and to protected river watershed.

4. URBAN HEAT ISLANDS EFFECT

Urban Heat Island (UHI) effects are created when natural vegetation is replaced by heat-absorbing surfaces such as building roofs and walls, parking lots, and streets. Through the implementation of measures designed to mitigate the UHI, urban people can decrease their demand for energy and effectively "cooler" the urban landscape. [4] [5] The analysis of the UHI issues will focus on the natural aspect of environment particularly vegetation, that is crucial component of the cooler urban landscape and it is able to reduce the demand of cooling energy when it is placed on the proper area in the urban landscape. Urbanization that followed by rapid development that make less vegetation in order to be replaced by concrete materials was determined as significant factors that causing urban heat island.

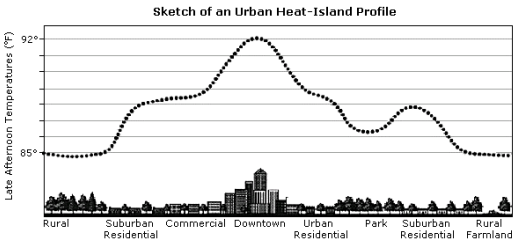

Figure 4. Urban Heat Island Profile

Heat islands develop when a large fraction of the natural land cover in an area is replaced by built surfaces (building and paving) that trap incoming
solar radiation during the day and then re-radiate it at night [6] [7]. This means that building and paving on urban areas replace land vegetated land cover will increase heat on the area.

The mitigation measures to reduce the heat island effect provide a link to local as well as global issues. The economic cost of implementation strategies is not only by the cooling energy savings, but also by the reduction in greenhouse gas emissions, esthetic value of urban forestry, and the increased quality of human health [8]. Therefore, the UHI issue recommends that urban areas are (1) to decrease building density and provide more open space for public, (2) to decrease paved land surface, and (3) to increase vegetation. This suggestion is relevant to the case study of the Code riverside that has been a very dens residential building with little vegetation.

5. INFORMAL SETTLEMENTS and URBANIZATION

The main reason of the urbanization movement, where rural people move to urban areas, is the insured job, high salary, and the other facilities such as education, health, culture etc. Primary objectives of the rural people migrating to urban areas is having a guaranteed and permanent job and then having a shelter. Nevertheless, if the financial inefficiencies of the local authorities, the level and quality of the services have been low, especially the lack of convenient residential areas has led to construction of informal settlements [1].

Informal settlements are usually a phenomenon which mostly occurs in developing and newly industrializing countries [9]. The UN [10] defines **informal settlements** as:
„*Areas where groups of housing units have been constructed on land that the occupants have no legal claim to, or occupy illegally; 2. unplanned settlements and areas where housing is not in compliance with current planning and building regulations (unauthorized housing).*“

Based on its conceptual categorization, informal settlements were classified into three types, (1) Unauthorized land development or informal subdivision, (2) squatter settlements, and (3) informal rental housing [11]. Those concept reflected most of informal settlements concept that marked it as visual pollution and social economic problem. The other concepts of informal settlements rely on the paradigms that informal settlements is a kind of solution for poor and marginal urban people to live in urban areas.

Table 1. Population Density and Flat Housing Need [12]

Population Density and Flat Housing Need			
Low	Medium	High	Very High

As ALTERNATIVE for special area	As RECOMMENDATION for urban central activities and special are	As REQUIREMENT for urban revitalization	As REQUIREMENT for urban revitalization

Source: Badan Stadarisasi Nasional, 2004

Informal settlements could be viewed as great intelligence in the use of resources, in shifting single use to mixed use, from low density to high density, and from absence of infrastructure to full infrastructure [13]. Therefore, the informal settlement on the Code riverfront is crucial to be analyzed by measuring the landscape based on the main causal factors of the UHI issue which are (1) building density, (2) vegetation, and (3) paving.

Table 1 will be used to analyzing the population density on the Code Informal Settlement and the need for flat housing development.

6. INFORMAL SETTLEMENT ON THE CODE RIVERFRONT AS A CASE STUDY AREA

Based upon regional administration, Code river is located in three local administrations which are the Sleman Districts, the Bantul District, and the Yogyakarta Municipality. The upper stream is drawn from north side of the mount Merapi until its lower downstream in the south that relate to a cross section with Opak River in the Bantul Ditrict. The middle downstreen of the Code River is situated in the Yogyakarta district where the riverside of Code is fully occupied by informal settlements [14]. Based on the Yogyakarta Statistic Office in 2005, from 151,420 households living in Yogyakarta Municipality, 2.14% of them lived next to riverside including in Code riverside called Code community. Code community consisted of 71% native people and 29% migrants. Most of them (53%) have been living there for more than 25 years. [15].

The expansion of Code riverside by squatters was determined by two reasons. The first one was the independent status of land, encouraging people to squatter. While the second reason for Code riverside expansion was represented cultural, economic, and social demands [16]. Based on the survey, it was found that the reason in choosing Code riverbanks as their settlements were compiled and classified into three main reasons, as an economic motivation (33%), for comfort living (40%), and as a forced movement option because they didn't have any alternative place for living (27%).

With high density and high population indeed, waste become an ecological problem. Littering it away to the river was an easy and cheap way for Code community. By recent years, it became a more serious problem causing degradation of river quality and higher risk of flood. From the other Code's study, it was founded that an area with high density would also raise the risk for groundwater pollution [17]. It was reported by Harian Jogja, 26 December 2007 that Code is the most polluted river among three main rivers in the Yogyakarta Province.

The two previous paragraphs proofs:
(1) The Code riverside is not treated a natural drainage as suggested by the North Carolina Department of Environment and Natural Resources Division of Water Quality
(2) The Code riverside is not protected to avoid any intensive development and make the Code River as the most polluted river in Yogyakarta.

According to government riverside policy that laid down by Indonesian Ministry of Civil Works in 1993, minimum space required between a river and built up area is 15 meters. However, by considering that the existing development growth on the Code watershed has been a high density informal settlement, the official government of the Yogyakarta Municipality has determined 3 meters space between river and built area on the Code riverside. This government policy does not concern with the value that rivers to be protected as a natural drainage system as suggested by the North Carolina Department of Environment and Natural Resources Division of Water Quality. This also suggests that the Yogyakarta municipality is not aware with the long term issue if the river conservation.

The term of informal could be determined as anything conducted without formality or ceremony [18]. Using this as analogy, informal settlements then referred as settlements without any supported formality aspects relating to the government. Informal settlement were often remarked with its illegal status of land ownership. Reported on this definition, most of dwellings settled on Code riverbanks were marked as an illegal or informal settlements. From data survey collected by the direct observation, it was founded that less than 50% of settlements have legal documents. Only 38% of settlements in Code riverbank already have the SHM (Certificate of Land Ownership) and 9% only have HGB (Right to Use the Property). Most of them (40%) have to pay for living in those areas by renting lands or rooms. The remaining precentage of Code community (11%) still lived in "Magersari"[1] landstatus. In term of rights for build property, 61% of them don't have IMB (Rights to Construct Building) that means, 61% of building settlements on Code riverbanks are illegal. Hence, the survey reported that 47% of people lived in Code riverbanks get their land as an inheritance land.

RT 69/RW 19 Dusun Karang Anyar Kelurahan Bronto Kusuman was recorded density value for 481 people/hectares, made it classified as very high density area. Within this area, more than 60% of settlements were too small to be noted as dwellings. Most houses on the Code riverbank have a mixed-use, commonly for economic and residential functions. Visually, the main characteristics of informal settlements in Code riverside were high density, small size houses, lack of ventilation, and narrow streets [19]. In the recent observation on April 2009, the population density in the kampung Jogoyudan was 480 persons/hectare. The research found that:
(1) Based on the Indonesian Standard of Urban Settlement (SNI 03-1733-2004) the population density in the Kampung Jogokaryan can be categorized as very high density and this will be required for revitalizing the Code settlement to flat housing.
(2) With the high density of population, the Code riverside also has a high density of building houses mostly one story building. This construction building density is contributing to the urban heat island. This fact also suggest that lowering building density and increasing more space for public activities more vegetation could reduce urban heat island problem in Yogyakarta city.
(3) The Code informal settlement is very high density of people and building creates the area lack of vegetation. This fact also supports to increase the urban heat of Yogyakarta (See Figure 5).

A crucial concept to transform horizontal housing to be vertical one can be adopted from [1] (See Figure 6). The concept suggests that the government should develop a new law put into practice to formalize illegal or informal settlements.

[1] Yogyakarta Province has a special policy referred to its special status that acknowledge Sultan's land for people to live in. People that lived in Sultan's Land called "magersari". They don't have any payment for live or settled on the Sultan land, form as Sultan's pity for his people in the previous time. The status of "magersari" is still debated by local government and national government.

Figure 5. Code River in Yogyakarta

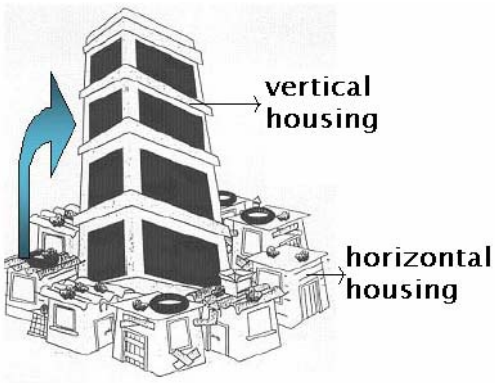

Figure 6. Transforming Horizontal to Vertical Housing

The urgent recommendations are as follows:

a. Slums or informal settlements are constructed in a low-qualified manner , not meet with river conservation, and support urban heat island effect. Therefore, the transformation of the informal settlement to horizontal building should be provided to support river conservation and reduce the UHI problems.
b. Instead of leaving settlement right to slum owner completely, this right should be shared with public authorities. In other words, slum or informal settlement owners should not be given all development right on building plot; instead, they should only be given a single flat.
c. Building contractors, called as land developer, which works according to the general rule of 'giving flats to land owners for their landownership', the remaining flat dwelling can be rented of sale with a long scheme of payments to other migrants who have no land or building certificate on the Code riverside area.

The scheme of transforming horizontal to vertical housing is appropriate with the government policy plan of "**one million towers**" for revitalizing urban slums and fulfilling the current and future urban housing need, especially for urban community with the low income segment.

7. CONCLUSIONS

Urbanization in Yogyakarta creates informal settlements on the riverside. The growth of informal settlement in Yogyakarta is due to lack of balance development between urban and rural improvement.

The informal settlements on the riverside perform a high density of population and buildings, and reduce open space with rich of vegetation in Yogyakarta urban riverfront, such as the Code river. The Code River with informal settlement proofs that imbalance landscape (between natural and man made construction) has occurred in Yogyakarta. This phenomenon has supported the problem of urban heat island in Yogyakarta urban area. The government policy on the Code riverside so far does not improve significantly the ecological landscape quality.

To mitigate the Urban Heat Island Effect in Yogyakarta, the local community, investor, and the government are to work together in transforming horizontal to vertical housing construction from now end then. This transformation suggests: (1) The Code riverside is to be protected from the intensive development, (2) vertical housing on the Code Riverside will give more open space and more vegetation to be planted., (3) paving can be used if necessary and porous paving is better construction.
By increasing the transformation of horizontal informal settlement to formal vertical housing, open space, public, and vegetation in urban areas will increase in urban areas, including the landscape on the riverside. This action will make the urban environment cooler and be able to mitigate the UHI problem.

ABSTRACT

This paper aims to investigate the idea of cityspace through third space, or as fully lived space, as an alternative in understanding a city. My argument is modernist visions of a city like Howard;s Garden City, Frank Lloyd Wright's Broadacre City, and Le Corbusier's Contemporary City have same fundamental principles such as segregation of use, dominance of private over public space, and focus on auto. The next generation learns that these utopias not only had sterile and suburban character but also disintegrated the street as the community's habitable common ground. According to Edward Soja, there is an alternative approach to a city that use the production of cityspace in its combined expression as contextualizing form and process By understanding a city as both form and process, or as third space, hopefully I can open up new understanding of a city by rebalancing our perspective in understanding complexity of our social, historical, and spatial dimensions of a city.

Keywords
modernist city, urban spatiality , thirdspace

1. INTRODUCTION

Our cities and its communities are at a critical point in terms of they will grow and deal with increasingly urgent environmental and social concerns. Ever since the modern time, new theories of cities emerged and stressed on the importance of technology and industry in our living space. They all have the same basic principles of segregation of use, focus on auto, and dominance of private over public space. Since then, our cities continue growing auto-dependent city, sprawls, and facilitating the loss of natural landscapes.

At the beginning, what modernist planners and architects proposed for our cities seems to be environmentally friendly. Ebenezer Howard defined a vision of small towns surrounded by a greenbelt. Le Corbusier developed urban and suburban areas for living and leisure all in blocks and surrounded by green areas. Frank Lloyd Wright proposed decentralization combining urban and suburban areas in green environment.

There are some critiques addressed to the ideas of modern cities proposed by architects and planners above. Even though all planners proposed the same idea about the importance of green areas in the city, all of the cities above has awareness that automobile will be the center for our lives. The cities have sterile character, disintegration between street as the community's habitable common ground, and lack of real living experience considerations. As a result, there is lack of fundamental qualities of real cities such as defined public space, pedestrian scale, and integrated diversity of use and population (Caltharpe, 1993). Sprawls and suburbs are also two problems that modern cities have to deal with.

Still there is a hope that our cities will be compact and green and become places that provide good social, cultural and recreational activities, and a feeling of community. The last idea of cities concerns ecological sustainability connects human settlement patterns to ecological conditions. Moreover, a new perspective in understanding our cities also should combines expression as contextualizing form and process.

In relation to rebalancing our perspectives in understanding cities, I want to further discuss some classic theories of city, including how they become the basic of modern cities and comparison between these theories. I then want to discuss how the next generation thinks these

utopias disintegrate the street as the community's habitable common ground. There should be an alternative vision of place and community that not only emphasizes physical form of a city but also unifies concerns about the environment and the quality of life. Here I want to investigate an alternative idea of understanding a city through the ecology of place, and also understanding a city through thirdspace or as fully lived space (Soja, 2000)[1]. Hopefully, there is an alternative concept of sustainable places that suggest a better model for planning our cities in the future that unites both social and environmental goals..

2. MODERNIST IDEAS OF A CITY

Ebenezer Howard envisaged his Garden City as a tightly organized urban center for 30,000 inhabitants, surrounded by a perpetual "green belt" of farms and parks[2]. In the city there would be both quiet residential neighborhoods and facilities for a full range of commercial, industrial and cultural activities. Howard thought the great cities of his time decreasing to insignificance as their people desert them for a new way of life in a decentralized society. The urban population would be distributed among hundreds of Garden Cities whose small scale and diversity of functions represent a world in which the little man has finally won out. No longer would a single metropolis control a whole region. The agricultural belt prevents the town from sprawling out into the countryside and make sure that the citizens enjoy both a compact urban center and ample open countryside.

There is a Central Park located at the center of the town, which gives recreation grounds within very easy access of all the people. This park is surrounded by a glassed-in arcade where manufactured goods are exposed for sale. Since Howard wanted to balance individualism and central organization, he rejected the idea of cooperative department stores. He proposed many small shops that offer only one for each category of goods.

There are two kinds of centers in the Garden City namely the neighborhood centers and the civic center. The neighborhood centers are slices in circular pie with the most substantial homes would be arranged in crescents bordering Grand Avenue. In the middle of Grand Avenue is the most important neighborhood institutions. Howard put the factories at the periphery of the city, adjacent to the circular railroad that surrounds the town and connects it to the main line. The factories would be close to the homes.

Howard's emphasis on the importance of a permanent girdle of open and agricultural land around the town soon became part of British planning doctrine that eventually developed almost into dogma. Its most impressive application was the plan for Greater London in 1944 and--following passage of the New Towns Act of 1946--the creation of a ring of new towns beyond the London Greenbelt. On practical grounds at least as strong a case could be made for an urban configuration based on wedges of open space thrusting inward and confining development to the intervening corridors.

Howard's verbal pictures and accompanying diagrams show his own beliefs about how a model garden city should be laid out. The ring and radial pattern of his imaginary Garden City was a plan that many other writers of the time also favored, because of its perceived superiority from both engineering and architectural viewpoints.

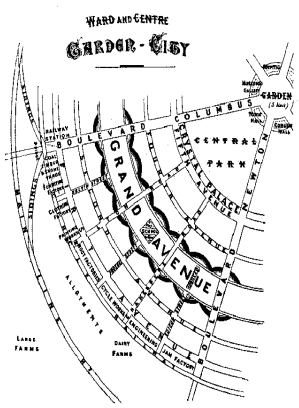

Figure 1: Howard's Garden City, Sources www.library.cornell.eduReps/DOC/Howard.html

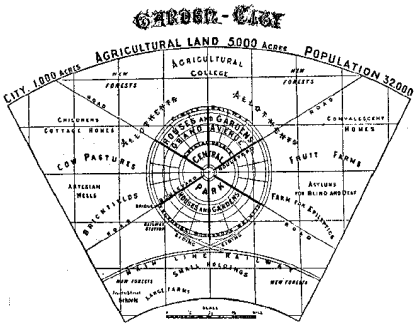

Figure 2: Howard's Garden City, Sources www.library.cornell.edu/Reps/DOC/Howard.html

There are six excellent boulevards, each 120 feet wide. The boulevards cross over the city from centre to circumference and divide the city into six equal parts or wards. In the centre is a circular space containing about five and a half acres, laid out as a beautiful and well- watered garden. Surrounding this garden, each standing in its own ample grounds, are the larger public buildings--town hall, principal concert and lecture hall, theatre, library, museum, picture-gallery, and hospital.

In *the City of Tomorrow and Its Planning* Le Corbusier stated that a city should consist of skyscrapers for commercial use surrounded by parks. In the center there would be a train station, the "hub" of the city, and three-story buildings with "luxury shops, restaurants and cafés." Surrounding the center there would be a belt of residential buildings, with small communities offering domestic services. Le Corbusier use zoning to accommodate "the exodus of city dwellers" from the centers of great cities, and the "replacement by business." His vision of a modern city is the idea that the center should be for business and some public services surrounded by two belts of residential areas – one with "blocks of dwellings on the 'cellular' system", and one outer garden city.

In the Contemporary City all dwellings are mass-produced, but they are not all alike. Every building's location depends upon one's position in the hierarchy of production and administration. The elite houses were in the center while the workers houses were at the periphery. Le Corbusier wanted to create a comprehensive environment in which man, nature, and the machine would be reunited. For Le Corbusier, order is expressed by pure forms, which is expressed in a perfectly symmetrical grid of streets. He designed an richly coordinated system of transportation; highways, even bicycle paths and pedestrian walks. The center of the city is a multilevel interchange for the whole system that serves people in motion. Surrounding the central terminal are twenty-four glass-and-steel skyscraper, each sixty stories high. The skyscraper allowed Le Corbusier to unite the apparent opposites of urban design: density and open space. The skyscrapers free the ground for greenery; they also are a fitting symbol for the grandeur of the functions they house.

The Contemporary City is a city of administration. The great towers would be the headquarters of the intellect as well as industry. To provide an appropriate setting for the public gatherings of the elite, Le Corbusier made the administrative center also the cultural and entertainment center. The proletarians in their satellite cities have none of the special privileges of the elite.

The Contemporary City grew out of this new conception of capitalist authority and a pseudo-appreciation for workers' individual freedoms. The plan shows clearance of the historic cityscape and rebuilding utilizing modern methods of production. The apartment was pre-fabricated with *les unites*, were available for everyone at the center of "urban" life based upon the needs of each particular family. The business center was located to the north of *les unites* and consisted of glass & steel skyscrapers every 400 meters. The skyscrapers were to provide office space for 3,200 workers per building. Sunlight and circulating air were also part of the design. The building would be placed upon pilotis, five meters off the ground, so that more land could be given over to nature. Setback from other unites would be achieved by *les redents*, patterns that Corbusier created to lessen the effect of uniformity.

Figure 3: Le Corbusier's Contemporary City, source http://tesugen.com/archives/04/06/corbus-city-of-tomorrow

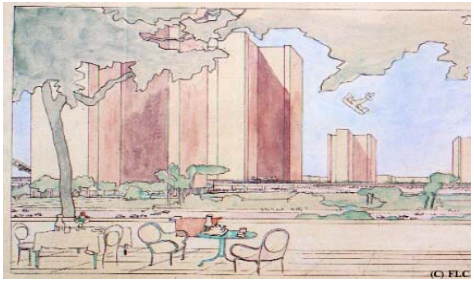

Figure 4: Le Corbusier's Contemporary City, source http://tesugen.com/archives/04/06/corbus-city-of-tomorrow

Inside *les unites* were the vertical streets, i.e. the elevators, and the pedestrian interior streets that connected one building to another. Corridor streets were destroyed. Automobile traffic was also to circulate on pilotis supported roadways

five meters above the earth. The entire ground was given to pedestrians, with pathways running in orthogonal and diagonal projections. Other transportation modes, like subways and trucks, had their own roadways separate from automobiles.

Each apartment block was equipped with supporting section in the basement, like catering and laundry. This would enable the individual to think, or utilize the play and sports grounds which covered much of the city's land. Children were to be dropped off at *les unites'* day care center. Transportation systems were also made to save the individual time

Many scholars thought Le Corbusier's vision of modern city was a compact and high-tech city. However, they have failed to consider individual freedoms. Certainly, Corbusier provided leisure activities that he enjoyed. There can be no extravagance or chaotic excess. Individuals were not allowed to have a voice in the governance of their lives; they are able to behave, but not to act. Additionally, there is no room in the Le Corbusier's City for individuals to act non-rationally, while in reality, it is improbable that humanity will ever behave in so-called rational ways. Thus, Corbusier's vision suffers from an naive conception of human nature.

Le Corbusier's idea of authority is both patriarchal and bureaucratic, what Richard Sennett refers to as the authority of false love and the authority of no love (Sennett 1980). Corbusier argued, following Plato, that universal truth, beauty, and goodness could be ascertained by those who had divorced themselves from matter (human bodies). *Les grand inities* could then prescribe a plan grounded in objective calculations and scientific facts. There could be no debate, i.e. no politics regarding the precepts of the plan. Humanity was to accept this discipline as a necessary, objective ordering of reality by a doting, paternalistic authority. Corbusier put it like this, "Authority must step in, patriarchal authority, the authority of a father concerned for his children," (Le Corbusier 1967: 152).

Le Corbusier saw himself as the one could step outside of history and uncover the good society through the glory of rationalism and established orthogonal order. This is the essence of utopian thought, the reliance on scientific fact and removal of memory. Any other thing is disorder and must be brought into line. Le Corbusier's designs for the city are grounded in the desire to escape the earth. The vertical street, the skyscraper, the death of the street, the destruction of the sensuality of city life are all proof positive that he was terrified of the earth and others. In the Contemporary City, Corbusier describes the view from the skyscraper as not of this earth; it is placid, serene, and harmonious.

Broadacre City was an urban or suburban development concept proposed by Frank Lloyd Wright late in his life. He presented the idea in his article *The Disappearing City* in 1932. A few years later he unveiled a very detailed model representing an hypothetical 10 km² community. The model was made by the student interns who worked for him at Taliesin.

Broadacre City was the antithesis of a city and the apotheosis of the newly born suburbia, shaped through Wright's particular vision. It was both a planning statement and a socio-political scheme by which each U.S. family would be given a one acre (4,000 m²) plot of land from the federal lands reserves, and a Wright-conceived community would be built anew from this. There is a train station, few office and apartment buildings in Broadacre City, but the apartment dwellers are expected to be a small minority. All important transport is done by automobile and the pedestrian can exist safely only within the confines of the one acre plots where most of the population dwells. Wright's emphasis on the completely detached house standing on its owner's ground derived from his belief in a society where the individual would enjoy the independence that comes from self-sufficiency.

Wright intended Broadacre City to be the place where this contradiction would be overcome. He wanted a city without spiritual or material walls, which would nonetheless be a secure community. In his ideal city, Wright made the family the central institution of his new society with the family as the key to the stability of the whole community. Broadacre City is thus as much a prevention of as it is a solution to its central problem: how can freedom and democracy be preserved in an industrial society?

Wright assumed that modern man had a car. If properly planned, cities could spread over the countryside and still not lose their cohesion or efficiency. The diffusion of population would generate conditions for the universal ownership of land. The world of concentrated wealth and power would be replaced by one in which the means of production would be widely held. The open plan of Broadacre City was a authentic departure from the neat concentric circles of the Garden City. Wright's idea is there must no longer be a physical separation between urban and rural areas.

All buildings are in the midst of farmland and forest with transportation system unites the citizens with many points of community exchange that provide the urban experience.

The merging of town and country, physical and mental labor, work and leisure – these were all part of Wright's effort to reduce the fragmentation of modern life from Broadacre City. Factories and other economic institutions were thus spread explicitly as “support units” for the family. Wright had hoped that decentralization would preserve the social value he prized most highly – individuality. The houses he designed ranged in size from “one-car houses” to “five-car houses.”

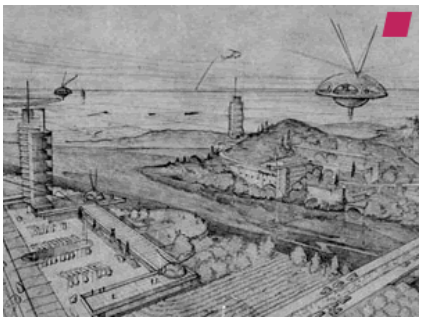

Figure 6: Wright’s Broadacre City, source: www.fba.fh-darmstadt.de

3. DISCUSSIONS: CRITIQUES OF MODERN CITIES

Howard, Wright and Le Corbusier based their ideas on the technological innovations that inspired their age, the express train, the automobile, the telephone and radio, and the skyscraper [3]. Howard realized that the railroad system that had contributed to the growth of the great cities could serve the planned decentralization of society equally well. Wright understood that the personal automobile and an elaborate network of rads could create the conditions for an even more radical decentralization. Le Corbusier looked to technology to promote an opposite trend. He made use of the skyscraper as a kind of vertical street which would permit intensive urban densities while eliminating the “soulless streets” of the old city.

Wright's and Le Corbusier's ideal cities confront each other. Both believe in industrialization had produced the conditions for a new era . This era would commence with the replacement of existing cities by new forms of community suited to the new age. Wright wanted to decentralize society, replacing existing cities with a continuous union of town and country where the individual and his family could flourish. Both recognized the city as the natural home of centralized power. Le Corbusier placed a corresponding faith in organization, and predicted a very different fate form modern society. For him industrialization meant great cities where large bureaucracies could coordinate production. Le Corbusier had the elite live in luxurious high-rise apartments close to the center while their subordinates were relegated to satellite cities at the outskirts. For Le Corbusier, the future would be a Radiant City of glass and steel skyscrapers set in parks. Both Radiant City and Broadacre city are an attempt to revitalize work and reconcile man with nature. Howard's deepest value was cooperation and Wright's indiviudalism, Le Corbusier's aim was a society in which both cooperation and individualism could find simultaneous expression.

In *The Death and Life of Great American Cities* (1961), Jacobs rejects Le Corbusier's concept of urban surgery, for it means imposing his one plan over everyone else's [4]. She argues that Le Corbusier’s neatly arranged skyscrapers in the park are a terrible oversimplification of urban order. Their rigid division of functions makes a true diversity impossible, their inhuman scale and vast empty spaces destroy the close-knit vitality of an attractive city. Above all, Jacobs believes that the planner must no longer try, as Howard, Wright, and Le Corbusier once tried, to define the central goals of his society and offer a unified plan for reaching them. The common good is served through maximizing the individual's opportunity to pursue his own ends. For Jacobs, the cities are already built. They can be renovated but never transformed.

Lewis Mumford;s phrase “Yesterday's City of Tomorrow” for all three ideal cities means the very concept of the ideal city appears to belong to the past [5]. The plans of Howard, Wright, and Le Corbusier suppose that conflict will eventually be overcome in a harmonious industrial society; that human understanding can resolve the problems of society. Sennett thinks the planners' search for harmony is not only bad urban policy but even worse psychology [6]. Sennett doubts that municipal authorities in a dense, uncontrollable human settlement might nevertheless try to force their own version of order. He wants to promote direct social life that people would be required to deal with people different from themselves and to experience in their own lives the movement from conflict to agreement.

A sustainable city is a city designed with consideration of environmental impact, inhabited by people dedicated to minimisation of required inputs of energy, water and food, and waste output of pollution. A sustainable city can feed itself with minimal reliance on the surrounding countryside, and power itself with renewable sources of energy. The sustainable city is specifically non-utopian. The authority of this city is one of quintessence in a place and space. Knowledge does not exist outside time and space. It is an authority of political education, where the knower and the known become one. Diversity is respected, and nature is not an object of gratification. Howard, Wright, and Le Corbusier see nature as fulfilling unlimited human needs and wants. Nature becomes "other" in their plans. A sustainable city would take the notion of inter-connectedness between men and nature: the deep ties that weave our lives together with the natural world. Nature is respected for its balance seeking process and its limits.

The idea of the city in the future is about nurturing sustainable cities, and sustainable places. Sustainable places seek more broadly to minimize the extent of their ecological footprint. The application of sustainability concepts to the field of urban planning is a relatively recent phenomenon. There are several dimensions in community planning stated by Beatley and Manning namely scale, sectoral and venues or spheres [7]. In the first dimension, there should be a multiscale approach such as vertical sustainability (the sustainability of a particular development project) and horizontal sustainability (the location of people and activities over space). In sectoral dimension, in order to create sustainable places we need concerted effort in policy arenas, including transportation,economic development and housing. In the last dimension sustainable places will require actions and in a number of different places in the community.

There are consequences associated with current growth patterns and approaches to city. The low-density, sprawling development patterns are very expensive in terms of the costs of public infrastructure, and dealing with environmental and social problems. This sprawling patterns of growth threaten our environmental resources. Sprawl breeds social isolation and undermines a sense of community and respect and appreciation for “otherness.” Langdon (1994) mentions about disconnection challenge the social ties that give individuals pleasure and invigorate community life. Living in gated communities reflects a lack of concern for the future of our society at large. The privatization of many functions of traditional government such as private security guards suggests a serious reduction of our social contracts. The greater our separation from the public the easier it is to believe that we Have few ethical obligations to others.

In *Thirdspace,* Edward Soja defines his concept of “Thirdspace,” a notion of space that combines spatiality with sociality and historicality [8]. Thirdspace is an interdisciplinary idea of space, history, and society that treats the micro-geographies of the everyday with as much seriousness as it treats the macro-geographies of larger historical trends. Both of these geographies are crucial for a nuanced interpretation of the site under investigation. For Soja, Thirdspace is “an-Other” space, a sprawling, radical zone created and populated by the marginalized. Thirdspace can be used as a radical, libratory concept of space, including our cities.

At the heart of critical spatiality is the recognition that, like history and society, space is not encountered as a transparent or objective “reality,” but is constructed in social practice and must therefore be theorized. Firstspace shows the concrete materiality of spatial forms or things that can be empirically mapped. Secondspace is ideas about space or thoughtful re-presentations of human spatiality in mental or cognitive forms. Thirdspace might be partially encapsulated in the notion of lived realities as practiced. Lefebvre in *the Production of Space* names these categories perceived space (or spatial practice), conceived space (or representations of space), and lived space (or spaces of representation) [9].

4. CONCLUSION

To conclude, Howard's, Le Corbusier's, or Wright's urban thought has had a direct effect on city planners. Some of their notions have made their way into urban renewal logic: clearance, the destruction of memory, the plan as scientific fact, sub-standard housing, etc. Certainly, their aseptic view of the city has destroyed the street theater that Jane Jacobs so lovingly describes. The landscapes of Howard, Wright, and Corbusier, regardless of its evocation of nature, are unsensual, ahistorical. None of them engage Thirdspace or lived space that embodies the real and imagined life world of experiences, emotions, events, and choices. Sustainable cities offer a better worldview, one that connects humans, nature, history, and place with a viable vision for the future. In this alternative or Third perspective, the spatial specificity of urbanism is investigated as fully lived space, a simultaneously locus of structured individual and collective experience and agency. Not like materialist approach, here city space is physically and empirically perceived as form and process, as measurable configurations and practices of urban life.

Symposium in Energy Conservation Through Efficiency in Design and Manufacturing

Symposium D

Center for Materials Processing & Failure Analysis

Dept. of Metallurgy & Material
Faculty of Engineering – University of Indonesia

CMPFA
Center for Material Processing and Failure Analysis

Center for Materials Processing & Failure Analysis (CMPFA), established in 2001, is a business unit of Dept. of Metallurgy & Material, Faculty of Engineering, University of Indonesia that provides services to oil and gas industries, chemical industries, power generating plants, steel fabricators and automotive industries. We are supported by high qualified staff (4 professors, 10 doctors & 13 masters) who have years of experience in dealing with clients' demand.

CMPFA is equipped with facilities of laboratories including chemistry lab, mechanical testing lab, metallography & heat treatment lab, metal forming lab, foundry lab, corrosion lab, non-destructive test lab, scanning electron microscope (SEM) & X-Ray Diffraction (XRD).

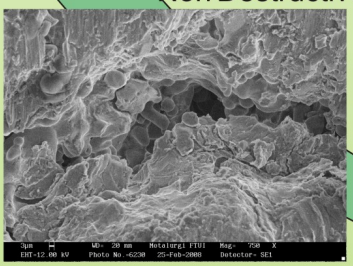
Since the beginning of 2008, CMPFA has been trying to implement Laboratory Management System (ISO 17025) to fulfill the customer need of accredited laboratory under the name of LABORATORIUM UJI MATERIAL.

CMPFA is divided into several divisions:

1. Material Testing Division

This division handles the clients' request for various material testing, material characterization and metallurgical analysis.
Some of the tests are but not limited to:

- Chemical Analysis
- Mechanical Testing
- Heat Treatment & Metallography
- Corrosion Test & Environment Simulation
- Non Destructive Testing



2. Training Division

The center also offers various in-house training or short course with the following subject areas:

- Basic metallurgy for non metallurgist
- Materials selection for design construction
- Metal heat treatment
- Mechanical testing for material
- Corrosion testing and prevention
- Metallography technique
- Foundry technology and mold design
- Welding metallurgy
- NDT radiation and non-radiation technique
- Polymer materials & technologies
- Costumized syllabus & curricullum depend on costumer request

3. Consultation & Analysis Division

The consultation & analysis group specializes in root-cause analysis, problem solving & product development. Our special expertise is in quantifying all aspects of failure analysis, forensic analysis, product comparison, performing in-depth investigations using material engineering analysis, metallurgy and materials testing.

This division offers several services:

- Failure analysis
- Insitu metallography
- Insitu NDT
- Casting assessment & reject reduction
- Welding procedure standard
- R & D support analysis

4. Approved Training Body (ATB) for welding certification

ATB is a special division for welding training that has been certified by Indonesian Welding Society (IWS) as Authorized Nation Body (ANB) - International Institute of Welding (IIW).

Conduct welding trainig activity including theoretical lectures and practical welding training for the following categories:

- International Welding Engineer (IWE)
- International Welding Technologist (IWT)

ABSTRACT

Fluidized bed insineration of biomass, such as coconut shell and branch trees or waste wood, has been conducted in University of Indonesia town jungle. This technology converts biomass to a useful and a cleaner energy, such as, heat for drying purpose. Observation finding the characterization of fluidization bed combustion is through primary air blower variation and coconut waste feeding variation. Results show that fluid bed combustion system worked properlu as expexted. Bed temperature during combustion test reached 800^{o}C to 850^{o}C.

Keywords
Fluid bed combustor, fluidization, self- sustaining combustion, good mixing

1. INTRODUCTION

Fluidized bed incineration systems can burn any kind of waste and have been proved to be highly efficient and environment friendly than other incineration systems. Fluidized bed reactors operate at relatively lower temperatures than other types. Complete combustion of the gases is ensured in the integrated combustion chamber with sufficient excess oxygen. The chamber is sized to ensure at least 2 second flue gas residence time at 850 ^{o}C or the temperature required by local legislation.

Fluidized bed incinerators are primarily used for liquids, sludges and shredded solid wastes. Fluidized bed incinerator consists of a vertical steel cylinder, usually refractory lined, with a sand bed on a supporting grid plate and air injection nozzles. *FB incineration of hospital waste*

2. RESEARCH METHODOLOGY

Conducting this research there are some important steps such as follows:

2.1. Preparation
- 2.1.1. Problem identification
- 2.1.2. Literature survey
- 2.1.3. Define the solid fuel waste type and size

2.2. Set Up Preparation
- 2.2.1. Laboratorium Set up
- 2.2.2.Defining solid fuel dimension & screening
- 2.2.3. Instrumentation Calibration

2.3. Testing and Data Collection
- 2.3.1. Measuring speed variation on screw feeding
- 2.3.2. Measuring mass-flowrate of solid fuel in screw-feeder.
- 2.3.3. Measuring air blower speed.
- 2.3.4. Measuring temperature at freeboard area with variation of solid fuel and air blower.

2.4. Data Interpretation and Plotting Graphs
- 2.4.1. Variation of feeding waste
- 2.4.2. Variation of Primary Air Blower
- 2.4.3. Analyzing of Ploting Graphs

2.5. Experimental Set-up

For this purpose a method has been done as follows. A fluidized bed combustion system has built & tested properly for this project. Figure 1 shows the complete installation of this system as follows:

Figure 1. Installation Fluidized Bed Combustion system.

3. RESULTS AND DISCUSSION

3.1. Characteristic of Feeder System

There are variation of feeding speed that depends on fuel solid size as shown on Figure 1. For fuel small size on average length (l) = 5-10 mm, width (w) = 5-10 mm and thickness (t)= 4-5 mm, the feeder will work on motor speed of 17 rpm or about 0.235 kg/s. For bigger size with average length (l) = 20-25mm, width (w) = 20-25 mm and thickness (t) = 4-5 mm, and the feeder will work on motor speed of = 21 rpm or about 0.527 kg/s.

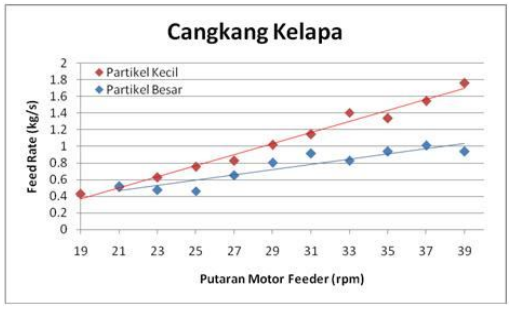

Figure 1. Feedrate of coconut shell against motor speed (upper graphs for small size & lower graph for big size)

Figure 2. Coconut shell as waste fuel (left: big size; right: small size)

For smaller size, increasing of feed rate is lower than bigger size, but at the same feeding-speed the feed rate of smaller size is higher than bigger size. This is due to density of smaller size is higher density than bigger size. Minimum feed rate of smaller size is 0.4 kg/s of 19 rpm and bigger particle is 0.5 kg/s at 21 rpm.

3.2. Characteristics of Blower

Figure 3 shows the minimum fluidization reachs 2.6 m^3/min at blower speed 2700 rpm. In this study working area where fluidization occurred, air blower supplies flowrate of 4.9 to 5.3 m^3/min.

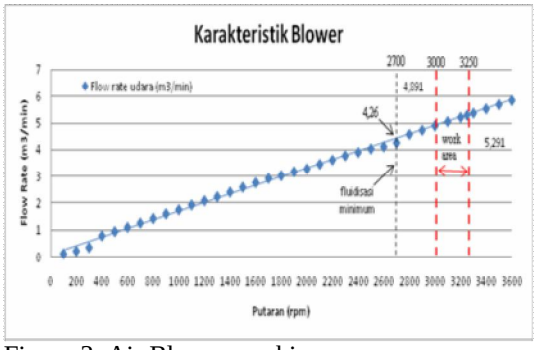

Figure 3. Air Blower working area.

3.3. Temperature Distribution inside the Furnace

There are five (5) Thermocouples corresponding to the height of furnace. Temperature are collected from thermocouples are average value after fuel burned. Fuel flowrate and air blower are varied so that temperature distribution along the height can be evaluated. Figure 4 is ploting, the commencing the combustion was used LPG gas burner for around 30 minutes, while this gas burner works in 20 minutes, coconut shell as support fuel was injecting in to the hot bed. After 10 minutes bed temperature T1 increases to around of 800°C, then LPG burner switch off immediately. From this point a *self-sustainable combustion* has started.

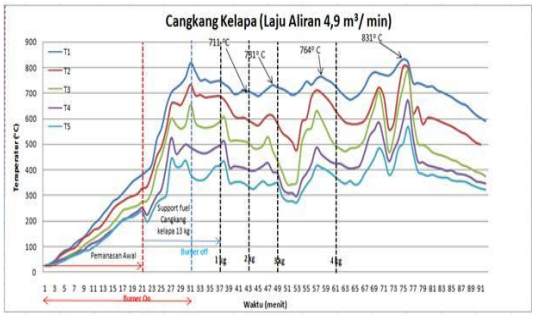

Figure 4. Temperature distribution from start-up to finish the operation combustion process.

Then bed temperature slightly decreases until reaching a steady state condition. On this condition starts feeding 1 kg/min of solid waste, and bed temperature T1 decreases around of 80°C or T1 is 700°C. But in the short time temperature increases again to 720°C. This transient

temperature indicates a burning process from a'cold' solid fuel, or heat from bed environment was needed to burn the solid fuel. Feeding process gradually rises to 4 kg/min, this followed by increasing the bed and freeboard temperature as shown in Figure 4 as well.

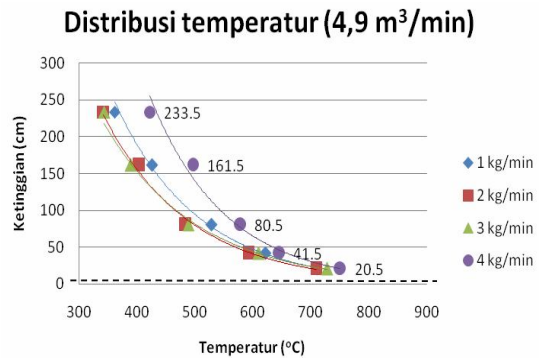

Figure 5. Temperature distribution inside the furnace at air flowrate 4.9 m^3/min corresponding to thermocouple height

Variation of furnace temperature at different fuel feeding speed and primary air blower (4.9m^3/min) is shown in Figure 5. The highest temperature reaches at bed temperature of 760^{o}C and the lowest is around of 233.5^{o}C. Also increasing of waste fuel feeding leads a higher temperature at thermocouple near the furnace outlet.

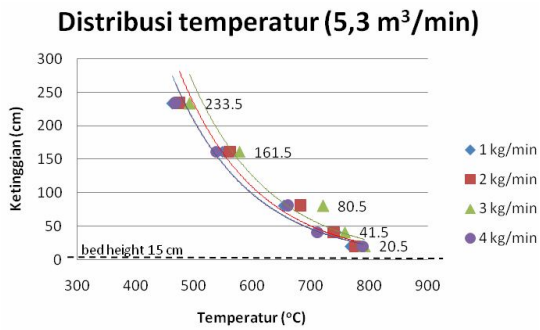

Figure 6. Temperature distribution inside the furnace at air flowrate 5.3 m^3/min corresponding to thermocouple height

Further rising of air supply to 5.3 m^3/min, increases average bed and freboard temperature. This indicates that increasing of air supply gives better combustion process. It is possible a secondary air could be needed to achieve a higher and cleaner combustion.

4. CONCLUSION

A fluidized bed combustion system has successfully constructed and tested for burning coconut shell as solid waste in Faculty Engineering University of Indonesia. General conclusion can be deducted as follows:

4.1. Increasing of feeding speed motor rises directly the feed rate of solid waste as well.

4.2. Rising the air supply influences the increasing of bed and freeboard temperature

4.3. A self sustainable combustion is achieved at temperature around 715 to 750^{o}C.

ACKNOWLEDGMENT

The authors are grateful to final year Mecahnical Engineering student 2009, namely, Arsya, Darma and Davin who have worked very hard and for their support during carry out the research work.

ABSTRACT

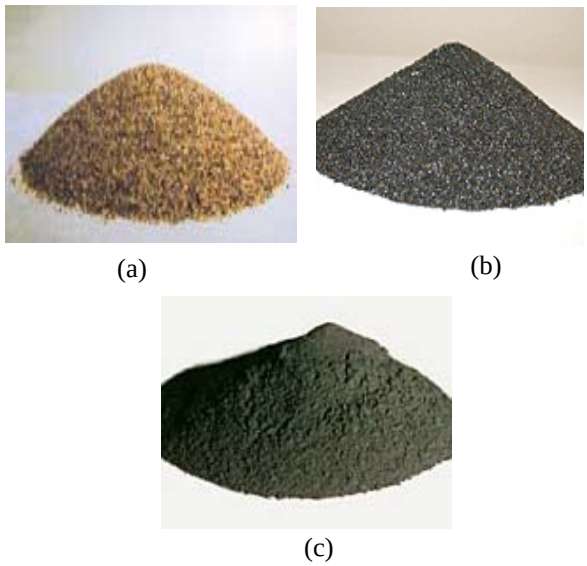
The analytical calculations of fluid mechanic in water filtration system have been done. This water filtration system consists of cyclone pre filter and several filters using media, such as: silica sand, manganese greensand, granulated activated carbon (GAC), sediment filter, porous ceramic, and post carbon. This system also completed with reverse osmosis (RO) system and two pumps (submerge and RO high pressure pump). The calculations were done using Darcy laws for porous medium; Stoke laws for particulate medium, and Reynold formulae to calculate the Reynold number and fluid flow type in the water filtration system. From the result it can be concluded that the flow rate and Reynold number inside cyclone pre filter, and filter using media: silica sand, manganese greensand, granulated activated carbon, sediment filter, porous ceramic, post carbon, and also reverse osmosis systems are the following, for flow rate capacity: 200.0, 160.7, 42.1, 32.9, 6.1, 3.1, 11.8, and 12.3 liter/minute. The Reynold number: 69359.4; 19478.1; 5101.4; 9674.3; 1123.7; 561.8; 3482.3; and 2247.4. From the calculations also, it can be concluded that the filtration system can reach for minimum 10 liter/minute capacity.

Keywords

Flood water, filtration, Darcy law, Stoke Law, Reynold number

1. INTRODUCTION

Flood is one of the disasters that have a lot of effect in human life, especially can cause illness and disease, because the rareness of drinking water. After a flood, water can be contaminated and can not be use by human, unless it proven safe. To solve this problem, the technology such as water filtration is needed. Water filtration is the process of removing undesirable chemical and biological contaminants from raw water. Filtration also remove solid particle from a fluid by passing the fluid through a filtering medium or septum, on which the solids are deposited **[1]**. The solid particle may be coarse, fine or aggregate, such as: silica sand, manganese greensand, granulated activated carbon and post carbon (figure 1) **[2]**.



(a) (b)

(c)

Figure 1. (a). Silica sand, (b). Manganase greensand and (c). Post carbon

In water filtration system, sand is an extremely effective filter media because its ability to hold back coagulum or precipitates containing impurities. Filter sand size, angularity and hardness are the important filter sand characteristics to ensure proper filtering **[3]**. Manganese greensand is a purple – black filter medium that is used for the removal of soluble iron, manganese and hydrogen sulfide from well water supplies. It also has the capacity to remove radium and arsenic. There are several sizes of carbon media that is used for filter media, granulated or fine. The use of carbon in water filtration is to remove chlorine and organic contaminants from tap water, also for color and taste removal in water **[4]**. Beside coarse, fine or aggregate media in filtration system, there is also other media to make sure the water filtered completely and to remove the suspend in water that not well for human body. The media are: sediment, porous ceramic and reverse osmosis (figure 2).

(a) (b)

Figure 2. (a). Sediment and (b). porous ceramic as filter media **[5],[6]**

Filters can be divided into two types: pressure and gravity. Pressure filters consist of closed vessels containing beds of sand or other granular material through which water is forced under pressure. These filters are frequently used in certain industrial situations, and a number have been installed for public water supplies. Gravity filters consist of an open-topped box (usually made of concrete) drained at the bottom, and partly filled with a filtering medium (normally clean sand). Raw water is admitted to the space above the sand, and flows downward under the action of gravity **[7]**.

The goal of water filtration is to produce water fit for a specific purpose. Most water is filtered for human consumption (drinking water) but water filtration may also be designed for a variety of other purposes, including to meet the requirements of medical, pharmacology, chemical and industrial applications. In general the methods used include physical process such as filtration and sedimentation, biological processes such as slow sand filters or activated sludge, chemical process such as flocculation and chlorination and the use of electromagnetic radiation such as ultraviolet light. The filtration process of water may reduce the concentration of particulate matter including suspended particles, parasites, bacteria, algae, viruses, fungi; and a range of dissolved and particulate material derived from the minerals that water may have made contacted after falling as rain **[8]**. Water filtration also relatively inexpensive and improves the overall taste of tap water as well as the smell, and appearance. Many filtrations will also remove some harmful chemicals found in drinking water.

2. DESIGN

This filtration system consists of cyclone pre filter, ceramic filter, reverse osmosis and several filters with media: sand, manganese greensand, granulated activated carbon, sediment, and post carbon. This filtration system also companied by submerge pump and reverse osmosis pump with capacity 200 and 50 liter/minute to make sure the target of 10 liter capacity can be revealed. The water filtration system was shown in figure 3.

The calculation of the system was used formulae from Darcy's law to calculate the flow in porous medium, Stokes's law to calculate the flow in particle medium, continuity law and Reynold number to calculate the velocity and flow rate in the system

In cyclone pre filter, the flow rate in pre cyclone filter was designed suitable with submerge pump (200 liter/minute) and the velocity can be calculated using formulae 1 **[10]**.

$$Q = A \times v \tag{1}$$

$$\mathrm{Re} = \frac{\rho \times v \times d}{\mu} \tag{2}$$

In formulae 2 **[10]**, water physical properties, such as density (ρ), dynamic viscosity (μ) and velocity must be substituted to calculate Reynold number (Re).

In sand filter media, manganese greensand, granulated activated carbon and post carbon, the velocity must be calculated first using Stoke law, formulae 3 **[3]** with media and water physical properties (density and dynamic viscosity). Then the flow rate and Reynold number in sand, manganese green sand, granulated activated carbon and post carbon media can be calculated using formulae 1 and 2 **[10]**.

The calculation of flow rate in sediment, ceramic and reverse osmosis can be calculated using formulae 4 **[11], [12**] by substituting permeability, pressure, area, density, gravity and length. Then Reynold number and flow rate in those media can be calculated using formulae 1 and 2

$$v_s = \frac{g \times (\rho_s - \rho) \times d_p^{\,2}}{18 \times \mu} \tag{3}$$

$$Q = \frac{K \times P \times A}{\rho \times g \times L} \tag{4}$$

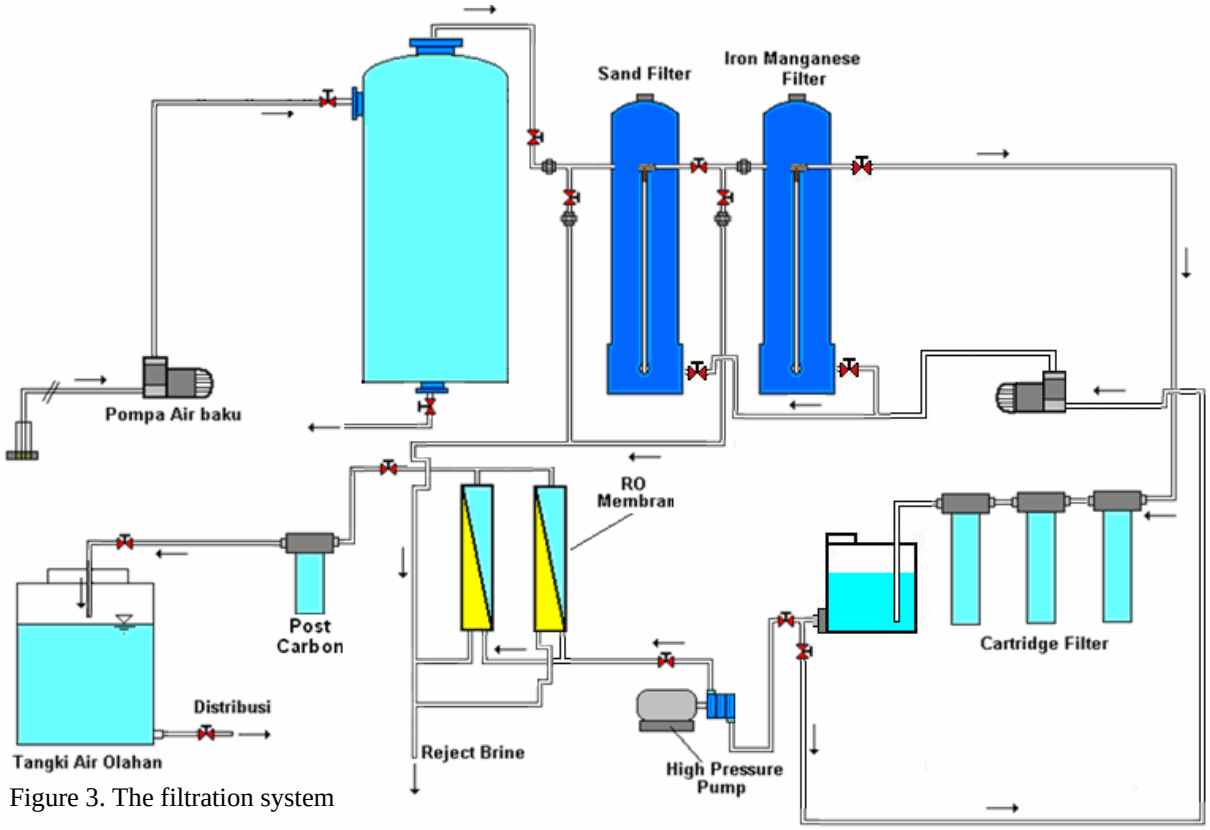


Figure 3. The filtration system

3. RESULT AND DISCUSSION

Cyclone separators are designed to remove suspended solids from liquids. The separating efficiency depends on the flow velocity and the density of the particle. Liquid enters the upper chamber and separated because of the density difference between water that has less density with sludge that has bigger density. The separating efficiency varies from 22 -70 μm and depends on the density of the solids, higher density leads to finer separation. Separated solid are removed with an automatic purge system or with manual purge valves. The separating efficiency in cyclone filter was shown in figure 4

In Darcy law for calculating fluid in porous media, permeability is very affected the flow in the system. Permeability depends on the combination of the fluid and porosity in porous media. Permeability describes how easily a fluid is able to move through the porous material.

In Stoke law for calculating fluid in particle medium, the density of media and particle diameter is very affected the overall flow rate and velocity in the system.

Beside that the velocity in the system is affected by surface area and design of the media itself. Velocity also affected by fluid physical properties, such as density and viscosity, the increase in velocity can make higher pressure drop in the system. In filter system, the velocity is maintained not too fast to ensure the media can filter the media well. Based on the calculation, it can be concluded that the flow type in cyclone pre filter, sand, manganese greensand, granulated activated carbon and post carbon are turbulence. And the flows in sediment, ceramic and reverse osmosis are laminar. This flow type different is cause by the permeability of the material and velocity, because higher permeability and velocity can result to higher Reynold number, resulting the flow type into turbulence.

The calculation result of velocity, and Reynold number in the filtration system was shown in table1. Based on the flow rate calculation, it can be concluded that the flow rate is decreasing from 200 liter/minute in cyclone pre filter to 3.07 liter/minute in ceramic filter, after flowed in several media: sand, manganese greensand, granulated activated carbon, sediment, and ceramic. The flow was increased again after pumped by reverse osmosis pump with flow rate 50 liter/minutes. Finally the flow rate was decreased until 11.83 liter/minute after passed in reverse osmosis and post carbon. This flow rate reduction can be cause by the fluid friction and pressure drop across the media to filter the water inside the water filtration system. The flow rate in the system after passed to several media was shown in figure 5.

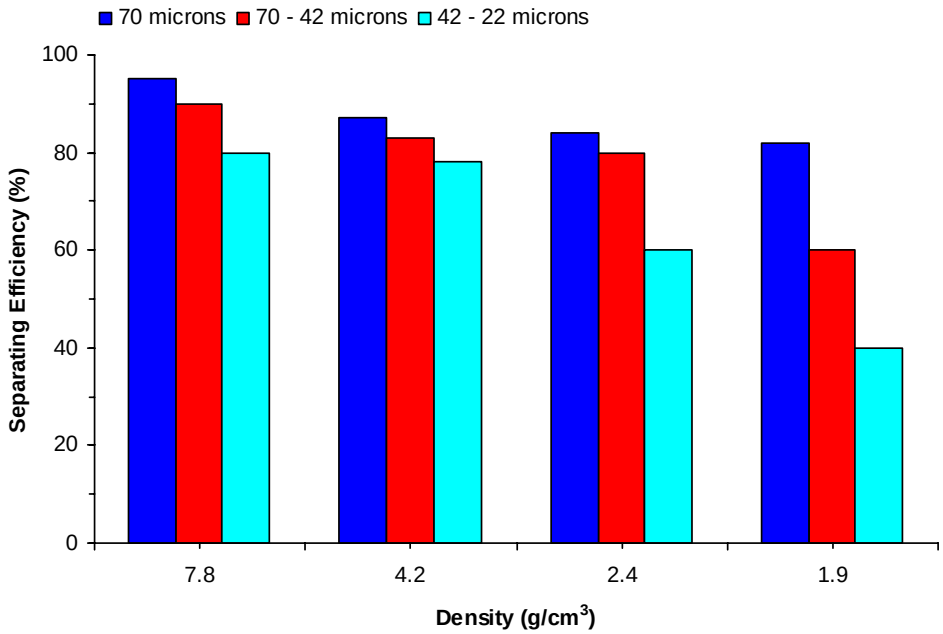

Figure 4. Separating efficiency in cyclone pre filter

Table 1. The calculation result of fluid mechanic in filtration system

Filter	v (m/s)	Re
Cyclone	0.73	69359.4
Sand	7.14×10^{-2}	19478.14
Manganese greensand	186.97×10^{-4}	5101.42
Granulated activated carbon	8.61×10^{-2}	9674.83
Sediment	1×10^{-2}	1123.67
Ceramic	5×10^{-3}	561.84
Reverse osmosis	2×10^{-2}	2247.35
Post carbon	3.1×10^{-2}	3482.27

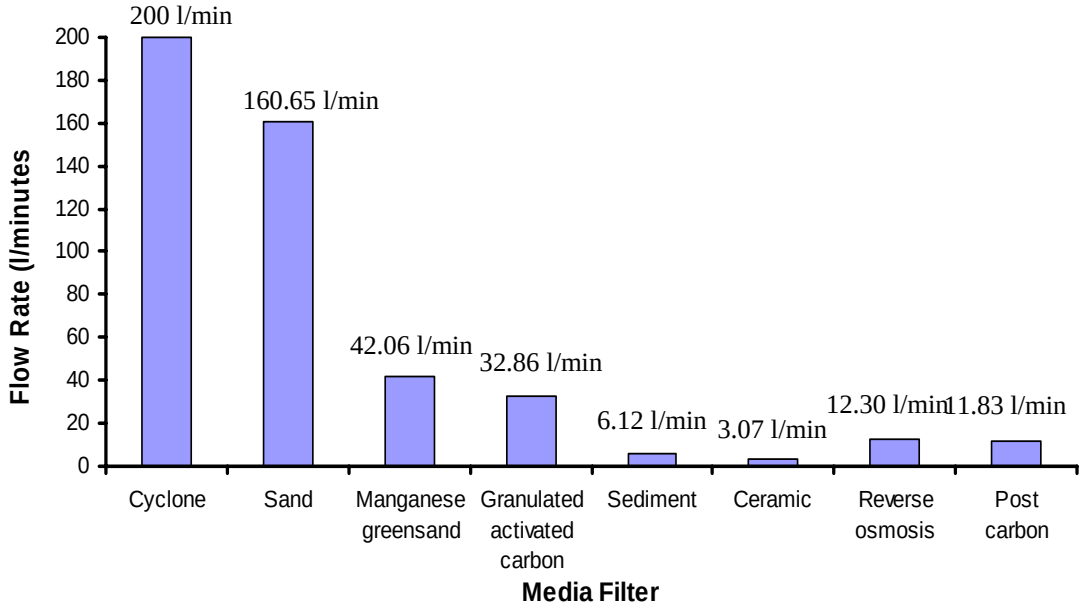

Figure 5. Flow Rate in several filter media

4. CONCLUSION

From the water filtration fluid mechanic calculations, it can be concluded that the filtration system can reach minimum 10 liter/minute capacity after flew in cyclone pre filter and several media, such as: silica sand, manganese greensand, granulated activated carbon, sediment, ceramic, reverse osmosis and post carbon.

ABSTRACT

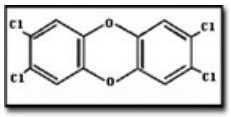
Dioxin is the most toxic chemical known in our environment. This group of compounds comprises 75 Polychlorinated dibenzo-p-dioxins (PCDDs) and 125 Polychlorinated dibenzofurans (PCDFs). Many of them are toxic substances, particularly from combustion of waste materials in incinerators and process high stability under various conditions. Many researchers calculated thermodynamic properties of dioxin with used different kind of methods. And each method has it own limitations. In this research, thermodynamic properties such as enthalpy, entropy and Gibbs free energies of PCDD/Fs were calculated using Gaussian '98 based on ab initio quantum chemistry B3LYP/6-311+G(2d,p)//B3LYP/6-31G(d) as a basis set. In the comparison with other methods show that this research has corrected value for thermodynamic of PCDD/Fs. The small errors appeared because of the differences model chemistry and methods. To make more accuracy of this thermodynamic calculation, it recommends to use higher level of theory using B3LYP/6-311+G(3df,2df,2p)//B3LYP/6-31g(d).

Keywords: *Thermodynamic properties, combustion, dioxins, enthalpy, Gibbs free energy*

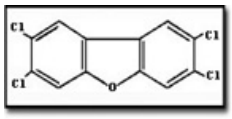
1. INTRODUCTION

Dioxin is the most toxic chemicals known in our environment and the name it's given to a group of molecules made up of two chlorinated benzene rings connected by one or two atoms of oxygen. This group of compounds comprises 75 Polychlorodibenzo-*p*-dioxins (PCDDs) and 125 related compounds called Polychlorodibenzo furans (PCDFs). Characteristic of all the compounds is a high melting point, a low vapour pressure, a low water solubility and a reasonable solubility in and affinity for apolar media.

Chemical Structure of a few the most toxic dioxins: PCDD and PCDF



2,3,7,8-Tetrachlorodibenzo-p-dioxin



2,3,7,8-Tetrachlorodibenzofuran

Dioxins occur in the environment in complex mixtures of the 226 congeners. Most of the 226 dioxin congeners are thought to pose no risk to human health, and only 17 congeners with chlorine are reported to have potential health effects. An International system has been developed which assigns toxicities to each congener relative to the most toxic form (2,3,7,8 TeCDD).

Dioxins are not manufactured as commercial products or ingredients. They occur in combustion process and certain chemical processes. It is now believed that dioxins and furans are formed in the low-temperature combustion region of incinerators through heterogeneous catalytic reactions occurring in the fly-ash environment. However, the detailed chemical reactions are not understood.

Study for dioxins formation in incinerator process would be very significant in determining the formation mechanism of polychlorinated dioxins (PCDDs) and furans (PCDFs), and would assist in design of strategies to effectively control or eliminate emissions of these compounds.

Unfortunately, the thermodynamic data from other researchers and experimental information on their thermodynamic properties is difficult to obtain.

In this research, all the thermodynamics of polychlorinated dibenzo-*p*-dioxins and dibenzofurans (PCDD/Fs) were calculated by *Gaussian '98*. Study for dioxin formation is very important to understand the formation mechanism of PCDD/Fs in thermal processes and It

would assist in the effective control or elimination of the PCDD/Fs emissions during the thermal combustion and reduction processes.

2. LITERATURE REVIEW

There are several investigations in calculating thermodynamic data in combustion process.

Shaub [6] calculated heats of formation at 298 K for 75 PCDD isometric species through the 'group additivity method' which Benson (1976) contrived, and estimated the values of standard entropy and heat capacity at constant pressure for Dibenzo-p-dioxin (C12H8O2), 1-Chlorodibenzo-p-dioxins (C12H7O2Cl), 2-Chlorodibenzo-p-dioxin (C12H8O2Cl)1, 2,3,7,8-Tetrachlorodibenzo-p-dioxin (C12O2Cl4), Octachlorodibenzo-p-dioxin (C12O2Cl8). However, the evaluation of thermodynamic functions through Benson's group additivity method is unreliable for the dibenzo species. This entropy values appear to contain considerable errors since they were derived from rough estimates of their molecular structures and vibration frequencies. As an example, Shaub estimate value of heats formation at 298 K of 2,3,7,8 TCDD is -345.14 kJ/mol, which is quite different from Domalski and Hearing (1993) estimated value of -168.2 kJ/mol. However, Domalski estimates for these thermodynamic parameters of heats of formation, entropy and heat capacity at constant pressure are limited only to those at 298 K, which prevent their use in the thermodynamic calculations at higher temperatures used in incineration and pyrometallurgical process. Thus, the earlier thermodynamic calculation using Shaub's estimates appears to be unreliable.

Huang [9] predicted the enthalpies and Gibbs free energies of formation of PCDDs by several methods. These included three semi-empirical methods (MNDO, AM1 and PM3); three different implementations of Benson's group additivity method were also evaluated. Huang reported that the CHETAH program is the best for evaluating gaseous enthalpies of formation of PCDDs.

Saito and Fuwa [8] calculated the thermodynamic parameters of heats of formation at 298 K using the semi-empirical molecular orbital method with the PM3 Hamiltonian. Their study aimed to determine thermodynamic data bases for these substances within a scientific error range.

Andrew McLennan [5] calculated the thermodynamic data using Gaussian '94 and used the MNDO semi-empirical and DFT/ab initio method in his calculations. The semi-empirical methods computed the heats of formation of PCDDs in their solid states.

Pengfu Tan [10] predicted of the toxic PCDD/Fs isomer distribution using the three different databases were compared with measured values from the industrial incinerator, wood combustion system, electric arc furnace, and iron ore sinter plant. The comparison showed that the MNDO method predicts more reliable isomer distribution than PM3 method and the Group additivity method.

2.1 An overview Of Computational Chemistry

There are two broad areas within computational chemistry devoted to the structure of molecules and their reactivity: *molecular mechanics and electronic structure theory*. They both perform the same basic types of calculation:

a. Computing the energy of particular molecular structure (spatial arrangement of atoms or nuclei and electrons).
b. Performing geometry optimizations, which locate the lowest energy molecular structure in close proximity to the specified starting structure. Geometry optimizations depend primarily on the gradient of the energy-the first derivative of the energy with respect to atomic positions.
c. Computing the vibrational frequencies of molecules resulting from interatomic motion within the molecule. Frequencies depend on the second derivative of the energy with respect to atomic structure, and frequency calculations may also predict other properties which depend on second derivatives. Frequency calculations are not possible or practical for all computational chemistry methods.

2.1.1 Molecular Mechanics

Molecular mechanics simulations use the laws of classical physics to predict the structures and properties of molecules. Molecular mechanics methods are available in many computer programs, including MM3, HyperChem, Quanta, Sybyl and Alchemy. There are many different molecular mechanics methods. Each one is characterized by its particular *force field*.

Molecular mechanics calculations don't explicitly treat the electrons in a molecular system. Instead, they perform computations based upon the interactions among the nuclei. Electronic effects are implicitly included in force fields through parametrization.

This approximation makes molecular mechanics computations quite inexpensive computationally, and allows them to be used for very large systems containing many thousands of atoms. However, it is also carries several limitations as well. Among the most important are these:

a. Each force achieves good results only or a limited class of molecules, related to those for which it was parametrized.
b. Neglect of electrons means that molecular mechanics methods can not treat problems where electronic effects predominate.

2.1.2 Electronic Structure Methods

Electronic structure methods use the laws of quantum mechanics rather than classical physics as the basis for their computations. Quantum mechanics states that the energy and other related properties of a molecule may be obtained by solving the Schrödinger equation:

$$H\Psi = E\Psi \qquad (1)$$

For any but the smallest systems, however, exact solutions to the Schrödinger equation are not computationally practical. Electronic structure methods are characterized by their various mathematical approximations to its solution. There are two major classes of electronic structure methods:

a. *Semi-empirical methods*, such as AM1, MINDO/3 and PM3, implemented in programs like MOPAC, AMPAC, HyperChem and Gaussian, use parameter derived from experimental data to simplify the computation. They solve an approximate form of the Schrödinger equation that depends on having appropriate parameters available for the type of chemical system under investigation. Different semi-empirical methods are largely characterized by their differing parameters sets.
b. *Ab initio methods,* unlike either molecular mechanics or semi-empirical methods, use no experimental parameters in their computations. Instead, their computations are based solely on the laws of quantum mechanics- the first principles referred to in the name ab initio –and on the values of a small number of physical constants:
    - The speed of light
    - The masses and charges of electrons and nuclei
    - Planck's constant

Gaussian offers the entire range of electronic structure methods. This work provides guidance and examples in using all of the most important of them. *Ab initio* methods compute solutions to the Schrödinger equation using a series of rigorous mathematical approximations.

Semi-empirical and *ab initio* methods differ in the trade-off made between computational cost and accuracy of results. Semi-empirical calculations are relatively inexpensive and provide reasonable qualitative descriptions of molecular system and fairly accurate quantitative predictions of energies and structures for systems where good parameter sets exist.

In contrast, ab initio computations provide high quality quantitative predictions for a broad range of systems. They are no imitated to any specific system. Early ab initio programs were quite limited in the size of system they could handle. However, this is not true for modern ab initio programs. On a typical workstation, Gaussian '98 can compute the energies and related properties for systems containing a dozen heavy atoms.

2.2 Methods

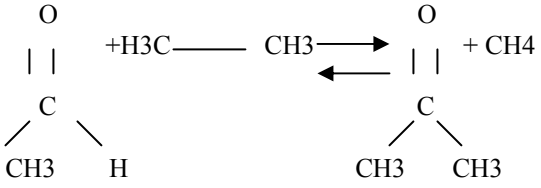
The Gaussian program contains a hierarchy of procedures corresponding to different approximation methods (commonly referred to as different levels of theory).

Table 1. Approximation Method of Gaussian Program

Keyword	Method	Availability
HF	Hartree-Fock Self-Consistent Field	Through 2nd derivatives
B3LYP	Becke-style 3-Parameter Density Functional Theory (Using the Lee-Yang-Parr correlation functional)	Through 2nd derivatives
MP2	2nd Order Moller-Plesset Perturbation Theory	Through 2nd derivatives
MP4	4th Order Moller-Plesset Perturbation Theory (including Singles, Doubles, Triples and Quadruples by default)	Energies only
QCISD(T)	Quadratic CI (Single, Double and Triples)	Energies only

2.3 Isodesmic Reaction

In this research ΔHf°of PCDD/Fs are calculated by using isodesmic reaction. An isodesmic reaction is one in which the total number of each type of bond is identical the reactants and products. Here is a simple example



In this reaction, there are twelve single bonds and one (C-O) double bond in both the reactants and products. Because of this conservation of the total number and types of bonds, very good results can be obtained relatively inexpensively for isodesmic reactions due to the cancellation of errors on the two sides of reactions.

In addition, isodesmic reactions may be used to predict the heats of formation for compounds of interest by predicting □H for the reaction and then computing the desired heat of formation by removing the known heats of formation for the other compounds from this quantity.

From the previous studies there are no paper reported the thermodynamic properties from all 226

ISSN 114-1284

congeners of PCDD/Fs. The thermodynamic properties of PCDFs are not easy to find. Therefore, in this paper the PCDFs data were compared with experimental data from incinerator.

The thermodynamic properties are calculated by using Gaussian '98. Thermodynamic properties such as enthalpy, entropy and Gibbs free energies of PCDD/Fs were calculated based on ab initio quantum chemistry using the B3LYP/6-311+g (2d,p)//B3LYPD/6-31 g(d) basis set.

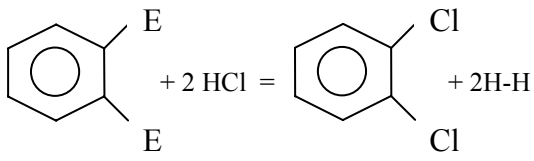
3. CALCULATION PROCEDURE

3.1 Calculation Enthalpy From Gaussian'98

From out put of Gaussian '98 we can get E (Sum of electric and thermal energies). The calculations of enthalpies of PCDD/Fs are isodesmic reactions, the reactions we can see above:

Reactant (A) + n*HCl = Product (B) + n*H2

For example:



ΔHf°(Dichlorobenzene) ={E (Dichlorobenzene)+ E(H2) - E(Benzene) - E(HCl)} + ΔHf°(Benzene)

Where:

ΔHf° = standard enthalphy
E = Sum of electronic and thermal energies from output file of gaussian'98

The condition of isodesmic reaction is the number of atoms and bonds of reactants are the same as one of products respectively.

The standard formation enthalpy of the objective is calculated as following:

ΔHf°(Dichlorobenzene) ={E (Dichlorobenzene)+ E(H2) - E(Benzene) - E(HCl)} + ΔHf°(Benzene)

3.2 Calculation of Thermodynamics PCCD/Fs

From the output file of Gaussian, enthalpies are calculated and NASA Polynomial table are made after. In NASA polynomial table the thermodynamic values are calculated based on JANAF table.

Molar specific heat capacity C_{pj}^0, molar enthalpy H^0,molar entropy S^0, and Gibbs free energy G^0 at given temperature under the standard pressure can be calculated by using a NASA polynomial based on JANAF table.

Molar specific heat capacity C_{pj}^0 for species j at standard pressure (1 atm) is defined as a function of temperature T as follows

$$\frac{C_{pj}^0}{R} = a1 + a2T + a3T^2 + a4T^3 + a5T^4 \qquad (T \geq 1000K) \quad (2)$$

$$\frac{C_{pj}^0}{R} = a8 + a9T + a10T^2 + a11T^3 + a12T^4 \qquad (298K(Tb) \leq T < 1000 \quad (3)$$

As molar enthalpy,

$$H_j^0 = \int_{Tb}^{T} C_{pj}\,dt + H_j^0(Tb) \quad (4)$$

As for molar entropy,

$$S_j^0 = \int_{Tb}^{T} C_{pj}^0\,d\ln T + S_j^0(Tb) \quad (5)$$

And The Gibbs free energy:

$$G_j^0 = H_j^0 - TS_j^0 \quad (6)$$

4. RESULT

4.1 Data of PCDDs and PCDFs

First of all we compared ΔHf° datas of the PCDDs with another methods.

Table 2. Calculated Ideal Gas Enthalpy of Formation for PCDD Compared to another methods

ΔHf° (kJ/mol)						
	This research (Gaussian '98)	MNDO Andrew's (Gaussian '94)	Shaub 1982	PM3 (Huang et al) 1996	Chetah (Huang et al) 1996	Fuwa Saito

1,2,3,4,6 PeCDD	-175.124	-171.62	-273	-140.56	-182.8	-141.5
1,2,4,6,7 PeCDD	-189.9	-184.65	-287.7	-144.58	-192.05	-145.6
1,2,4,8,9 PeCDD	-189.7	-184.5	-250.2	-144.57	-192.05	-145.5
1,2,3,4,6,7 HxCDD	-198.19	-187.17	-339.1	-162.5	-203,.4	-163.5
1,2,4,6,8,9 HxCDD	-211.83	-198.4	-312.25	-163.66	-221.8	-164.7
1,2,3,4,6,7,8 HeCDD	-217.81	-199.91	-401.15	-183.74	-223.84	-184.8
1,2,3,4,6,7,9 HeCDD	-219.83	-200.6	-365.54	-181.54	-233.05	-182.6
OCDD	-227.77	-202.41	-418.8	-199.36	-244.35	-200.5

From PCDDs data showed that this work accurate enough with MNDO semi-empirical method by Andrew's [6]. For the comparison between shaub's have very big differences. The numbers of studies have been reported that shaub's data is inaccurate and unsatisfactory. Because the enthalpy formations have very big differences compared to others studies.

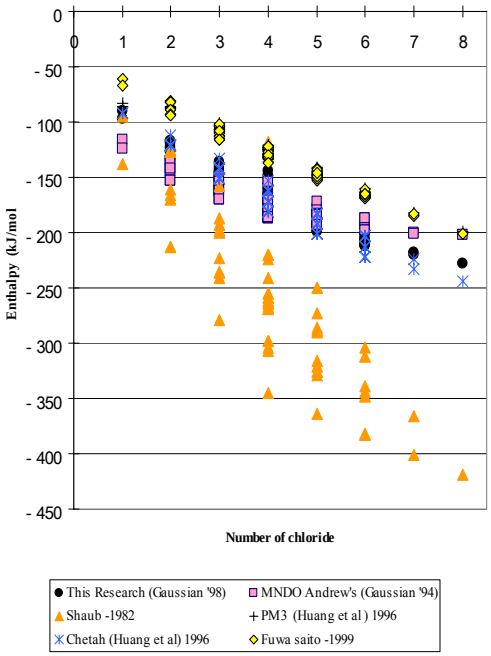

Figure 1. The Enthalpy Comparison of PCDDs at 298.15 K

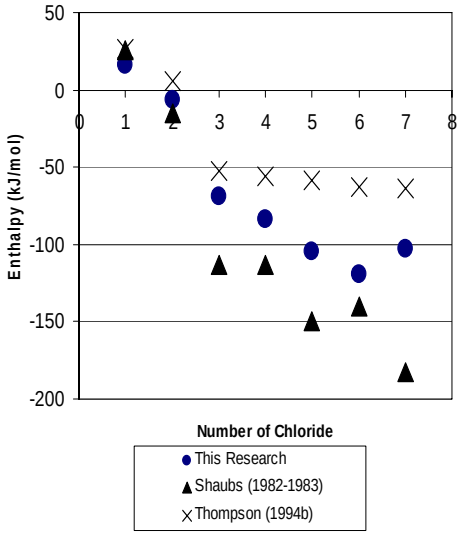

Figure 2. The Enthalpy Comparison of PCDFs at 298.15 K

In comparing between this research and shaub's, its correlation is shown very big and inaccurate. The discrepancy between shaub's value and this research become larger as the number of Chloride in horizontal axis. It is clear that the shaub's method overestimates. The change in heats of formation caused by chlorine allocation change estimated in shaub's study is unrealistically large compared with this research. For example, Shaub's heats of formation difference between 2,3,7,8-TeCDD. In this research -181.673 kJ/mol and shaubs is -344.85 kJ/mol, which is obviously unrealistic for the difference caused of chlorine atom allocation.

4.2 Comparison with Experimental Value

The experimental values of the enthalpies of PCDD/Fs are limited. Therefore, in this research the comparison of PCDD/Fs are compared with the available datas.

Table 3. Comparison with Experimental Value

Products	Enthalpy (kJ/mol)				
	MNDO (1998) Andrew	This Research	Exp Value Pedley (1994)	Exp-Andrew (%)	Exp-This Research (%)
Methane	-50.08	-89.9	-	-	-
Benzene	88.75	71.108	82.6	6.93	16.16
Chlorobenzene	55.92	-	52	7.01	-
1 CDD	-115.64	-89.594	-85.7	25.89	4.35
2 CDD	-123.91	-97.04	-74.1	40.20	23.64
2,3 DCDD	-141.95	-121.94	-111.9	21.17	8.23

From table 3 shows that this research has a good agreement in comparing with experimental value. The errors values are small than using MNDO method.

5. DISCUSSION

The differences results of enthalpy PCDD/Fs from other research because each researcher used their own method. And for discussion in this research, the results of enthalpy are influenced by B3LYP/6-311+G(2d,p)//B3LYP/6-31G(d) as a basis set

5.1 Discussion of Differences Basis sets

A basis set is the mathematical description of the orbitals within a system used to perform the theoretical calculation. Larger basis sets more accurate approximate the orbital by imposing fewer restrictions on the locations of the electrons in space.

Standard basis sets for the electronic structure calculations use linear combinations of Gaussian functions to form the orbitals. Basis sets assign a group of basis functions to each atom within a molecule to approximate its orbitals.

In Andrew's calculation using a semi-empirical method (MNDO), the basis set did not need to be specified since a basis set is inherent in the method.

In this research using the ab initio method, the basis set was B3LYP/6-311+G(2d,p). It means puts 2d functions and 1 function on heavy atoms (plus diffuse functions), and 1p function on hydrogen. Basis sets with diffuse functions are important for systems where electrons are relatively far from the nucleus: molecules with lone pairs, anions and other systems with significant negative charge, systems in their excited states, systems with low ionization potentials, descriptions of absolute acidities, and so on.

In this research was using the B3LYP/6-311+G(2d,p)//B3LYP/6-31G(d) for basis set because it has high level theory than others but to calculate the data it took more than 8 hours to finish.

5.2 Discussion of B3LYPD/6-311+G(2d,p)//B3LYPD/6-31G(d)

The calculated data in this research were accurate enough because of these reasons:

a. B3LYPD/6-311+G(2d,p)//B3LYP/6-31G(d)is also include as high level single point energy calculation. The most highest is B3LYP/6-311+G(3d,2df,2p)//B3LYP/6-31G(d) and the second is B3LYP/6-311+G(2d,p)//B3LYP/6-311+G(2d,p). The basis set is very important to have accuracy data. The more high level of theory will get more accuracy of the results.
b. The Mean Absolute Deviation from Experiment (MAD): The average differences between the computed and experimental values have very small errors.

6. CONCLUSION

1. Calculating Thermodynamic with gaussian'98 by using B3LYP/6-311+G (2d, p)//B3LYP/6-31G (d) as a basis set is accurate enough.
2. The small errors appeared because of the differences model chemistry and methods.
3. This method has a good agreement in comparing with experimental value because the small error values appeared.
4. To make more accuracy of this thermodynamic calculation, it recommends to use higher level of theory using B3LYP/6-311+G(3df,2df,2p)//B3LYP/6-31g(d).

ACKNOWLEDGMENT

I wish to express sincere appreciation and gratitude to Professor Yoshihara Yoshinobu for his support, advices and encouragement help me in this research. The last, I would like to say deepest sincere to my husband and my son and also my father and my mother whose support me and giving me advice for many things in my life.

ABSTRACT

Ethanol is one of the most populer and attractive fuel alternative for Spark Ignition Engine (SIE). The addition of ethanol to gasoline will change most of the physicochemical properties of gasoline-ethanol blends. The properties change of gasoline-ethanol blends lead to alter engine performances, and emissions. The tested fuel of gasoline-ethanol blends compose the Indonesian regular unleaded gasoline and anhydrous ethanol in diferent compositions. The gasoline was blended with ethanol to get 10 test blends ranging from 0% to 40% by volume of ethanol with an increament of 5%. The blends were tested based on the ASTM standards. The results are the addition of ethanol to gasoline lead to increase in the RVP up to a maximum of 71.3 kPa – increased by 11.3% compared with the gasoline - with 5% of ethanol added and tends to decrease with percentage over 10%. The RON of gasoline-ethanol blends increased proportionally with the addition of ethanol. In average the addition of 5% volume of ethanol increased 1.95 point of RON.

***Key words**: gasoline-ethanol blends, properties, vapor pressure, and RON*

1. INTRODUCTION

Gasoline as a fuel of Spark Ignition Engine (SIE) is a complex mixtures composed hundreds volaitile and flammable hydrocarbons ranging from 4 to 12 carbon atoms per molecule. Gasoline can be classified as parafanic, naphtanic and aromatic had a boiling point between 30°C and 220°C. The properties of gasoline are influenced by the origin of crude oil (API and chemical composition), refinement process (distilation, alkylation, hydrocracking, and catalitic cracking process), specification and properties that fit to a climate, requirement and specification of automotive manufacturer (based on applied technology of engine), and emission standards. Recently most gasoline the contain octane booster compound to improve anti knock properties, such as: MTBE, ETBE, TAME, ethanol (oxygenate octane booster), toulene, xylene or iso-octane and other additives.

Ethanol is one of the compounds that improve octane booster for gasoline and one of the most populer alternative and renewable fuel for a Spark Ignition Engine (SIE). As an alternative fuel, ethanol can be used as a dedicated or blending fuel. As an octane booster, ethanol is the most effective to increase octane number of gasoline compared to other compounds such as: ETBE, MTBE, iso-octane and toluene[1] as seen in Fig. 1. The advantages of ethanol addition into gasoline are not only increase the octane number effectively but also improve a combustion process due to containing oxygen molecules.

The effects of addition of ethanol into gasoline has been reported by many researchers,

in which it reduces emission pollutans: CO (in the range of 5-90%) and HC (in the range of 7-85%)[1,2,3,4,5] depend upon the engine technologies applied and proportion of ethanol in the gasoline-ethanol blends. On the other hand, the impact of the addition ethanol into gasoline toward engine performance are increase a torque/power and fuel consumption by 3-9% and 3-21% respectively compared to the reference fuel[3,4,5,6].

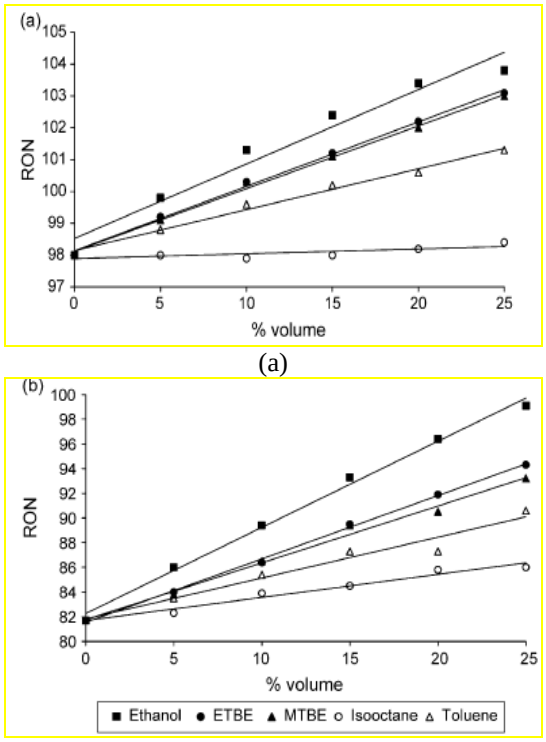

Figure 1. Motor Octane Number graphics for (a) Gasoline A dan (b) Gasoline B containing octane booster coumponds– specification of Gasoline A dan B are available on Table 2[6]

The addition of ethanol to gasoline will change phsycochemical properties significantly, mainly: volatility, density, viscosity, heat of combustion and octane number. The significancy of the properties change depend on the percentage presents influence of anhydrous ethanol addition (up to 40% v/v) on the physcochemical properties of Indonesia reguler unleaded gasoline (premium). and purity of ethanol as well as the chemical composistion of gasoline[7,8,9,10,11]. This paper presents influence of anhydrous ethanol addition (up to 40% v/v) on the physcochemical properties of Indonesia reguler unleaded gasoline (premium).

2. MATERIALS AND METHODS

2.1 Materials

An anhydrous ethanol is obtained directly from one of the Indonesian ethanol manufaturers located in Malang and did not experience the denaturation process. The denaturation process is the addition of a small quantity (less than 5%) of hydrocarbon fuel into ethanol. The denaturated anhydrous ethanol ussually call as ”fuel grade ethanol”[12]. The specification of anhydrous ethanol used for a research can be seen in the Table 1.

Table 1. Specification of anhydrous ethanol

Parameter	Specification	Test Method
Appearance	clear colorless liquid free of suspended matter	Visual
Strength at 15°C	Min 99.7 % v/v	Alcoholmeter
Total Acid as Acetic Acid	Max 30 ppm	Test by Titrimetry
Moisture Content	Max. 0.30 % w/w	Karl Fischer titration
Density at 20°C (at point of production)	Max. 0.792	Hydrometer
Material non volatile at 105°C (at point of production)	Max. 30 ppm	Gravimetry

The gasoline used for a research is the Indonesian reguler unleaded gasoline (premium) with specification as stated in the Table 2 and obtained from the Pertamina Gas station labeled ”Pasti Pas” in order to attain an accurate and good quality of product. The Table 2 also gives specification of other gasoline used for some researchers.

2.2 Methods

To verify the volatility (Reid Vapor Pressure - RVP), distillation curve, octane rating, density and kinematic viscosity of premium-ethanol blends, equipment approved by the American Society for Testing Materials – ASTM was used. The RVP tests were performed using a Grabner Instruments Minivap VPS device, following the ASTM D 5191 standard. The RON tests were carried out with a CFR engine according to the ASTM D-2699-96. The density tests were conducted following the ASTM3237-97 procedures as well as the kinematic viscosity tests were based on the ASTM D-445. Heat of combustion tetst were carried out with a Parr bomb calorimeter.

3. RESULTS AND DISCUSSIONS

All of the tests were carried out using the ASTM procedures and standards as tabulated in Table 3.

Table 3: Properties of premium, ethanol and premium-ethanol blends.

3.1. Research Octane Number (RON)

The quality of gasoline is constantly based on its octane number, which indicates its antiknocking strength. Research Octane Number (RON) is one of the extremely important property of SIE fuel concerning antiknocking during combustion occurs in the cylinder combustion chamber. The combustion of gasoline in the SIE occurs initiation by sparking from spark plug and flame propaggate to burn mixture of gasoline and air while combustion mixture by compression/ autoignition is prohibited. Gasoline having a high octane number produces more effective combustion in Spark Ignition Engine. The efficiency of a gasoline fueled engine is highly influenced by the fuel's antiknock characteristics. The RON of anhydrous ethanol is much higher - i.e. around 127 - compared to the premium as shown in the Table 3.

The addition of ethanol into gasoline caused a linear increase in the RON as shown in Fig. 1. The increase of the RON of gasoline-ethanol blends are influenced by some factors such as, RON of the based gasoline, chemical composition of gasoline and the proportion of ethanol in the blend. The increase of RON improves combustion procces lead to efficiency of engine rise.

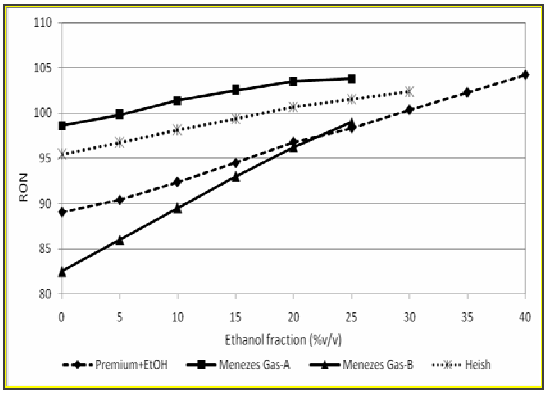

Figure 1: Octane Number for several gasolines

Every 5% v/v addition of ethanol into premium increased around 1.9 point of the RON and at the 40% of ethanol in the blend, the RON reached 104 point. The Fig. 1 shows that a higher RON of the base gasoline tends to decrease the effectiveness of ethanol addition for increasing RON of the premium-ethanol blends and vice versa. The addition of 5% volume of ethanol into the Menezes type A gasoline that has RON of 82.5 increased around 3.3 point of the RON. On the other hand for the Menezes type B gasoline that has RON of 95.4 only increased around 1.7 point of RON for every 5% volume of the ethanol addition.

3.2. Volatility and Reid Vapor Pressure (RVP)

Volatility can be undestood as the ease with wich fuel evaporates. The volatilty expressed as vapor pressure is the most important of property of fuel for SIE due to the combustion process take place in a gaseous environment. In inside of combustion chamber of SIE, where the gasoline must first vaporized and mixed with air so that combustion can occur. The vapor pressure can be determined by a variety of methods, most of them are based on the properties of Reid Vapor Pressure (RVP) and distillation curve.

Gasoline contains hundreds volatile and flammable liquid hydrocarbon compounds from light fractions (C_4) to medium fractions (C_{12}) each having a boiling point that interfres with the others when mixed.The RVP is an indicator of the volatility of the lightes fraction of the gasoline (i.e. of the most volatile compounds) meanwhile the distilation curve gives an idea of the volatility of the gasoline throughout the range of distillation.

Figure 2 describes an evolution of vapor pressure in kPa measured at 37°C (RVP) of the addition of ethanol into gasolines. In general, the addition of ethanol into premium lead to a significant increase with the first 5% of ethanol volume added. Cotinuoesly increasing the percentage of ethanol in the blends more than 5% by volume into gasoline tends to decrease vapor pressure steadily – the same result obtained by API[15]. Some researchers found that the highest increase of vapor pr**e**ssur occur between 5% and 10% the addition of ethanol[6,10,11]. The vapor pressure of blending premium and ethanol which is higher than each of vapor pressure of compossed fuels called as azeotrope effect. The hydrocarbon structure of gasoline-ethanol which cause azeotrope is not yet known. However, the vapor pressure, being an indicator of fuel volatility, is closely related to the molecular interaction of the mixture components[16]. Some researchers consider that the polar molecular structure of ethanol is responsible for increasing vapor pressure of gasoline-ethanol blend due to molecular interaction between ethanol and gasoline (non-polar structure) becomes weak[2,11].

The addition of 5% anhydrous ethanol into premium increased Reid Vapor Pressure by 11.5% from 64 kPa (pure premium) to 71.3 kPa. Azeotrope effect of gasoline-ethanol blends are influenced by chemical compistions of gasoline. Gasoline has a high concentration of paraffin and naphtene provide a higher azetrope effect, the RVP increade by 30% with the addition of ethanol. Meanwhile gasoline contains a rich of aromatic lead to a 15% increase in the mixture's RVP[6]. In term of the spesification of a base gasoline (Table 2) used by the author and Takeshita are similar to the commercial Brazilian gasoline, the azeotrope effects of them are also similar as showed in Fig. 2.

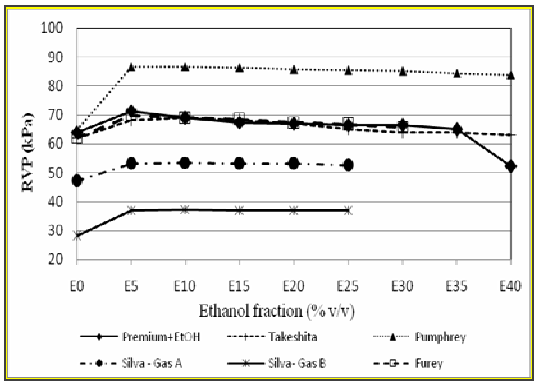

Figure 2: Reid Vapor Pressure for several gasolines

The vapor pressure is related to evaporative emissions occur by a wide variety of mechanisms, including fuel spillage and vapor displacement during refuelling, venting of fuel tank vapor as ambient temperature change, fuel evaporation from engine compartment of parked vehicles due to residual engine heat, liquid leaks in vehicles fuel systems, and so on[2]. However, the presence of ethanol into gasoline mixture increase the mixture's vaporization enthalpy, rendering vaporization difficult and reducing the temperature in the intake haeder, thus allowing a greater mass of fuel to enter the cylinder. In addition, the ethanol consist of oxygenate compounds show a lower combustion enthalpy which, in some cases, compensate for the increase in density of the mixture in intake header lead to maintaining the engine's power. The vapor pressure property is related to safety, transport, and storage of fuel.

The vapor pressure of pure premium and premium-ethanol blends is higher than vapor pressure specified in the Decree of Directorate Generale of Energy and Natural Resources. Based on the specification, the maximum vapor pressure either for pure gasoline (premium) or oxygenate gasoline is 62 kPa, as stated in (Table 2). It is recommended that the specification for oxygenate gasoline (bio-premium contains 3-5% v/v of ethanol) should be revised in order to fit the tested RVP as well as apllied in the Brazilian oxygenate gasoline.

3.3. Volatility and Distilation Curve

Volatility can also be determined by using distillation curve according to the ASTM D-86 standard and procedure. The distillation curve gives an idea of the volatility of gasoline throughout the range of distillation (light up to heavy fraction of hydrocarbon), since the RVP vapor pressure is just a good indicator of the volatility of light fraction of the gasoline. The distillation curve can, in simple terms, be represanted by three points: T10, T50 and T90 which represent the temperatures at which 10, 50 and 90% vaporization of the gasoline's initial occurs. These temperatures characterize the volatility of the fuel's light, medium and heavy fraction. These fractions, in turn, affect the engine's different operating regimes.

Figure 3, shows the distillation curve for the anhydrous ethanol and gasoline used by author and Takeshita. Temperature of vaporization of the both ethanol is similar at around 78°C for a whole volume of vaporization. Ethanol, being a pure compound, has a single distillation point, unlike the other compounds which are mixtures of hydrocarbon.

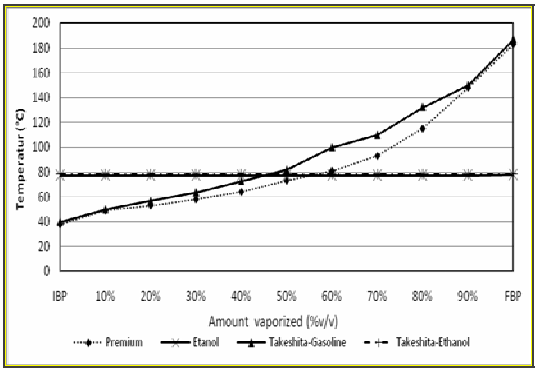

Figure 3: Distillation curves anhydrous ethanol and gasoline

Based on the specification of gasoline (Table 2), premium and gasoline used by Takeshita for the research is similar as well as the distillation curve for the both gasoline. The

slight different occurs in the middle of the curve in which the vaporization temperature of medium fraction is slightly higher compared to premium. It indicates that a higher concentration of medium fractions for the Takashita's gasoline than the premium.

Figure 4 shows the distillation curve for the premium, anhydrous ethanol and premium-ethanol blends, these curves as reference in the analysis of the effect of the addition of ethanol to premium. The distillation of premium shows continuous and smooth increase in temperature as the distillation process progresses (Fig. 3). In general, except for the addition of 5% v/v of ethanol, the increase of addition of ethanol to premium tends to increase the Initial Boiling Point (IBP). The addition of ethanol did not change the Final Boiling Point (FBP).

The addition of 5% v/v of ethanol to premium a sudden change in temperature can be observed, which occurred after 40% distillation of the initial volume. With the addition of 10% v/v of ethanol to premium the same sudden change occurred, however, after a distillation of 50% of the initial volume. With the consecutive increase in the proportion of ethanol in the blends, the location of this sudden increase in temperature tends to occur closer and closer to the final percentage of distillation.

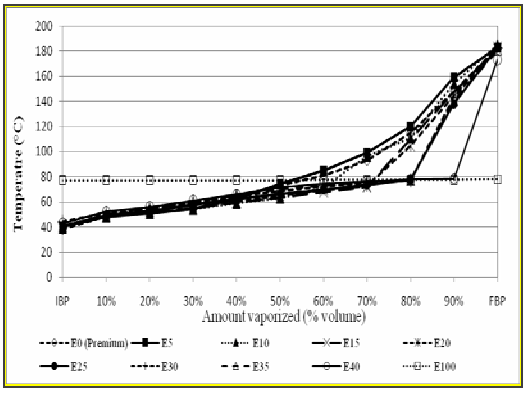

Figure 4: Distillation curves for anhydrous ethanol-premium blends (E0-E40 and E100)

The distillation point that corresponds to 10% of the evaporated volume is related to the engine ignition, mainly for the cold start. The addition of ethanol into gasoline that increases the volatility of the gasoline-ethanol blends can cause the formation of vapor bubbles in the fuel, interrupting the flow and resulting in the engine stalling. In addition, the 50% distilled limit is monitored by its relation with the heating and accelerating of the engine and with the fuel economy. The maximum limits established for the temperature of a 90% evaporated volume and of the FBP aim to control the quantity of high boiling point compounds and to avoid the formation of carbon deposits inside the engine[17].

3.4 Viscosity

Viscosity is defined as the easy with which is fuel can flow. Kinematic viscosity test was carried out correponding to the ASTM D-445 at 40°C. The kinematic vicosity of ethanol is much higher as much as two fold than compared to the premium. The addition of ethanol to premium caused the vicosity of mixture increase is not proportionally with the percentage of ethanol in the mixture. More ethanol in the mixture much more increase in the kinematic viscosity as shown in Fig. 5.

Viscosity is related to droplet formation and development when fuel is injected into manifold or combustion chamber. In general, the higher viscosity of fuel tends to make a bigger dropplet size and spray properties change. Although the gasoline-ethanol blends has higher viscocity than pure gasoline, based on the Gao's research there was no significant change in the spray developing pattern for different blends of gasoline-ethanol (25%, 50%, 75% and 100% ethanol) compared to gasoline[18].

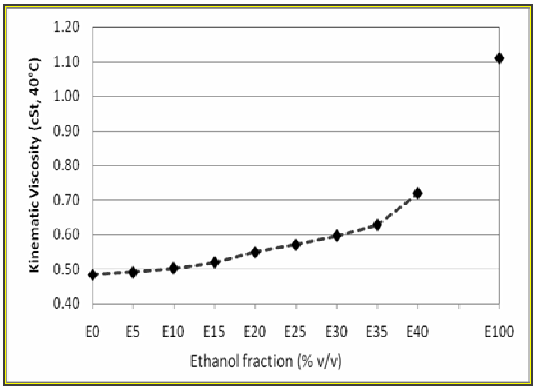

Figure 5: Kinematic viscosity curve for anhydrous ethanol-premium blends (E0-E40 and E100)

3.5. Density

Figure 6, gives density among gasoline-ethanol blends at 15°C used by some researchers. As can be seen in the Figure 6, the increase in the addition of ethanol in the gasoline increase the density of the mixtures,

which may attributed to the higher density of the ethanol. The increase of mixtures is propositional to the amount of ethanol addition. Changes in the density affect the quantity of fuel that is injected into the combustion chamber during each cycle, lead to altering the ideal-fuel burning ratio. In general the mixture that has a higher density, the burning will be incomplete, resulting in the emission pollutants increase also. In the case of ethanol in which a density compound is higher than the premium, due to ethanol contains oxygen so it will improve the combustion efficiency. In other words, without any reduction air combustion, it makes the ratio of fuel-air of gasoline-ethanol mixture becomes lean.

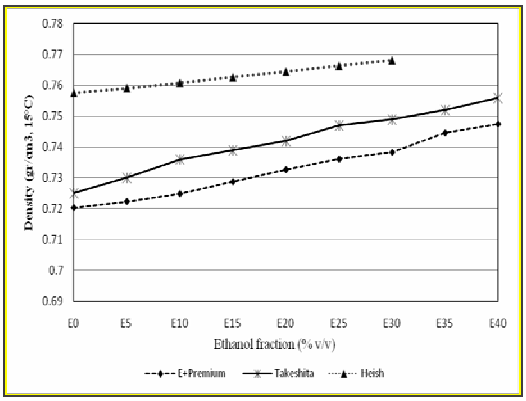

Figure 6: Density of gasoline-anhydrous ethanol blends

3.6. Heat of Combustion

Heat combustion is the amount of heat releases per unit mass or unit volume of a substance when the substance is completely burned. Heat combustion of the anhydrous ethanol is 21.04 MJ/liter - only around 72% of the heat combustion of premium (Table 2). The heat combustion of the tested premium tends to low compare the other gasoline used by other researchers in which the heat of combustion of gasoline in the range of 31-33 MJ/liter[1,3,4,57].

Heat of combustion is important properties of fuel for the Spark Ignition Engine (SIE), in which most of the SIE are used for automotive. One of the most important prerequisite of fuel for the automotive engine is having a high energy density. If there is no change in the gasoline engines modifications when using ethanol fuel, the engines consume 30% more than gasoline. However, some researchers have been succeeded to reduce fuel consumption for the SIE using ethanol by engine modifications and setting engine operational parameters[3], even fuel consumption of gasoline-ethanol blends for the SIE is lower than pure gasoline[1].

4. CONCLUSION

The main results of experiment are the addition of ethanol to gasoline lead to increase in the RVP up to a maximum of 71.3 kPa – increased by 11.3% compared with the gasoline - with 5% of ethanol added and tends to decrease with percentage over 10%. The RON of gasoline-ethanol blends increased proportionally with the addition of ethanol. In average the addition of 5% volume of ethanol increased 1.95 point of RON.

ACKNOWLEDGMENT

The authors would like to thank to Heads and staffs of the Laboratory of Surabaya Lubrication Production Unit (UPPS) and Jakarta Lubrication Production Unit (UPPJ) PT. Pertamina (Persero) which allowed us to conduct test of fuel properties according to the ASTM standard and procedures.

ABSTRACT

Hybrid refrigeration machine is the machine with refrigeration principle and heat pump in one machine, so-called the hybrid refrigeration vapor compression. Air-conditioning and refrigerating industries weathered the phase out of chlorofluorocarbons (CHCs) and hydro chlorofluorocarbons (HCFCs), which caused from the ozone layer depletion, by developments of hydro fluorocarbons (HFCs) as alternative refrigerants. However, the HFCs will also phase out because they are greenhouse gases as a cause of global warming. Therefore, natural substances, such as ammonia, hydrocarbons, carbon dioxide, are getting great interest. The research result is indicated that the use of mass HCR22 (hydrocarbon refrigerant of substitution R22) at hybrid refrigeration machine more economical 57.78% compared to R22 (halocarbon refrigerant), because HCR22 has the higher level of latent heat compared to R22. Cooling rate and heating rate by HCR22 compared to R22, is more efficient too. The Power consumption of compressor use of HCR22 is more economical 25.12% compared to hybrid refrigeration machine that use R22. In conclusion using of hydrocarbon refrigerant can economize of electrical energy consumption and environmental friendly.

Keywords

refrigeration, refrigerant, hybrid, hydrocarbon, halocarbon

1. INTRODUCTION

Refrigeration machine generally is used for conditioning room as cooling effect from evaporator that give comfortable and chilly sense for human in working room or office building, houses, apartment, industry, office, hospital, etc. Refrigeration machine is one of energy conversion machine type, where a number energy is needed to result refrigeration effect [1]. On the other side, heat losses waste by system goes to environment as requirement thermodynamics principle that machine can be function. Heat from the condenser escaped to environment usually castaway off hand without exploited. And so do at heat pump machine, a number of energy required to give the warming effect by absorbing heat from environment. Absorbing heat from the environment can be exploited to make cool something, but usually tend to let castaway [2].

Starting from case of refrigeration machine and heat pump machine above, hence various effort have been done to develop a system using principle of refrigeration and heat pump in one machine. At this machine, cooling effect and heating effect can be yielded and exploited simultaneously, so that useful power of machine becomes higher. Inwrought machine with the this double function is recognized as hybrid refrigeration machine, because refrigeration machine generally operating with the vapor compression cycle, hence this machine is referred as refrigeration machine vapor compression cycle [3].

To operate the refrigeration machine with hybrid vapor compression cycle is required the refrigerant as working fluid. The refrigerant usually used is the halogenated refrigerant; one of them is type HCFC-22 /Hydro chlorofluorocarbon or R-22. But from the result of research, halocarbon refrigerant show the nature of which can destroy the ozone layer and have big potency to make-up of global warms effect, so that the use refrigerant will be discontinued inclusive of also making and its usage [4].

One of alternative refrigerant for substitution of halocarbon refrigerant is hydrocarbon refrigerant. Some excess owned by the hydrocarbon refrigerant, that is serve the purpose of direct substitution (drop in substitute) without component replacement, environmental friendly (do not damaged the ozone layer), a little usage refrigerant, economize the energy, and fulfill the international standard [5].

This research aim to know the parameter influencing performance of air conditioning, what modification have become the hybrid refrigeration machine, among other things is cooling capacities, warming capacities, energy for compressor, coefficient of performance (COP) and performance factor (PF). This Research is done because exploiting of evaporator and condenser simultaneously of course will be give the trouble or change to influence the machine performance. At this research is used hydrocarbon refrigerant as replacement of halocarbon refrigerant (R-22). With hydrocarbon refrigerant, the air conditioning apparatus

remain to admit of used without component replacement and expected do not go down the system performance.

2. RESEARCH METHOD

The refrigeration machine used in this research, is modification from air conditioning machine become the hybrid refrigeration machine. This apparatus, evaporator and condenser use water as cooling and heating load.

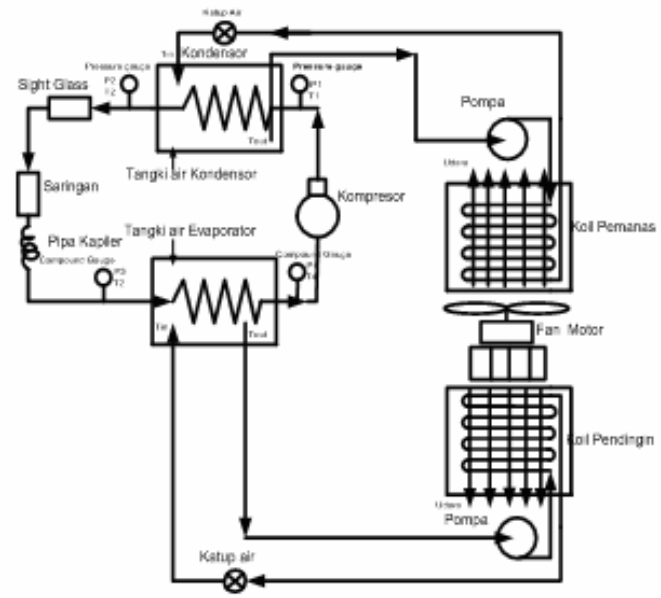

Figure 1: Simple scheme of hybrid refrigeration machine of vapor compression cyle.

Research method done through few step in the following is:

1. Phase of Research Preparation.

This step is done by literature study and understanding to concept of refrigeration machine of vapor compression cycles that using hydrocarbon as refrigerant, by learning book and relevant recent of research journal.

2. Phase of Design and Apparatus Making Test.

At this step is done design of test apparatus base on literature study or recent research journal publication. Furthermore, result of design is realized by doing equipment making test that is a refrigeration machine of vapor compression

3. Phase of Test Data Result

At this step is done data record that needed by using some kinds of measuring instrument for example: pressure gauge, thermometer, millimeter, stopwatch, etc. Data taken cover the power of compressor, temperature input and output from the evaporator, temperature input and output from the condenser, flow rate of water in to cooling and heating water tank, pressure input and output from the compressor, pressure of condenser and pressure of evaporator

4. Phase of Data Analysis

Data obtained will be tabulation and done calculation according to principles of thermodynamics, the data will be plotted in graphics which can give the information about influence of temperature input and output from evaporator, influence of temperature input and output from condenser, water flow rate from heating and cooling water tank, pressure input and output from compressor, pressure from condenser and evaporator, that compared to system performance.

5. Phase of expression about conclusion

At this step the entire result obtained from step 1 to step 4 previously concluded to become the final conclusion obtained from this research, and suggestion for the perfection of next research.

3. RESULT AND DISCUSSION

3.1 Result of Design the Hybrid Refrigeration Machine

The result of design the hybrid refrigeration machine is:

1. Compressor, in this machine used hermetic compressor, with rotary type, the power of compressor is 1 HP.
2. Evaporator, in evaporator used copper pipe 3/8 “, that have one pass with 31 cm long. The entire evaporator have 66 pass with 11 level. Each level have 6 pass. The design data from evaporator :
   a. Temperature of outer pipe surface, *Ts* is 9.17 ^oC
   b. Total surface area of pipe, *Ao* adalah 0.6175 m^2
   c. Lenght of pipe, *L* adalah 20.69 *m*
   d. Coefficient of mean heat transfer, h_0 = 219.018 $W/m^2.^0C$
   e. Overall heat transfer coefficient, U_0 = 172.7496 $W/m^2.^0C$
3. Condenser, in condenser used copper pipe 3/8”, that have one pass with 33 cm long. The entire evaporator have 66 pass with 11 level. Each level have 6 pass. The design data from evaporator :
   a. Temperature of outer pipe surface, *Ts* is 40.93 ^oC
   b. Total surface area of pipe, *Ao* adalah 0.6489 m^2
   c. Total Lenght of pipe, *L* adalah 21,74 *m*
   d. Coefficient of mean heat transfer, h_0 = 315.738 $W/m^2.^0C$
   e. Overall heat transfer coefficient, U_0 = 236.649 $W/m^2.^0C$
4. Capillary pipe, the diameter of capillary pipe is 1.7 mm, that working at condensation temperature 45 ^oC and evaporation pressure 5 ^oC, the lenght of capillary pipe is 1.65 m.

3.2 Data Processing of Test Result

Data obtained from testing through measurement is in the form of nature of from refrigerant, water, and electrics data. Nature of the among other things is temperature, pressure, mass, time, speed and also voltage and electrics current.

Calculation Sample:

Power of compressor:

$$W_k = \eta_m \times \sqrt{3} \times V \times I \times Cos\phi = 0.82kW$$

Where: η_m = 0.8, $\cos\phi$ = 0.83, V = 223 volt,
I = 3.2 A

Cooling capacity in the evaporator box:

$$Q_e = \dot{m}_{ae} \times C_{P,ae} \times \Delta T_{ae} = 2.17kW$$

Where: $\dot{m}_{ae}$ = 0.1234 kg/s,

C_{Pae} = 4.183 kJ/ (kgK),

ΔT_{ae} = 4.2 ^{o}C

Heating capacity in condenser:

$$Q_k = \dot{m}_{ak} \times C_{P,ak} \times \Delta T_{ak} = 2.91kW$$

Where: $\dot{m}_{ak}$ = 0.0883 kg/s,

C_{Pak} = 4.178 J/ (kgK),

ΔT_{ak} = 7.9 ^{o}C

Coefficient of performance:

$$COP = \frac{\dot{Q}_e}{\dot{W}_k} = 2.64 \quad , \; PF = \frac{Q_k}{W_k} = 3.55$$

$$TP = \frac{(q_k + q_e)}{w_k} = 6.19$$

3.2 Discussion

At this research will be analyzed influence of water mass flow rate in evaporator water tank to performance of hybrid refrigeration machine (COP, PF and TP). Analyze also will learn about the water mass flow rate in evaporator to cooling effect, heating effect, and the power of compressor. Furthermore watch closely about change of water mass flow rate in evaporator/condenser to water temperature input and output, temperature and pressure in refrigeration machine

3.2.1 Mass of Refrigerant R22 and HCR22

Comparison of between amount of R22 refrigerant mass to HCR22 refrigerant (figure 2), the optimum mass of R22 is 900 gram at COP 2.42, while the optimum mass of HCR22 is 380 gram at COP 2.55. So the uses of HCR22 refrigerant, the refrigerant mass more efficient 57 percent to the mass of refrigerant R22.

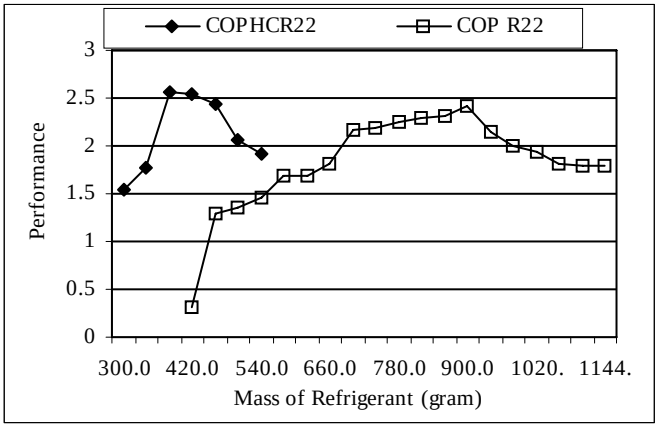

Figure 2: Optimum mass and optimum COP of refrigerant HCR22 and R22

3.2.2 Cooling Rate and Heating Rate

At transient condition that is condition of moment of hybrid refrigeration machine at first start run until steady condition, figure 3 shows that cooling rate of HCR 22 compared to faster than cooling rate of R22.

The cooling time until steady condition for HCR22 around 40 minutes at temperature 7.1 ^{o}C, whereas R22 need time around 60 minutes at temperature 8.3 ^{o}C. Heating rate until steady condition for HCR22 around 40 minutes at temperature 44.8 ^{o}C whereas R22 need time around 60 minutes at temperature 44.4 ^{o}C. Appear that cooling rate and heating rate for HCR22 faster than R22 with cooling time and heating time almost at the same period.

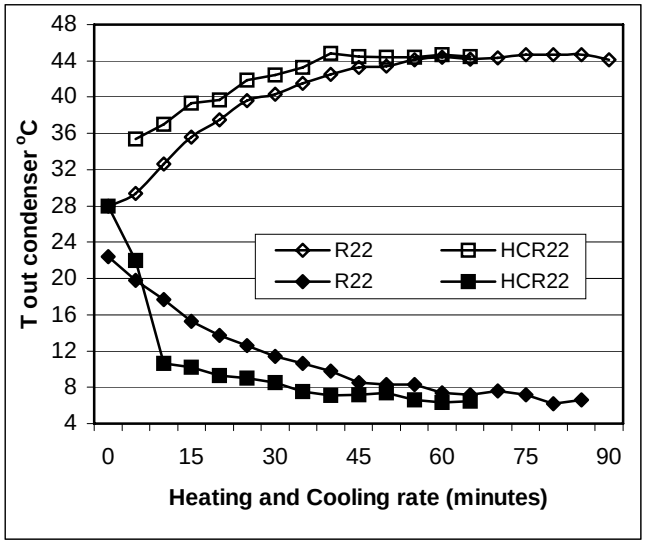

Figure 3: Cooling rate and heating rate of refrigerant HCR22 and R22

Performance of hybrid refrigeration machine : COP, PF and TP at water speed rate in evaporator and condenser at 0.067 kg/s and 0.088 kg/s, with R22 refrigerant and HCR22 refrigerant.

3.2.3 Performance of Hybrid refrigeration machine (COP, PF, TP)

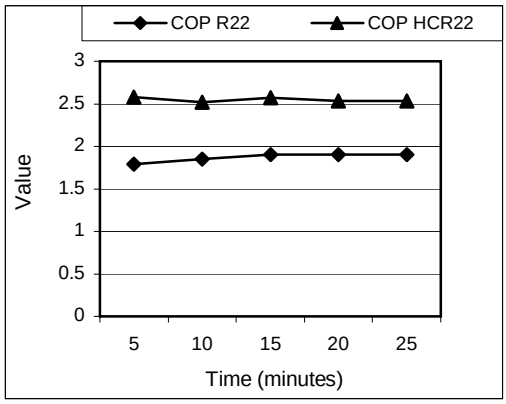

Figure 4: COP hybrid refrigeration machine with HCR22 and R22 refrigerant

The performance of hybrid refrigeration machine is COP, PF and TP at water speed rate in evaporator and condenser at 0.067 kg/s and 0.088 kg/s, with R22 refrigerant and HCR22 refrigerant (figure 4).

From the figures, we knows that COP, PF, ITP with HCR22 at hybrid refrigeration machine higher than R22. COP, PF and TP is 2.548, 3.203 and 5.751 for HCR22. COP, PF and TP is 1.834, 2.62 and 4.454 for R22. HCR22 can absorb energy bigger than R22 at the same pipe volume refrigerant.

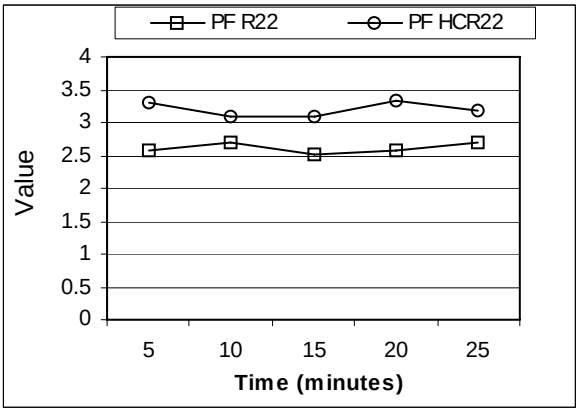

Figure 5: PF hybrid refrigeration machine with HCR22 And R22 refrigerant

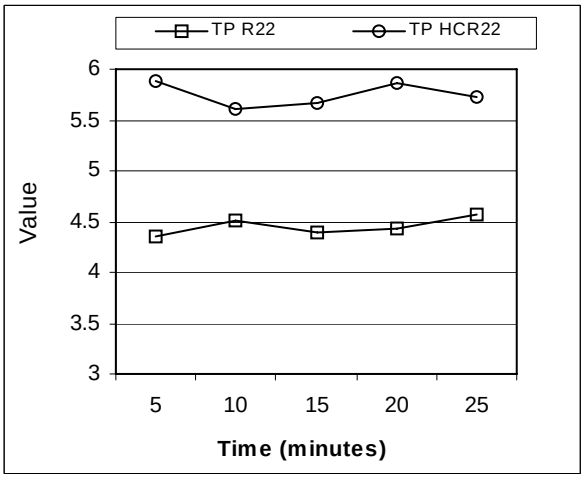

Figure 6: TP hybrid refrigeration machine with HCR22 and R22 refrigerant

3.2.4 Cooling Capacity, Heating Capacity and Power of Compressor

Cooling capacity with HCR 22 higher than cooling capacity with R22, because HCR22 can absorb heat higher than R22, HCR22 have latent heat higher than R22. For the same cooling capacity HCR22 need refrigerant mass lower than R22 (about 50% mass for HCR22 compared to R22). Figure 7 shows cooling capacity between HCR22 and R22 is 1.943 kW and 1 834 kW.

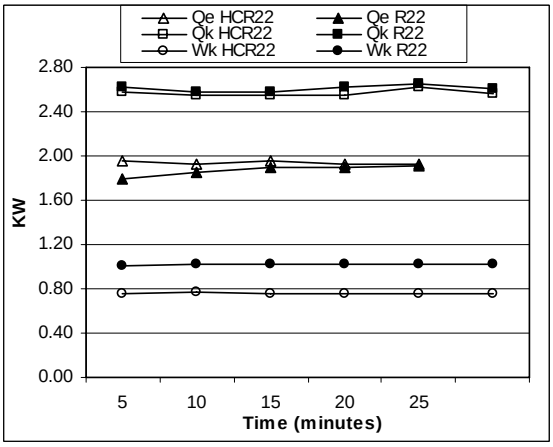

Figure 7: Cooling capacity, heating capacity and power of compressor with HCR22 and R22

Table 1 shows the experimental data form this research, this table summary data from the research.

Table 1: Experimental data research with HCR22 and R22

Description	Refrigerant	Value	Unit	Result	Efficiency%
Refrigerant Mass	HCR22	380	gram		57.78
	R22	900			
Cooling Rate	HCR22	40	minutes	faster	33.33
	R22	60			
Heating Rate	HCR22	40	minutes	faster	33.33
	R22	60			
COP	HCR22	2.548	unit	Increase	38.93
	R22	1.834			
PF	HCR22	3.203	unit	Increase	22.25
	R22	2.62			
TP	HCR22	5.751	unit	Increase	29.12
	R22	4.454			
Cooling Capacity	HCR22	1.943	kWatt	Increase	5.94
	R22	1.834			
Heating Capacity	HCR22	2.567	kWatt	decrease	-1.69
	R22	2.611			
Condenser Pressure	HCR22	260	Psig	decrease	-18.60
	R22	319.4			
Compressor Power	HCR22	0.763	kWatt	decrease	-25.12
	R22	1.019			

Heating capacity with HCR22 is lower than heating capacity R22. Because pressure at condenser with R22 higher than HCR22 (figure 8). At higher pressure condenser, the temperature higher too, so heating energy for water at condenser bigger at higher temperature. Figure 7 shows that heating capacity that comparison HCR22 and R22 with heating effect between HCR22 and R22 whereas heating capacity for HSR22 and R22 is 2.567 kW compared to 2.611 kW.

The mean pressure of compressor with HCR22 refrigerant is 260 Psig and the mean pressure of compressor with R22 is 319.4 Psig. Figure 7 shows that the comparison between power of compressor with HCR22 (0.763 kW) to R22 (1.019 kW). The power of compressor with HCR22 more efficient compared to R22 about 25%.

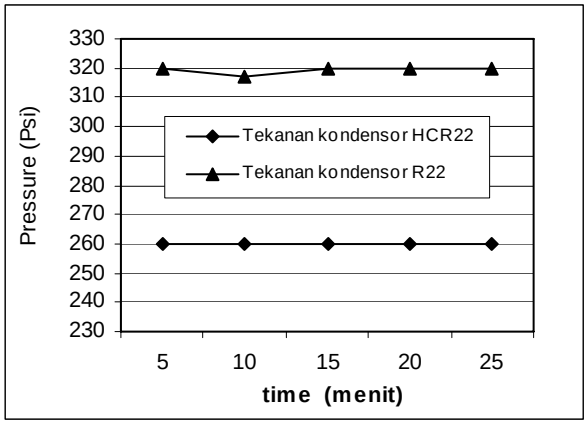

Figure 8: Pressure at condenser with HCR22 refrigerant and R22 refrigerant

4. CONCLUSION

At this research, from result of design and discussion done to experimental data, can conclude that:

1. Design output from the experimental apparatus is : the length of evaporator pipe is 20.69 *m* with surface area 0.6175 m^2 and heat transfer coefficient 172.7469 $W/(m^2.^0C)$. The length of condenser pipe is 21.74 *m* with surface area 0.6489 m^2 and heat transfer coefficient 236.469 $W/(m^2.^0C)$. The length of capillary pipe is 1.65 m with 1,7 mm diameter.
2. The use mass of hydrocarbon refrigerant HCR22 more efficient 57.78 % compared to R22 refrigerant, because latent heat of HCR22 higher than R22.
3. Cooling rate and heating rate with HCR22 faster than 33.33 % compared to R22. Performance of HCR22, the COP increase 38.93%, PF increase 22.25% and TP increase 29.12% compared to R22.
4. At the use of hydrocarbon refrigerant HCR22, cooling rate increase 5.94%, while heating rate decrease 1.69% because the pressure of condenser decrease 18.6%. The power of compressor with hydrocarbon refrigerant HCR22 more efficient 25.12 % compared to R22.

ABSTRACT

Air ventilation system is needed in the purpose of maintaining clean and fresh air. It will improve the comfort, wealthy and productivity of occupant. This research investigates the influence of fresh air diffuser position to the indoor air quality (IAQ) where it focuses on CO_2 gas contaminant concentration. The aim of this investigation is to explore the establishment of the flow pattern uniqueness depend of the diffuser position which is discussed in convection heat transfer and fluid dynamics fields.

Using Fluent 6.2 as computational fluid dynamics, several variables will be exploited. The specify boundary types room model is established in GAMBIT software generating such a specific office room. The full scale experiment is accomplished to obtain the research validation. The dimensionless analysis derived from the ratio between the distance of diffuser to the wall and the length of the ventilated room. The CO_2 gas contaminant in the exhaust diffuser are always higher in the displacement ventilation, therefore they are lower inside the room with the displacement ventilation system. The displacement ventilation is more effective in the treatment of indoor contamination.

Keywords:

Dimensionless, contaminant, mixed, displacement, diffuser

1. INTRODUCTION

Air ventilation system is activated to take outside contaminant immediately from the room. The achievement of ventilation design needs the system which is not suffering overload with adequate capacity.

What kinds of performance characteristics are required in analyze of air displacement ventilation system should be paid close attention from the preceding research. The researches focus to the displacement ventilation system was done by some researchers (Figure 1).

King and Clements [6] concluded that the accurate application of stratification air conditioning system for the building where the indoor air quality increases could offer some benefit. In case study, 1.138.195 kilowatt per annum electrical power operation could be saved, 50.55% of the operation cost prediction with the conventional system.

Stratification air temperature and ventilation effectiveness are some significant characteristics of displacement ventilation in accordance with Hu and Glicksman [8]. Nielsen [9] accomplished an experiment with air terminal device which is mounted next to the lower wall.

The purpose of Xu, Yamanaka and Kotani [13] is investigating the influence of heat loss through the wall to temperature gradient and contaminant concentration inside the room with the displacement ventilation.

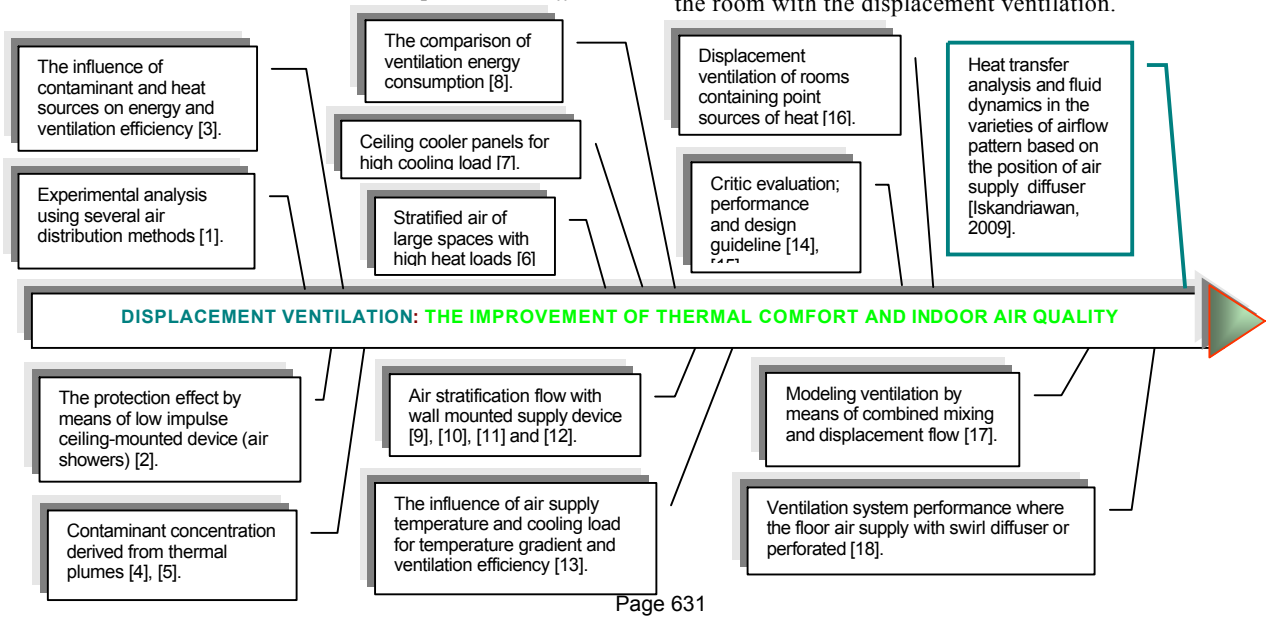

Figure 1. The fish bone diagram of displacement ventilation system research

Lau and Chen [18] examine the performance of displacement ventilation where the air is supplied at floor area with swirl diffuser is compared to perforated diffuser in the high cooling load (about 90 W/m^2). Experiment method as the validation is applied used for comparison. Some considerations are implemented such as air change hour, the diffuser number and location also occupant, furniture, partition and the exhaust location.

The aim of this research is to explore the establishment of unique airflow depend of the position of air supply diffuser (locally behavior) is linked to the convective heat transfer knowledge based on computational fluid dynamics method. The result of this investigation is expected could contribute the long journey to obtain the substantial enhancement to improve the thermal comfort and indoor air quality (IAQ).

2. METHOD

This research based on the simulation of CFD (Fluent 6.2) with makes use of the location of fresh air diffuser parameter. The CFD simulation is set up with the design of ventilation system and the interior of office room derived from the existing principle. The office room model is generated in GAMBIT (Geometry and Mesh Building Intelligent Toolkit) software subsequently meshing process is completed. In the Fluent 6.2 is clarified boundary condition system. There are four types of viscous flow: laminar flow also k-epsilon standard, RNG and realized. In this case k-epsilon standard is selected by reason of the most similarity toward the air ventilation experimentation.

Based on the air ventilation experiment room (Figure 2), the model of office room with the air ventilation system is created as we can see at Figure 3. The dimension of the room is x_L=4.315m × z_W=3.81m × y_H=3m.

Figure 2. Experiment room of the air ventilation system

There are a number of heat sources in the room: occupants, lamp and computer. The air duct installation possibly it is used the same as the air mixed or displacement ventilation system. The CO_2 contaminant gas is sprayed from the mouth of occupants to spread inside the room.

Table 1 shows us the validation of CFD simulation by means of the measurement of air temperature in air ventilation experiment. The measurement is conducted for the extreme position of supply air diffuser: mixed centre (mc), mixed side (ms), displacement centre (dc) and displacement side (ds).

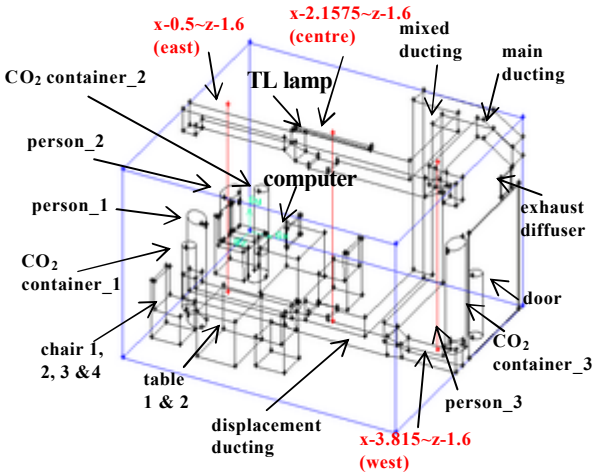

Figure 3. Established office room model in GAMBIT software which is exported to Fluent 6.2 CFD

Dimensionless study

There are five variables of a/A: ≈0, 1/5, 1/4, 1/3 and 1/2. The extreme positions are where the location of supply air diffuser at side (a/A≈0) and at centre (a/A=1/2). Where *a* = the distance of supply air diffuser to the side wall and *A* = the room length (see Figure 4). We need to recognize the performance of air ventilation where the positions of air supply diffuser are not simply at the side or at the centre of the room, that's why the dimensionless analysis of air ventilation is required to examine.

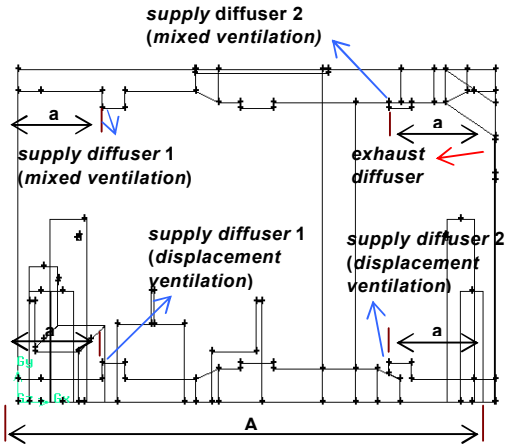

Figure 4. Dimensionless analysis of air ventilation system with a/A variables

In addition it is accomplished some assessment of thermal comfort and indoor air quality aspects that are velocity, heat energy at the exhaust and the intensity of CO_2 contaminant gas inside the room. The investigation is accomplished for two systems of air ventilation: mixed and displacement system.

3. RESULT AND DISCUSSION

The airflow pattern is identifiable for each condition of the supply air diffuser position derived from the value of ratio a/A (Figure 5). They have a tendency to change from badly behaved toward fine arrangement while the dimensionless ratio increase moreover in mixed or displacement ventilation. There is a low behavior of airflow pattern due to wall effect where the air supplies diffuser too adjacent to the side wall. Air supply near the wall boundary layer tends to generate separation zone henceforth it leads to death air area inside the room.

Supply air distribution flow is improved whereas the supply diffuser moves to the centre.

A number of air conditioning designers still decide to place the air supply diffuser close to the wall perhaps the reason of the aesthetic parameter merely.

Air velocity

At the centre of room, the higher the value of ratio a/A the velocity tends to increase (see Figure 6) since the location which is measured is more close to the air supply source. The contradictory situation is happen at the east and west location where the greater the value of ratio a/A, the velocity will decrease (see Figure 7 and 8) for the reason that the air supply diffuser more far away.

There is a broken velocity at the centre of room where the velocity is decline that is at the room height about 0.5m (lower zone) in displacement centre and about 2.5m (upper zone) in mixed centre ventilation.

At the room east side, the air velocity in ratio a/A =1/3 is lower than that of ratio a/A=1/2 (mixed centre) in the area less than the height about 1.5m. This phenomenon will influence the quality of ventilation such as room air temperature and exhaust heat energy.

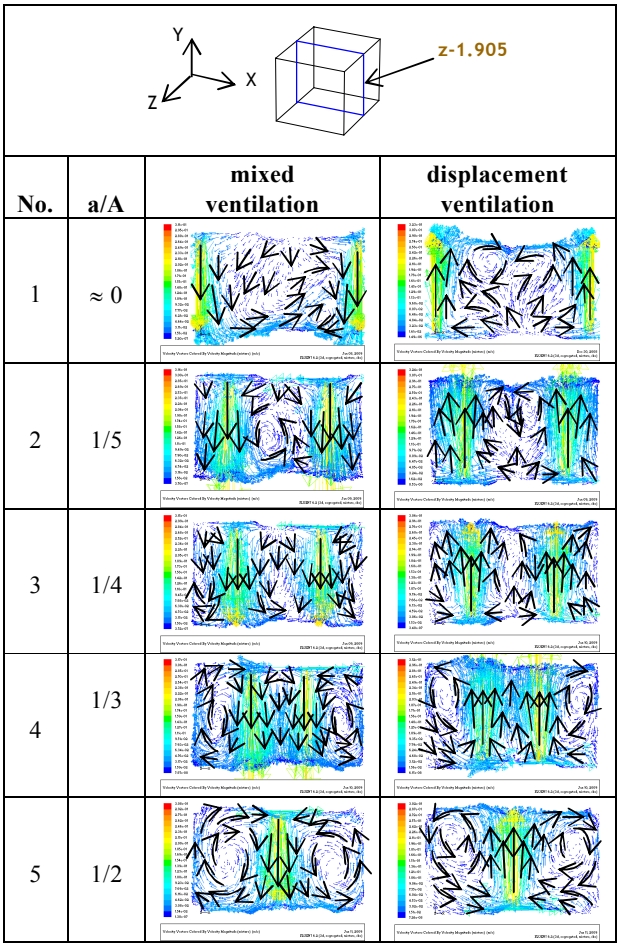

Figure 5. Room air velocity vector at z-1.905 vertical plane (centre of width) through some a/A variables

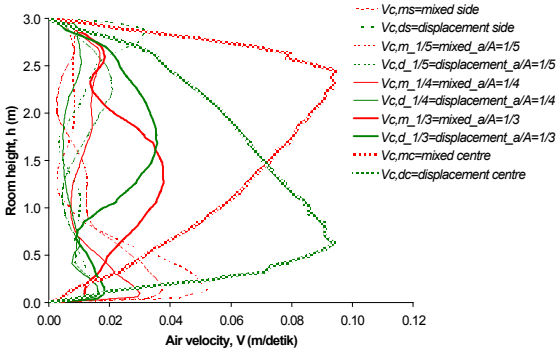

Figure 6. Air velocity at the centre of room with some a/A variables

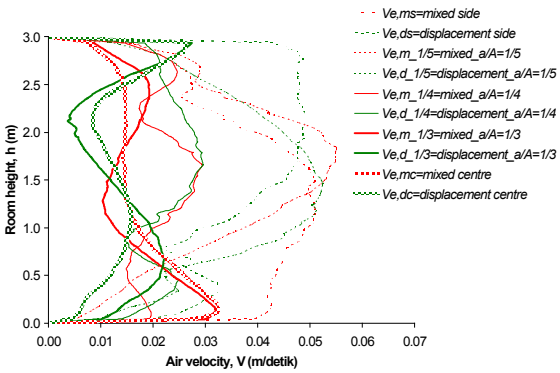

Figure 7. Air velocity at the east side of room with some a/A variables

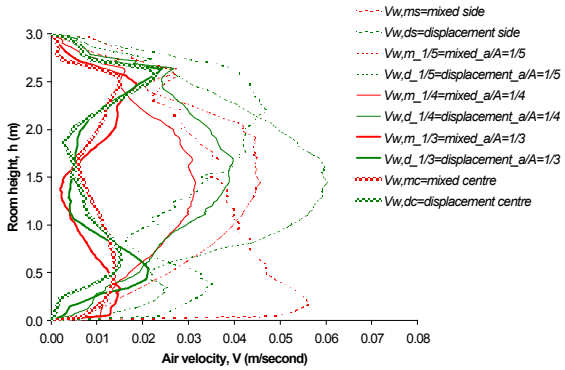

Figure 8. Air velocity at the west side of room with some a/A variables

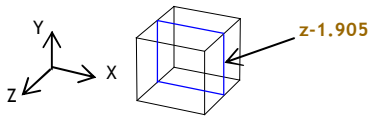
Exhaust heat energy

It can be seen from Figure 9 that the higher the ratio a/A (supply air diffuser moves to the centre of room), the room air temperature is go down moreover in mixed or displacement ventilation. The circumstances in a/A ≈ 0 where the supply air diffuser close to the side wall are not so do well. As a result of death air area which is created by the wall boundary layer tends to develop separation zone therefore the room air temperature is high.

The greater the value of ratio a/A, the exhaust heat energy, Q_e tends to improve likewise in mixed or displacement ventilation. The higher the value of Q_e, the room air temperature tends to decrease. The exception is come about in a/A =1/3 mixed ventilation, the Q_e is larger than that in a/A =1/2(mixed centre), that means there is an optimum value of supply diffuser movement which is related to the exhaust heat energy. Moreover, it is better than displacement ventilation of a/A =1/4.

As well there is no significant escalating of exhaust heat energy, Q_e within a/A =1/3 compare to a/A = a/A in displacement ventilation.

There is no effect of heat energy generated by means of person_2 in displacement centre ventilation (a/A =1/2) even in ratio a/A =1/3 displacement ventilation in the height of occupation zone (around 1.5m). Only person_1 and person_3 have an effect on the raising of room air temperature. It means that they more effective compare to the others which is linked to the task of air ventilation to reduce the room air temperature.



No.	a/A	mixed ventilation	displacement ventilation
1	≈ 0	Q_e=110.72 Watt	Q_e=118.46 Watt
2	1/5	Q_e=118. 08 Watt	Q_e=123.95 Watt
3	1/4	Q_e=120.59 Watt	Q_e=125.73 W
4	1/3	Q_e=126.65 Watt	Q_e=131.13 Watt
5	1/2	Q_e=122.91 Watt	Q_e=131.25 Watt

Figure 9. Room air temperature contour at z-1.905 vertical plane (centre of width), T= (18-22)^{o}C and exhaust absorbed heat, Q_e (Watt) among some a/A variables

Displacement centre constructs the lowest room air temperature at the centre of room (Figure 10). It creates a stratification temperature even though it is not excessively significant. The hot zone in the upper region and the cold zone in the lower region are generated by means of the accurate displacement ventilation system.

Unfortunately, the room temperature rise at the height below about 0.5m for displacement centre. It is suspected that the airflow is not passing through the area since the displacement supply air diffuser too high. It is can be reduced with the using of floor air supply diffuser.

At the east side of room, the displacement ventilation with a/A =1/2 and a/A =1/2 are the best particularly in the area only higher than more or less 1m. This is happening because several obstacles such as table, chair and person_2 block the fresh air supply at the east side. At the height area lower than 1m, the outstanding ventilation are the mixed ventilation of a/A =1/2, a/A =1/3 and a/A =1/5.

At the west area, the existing of person_3 damage the action of displacement ventilation especially for a/A =1/2 and a/A =1/3. Possibly the most excellent operation are mixed ventilation for a/A =1/4 and a/A =1.5 in the west area of room.

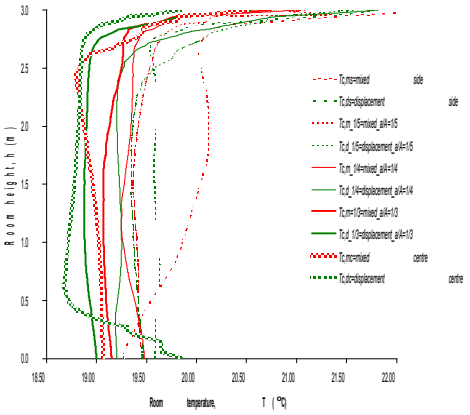


Figure 10. Air temperature at the centre of room with some a/A variables

CO_2 contaminant gas

The amount of contaminant gas in this case CO_2 inside the room influences the indoor air quality as well as the comfort for occupant. Too many CO_2 gas will give the terrible effect to the work attitude of the occupant. The problem is how the ventilation system could optimum to reduce the gas concentration. In this paper, the sources of CO_2 gas are the mouth entrance of person_1, person_2 and person_3.

As we can see at Figures 11, 12 and 13, the displacement ventilation for a/A=1/2 and a/A=1/3 are the most excellent compare to the others. Moreover they are able to bring the largest CO_2 gas which is shown in the exhaust diffuser area. Especially in the displacement ventilation, the upper the value of a/A, the higher CO_2 gas concentration in the exhaust diffuser. Again the position of supply diffuser close to the wall should be prevented because it creates unsuccessfulness in the task to reduce the contaminant gas. Figure 14 present us, at the centre of room the displacement ventilation system with a/A =1/3 is the most doing well to cut down CO_2 gas concentration.

At z-0.43 vertical plane the displacement ventilation for a/A=1/3 compete together with that for a/A=1/2 create the low CO_2 gas concentration in the room. Some of them display us the concentration of CO_2 gas are thick at the area close to the exhaust diffuser.

At a/A≈0 and a/A=1/5 the quality of indoor air are the worst in support of mixed ventilation as well as displacement ventilation. That's mean the location of supply diffuser close to the wall are not respectable in case of air ventilation mission to transport the gas contaminant leave out from the room point of view.

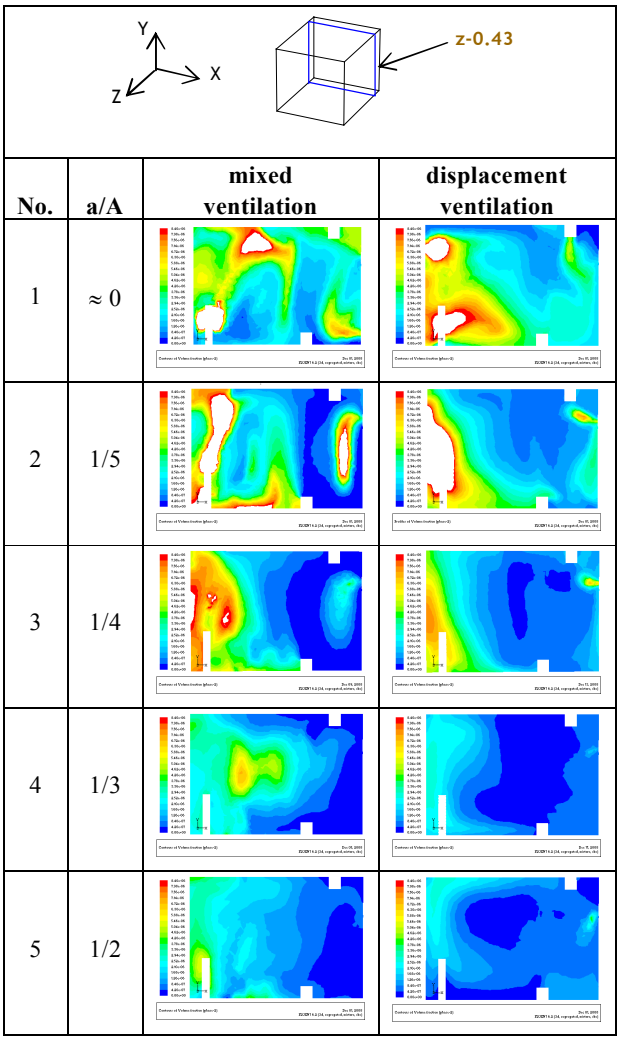

Figure 11. CO_2 gas contaminant contour at z-0.43 vertical plane (exhaust diffuser area), C=(0-8.4)ppm with some a/A variables

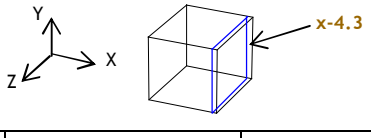
At x-4.3 vertical plane displacement ventilation, the maximum CO_2 gas concentration is existent in the area close to the exhaust diffuser. The higher the ratio a/A, the CO_2 gas concentration will increase in the exhaust diffuser. Particularly in the displacement ventilation for a/A≈ 0, the direction of air supply velocity is not effective to drive the contaminant as a result the CO_2 gas is still in the lower zone. On the other hand, it is complicated to draw closing

stages in the mixed ventilation because the maximum CO_2 gas concentration is not occurring in some of the exhaust diffuser.

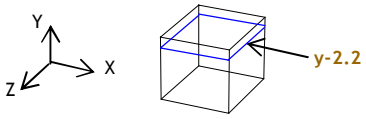


No.	a/A	mixed ventilation	displacement ventilation
1	≈ 0	C=(0~32.9)*ppm*	C=(0~2.6)*ppm*
2	1/5	C=(0~5.3)*ppm*	C=(0~5.2)*ppm*
3	1/4	C=(0~23)*ppm*	C=(0~8.6)*ppm*
4	1/3	C=(0~0.91)*ppm*	C=(0~10.6)*ppm*
5	1/2	C=(0~0.9)*ppm*	C=(0~11.3)*ppm*

Figure 12. CO_2 gas contaminant contour at x-4.3 vertical plane (exhaust diffuser area) with some assessment of contaminant, C and a/A variables

At y-2.2 horizontal plane, the displacement ventilation system always achieve succeeds to move CO_2 gas contaminant close to the exhaust diffuser. The area size of CO_2 gas concentration increase whiles the ratio a/A enlarges. Faithfully, the accurate implementation of displacement ventilation will create the clean zone in the lower region and the polluted zone in the upper region.

Based on the result of CO_2 gas contaminant at the room centre, it is better to comprehensive correlated for all time the relation between CO_2 gas concentration with the air velocity vector at the certain location. Of course we need moreover to confirm them in the others area of room before we determine the best location of air supply diffuser.



No.	a/A	mixed ventilation	displacement ventilation

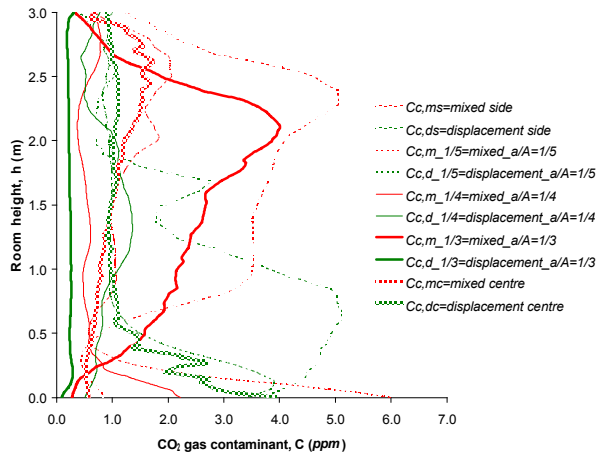

Figure 14. CO_2 gas contaminant at the centre of room through some a/A variables

4. CONCLUSION

The position of air supply diffuser will determine the performance of ventilation. The air flow patterns of ten air ventilation systems are contradictory considerably.

At the position where fresh air supply diffuser is present, the air velocity decrease with the room height increase for displacement ventilation system. The opposite condition in the mixed ventilation, the velocity decrease when the position decreases. Rely on the dimensionless ratio the air velocity are change. They increase or decrease is depending on the position toward the supply air diffuser.

The room air temperature is lower in the value of dimensionless ratio where the supply air diffuser around the centre moreover in the mixed or displacement ventilation. However high quality distribution is essential that's why the mixed centre is quiet better compare to the mixed and displacement side. There is an optimum value of dimensionless ratio where the fresh air could absorb heat energy in the exhaust diffuser.

In line to the result of room air temperature, the displacement ventilation systems within highest dimensionless ratio are the supreme to transport CO_2 contaminant gas out the room through exhaust diffuser.

In displacement centre, the height of ducting need to be considered because of the supply air couldn't get through to the hot air commencing the heat source especially in the lower zone.

The wall boundary layer could generate separation zone which is easily construct the death air area. The supply air diffuser is placed nearby to the side wall perhaps only aesthetic parameter purpose.

The arrangement of furniture and the other equipment in the room interior is crucial with displacement ventilation. The existence of them can block the fresh airflow to transfer heat to the exhaust diffuser.

The thermal comfort and indoor air quality are compared for mixed and displacement ventilation system with several value of the dimensionless ratio. The exploration can be continued to obtain the better variable for the best ventilation system such as the position of exhaust diffuser, ventilation capacity and the room form.

ABSTRACT

In this study, The Taguchi method is used to find the optimal heating characteristic and energy consumption of bearing heater U model that it make in Electronic Laboratory of PTKI Medan. An orthogonal array, the signal to noise (S/N) ratio, and the analysis of variance (ANOVA) are employed to investigate the heating characteristic and energy consumption of bearing heater U model 220 volt using bearing type 6308. Through this study, not only can the optimal the heating characteristic and energy consumption be obtained, but also the main parameter that effect the heating time and energy consumption can be found. As shown in this study, the Taguchi method provides a systematic and efficient methodology for design optimization of heating characteristic and energy consumption. It has been shown that heating characteristic and energy consumption can be improved significantly. The confirmation experiments were conducted to verify the optimal heating time and energy consumption. The improvement of the optimal heating time and energy consumption from initial parameter to the optimal parameter is about 794 %.

1. INTRODUCTION

The reliability of machine is of paramount importance in industry. Bearing play an important role in the reliability and performance of machine. Due to the closed relationship between machine development and bearing assembly performance, it's difficult to imagine the progress of modern rotating machinery without consideration of wide application of bearings. In additional faults a rising in machinery are often linked to bearing faults. The result of various studies show that bearing problems accounts for over 40 % of all machine failures [1]

The main factor of bearing faults is dust and corrosion. Dirt and other foreign matter that is commonly present often contaminate the bearing lubrication. Bearing corrosion is produced by presence of water, acids, deteriorated lubrication and even perspiration from careless handling during installation. Bearing problems are also caused by improperly forcing the bearing onto the shaft. This produces physical damage in the form of brinelling or false brinelling of the race way, which lead to premature failure [2]

In practically, the way to maintenance and the best process during installation of bearing are tools to avoid the failure this component. Study of bearing show premature failure at bearing cause of the way during installation bearing use a simple method (improperly forcing the bearing) contribute 25 % until 30 % from total failure at bearing [3]. Failure this part will disturb working efficiency of machine and this condition create new problem at industry. To reduce and solve this problem, studying bearing and method of installation become important. A recent method during installation of bearing had been developed by induction electromagnetic principles. Methods use bearing heater which is heating by winding of wire through current

electricity. These methods will generated energy then use induction process to transfer of heat and change the dimension of bearing. Research had been done by Candra Bachtiyar and Golfrid Gultom (2008) at Electronic Laboratory – Pendidikan Teknologi Kimia Industri (PTKI - Medan) success made bearing heater Umodel at laboratory scale and observed this equipment [4,5,6]. Recent bearing research shown prevent failure focused on condition based on monitoring. Advantages this monotoring is prevent catastropic breakdown and eficiency during production. Application this method on motor using vibration monitoring, current analysis, and thermal analysis [7,8,9,10]. On other side, mounting bearing to shaft to reduce failure focus on chossing type of bearing, tolerance and prevent missaligment. In 2009, this equipment increased a number of winding that can connect to 220 volt [11]. Study installation of capasitor at electric equipment could improve power factor [12]. Through this study, implementation of capasitor and Taguchi method at this equipment will adopt to improve power factor and get optimum design parameter.

Basically, the Taguchi method is a powerful tool for the design of high quality systems. It provides a simple, efficient and systematic approach to optimize designs for performance, quality, and cost. The methodology is valuable when the design parameters are qualitative and discrete. Taguchi parameter design can optimize the performance characteristics through the settings of design parameters and reduce the sensitivity of the system performance to sources of variation. In recent years, the rapid growth of interest in the Taguchi method has led to numerous applications of the method in a world-wide range of industries and nations [13]. In the following, the Taguchi method is introduced first. The experimental details of using the Taguchi method to determine and analyze the optimal parameters are described next. The optimal heating characteristic and energy consumption parameters with regard to performance indexes such as heating time and energy consumption are considered. Finally, the paper concludes with a summary of this study.

2. DESCRIPTION OF THE TAGUCHI METHOD

Taguchi is the developer of the Taguchi method. He proposed that engineering optimization of a process or product should be carried out in a three-step approach, i.e. system design, parameter design, and tolerance design. In system design, the engineer applies scientific and engineering knowledge to produce a basic functional prototype design, this design including the product design stage and the process design stage. In the product design stage, the selection of materials, components, tentative product parameter values, etc., are involved. As to the process design stage, the analysis of processing sequences, the selections of production equipment, tentative process parameter values, etc., are involved. Since system design is an initial functional design, it may be far from optimum in terms of quality and cost. Following on from system design is parameter design. The objective of parameter design is to optimize the settings of the process parameter values for improving quality characteristics and to identify the product parameter values under the optimal process parameter values. In addition, it is expected that the optimal process parameter values obtained from parameter design are insensitive to variation in the environmental conditions and other noise factors. Finally, tolerance design is used to determine and analyze tolerances around the optimal settings recommend by the parameter design. Tolerance design is required if the reduced variation obtained by the parameter design does not meet the required performance, and involves tightening tolerances on the product parameters or process parameters for which variations result in a large negative influence on the required product performance. Typically, tightening tolerances means purchasing better- grade materials, components, or machinery, which increases cost. However based on the above discussion, parameter design is the key step in the Taguchi method to achieving high quality without increasing cost. To obtain high cutting performance in turning, the parameter design proposed by the Taguchi method is adopted in this paper. Basically, experimental design methods were developed originally by Fisher [13,14]. However, classical experimental design methods are too complex and not easy to use. Furthermore, a large number of experiments have to be carried out when the number of the process parameters increases. To solve this problem, the Taguchi method uses a special design of orthogonal arrays to study the entire parameter space with a small number of experiments only. The experimental results are then transformed into a signal-to-noise (S/N) ratio. Taguchi recommends the use of the S/N ratio to measure the quality characteristics deviating from the desired values. Usually, there are three categories of quality characteristic in the analysis of the S/N ratio, i.e. the-lower-the-better, the-higher-the-better, and the nominal- the-better. The S/N ratio for each level of process parameters is computed based on the S/N analysis. Regardless of the category of the quality characteristic, a greater S/N ratio corresponds to better quality characteristics. Therefore, the optimal level of the process parameters is the level with the greatest S/N ratio. Furthermore, a statistical analysis of variance (ANOVA) is performed to see which process parameters are statistically significant. With the S/N and ANOVA analyses, the optimal combination of the process parameters can be predicted. Finally, a confirmation experiment is conducted to verify the optimal process parameters obtained from the parameter design.

To summarize, the parameter design of the Taguchi method includes the following steps: (1) identification of the quality characteristics and selection of design parameters to be evaluated; (2) determination of the number of levels for the design parameters and possible interactions between the design parameters; (3) selection of the appropriate

orthogonal array and assignment of design parameters to the orthogonal array; (4) conducting of the experiments based on the arrangement of the orthogonal array; (5) analysis of the experimental results using the S/N and ANOVA analyses; (6) selection of the optimal levels of design parameters; and (7) verification of the optimal design parameters through the confirmation experiment. Therefore, three objectives can be achieved through the parameter design of the Taguchi method, examples: (1) determination of the optimal design parameters for a process or a product; (2) estimation of each design parameter to the contribution of the quality characteristics; and (3) prediction of the quality characteristics based on the optimal design parameters [13,14].

3. PROCESS EXPERIMENT

Researchers decide to divide activity become 4 steps during experiment to find contribution parameter that chosen during heating time and energy consumption at bearing heater U model :

1. Literature study. Consist of collecting books, especially related with bearing, failure at bearing, induction electromagnetic process topic, and Taguchi method
2. Journal. Collect journal also activity to support literature study which is information from journal will use to support final report in this paper.
3. Collect data of experiment. Activity collect data of experiment based on lay out experiment to find heating time and energy consumption
4. Conclusion of Experiment. After study data of experiment, the next step is concluding of experiment based on orthogonal array, signal-to-noise (S/N) ratio and analysis of variance (ANOVA).

Figure. 1 Design experiment

3.1 Selection of parameter and their level

The experiments were carried out on bearing heater U model 220 volt and bearing type 6308. The initial parameters were as follows: capasitor, sensor location and ratio heating area and inner diameter bearing 6308. The feasible space for parameters was defined by varying the capasitor in the range 0-64 μF , sensor location rate in the range inner side of bearing, middle and outer side, and ratio in the range 0.016-0.033. In the parameter design, three levels of the parameters were selected, shown in Table 1.

Table 1: Parameter and their level

Symbol	Parameter	Unit	Level 1	Level 2	Level 3
A	Capasitor	μF	0	48 [a]	64
B	Ratio heating area and diameter bearing	-	0.016	0.025 [a]	0.033
C	Sensor Location	mm	Inner	Mid [a]	out

a initial parameter , mid = middle and out = outer

3.2 Performance measurement

Heating characteristic of bearing heater consist of three parameter, heating time and energy consumption. Heating time measured from heating bearing until reach set point temperature. Energy consumption measured from variable of voltage, current, cos phi and time to reach set point of this equipment during heating bearing.

4. DESIGN AND ANALYSIS OF PARAMETER

In this section, the use of an orthogonal array to reduce the number of the experiments for design optimization of the heating characteristic and energy consumption parameters is reported. Results of the experiments are studied using the S/N and ANOVA analyses. Based on the results of the S/N and ANOVA analyses, optimal settings of the parameters for heating time and energy consumption are obtained and verified [13].

4.1 Orthogonal Array Experiment

To select an appropriate orthogonal array for the experiments, the total degrees of freedom need to be computed. The degrees of freedom are defined as the number of comparisons between design parameters that need to be made to determine which level is better and specifically how much better it is. For example, a three-level design parameter counts for two degrees of freedom. The degrees of freedom associated with the interaction between two design parameters are given by the product of the degrees of freedom for the two design parameters [13,14]. In the present study, the interaction between the heating characteristic and energy consumption parameters is neglected. Therefore, there are eight degrees of freedom owing to there being three parameters. Once the required degrees of freedom are known, the next step is to select an appropriate orthogonal array to fit the specific task. Basically, the degrees of freedom for the orthogonal array should be greater than or at least equal to those for the design parameters. In this study, an L_9 orthogonal array with four columns and nine rows was used. This array has eight degrees of freedom and it can handle there -level design parameters. Each parameter is assigned to a column, nine parameter combinations being available. Therefore, only nine experiments are required to study the entire parameter space using the L_9 orthogonal array. The experimental layout for the three heating characteristic and energy consumption parameters using the L_9 orthogonal array is shown in Table 2. Since the L_9 orthogonal array has four columns, one column of the array is left empty for the error of experiments: orthogonality is not lost by letting one column of the array remain empty.

Table 2 : Experiment Layout using L 9 an orthogonal array

Experiment No.	Heating Characteristic Parameter Level

3	1	3	3	
4	2	1	3	
5	2	2	1	
6	2	3	2	
7	3	1	2	
8	3	2	3	
9	3	3	1	

4.2 Analysis of S/N Ratio

In the Taguchi method, the term 'signal' represents the desirable value (mean) for the output characteristic and the term 'noise' represents the undesirable value (S.D.) for the output characteristic. Therefore, the S/N ratio is the ratio of the mean to the S.D. Taguchi uses the S/N ratio to measure the quality characteristic deviating from the desired value. The S/N ratio η is defined as

$$\eta = -10 \log (\text{M.S.D.}) \qquad (1)$$

where M.S.D. is the mean-square deviation for the output characteristic. As mentioned earlier, there are three categories of quality characteristics, the-lower-the-better, the higher- the-better, and the-nominal-the-better. To obtain optimal heating characteristic and energy consumption, the-lower-the-better quality characteristic. The mean-square deviation (M.S.D.) for the-lower-the-better quality characteristic can be expressed as:

$$\text{M.S.D.} = \left[\frac{1}{n} \sum_{i=n}^{n} Y_i^n \right] \qquad (2)$$

where n is the number of tests and Y_i is the value of heating time and the i the test [13]. Table 3 shows the experimental results for heating time and the corresponding S/N ratio using equation (Eqs. (1) and (2)). Since the experimental design is orthogonal, it is then possible to separate out the effect of each parameter at different levels. For example, the mean S/N ratio for the capasitor at levels 1 and 2 can be calculated by averaging the S/N ratios for the experiments 1–3, and 4–6, respectively.

Table 3 : Experiment result for heating time and S/N ratio

Experiment No.	Capasitor	Ratio	SensLoct	Heat. time (s)	S/N ratio (dB)
1	0	0.016	In	1614	-64.15
2	0	0.025	Mid	5040	-74.04
3	0	0.033	out	918	-59.25
4	48	0.016	Out	8190	-78.26
5	48	0.025	In	3240	-70.21

7	64	0.016	Mid	5670	-75.07
8	64	0.025	Out	3331	-70.45
9	64	0.033	In	1051	-60.43

Ratio = ratio heating area and diameter of bearing
Sens Loct = Sensor location
Heat time = Heating time

The mean S/N ratio for each level of the other parameters can be computed in the similar manner. The mean S/N ratio for each level of the parameters is summarized and called the S/N response table for heating time (Table 4). In addition, the total mean S/N ratio for the four experiments is also calculated and listed in Table 4. Fig. 2 shows the S/N response graph for heating time.

Table 4 :S/N response for heating time

Symbol	Parameter	Mean / SN Ratio (dB)			
		Level 1	Level 2	level 3	Max -Min
A	Capasitor	-65.82	-70.50	-68.65	4.68
B	Ratio	-72.49	-71.57	-60.91	11.5
C	Sensor Location	-64.93	-70.72	-69.32	5.78

The total mean S/N ratio = - 68.32 dB.

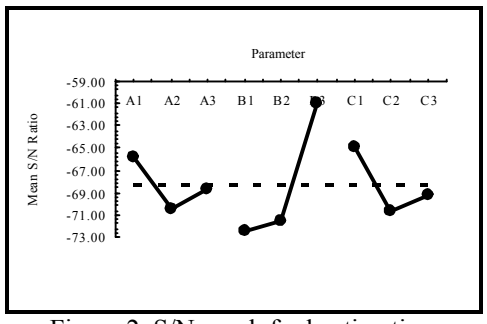

Figure 2 :S/N graph for heating time

On the other hand, the-lower-the-better quality characteristics for energy consumption should be taken for obtaining optimal energy consumption during heating period. The M.S.D. for the the-lower-the-better quality characteristic.

Table 5: Experiment result for energy consumption and S/N Ratio

Experiment No	Capasitor	Ratio	Sens Loct	Energy Cons	S/N ratio (dB)
1	0	0.016	In	69.04	-36.78
2	0	0.025	Mid	176.4	-44.93
3	0	0.033	out	39.27	-59.25
4	48	0.016	Out	268.63	-48.58

8	64	0.025	Out	199.19	-45.98
9	64	0.033	In	62.84	-35.96

Ratio = ratio heating area and diameter of bearing
Sens Loct = Sensor location
Energy Cons = Energy consumption

Table 5 shows the experimental results for energy consumption and the corresponding S/N ratio using Eqs. (1) and (2). The S/N response table and S/N response graph for energy consumption are shown in Table 6 and Fig. 3. Regardless of the-lower-the-better of the the higher-the-better quality characteristic, the greater S/N ratio corresponds to the smaller variance of the output characteristic around the desired value (Eqs. (1)–(2)).

Table 6 : S/N response for energy consumption

Symbol	Parameter	Mean / SN Ratio (dB)			
		Level 1	level 2	level 3	Max-Min
A	Capasitor	-46.98	-40.82	-44.18	6.16
B	Ratio	-45.32	-43.81	-42.86	2.46
C	Sensor Location	-37.75	-42.96	-51.27	13.51

The total mean S/N ratio = - 44.00 dB.

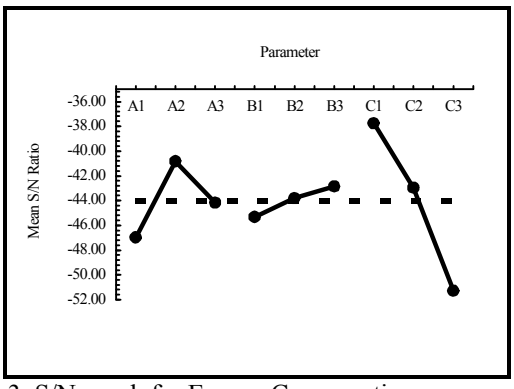

Figure 3 :S/N graph for Energy Consumption

4.3 Analysis of Variance

The purpose of the analysis of variance (ANOVA) is to investigate which design parameters significantly affect the quality characteristic. This is to accomplished by separating the total variability of the S/N ratios, which is measured by the sum of the squared deviations from the total mean S/N ratio, into contributions by each of the design parameters and the error. First, the total sum of squared deviations SS_T from the total mean S/N ratio η_m can be calculated as:

$$SS_T = \sum_{i=1}^{n} (\eta_i - \eta_m)^2 \qquad (3)$$

where n is the number of experiments in the orthogonal array and η_i is the mean S/N ratio for the i the experiment.

The total sum of spared deviations SS_T is decomposed into two sources: the sum of squared deviations SS_d due to each design parameter and the sum of squared error SS_e. The percentage contribution r by each of the design parameters in the total sum of squared deviations SS_T is a ratio of the sum of squared deviations SS_d due to each design parameter to the total sum of squared deviations SS_T. Statistically, there is a tool called an F test named after Fisher to see which design parameters have a significant effect on the quality characteristic. In performing the F test, the mean of squared deviations SS_m due to each design parameter needs to be calculated. The mean of squared deviations SS_m is equal to the sum of squared deviations SS_d divided by the number of degrees of freedom associated with the design parameter. Then, the F value for each design parameter is simply the ratio of the mean of squared deviations SS_m to the mean of

squared error. Usually, when F >4, it means that the change of the design parameter has a significant effect on the quality characteristic [13,14,15,16]. Table 7 shows the results of ANOVA for heating time. It can be found that capasitor and location of sensor are the un significant parameters for affecting heating time. The change of ratio heating area and diameter of bearing in the range given in Table 1 has an significant effect on heating time. Therefore, based on the S/N and ANOVA analyses, the optimal parameters for heating time are the capasitor at level 1,ratio heating area and diameter of bearing at level 3, and the location of sensor at level 1.

Table 7 : Analysis of Variance (ANOVA) for heating time

Smb	Parameter	*DOF*	*Sum of Square*	*Mean Square*	F	Contr
A	Capasitor	2	33.41	16.70	0.87	8.91
B	Ratio	2	248.72	124.36	6.53	66.33
C	Sens Loct	2	54.73	27.36	1.43	14.59
Error		2	38.05	19.02		10.14
Total		8	374.93			100

Smb = Symbol, DOF = degree of freedom,
Contr = Contribution, Sens. Loct = Sensor location
Ratio = ratio heating area and diameter of bearing

Table 8 shows the results of ANOVA for energy consumption. capasitor, ratio heating area and diameter of bearing, and location of sensor are the un significant energy consumption parameters for affecting energy consumption. However, the contribution order of the parameters for energy consumption is location of sensor, then capasitor, and then ratio heating area and diameter of bearing. The optimal parameters for energy consumption are the capasitor at level 1, ratio heating area and bearing diameter at level 3, and the location of sensor at level 1.

Table 8 : Analysis of Variance (ANOVA) for energy consumption

Smb	Parameter	*DOF*	*Sum of Square*	*Mean Square*	F	Contr
A	Capasitor	2	57.16	28.58	0.28	10.50
B	Ratio	2	9.24	4.62	0.04	1.69
C	Sens Loct	2	278.84	139.42	1.40	51.25
Error		2		198.79	99.3	
Total		8	544.04			100

Smb = Symbol, DOF = degree of freedom,
Contr = Contribution, Sens. Loct = Sensor location
Ratio = ratio heating area and diameter of bearing

4.4 Confirmation Test

Once the optimal level of the design parameters has been selected, the final step is to predict and verify the improvement of the quality characteristic using the optimal level of the design parameters. The estimated S/N ratio using the optimal parameters for heating time can then be obtained and the corresponding energy consumption can also be calculated by using Eqs. (1) and (2).

Table 9 shows the comparison of the predicted heating time with the actual heating time using the optimal parameters, good agreement between the predicted and actual heating time being observed. The increase of the S/N ratio from the initial heating time parameters to the optimal heating time parameters is 18 dB, which means also that the heating time more fast about 7,94 times.

Table 9 : Results of the confirmation experiment for heating time

	Initial Parameter	Optimal Parameter	
		Prediction	Experiment
Level	A2B2C2	A1B3C1	A1B3C1
Heating time (s)	3600	182.78	453
S/N Ratio (dB)	-71.12	45.23	-53.12

Improvement of S/N ratio = 18 dB

Table 10 shows the comparison of the predicted energy consumption with the actual energy consumption using the optimal parameters. The increase of the S/N ratio from the initial energy consumption parameters to the optimal energy consumption parameters is 15.98 dB and therefore the energy consumption value is improved by 6.09 times. In other words, the experiment results confirm the prior design and analysis for optimizing the heating time and energy consumption parameters.

Table 10 : Results of the confirmation experiment for energy consumption

	Initial Parameter	Optimal Parameter	
		Prediction	Experiment
Level	A2B2C2	A1B3C1	A1B3C1
Energy consumption	118.08	19.37	19.37
S/N Ratio (dB)	-41.44	-25.7463	-25.7463

Improvement of S/N ratio = 15.98 dB

5. CONCLUSION

This paper has discussed an application of the Taguchi method for optimizing the heating characteristic and energy consumption at bearing heater U model 220 Volt. It has been shown that heating time and energy consumption can be improved significantly. The confirmation experiments were conducted to verify the optimal parameters. The improvement of heating characteristic and energy consumption from the initial parameters to the optimal parameters is about 794 %.

ABSTRACT

This research was conducted with the purpose to analyze according to the dynamic and experiment investigates of vibration characteristics in the bearing clearance result on internal combustion engine. Inertia force mass due motion to engine components that work on the bearing as a component of rotation, translation and swung. Experimental results showed the condition of engine static amplitude biggest impact in the vertical direction at a frequency of 200 Hz and amplitude 1.14 m/sec2/N horizontal direction while the 0.03 m/sec2/N, obtained stiffness and attenuation vertical direction k_{eqv} = 11150 N/m and c_{eqv} = 1750 Nm / s, horizontal direction k_{eqh} = 374 390 N/m and c_{eqh} = 20525 Nm/s. Results of measurement clearance 0:33 mm in the cylinder, 0.26 mm in the small gudgeon pin, 0.65 mm in biggest the gudgeon pin and 0:20 to 0:40 µm to the main bearing. Dynamic experimental results are obtained after reconstruction signal characteristic vibration due to imbalance of force amplitude signal 0:05 m/sec2 horizontal direction and vertical direction 0:11 m/sec2 engine on circle 15 Hz or 900 rpm, on the condition does not use compression. This research is useful as an initial study, the application of technology for predictive maintenance in the main engine ships based monitoring vibration signals according to periodically.

Key word : *Main engine, Amplitude, Force, Compression, Reconstruction Signal*

1. INTRODUCTION

As a means product of power the engine component composed of a static like engine body and dynamic like components s piston, connecting rod, crank shaft and bearing. Use of bearing on the dynamic component is to connect the components one with another and provide flexibility for them to trick movement. Bearing on the gudgeon-pin connecting rod to receive the of the piston load is the load due to combustion and other load such as inertia force, gravity force of the engine components motion. Forces are forwarded to the crankshaft through the connecting rod and main bearing, the forces in to provide bearing house (engine body), like in [1].

Impulsive load due to compression and combustion of the causing presence contact load that will occur when the engine operates. This mentioned resulting in over heating and clearance on the bearing ball. Lubrication condition that does not perfect and presence pattern of movement that can also cause clearance on the main bearing ball and the bearing on the gudgeon-pin connecting rod. Clearance on all of the bearing exceeds the maximum value that can be received, then specific actions should be taken, or damage from the engine shattered likely occurs. Therefore, the need to developing techniques to detect damage diagnosis damage on all the conditions bearing on the engine before damaged.

This research is useful as a basic to develop maintenance technology on base monitoring the vibration signals periodically, as an effort to replace conventional maintenance in the field of marine power in Indonesia. Conventional maintenance is not accurate because the repair was based on visual, hearing and schedules operational main engines.

Maintenance main engine like this is very harmful the owner because to predictive as faulty which the engine is still in the normal at repair, the components are still good in the change. With maintenance technology based measurement of the vibration signal main engine breakdown time can be predicted.

2. METHOLOGY DYNAMIC ANALYSIS EXPERIMENTAL INVESTIGATION of VIBRATION CHARACTERISTIC

Main problem is how to do in order to obtain experimental vibration response signals in the form of time-domain and frequency influence inertia force. Measurement results analyzed to obtain the vibration characteristics at a frequency that is lower than 0 to 100 Hz. The characteristics vibration problem is depending on the engine that is n = 900 rpm, which is obtained from this revolution of frequency n/60 = 15 Hz. These frequency as a basis 1xrpm then harmonic next 2xrpm of up to 6xrpm.

The vibration is in the form of a waveform that is focused on the relationship between the acceleration as a function of time, which is the acceleration magnitude can be scale in the simulation curve as Figure 13, Figure 14 waveform in the FFT to frequency spectrum to be make in MATLAB and can be read in curve as Figure 15, Figure 16. The characteristics vibration comes from the physical nature of the dynamics of engine components and the nature of the physical components bearing.

Experimental frequency characteristics of vibration is coming from the physical nature of the engine components to provide force imbalance and roller main bearing, such as ball pass frequency outer (BPFO), inner ball pass frequency (BPFI), ball spin frequency (BSF), fundamental train frequency (FTF) and waviness. As a result of the many signals that the record was held by the accelerometer vibration response analysis of the experimental gradually, as in [2].

2.1 Dynamic Modeling

Determining the vibration response in the house pad holder is determined based on the style of the work on the main bearing. Based on the actual condition of the vibration response can be determined by using dynamic modeling, as shown in Figure 1 and Figure 2.

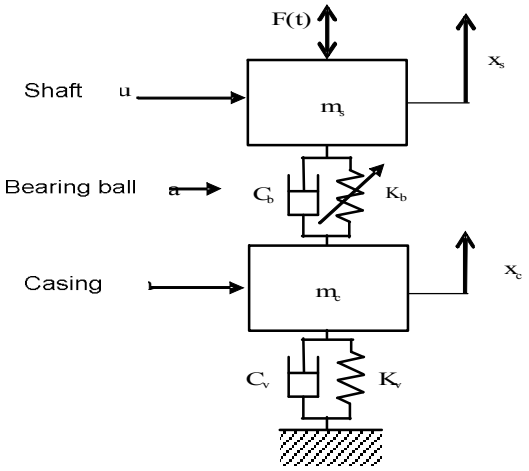

Figure 1 : Dynamic model main bearing

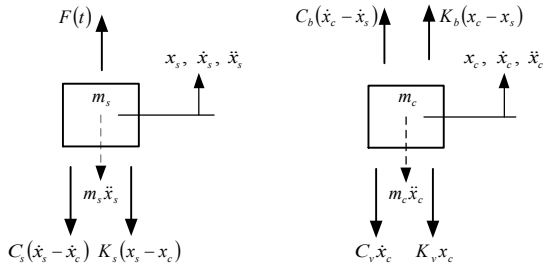

Figure 2 : Free body diagram ball bearing

Force F(t) that work on the model of the ½-axis is the force that works on the main bearing. This occurs because the axis on the vertical cylinder model is supported by 2 ball roller fruit. Dynamic modeling is done on the system axis applies to a main bearing modeling is also valid for the main bearing to two.

Modeling system is used with two degrees freedom (two-degree-of-freedom system). View from the physical nature of the system the rigidity crankshaft bearing ball can be assumed that with the settlement of non-linear system. Force is excogitation force $F(t)$, the force that inertia $m_s\ddot{x}_s$ meets the legal Newton to two, due to attenuation $c_s(\dot{x}_s - \dot{x}_c)$ and force due to stiffness $k_s(x_s - x_c)$. Diagram of free mass with 2 classified in the two-degree-of-freedom system can appear as movement equation 2 below.

$$m_s\ddot{x}_s + C_b(\dot{x}_s - \dot{x}_c) + K_b(x_s - x_c) = F(t) \qquad (1.a)$$

$$m_c\ddot{x}_c - C_b(\dot{x}_c - \dot{x}_s) + C_c\dot{x}_c - K_b(x_c - x_s) + K_c x_c = 0 \qquad (1.b)$$

2.2 Modeling Load on Ball Bearing

Depending on the size of the load zone on the following scale (1) the value force of work, (2) geometry bearing and (3) the value of diametrical clearance (Cd). By using the method of contact Hertzian and know geometry, the cushion stiffness can be determined. Cushion stiffness on the condition of dry contacts can be developed based on the relationship Hooke, so that relationships can be expressed in the equation (2).

$$K_{br} = \frac{\partial F_r}{\partial \delta_r} \qquad (2)$$

As a preliminary approach, the condition of dry contacts can be used so that the Hertzian contact model can be applied by the elastic force is assumed only dependent on the deflection. Relationship can be expressed in equation 3, as in [3].

$$Q = K_n.\delta^n \qquad (3)$$

Value of *n*, on the condition of the contact line (roller bearing) is 1:11 and a condition for the contact point (ball bearing) is 1.5. Depending on the value of KN geometry cushion material and the wheel can be determined using equation (4).

$$K_n = \frac{4}{3\pi\left(h_1 + h_2\right)}\sqrt{\bar{R}} \qquad (4)$$

Where :

$$\bar{R} = \frac{R_1 R_2}{R_1 + R_2}; \qquad h_i = \frac{1-\upsilon_i^2}{\pi E_i}, \qquad \text{i = 1, 2}$$

Harris, simplify the equation (3) into equation (4), as in [3].

$$K_n = \left[\frac{1}{(1/K_{pi})^{1/n} + (1/K_{po})^{1/n}}\right]^n \qquad (5)$$

K_{po} and K_{PI} values elements of the ball to contact with the steel roller line as the equation (5) can be determined using equation (6).

$$K_{pi/o} = 2{,}15\ x\ 10^5\ \Sigma\rho^{-1/2}\left(\delta^*\right)^{-3/2} \qquad (6)$$

Where is the curvature summing $\left(\Sigma\rho\right)$, it can be determined using the equation 7.a, equation 7.b as below.

$$\Sigma\rho_i = \frac{1}{D}\left(4 - \frac{1}{f_i} + \frac{2\gamma}{1-\gamma}\right) \qquad (7.a)$$

$$\Sigma\rho_o = \frac{1}{D}\left(4 - \frac{1}{f_o} - \frac{2\gamma}{1+\gamma}\right) \qquad (7.b)$$

$$\gamma = \frac{D\cos\alpha}{d_m} \qquad (7.c)$$

Dimensionless contact deformation (δ), determined by using a table that had been developed by Harris based on the curvature difference. Curvature difference is determined by using equation 7.a, equation 7.e.

$$F(\rho)_i = \frac{\frac{1}{f_i} + \frac{2\gamma}{1-\gamma}}{4 - \frac{1}{f_i} + \frac{2\gamma}{1-\gamma}} \qquad (7.d)$$

$$F(\rho)_i = \frac{\frac{1}{f_i} + \frac{2\gamma}{1-\gamma}}{4 - \frac{1}{f_i} + \frac{2\gamma}{1-\gamma}} \qquad (7.e)$$

When the radial direction of the working force of co-linear with the position of roller elements bearing, the deflection at the point roller contact elements can be determined using equation 8, as in [3].

$$F_r = ZK_n\left(\delta_r - \tfrac{1}{2}C_d\right)^{1,5} Jr\left(\varepsilon\right) \qquad (7.f)$$

$$\left(\delta_r - \tfrac{1}{2}C_d\right)^{1,5} = \frac{F_r}{ZK_n\, Jr\left(\varepsilon\right)} \qquad (7.g)$$

$$\left(\delta_r - \tfrac{1}{2}C_d\right) = \sqrt[1,5]{\frac{F_r}{ZK_n\, Jr\left(\varepsilon\right)}}\ ; \ \left(\delta_r - \tfrac{1}{2}C_d\right) \text{ is } \delta_{\max} \qquad (7.h)$$

$$\delta_{\max} = \sqrt[1,5]{\frac{F_r}{ZK_n\, Jr\left(\varepsilon\right)}} \qquad (8)$$

$$\delta_r = \sqrt[1,5]{\frac{F_r}{ZK_n\, Jr\left(\varepsilon\right)}} + \frac{1}{2}C_d \qquad (9)$$

Deflection on the ball bearing by the because of the total radial force, Fr, can be defined as a deflection from resultant two elements bearing ball. Deflection of each element is calculated based on the force of co-linear elements that work on the bearing by using the equation 10, as in [3].

$$\delta = \left(\frac{Q}{K_n}\right)^{1/n} \qquad (10)$$

Deflection of the roller ball is determined as resultant deflection of each element by using the equation. (9).

$$\delta_\phi = \sqrt{\delta_A^2 + \delta_B^2 - 2\delta_A\,\delta_B\cos(180 - \theta)} \qquad (11)$$

Thus the force of the work on radial roller ball can be determined using equation 12.

$$F_r = \frac{1-E_\phi}{1+E_\phi} Z\,K_n\,\delta_{\max}^n\, Jr(\varepsilon) \qquad (12)$$

Where $E\Phi$ is the error factor due to the position of the element ball of force radial direction of the work. Value Φ can be determined using equation 13.

$$\phi = (\omega_i - \omega_c).\Delta t \qquad (13)$$

In the experimental knowledge, accelerometer placed on the bearing house with the horizontal direction x, and vertical y. Modeling force of the work on the bearing shown in Figure 7. Observed radial force and analysis in vertical or horizontal direction and the load that zone. Refer to the model the system stiffness in the system x and y can be written on equation 12.

2.3 The Process of Loading the Ball Bearing

Study experimental conducted to measure the vibration response in the vertical direction (y), and the horizontal direction (x). By the influence of the load of the dynamic force imbalance, then the total angle style radial oscillation can. This is shown in Figure 3 where the angular position of the angle of load zone will be changed according to the total

force radial direction. Thus, the stiffness bearing a global system of coordinates (x, y) will be affected. Stiffness value in such conditions can be determined using equation 17.

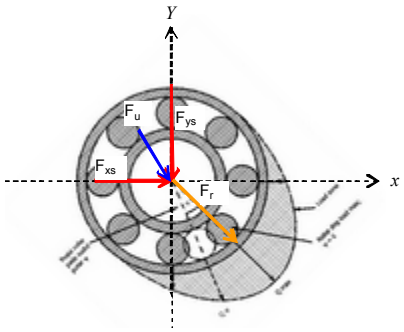

Figure 3 : Curve load zone of bearing

$$k_{bij} = \frac{\partial F_i}{\partial \delta_j}, \text{ i, j = x, y} \qquad (14)$$

Where :

$$\begin{Bmatrix} F_x \\ F_y \end{Bmatrix} = F_r \begin{Bmatrix} \cos\alpha_o \cos\psi \\ \cos\alpha_o \sin\psi \end{Bmatrix} \qquad (15)$$

$$\begin{Bmatrix} F_x \\ F_y \end{Bmatrix} = \frac{1-E_\phi}{1+E_\phi} Z\, Jr(\varepsilon) K_n \delta_{\max}^n \begin{Bmatrix} \cos\alpha_o \cos\psi \\ \cos\alpha_o \sin\psi \end{Bmatrix} \qquad (16)$$

Hence,

$$K_b = \begin{bmatrix} K_{bxx} & K_{bxy} \\ K_{byx} & K_{byy} \end{bmatrix} = \frac{1-E_\phi}{1+E_\phi} n Z\, Jr(\varepsilon) K_n \delta_{\max}^{n-1} \begin{bmatrix} \cos^2\psi & \cos\psi\sin\psi \\ \cos\psi\sin\psi & \sin^2\psi \end{bmatrix} \qquad (17)$$

2.4 Stiffness and Attenuation Bearing House

Attenuation and stiffness bearing is determined through the identification process. In regard to study experimental frequency response function of the system test bearing ball and the home supporters made. Curve function frequency response function of the system of multi-degree freedom "MDOF" can be obtained with assumption as a combination of several systems "SDOF". Thus the system of reacceptance "MDOF" can be expressed in equation 18, as in [4].

$$\alpha_{jk}(\omega) = \sum_{s=1}^{N} (SDOF)_s = \sum_{s=1}^{N} \frac{{}_sA_{jk}}{\omega_s^2 - \omega^2 + i\eta_s \omega_s^2} \qquad (18)$$

2.5 The Dynamic Model

Studies theoretic developed can be directed to build a dynamic system modeling slider crank. The truth model is the dynamic response, vibration fitness model with the measurement of vibration response. Based on the dynamic model as shown in Figure 1, the movement equation can be written as the system in equation 19.

$$m_s \ddot{x}_s + C_v (\dot{x}_s - \dot{x}_c) + K_v (x_s - x_c) = 0 \qquad (19.a)$$

$$m_c \ddot{x}_c + C_b (\dot{x}_c - \dot{x}_s) + K_b (x_c - x_s) = F_s \qquad (19.b)$$

Equation 19.a, equation 19.b, can be expressed in matrix form as written in equation 20 below.

$$\begin{bmatrix} m_s & 0 \\ 0 & m_c \end{bmatrix} \begin{Bmatrix} \ddot{x}_s \\ \ddot{x}_c \end{Bmatrix} + \begin{bmatrix} C_v + C_b & -C_b \\ -C_b & C_b \end{bmatrix} \begin{Bmatrix} \dot{x}_s \\ \dot{x}_c \end{Bmatrix} + \begin{bmatrix} K_v + K_b & -K_b \\ -K_b & K_b \end{bmatrix} \begin{Bmatrix} x_s \\ x_c \end{Bmatrix} = \begin{Bmatrix} 0 \\ F_s \end{Bmatrix} \qquad (20)$$

By using the equation 20, the reacceptance system dynamic model can be expressed as in equation 21, as in [4].

$$\alpha_{jk}(\omega) = \sum_{r=1}^{N} \frac{(\psi_{jr})(\psi_{kr})}{(K_r - \omega^2 M_r) + i(\omega C_r)} \qquad (21)$$

Where,

$$\{\psi\}^T [m] \{\psi\} = [M_r];$$

$$\{\psi\}^T [c] \{\psi\} = [C_r];$$

$$\{\psi\}^T [k] \{\psi\} = [K_r]$$

Thus, the vibration response of the system can be expressed in equation 22.

$$\begin{Bmatrix} x_s(t) \\ y_s(t) \\ x_c(t) \\ y_c(t) \end{Bmatrix} = \begin{bmatrix} \alpha_{11} & \alpha_{12} & \alpha_{13} & \alpha_{14} \\ \alpha_{21} & \alpha_{22} & \alpha_{23} & \alpha_{24} \\ \alpha_{31} & \alpha_{32} & \alpha_{33} & \alpha_{34} \\ \alpha_{41} & \alpha_{42} & \alpha_{43} & \alpha_{44} \end{bmatrix} \begin{Bmatrix} f_{xs} \\ f_{ys} \\ f_{xc} \\ f_{yc} \end{Bmatrix} \qquad (22)$$

2.6 Bearing Vibration Response

From equation 19.a and 19.b, can be simplified and written in the form of the following;

$$\begin{bmatrix} m_s & 0 \\ 0 & m_c \end{bmatrix} \begin{Bmatrix} \ddot{x}_s \\ \ddot{x}_c \end{Bmatrix} + \begin{bmatrix} c_b & -c_b \\ -c_b & c_b + c_v \end{bmatrix} \begin{Bmatrix} \dot{x}_s \\ \dot{x}_c \end{Bmatrix} + \begin{bmatrix} k_b & -k_b \\ -k_b & k_b + k_v \end{bmatrix} \begin{Bmatrix} x_s \\ x_c \end{Bmatrix} = \begin{bmatrix} F(t) \\ 0 \end{bmatrix} \qquad (23)$$

With assume that,

$$x = Xe^{i\omega t}; \dot{x} = i\omega Xe^{i\omega t}; \ddot{x} = -\omega^2 Xe^{i\omega t}$$
$$F(t) = F_o e^{i\omega t} \quad (24)$$

Equality applied to 23 of 24 that can be re-written as:

$$-\omega^2\begin{bmatrix} m_s & 0 \\ 0 & m_c \end{bmatrix}\begin{Bmatrix} \ddot{x}_s \\ \ddot{x}_c \end{Bmatrix}e^{i\omega t} + i\omega\begin{bmatrix} c_b & -c_b \\ -c_b & c_b + c_v \end{bmatrix}\begin{Bmatrix} \dot{x}_s \\ \dot{x}_c \end{Bmatrix}e^{i\omega t} + \begin{bmatrix} k_b & -k_b \\ -k_b & k_b + k_v \end{bmatrix}\begin{Bmatrix} x_s \\ x_c \end{Bmatrix}e^{i\omega t} = \begin{Bmatrix} F(t) \\ 0 \end{Bmatrix}e^{i\omega t} \quad (25)$$

$$-\omega^2\begin{bmatrix} m_s & 0 \\ 0 & m_c \end{bmatrix}\begin{Bmatrix} \ddot{x}_s \\ \ddot{x}_c \end{Bmatrix} + i\omega\begin{bmatrix} c_b & -c_b \\ -c_b & c_b + c_v \end{bmatrix}\begin{Bmatrix} \dot{x}_s \\ \dot{x}_c \end{Bmatrix} + \begin{bmatrix} k_b & -k_b \\ -k_b & k_b + k_v \end{bmatrix}\begin{Bmatrix} x_s \\ x_c \end{Bmatrix} = \begin{Bmatrix} F(t) \\ 0 \end{Bmatrix} \quad (25.a)$$

$$\begin{bmatrix} k_b + i\omega c - \omega^2 m_s & -(i\omega c_b + k_b) \\ i\omega c_b + k & (k_b + k_v) + i\omega(c_b + c_v) - \omega^2 m_c \end{bmatrix}\begin{Bmatrix} X_s \\ X_c \end{Bmatrix} = \begin{Bmatrix} F_o \\ 0 \end{Bmatrix} \quad (26)$$

By using the Kramer theorem, then the equation 26 can be completed and obtained as follows:

$$\Delta = \left(k_b + i\omega c - \omega^2 m_s\right)\left\langle (k_b + k_v) + i\omega(c_b + c_v) - \omega^2 m_c \right\rangle - \left\langle (i\omega c_b + k)(i\omega c_b + k_b) \right\rangle \quad (27)$$

$$X_s = \frac{F_o\left\langle (k_b + k_v) + i\omega(c_b + c_v) - \omega^2 m_c \right\rangle}{\Delta} \quad (28)$$

$$X_c = \frac{F_o(i\omega c_b + k_b)}{\Delta} \quad (29)$$

Thus, the response ancillary casing (bearing house) can be written in the following equation.

$$X_c(t) = \frac{F_o(i\omega c_b + k_b)}{\Delta}e^{i\omega t} \quad (30)$$

And,

$$X_c(t) = \frac{(i\omega c_b + k_b)}{\Delta}F_o(t) \quad (31)$$

Structure has a close cushion that can be assumed as attenuation hysteretic, by 'Lim'

2.7 Reconstruction Vibration Response

Reconstruction in the frequency response is selected is 15, 30, 45, 60, 75 and 90 Hz above equation can be done with the synthesis, such as below and the results shown in the picture below. Equation 32, equation 33 below apply to the test with the condition of spark plugs for condition of horizontal and vertical angle and phase, as in [2].

$$R_x = m_{gh}\cos(\omega t) + \phi_h \quad (32)$$

$$R_y = m_{gv}\cos(\omega t) + \phi_v \quad (33)$$

Figure 16, Figure 17, the waveform is measured on the accelerometer due to the multi-complex derived from the multi-component engine. Waveform reconstruct this signal is derived from the pure components of the engine measured on the vertical and horizontal direction, the condition of spark plugs is closed or open and use. Waveform is what is used as a signal reverence for validation. The picture above can be used as engine vibration and the response is validated with the standard response to vibration theoretic technology for use in predictive maintenance.

3. EXPERIMENTAL

Internal Combustion Engine

Main component is a piston engine composer, the piston, , connecting rod, Crank shaft , cylinder block and engine block as Figure 4, piston has a translation movement, Crank shaft rotation and movement to connecting rod the movement has a swing that is more complex, as in [1], [7] . On this research, the process does not involve data compression and force from the combustion engine because it played by AC motor, so that the work is inertia force.

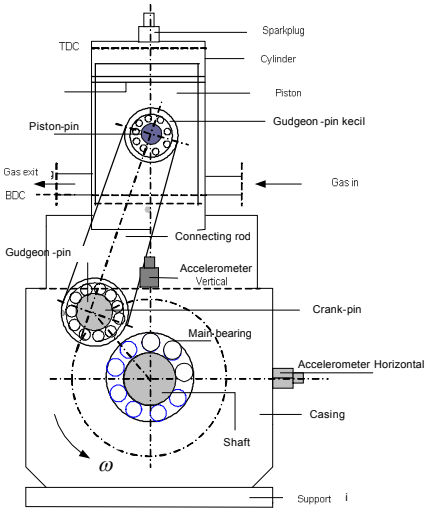

Figure 4 : Construction Engine

Bearing Data

Study computing conducted in this research refers to the test device is used. Test the device using the bearing ball that has the following specifications: Trademarks: Koyo 6205, type: Ball bearing, in Diameter (in): 25 "mm", Diameter outside

(do): 50 "mm", Diameter pitch (dm :) "mm", Diameter ball (D): 7.6 "mm", roll number of elements: 9, Corner contact (α): 0, Basic load rating: Dynamic (C): "N", Static (Co) : "N". Radial load of work on the bearing ball is determined through study kinematical. Movement by the slider crank happen because of the electric motor on 900 rpm.

Measuring Clearance

The problems that clearance is very dominant, so the diameter measurement was held at the cylinder, piston, bearing piston and piston-pin, is to analyze the loose (clearance) the cylinder and bearing piston. Results obtained for loose cylinder is 0:33 mm, and to bearing is 0:19 mm. Earned a respite on the price obtained at the reference (dedy Satria 1995). Looseness between the road and bearing pen crank pen is 0.65 mm while the main bearing is 20 μm.

Dynamic Characteristics Measurements

Research conducted on the engine on the dynamic characteristics of measurement methods excitation cushion shock (shock excitation). With the method, excitation force form impulse force given to the measured object, so hopefully the system will vibrate at a frequency of free personality. Set up a test frequency response function shown in Figure 5 is as follows: 1.Computer system, 2. Hammer exits (impact hammer), and 3. Amplifier conditioning, 4. Accelerometer, 5. Power amplifier, 6. IO port, 7. Multi channel spectrum analyzer.

Impulse force given to the engine body is done by using the impact hammer with a strike near the accelerometer on the vertical and horizontal directions so that the response vibration measured by accelerometer. Giving force impulse engine on the body caused by the region at the assumed close to the ball. Results and measurement data processed by signal analyzer multi "MSA" and the result displayed on the computer system.

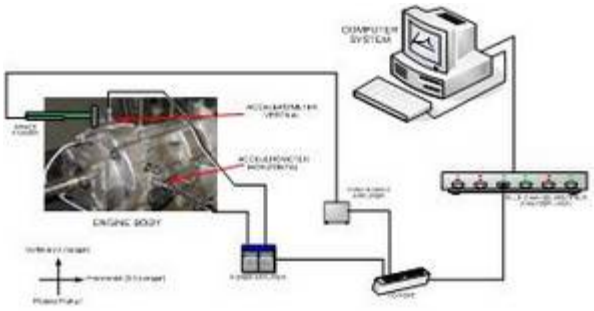

Figure 5 : *Set up* experimental for investigate frequency respons function

Vibration Response Measurement

Set up a vibration measurement instrumentation used in this research as shown in Figure 6 below. Body around the engine crankshaft is assumed as the ball home in the area because there is a bearing ball (ball bearing) as the main bearing support crankshaft. Measurements conducted on the bearing house at the crank at 0 degrees on the piston reaches tdc direction by 90 degrees vertical and horizontal direction at the position began to exhaust of the doors open.

Accelerometer placement on the position so that the signal caused record response vibration direction is vertical and horizontal. Control engine settings can be done with the change of motor cycles (ac motor) use a converter, also inserted key phase as optical pulse generator for measurement of vibration. Charge amplifier is used to signal control vibration measurement by accelerometer, which is very dominant "Multi Signal Analyzer" is a working process for the measurement signal to obtain the frequency spectrum and waveform. Then the computer system by a signal formed by MSA is shown in the image signal of the vibration response.

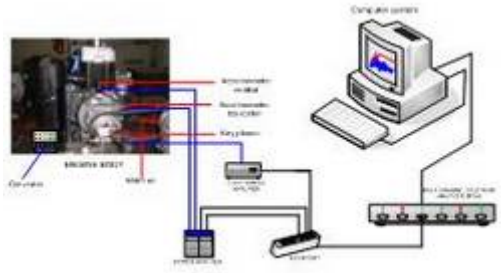

Figure 6 : Set up Experimental dynamic vibration

4. RESULTS AND DISCUSSION

4.1 Force on Main Bearing

Correction of determining the vibration response using the modal synthesis with the force that comes from the main bearing as shown on curve below. Observed in Figure 7, Figure 8 is that the force of the maximum occurs at the vertical direction of the work on the main bearing to the slider crank case under study, 90 N, the force is at least 15 N. Thus, by using test cases obtained curve stiffness, as shown in Figure 9, as in [6]. The size of the force shown in this curve stiffness is 100 N and the maximum amount of the maximum value of stiffness is 10e +6, curve is a form of non-linier.

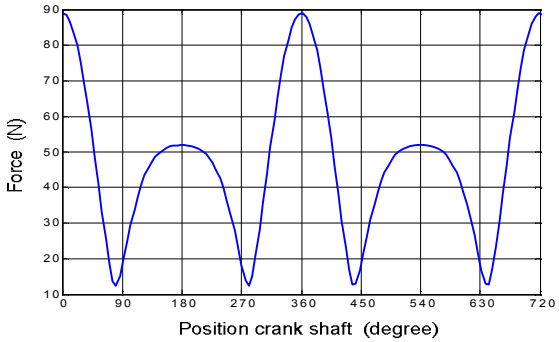

Figure 7 : Curve force vertical direction computation simulation result

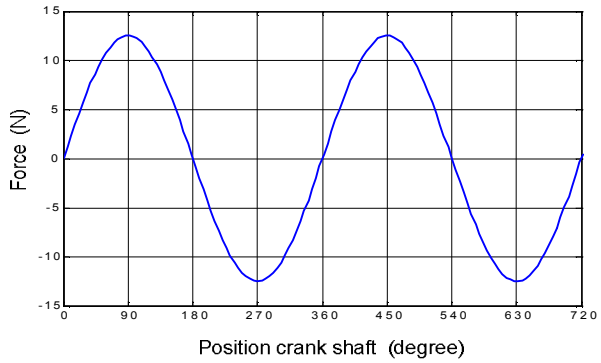

Figure 8 : Curve force horizontal direction computation simulation result

4.2 Stiffness Bearing Ball

Computing studies the determination of stiffness bearing test is done by using mathematical modeling. Condition that represents the diametrical clearance bearing and tears on the ball used computational knowledge that is 20 µm. Knowledge computational results are shown in Figure 9. Curve stiffness as a function of radial force ball bearing on the shows that are on the stiffness values from 0 to 9.6e +6 N/m with a range of force values from 0 to 100 N as Figure 7, Figure 8.

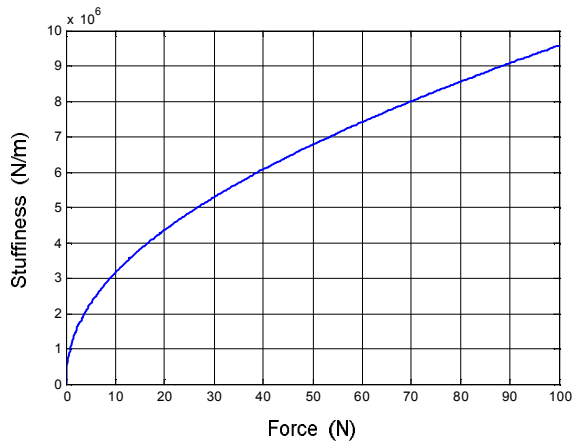

Figure 9 : Stiffness Curve versus radial force

4.3 Results Static Test

Length Crank shaft one-cylinder engine test object between the two is quite short, as observed in Figure 4. Because of the short axis, then stiffness be high so that it can be observed as a rigid axis (rigid shaft). Thus the dynamic stiffness model of the system can be dimodelkan two-degree freedom system as shown in Figure 1, Figure 2. Model underpinning the value of stiffness can be determined with knowledge computational using Hertzian contact rule, home cushion while stiffness is determined through the identification process. Study conducted with the knowledge FRF analysis results in a frequency of 100 Hz (about 6 x frequency circle) using circle-fit method. Knowledge results in the frequency response function horizontal and vertical direction can be observed in Figure 10, Figure 11.

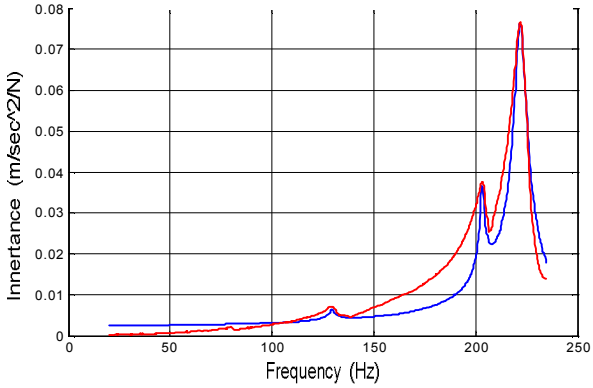

Figure 10 : Circle fit result on vertical direction

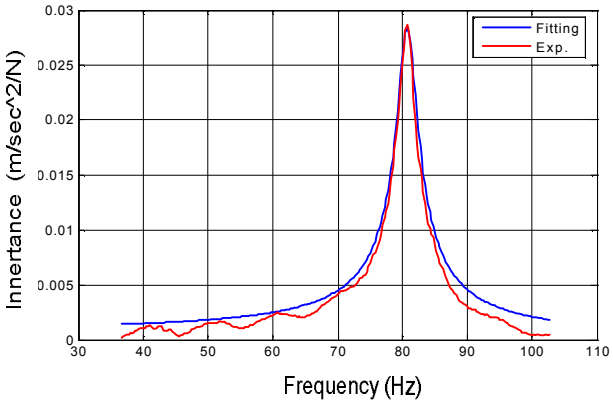

Figure 11 : Circle fit result horizontal direction

Characteristic of bearing house in the research is determined through process identification. Circle-fit method used to obtain stiffness values and attenuation system based on the home support in the data frequency response function. Plot data penguin frequency response function and the circle-fit in Figure 10, Figure 11 shows 2 curve each with a circle-fit and curve point frequency response function experimental results for vertical and horizontal direction. Value of dynamic parameters of the circle-fit will be used in modeling the response to the vibration direction is vertical k_{eqv} = 11150 "N/m" and c_{eqv} = 1750 "Nm/s" and the horizontal direction k_{eqh} = 374 390 "N / m" and c_{eqh} = 20525 "Nm/s".

4.4 Results of Dynamic Experiment

Engine driving by motor cycles with 900 rpm in the condition of spark plugs open so that it does not happen all the compression in the cylinder. Figure 12, Figure 13, the signal is measured on the accelerometer due to the multi-complex derived from the multi-component engine. Signal with the color blue is the signal transient measured in horizontal and vertical direction, with the condition of spark

plugs do not use open burning, Signal red with a key derived from the phase of the time to reach the 1 cycle of crankshaft .. Waveform of record this signal is coming from the engine components and parts dynamic main bearing. Super position of this signal with the signal clear in the frequency domain like in Figure 14, Figure 15 indicates the signal in the frequency domain measured on the accelerometer due to the multi-complex derived from the multi-component engine that is the result of the function of the Fourier transport waveform is created in the program Mat lab. This describes the frequency domain nature of the physical components of the engine vibrates, the condition of spark , open or does not use combustion, which is measured on the vertical and horizontal direction.

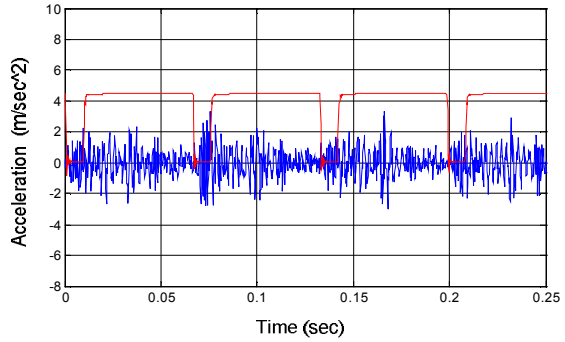

Figure 12 : Result Experimental curve on horizontal direction

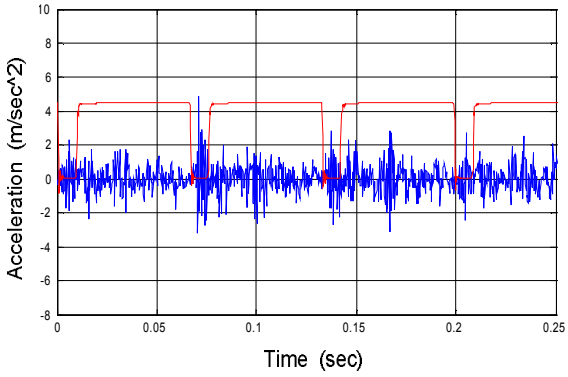

Figure 13 : Result Experimental curve on vertical direction

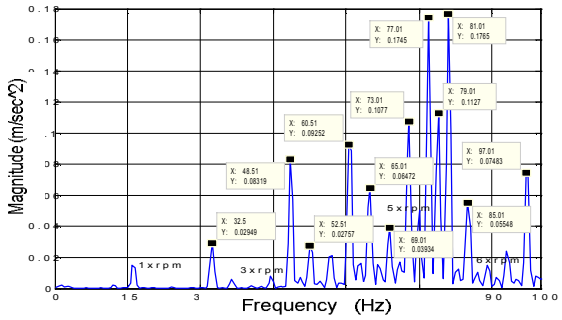

Figure 14 : Result experimental curve in horizontal direction on frequency domain before reconstruction

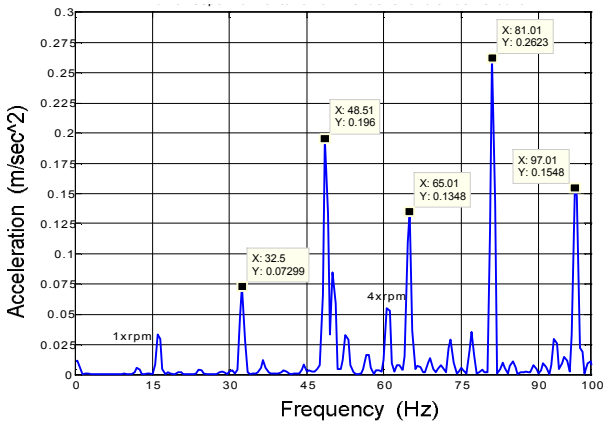

Figure 15 : Result experimental curve in vertical direction frequency domain before reconstruction

5. RECONSTRUCTION RESULTS DISCUSSION SIGNAL VIBRATION

Signals obtained from the results of reconstruction of the movement of engine horizontal direction, due to the force of the imbalance that occurred at the time of engine operation. In Figure 16, observed that the signal is not purely sinusoidal, but no signal going to the super position amplitude that varies from 0 to 0.0175 m/sec2 is the acceleration in the horizontal direction. Movement direction of the horizontal acceleration with the engine this is the case for a round of crankshaft within 0:05 seconds.

Can be observed in Figure 17, that the size of the style of the work on the crankshaft in a different round of dimension. Position on the Super curve signal that describes the position on a particular style of fluctuations occurs in the crankshaft. Force engine of the shake (shaking) the direction to the left or to the right with amplitude and acceleration as shown in the curve, the conditions on the open plug (not compression). Movement of the engine in the horizontal direction in which work force shake (shaking) is smaller/less than the vertical direction, as in [8], [9].

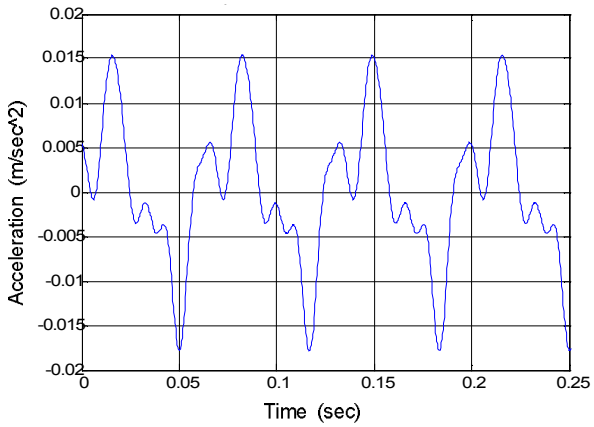

Figure 16 : Result experimental curve in horizontal direction on frequency domain after reconstruction

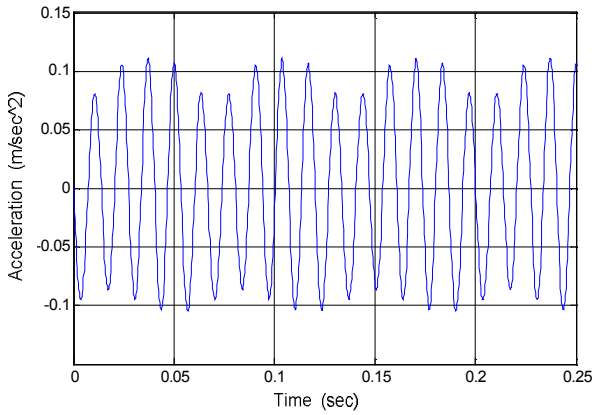

Figure 17 : Result Experimental curve in vertical direction time domain after reconstruction

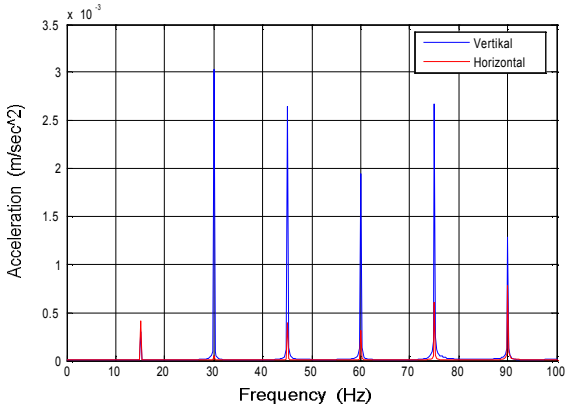

Figure 18 : Result Experimental curve in horizontal and Vertical direction on frequency domain after Reconstruction

Figure 17, the signal is curve vibration caused by shake-force vertical direction (towards the top and down direction), with a pure sinusoidal shape. 1 cycle on the crank with 0:05 seconds of time going three sinusoidal waves, amplitude achieve 0:13 m/detik2, on the condition of all spark plugs (do not use compression pressure). Movements of the engine in the vertical direction in which work style shake (shaking) more than the horizontal direction.

Figure 18, is curve frequency domain response of the reconstruction plug open vertical and horizontal. At the direction of vertical acceleration of 0:31 m/sec^2 at a frequency of 30 "Hz", in the horizontal direction is smaller than the vertical direction of 0:01 m/sec^2 on the same frequency. The frequency of the waveform and the other can be seen in this curve.

6. CONCLUSION

Results of dynamic analysis and experimental knowledge characteristic vibration due to looseness in the bearing internal combustion engine such as the above can be conclusion that signals obtained from the experimental multi-effects, namely the physical nature of the main bearing and imbalance of the piston crank system, this can be seen curve in the waveform and frequency domain. This research is useful as an initial study, the application of technology for predictive maintenance in the main engine ships in based monitoring vibration signals.

ABSTRACT

Multi-axis (5-axis) milling is used in the machining of complex shaped surfaces in a wide range of industries such as aerospace, automotive and ship building. Commercial CAM systems have however limited functionality. These limited functions restrict users to obtain high quality product in a efficient manner. Most of provided milling strategies still need user interactions and decisions which are often very troublesome. This paper describes the research conducted to enhance the CAM-system functionality and eventually optimize multi-axis milling processes. Three machining operation strategies are investigated and the results are implemented in the CAM-system based on faceted models developed by Laboratory of Manufacturing Technology and Automation, Department of Mechanical Engineering – University of Indonesia. These strategies are : 1) proper combination of tool type and cutting feed direction for 3-axis roughing and 5-axis finishing, 2) curvature based milling (feed direction) direction and segmentation, and 3) inclination angle control.

Keywords: *Multi-axis Milling, Milling Optimization, CAM-system*

INTRODUCTION

Current existing CAM-systems are still lack of functionalities that needs to optimize milling operation in order to enhance quality and minimizing machining time. The optimization means obtaining higher efficiency in machining processes and better surface quality. This research was investigating three strategies that can greatly improve machining operation functionalities. First, when 5-axis machining needs to be used following the common 3-axis roughing. In this case, the appropriate combination of tool-type and feed direction during 3-axis roughing and 5-axis finishing play important role. Furthermore, strategy when machining sculptured/contoured surfaces on which surface features (e.g. concave, convex, saddle and flat) are exist. In this kind of surfaces, each surface feature has its optimal tool type and feed direction. The last strategy is possibilities and condition to use multi-axis milling with dynamic inclination angle. The investigation of the above strategies is explained as the following.

FIRST MILLING STRATEGY for OPTIMISATION

The first strategy is to implement optimal combination of cutting directions and tool types during 3-axis roughing and 5-axis finishing process, since most of roughing and finishing processes are conducted using 3-axis and 5-axis machining, respectively.

In most practical cases, when the 5-axis machining is needed after the 3-axis roughing, the operator would simply assign the feed direction without considering the appropriate direction and tool type which result best machined quality. In order to know the influence of using different feed direction and cutting tool type, in this research, three type of cutting tools (Flat-end, Ball-nose, and Thoroidal cutter) are combined with two feed directions for 3-axis roughing and 5-axis finishing.

Experimental Setup

Cutting Tools
Material : solid carbide cutter, diameter : 10 mm. Total flute : 4. Type : 1. *Flat-end :* 2. Thoroid with 1,0 mm corner radius and 3. 5 mm Ball nose radius, as seen at following figure.

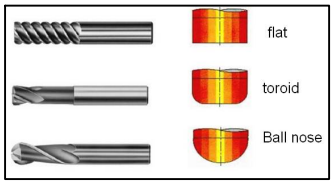

Figure 1. Cutter type, flat end, toroid dan ball-nose

Cutting Condition :
- Cutting velocity (V_c) = 150 meter per minute, for mild steel material
- Cutting speed per tooth (f_z) = 0,04 - 0,1 mm/flut, for 10 mm diameter
- spindel speed (n) is n = 4500 rpm
- the feed rate (Vf) is 700 mm/min
- *roughing process,* depth of cut : 0.5, *scallop* 0.3 mm
- *finishing process,* no additional cutting, *scallop* 0.2 mm
- cutter *Overhang* 35 mm

Factor and Test Level
Factor and test level can be seen in table 1:

Tabel 1. Factors and Test Level

FACTOR / LEVEL	Tool Type roughing	Tool Type finishing	Feed Direction
Level 1	Flat	Thoroid	*across*
Level 2	Thoroid	Ball Nose	*parallel*

Because of there were 3 factors; and 2 levels, so that the amount of test based on full factorial is 2^3 = 8. In roughing process, the test was done in 2 ways, across and parallel. The finishing proses was done by machining across to roughing direction. The optimal combination is the one that produce higher quality of the machined surfaces. The following table shows the results of the combination.

Table 2. Machine surface quality produced by several combination of tool-type and machining direction during 3-axis roughing and 5-axis finishing

No	Tool type Roughing	Tool type Finishing	3-axis vs 5-axis Direction	Ra (μm)	Wt (μm)
1	Flat	Ball nose	Across	0.419	1.839
2	Flat	Ball nose	Parallel	0.279	1.486
3	Flat	Toroidal	Across	0.697	2.205
4	Flat	Toroidal	Parallel	0.332	1.060
5	Toroidal	Ball nose	Across	0.709	2.628
6	Toroidal	Ball nose	Parallel	0.439	1.442
7	Toroidal	Toroidal	Across	0.797	2.546
8	Toroidal	Toroidal	Parallel	0.475	1.419

The results are as the following :
1. For *finishing*, ball-nose cutter produces lower Ra than toroidal type
2. For cutting direction, parallel direction produces lower Ra than across direction.

For *roughing* and *finishing interaction* :
1. *Roughing* with *flat*-end tool and *finishing* with ball-nose produces lower Ra than *roughing* with *flat-end* and *finishing* with *toroidal*.
2. *Roughing* with *toroidal* and *finishing* with ball-nose cutter produce lower Ra than *roughing toroidal* and *finishing toroidal types*.
3. The combination that produces lowest Ra is between *roughing* with *flat* and *finishing* with ball-nose cutter

For interaction of *finishing* and direction :
1. *finishing* ball-nose cutter type and parallel direction produce smoother Ra than *finishing* ball-nose cutter type and across direction
2. *finishing toroidal* cutter type and parallel direction produce smoother Ra than *finishing toroidal* type and across direction
3. The lowest Ra is produced by combining *finishing* ball-nose cutter type with parallel direction, but the difference is very small to *finishing toroidal* type with parallel direction.

The effect to The Machined Surface Waviness (Wt)
For cutting direction, parallel direction produces smaller Wt than across direction. In more detail :
for interaction of *finishing* and direction :
a. *finishing* ball-nose type and parallel direction produce smaller Wt than *finishing* ball-nose type and across direction
b. *finishing toroidal type* and parallel direction produce smoother Wt than *finishing toroidal* type with across direction.
c. The smoothest will be produced by combining *finishing* toroidal type with parallel direction

SECOND MILLING STRATEGY for OPTIMISATION

The next strategy is conducting the optimal 5-axis finishing direction on each surface contour classified by convex, concave and saddle region identified in the workpiece that would produce higher quality machined surface with lower machining time. The identification is done by curvature evaluation of the model. Once the surface feature (contour) is identified, an appropriate milling direction can be applied.

In this research, the curvature estimation methods, modified *Spherical Image* and Gauss-Bonnet Scheme, are combined and implemented to determine the shape of the model as the characteristic of curvature and then segment it based on the shape of surface model, where an area would be put in the same segment if it has the same curvature characteristics and adjacent location.

Developed Methods

Approximations to the surface normal and Gaussian curvature of a smooth surface are often required when the surface is defined by a set of discrete points rather by a formula (Meek et al., 2000). In this study, the used objects are 3D faceted models where they are composed by discrete points forming mesh of triangles. This approximation is only valid for smooth surface; a surface that is continue, is not coarse, and does not make angle in any area (Figure 2).

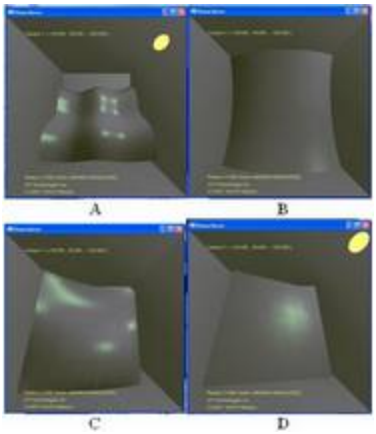

Figure 2: 3D faceted models that were used for curvature estimation tests

Surfa ce Curvature

Curvature is a deviation of an object or of space from a flat form and therefore from the rules of geometry codified by *Euclid*. At any point on the surface, one may consider surface curves passing through that point; locally such a curve lies in some plane intersecting the surface at that point (Kresk P et al., 2001).

Theorem 1. Meusnier's theorem :

$$k_C = k_n \cos\Theta \qquad (1)$$

where :

k_c = curve curvature; curvature of the curve
k_n = normal curvature; the curvature of any curve lying in an intersection plane which contains the surface normal direction at the given point
θ = the angle between the intersection plane and the surface normal.

Principal curvatures are primary and secondary directions and magnitudes of curvature. A given direction in the tangent plane is chosen and θ is defined as the angle between this preferred direction and the intersection plane. For θ (0, π) the function $kn = f(\theta)$ has two extrema. These extrema are called the principal curvatures (Kresk P, et al).

Theorem 2. Euler's theorem :

$$k_n = k_1 \cos^2\alpha + k_2 \sin^2\alpha \qquad (2)$$

where :

k_1 & k_2 = principal curvatures
k_n = normal curvature
α = the angle between the direction of k_1 and desired direction

Gaussian curvature (global curvature) is the product of principal curvatures k1 and k2 as follows:

$$K = k_1 \bullet k_2 \qquad (3)$$

And mean curvature is the average of principal curvatures:

$$H = \frac{(k_1 + k_2)}{2} \qquad (4)$$

Modified Gauss-Bonnet Scheme

Gauss-Bonnet Scheme is usually called Angle Deficit Method, because this method uses the total

of angle which is surrounding a vertex in an area, compared to the full circumference angle 360°. If an area, or a curvature calculation zone, is convex or concave, then the surrounding angle is less then 360°. Furthermore, if the area is flat, then the angle is +/- 360°. On the other hand, if the area is rather wavy or saddle, or formed a hyperbolic shape, then the angle is more than 360°.

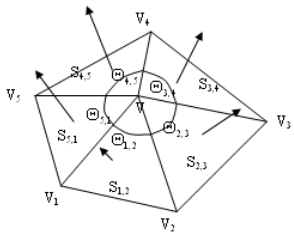

Figure 3: Surface of angle deficit method

Area of every triangle (which is represented by symbol $S_{x,y}$ in Figure 3) can be partitioned into three equal parts, one corresponding to each of of its vertices, so that the total area of a path on the surface around V on the polyhedron is

$$total\ area = \frac{1}{3}\sum S_{i,i+1} \qquad (5)$$

where $S_{i,i+1}$ is the area of triangles, formed by vertices V, V_i, dan V_{i+1} (Meek, et al., 2000).

The total angle of the triangles on the vertex V (in figure 3) is angle deficit of the polyhedron which are formed from the related triangles,

$$angle\ deficit = 2\pi - \sum \Theta_{i,i+1} \qquad (6)$$

Then total is the angle deficit in equation (6), compared with the area related to the vertex V in equation (5),

$$K = \frac{2\pi - \sum \Theta_{i,i+1}}{\frac{1}{3}\sum S_{i,i+1}} \qquad (7)$$

Modified Spherical Image

The estimation of the curvature value using Spherical Image method is conducted by creating a closed curve on the surface, surrounding a vertex which is being a chosen point to determine the value of the curvature. On the path that has been created, some points should be put (Figure 3), whereas the surreounding points are adjacent with the center point.

Vertices which compose the path and the center vertex will form a polyhedron that consists of triangles of the faceted model, just like the triangles that are used in Gauss-Bonnet Scheme (Figure 4).

After the vertices for curvature estimation have been acquired, then the next step is creating normal vectors on the surface for every vertex, and that is center vertex, as well as the surrounding vertices. If the tails of the unit normals to the surface along the path are placed at the origin, then the heads of those unit normals are the vertices located on the top of the normals. If the vertices on the top are connected, then a path called *spherical image* of the vertices located on the surface is formed.

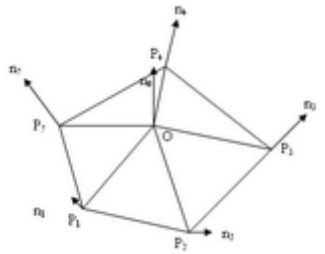

Figure 1: Surface of spherical image method

The theorem states that the curvature at the given point on a surface (in figure 4, the vertex is characterized with 'O') is the limit of the area of the spherical image of the path divided by the area of the path as the path shrinks around the point (Meek, et al). In Figure 4 above, a path that forms spherical image is a closed curve which surrounds a non-planar polygon $P_1P_2...PnP_1$. And then spherical image of this path is a polygon $n_1n_2..n_nn_1$, where n_i is unit normal of P_i. The ratio of the area of all triangles $n_in_0n_{i+1}$ over the area of all the triangles is an approximation to the total curvature at point O.

$$K = \frac{\sum L_{n_i n_o n_{i+1}}}{\sum L_{P_i P_o P_{i+1}}} \qquad (8)$$

The experiment is conducted to the several faceted models. Every model represents the shape which has been divided, concave, convex, saddle and flat. The experiment models can be seen in figure 2.

The value of curvature estimation method is determined in every point of calculation. The value of curvature shows the shape of surface on the specific location.

Using the Spherical Image method, the value of +/- 1 shows that the shape of the surface is flat or saddle, while the value which is less than 1 means that the surface is concave. If the value from the calculation is more than 1, then the surface which is located at that point is convex. The example of the result using the spherical image method for the model that has been shown in Figure 1(A) can be seen in Table 1. Every cell represents the location of every point of calculation of the model. The visualization by using some colors in every point of the model which represents the result of the calculation can be seen in Figure 5.

In Figure 5, the result of the points which show value less than 1 means the shape is concave, are colored by blue, whereas the result which value is more than 1 (convex) is colored by red. If the value is +/- 1 (the shape is flat or saddle) then the color would be white. The presentation by using colors are meant to make easier to understand what the value is trying to tell, since visual approach is often clearer than the series of numbers for a human.

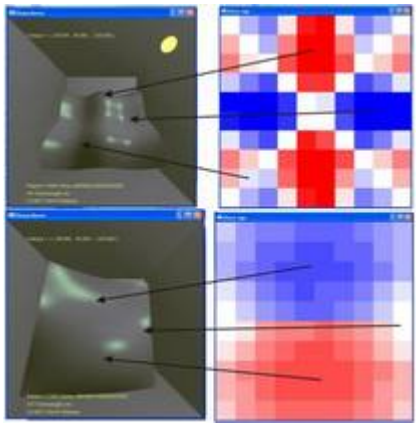

Figure 5: Segmentation of models using Spherical Image

For Gauss-Bonnet Method, the value of +/- 0 indicates that the shape of the surface is flat, and the negative value indicates that the shape is saddle. If the value is positive, then it means that the shape is convex or concave. Same as above, every cell represents the location of every point of calculation of the model. The visualization of the result by using colors can be seen in Figure 6.

Table 3 . The example result of spherical image method for the faceted model in Figure 2(A)

Row/ Col	1	2	3	4	5	6	7	8	9	10
1	1.001	0.980	0.973	1.009	1.047	1.051	1.007	0.972	0.984	1.000

3	1.027	1.008	0.998	1.039	1.091	1.088	1.039	0.998	1.010	1.027
4	0.989	0.972	0.960	0.998	1.042	1.041	0.998	0.960	0.974	0.991
5	0.946	0.926	0.911	0.959	0.997	0.993	0.956	0.920	0.929	0.948
6	0.951	0.929	0.916	0.959	1.003	0.999	0.962	0.914	0.926	0.949
7	0.991	0.972	0.963	1.001	1.046	1.035	0.999	0.962	0.971	0.991
8	1.025	1.010	0.999	1.039	1.092	1.084	1.037	0.998	1.011	1.028
9	1.017	0.993	0.986	1.030	1.074	1.069	1.023	0.988	1.003	1.015
10	0.998	0.9809	0.9721	1.0098	1.048	1.053	1.0086	0.974	0.9819	0.999

In Figure 6, the red color represent that the result of the curvature calculation is positive, which means the shape of the surface is concave or convex. On the other hand, if the color is blue, then then the value of the curvature is negative and the shape is saddle. The shape of flat will be indicated by white color and the value is +/- 1.

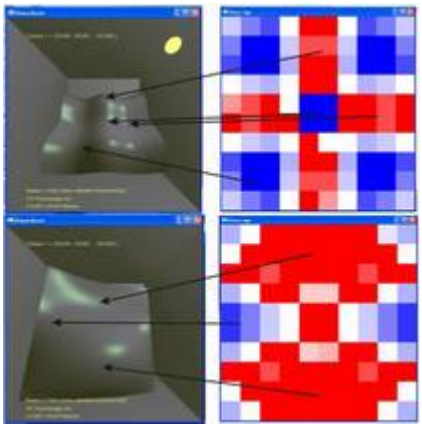

Figure 6: Segmentation of models using Gauss-Bonnet

Segmentation will be done based on the result of the curvature estimation. For each point which has the same / similar curvature value and is adjacent to each other will be included in the same segment. An example is shown in the visualization of the result in Figure 5 and 6. In the figure, some points in an area which has the same color can be included in a segment. On the other hand, the neighboring area which is covered by the same color, but different color with its neighbor will be included in the other segment. From this result, there will be one or more segment(s) in a model which will become a hint to make a tool path and determine each segment's the best milling direction based on its curvature characteristic which has been known. The result of the surface-shape (contour) identification is shown below.

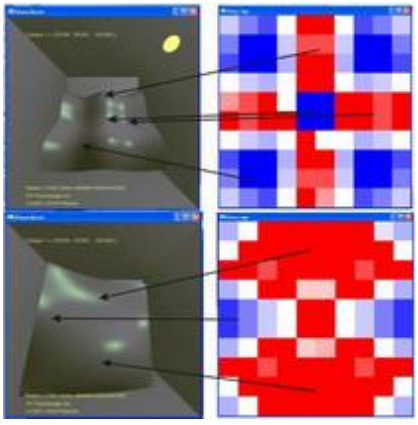

Figure 7. Surface feature (contour) identification by curvature analysis

Once the surface feature (curvature value) can be identified, the appropriate feed direction must be known for each surface feature.

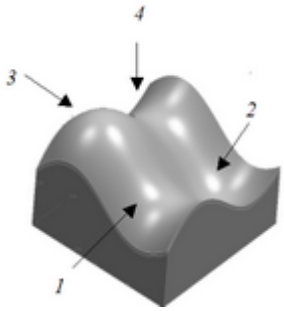

Figure 8. Sculptured surface with concave-convex combination

The milling operation is conducted into the surface model (Figure 8) in order to know the relation between the curvature and appropriate milling direction. The result is shown in Figure 9.

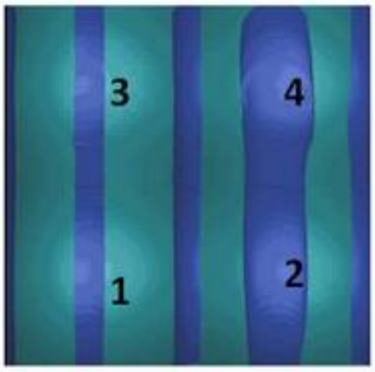

Figure 9. Cut width area w.r.t milling direction

As shown in Figure 9, milling direction (4-to-2) would result larger cut width area compared to the one using milling direction (3-to-1). The larger the cut width area the larger the material removed. Since, point 4 and 1 resemble the same curvature (and applied with different milling direction), therefore, it is clear that milling direction along minimum curvature direction is more preferred.

THIRD MILLING STRATEGY for OPTIMIZATION

The third or last strategy is to apply optimal tool orientation (inclination angle) during the 5-axis finishing with respect to the surface contour. In this part, the relationship or influence of changing inclination angles to the machined surface roughness is investigated.

ISSN 114-1284

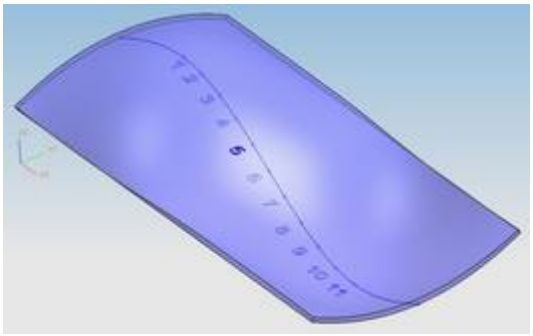

Figure 10. A surface model having covex/concave region

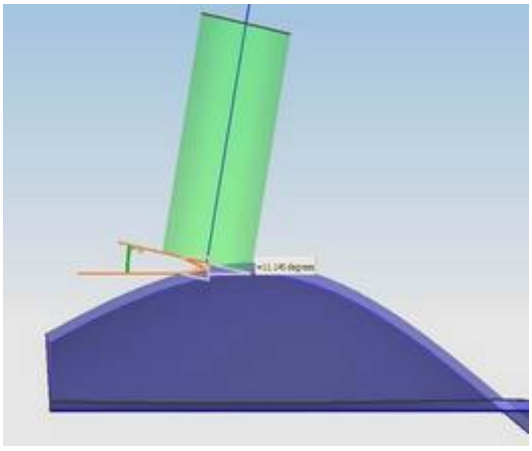

Figure 11 . Inclination angle influencing the cut-area

A contoured surface/model as shown in the Figure 10 is used on which the tool paths are generated along the surface with various inclination angles which are 10, 15, 20, 25, and 30. Each tool inclination angle is used along the tool path, and the cut-area (Figure 12) at several positions on the surface which having different curvatures are measured. The result shows in Figure 13.

It can be seen that, the lower the inclination angle the higher the cut area is produced. Furthermore, with the same inclination angle, the cutting tools cut more material at the concave region compared to the convex one. In other words, the highest cut-areas are on the concave region of the surface model.

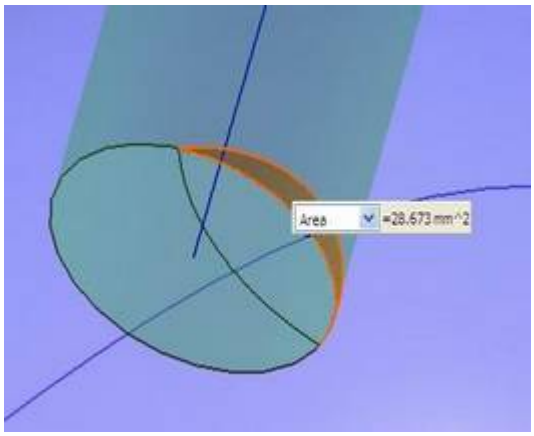

Figure 12. Cut area at the tool end

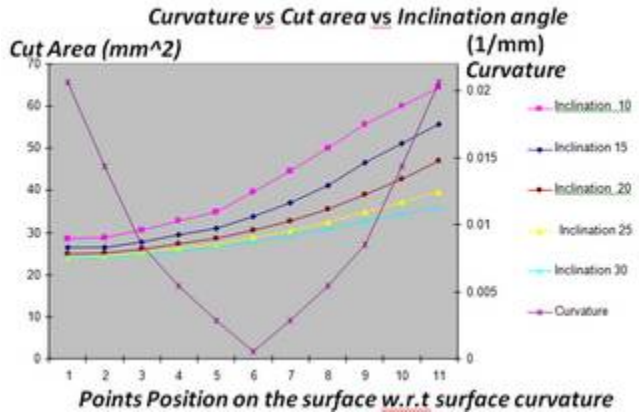

Figure 13. Inclination angle vs Curvature vs Cut-area

CONCLUSION AND FURTHER RESEARCH

The research investigates three milling optimization strategies:

a. Proper combination of tool-type and cutting direction during 3-axis roughing and 5-axis finishing
b. Feature (curvature) based optimal milling direction
c. Optimal inclination angle

The above three strategies can be implemented to improve the CAM-system functionalities.

Further research is needed to intelligently analyze the surface and provides suggestion for the optimal machining strategies.

ABSTRACT

High strain rate properties measurement of polymer materials has been limited due to difficulties in the measuring equipment, although high strain rate properties data is very essential as constitutive material for impact simulation. This work is aimed to get suitable visco-elastic data at desired high strain rate for impact simulation using Finite Element Analysis (FEA). Dynamic Mechanical Properties Testing in tensile oscillation at frequency of 10 Hz and 100 Hz was performed for Nylon and GFRP materials. Experimental data from that testing shown as tensile storage and loss moduli was converted to shear storage and loss moduli based on principle corresponding between Young's modulus, shear modulus and Poison's ratio. High strain rate properties data for both materials at desired frequency, about 2500 Hz, indicated as Short time shear modulus (G_0), Long time shear modulus (G_∞) was obtained by extrapolation technique on experimental result performed at low to moderate strain rate material properties. The extrapolation is based on a linear relationship between several mechanical properties (visco-elastic data) and logarithm of its strain rate. The result showed that high strain rate properties data for nylon and GFRP composite material, at desired frequency are suitable enough for impact simulation.

Key words
Visco-elastic data, high strain rate, impact simulation, finite element analysis.

1. INTRODUCTION

Since the 1960s, composite materials have been a major factor in weight reduction of structural components in the aerospace and automotive industries. Fiber-reinforced composites (FRC) are still regarded as relatively new materials within the mechanical engineering field and often lack the detailed material property data associated with metals. In particular, the use of composites in safety critical applications, such as an aircraft structure, leads to uneasiness since the mechanical response in crash applications is not well understood.

Composite materials have high specific strength, stiffness and excellent resistance against fatigue. Unfortunately, the materials are very sensitive to impact damage due to impingement of raindrops, hailstones, debris, and tools dropped by maintenance personnel. These impacts can generate significant damage inside composite materials called Barely Visible Impact Damage (BVID). When the long term usage of structures fabricated by composite materials is considered, an impact of single raindrop at velocity of 200 m/sec may produce no damage but repetition of the raindrop impact will bring about erosion on the materials [1)].

An experimental research of repeated raindrop impacts using nylon beads as impactor and GFRP as target materials has been conducted [2)]. Damage generated from that experiment is ring crack at front surface of specimen, star crack at back surface of specimen, and internal damage showing as debonding, matrix cracking, and delamination.

In order to analyze above impact damage, a series of attempts should be conducted. One of those attempts is to do impact simulation to get internal and surface transient stresses , contact duration, etc., using FEM. Since, Nylon and GFRP materials behave as visco-elastic materials at high strain rate deformation, therefore it is necessary to obtain visco-elastic data as a constitutive materials during simulation.

High strain rate testing has been used widely in the test of FRC material properties, However, at high crosshead rates, up to and above 2 m/s, inertial disturbances become inherent and cause inaccuracies in the analysis [3)]. These disturbances are due to the phenomenon of mechanical resonance and control problems that the test equipment acquires at high speeds. Therefore, the objective of this research work is to estimate high strain rate properties data at desired frequency, which is about 2500 Hz.

2. EXPERIMENT AND METHOD

2.1 Experiment

Dynamic mechanical properties testing was carried out based on ASTM Standard D 4065-1 using Visco-elastometer [4]. Due to limitation of experimental apparatus, selected frequency for this testing were 10 Hz and 100 Hz, and the range of testing temperature was between 15°C to 150°C. A typical data of tensile storage mudulus and tensile loss modulus for nylon and GFRP materials can be seen in Fig.1 and Fig.2, respectively, as shown below. Element of viscoelastic data for Nylon and GFRP composite materials can be shown in Table 1 and Table 2, below.

2.2 Method

In order to predict high strain rate properties of Nylon and GFRP composite materials, experimental data from Dynamic Mechanical Properties testing above shown as tensile storage (E') modulus and loss modulus(E") was converted to shear storage modulus and shear loss modulus based on principle corresponding between Young's modulus, shear modulus and Poison's ratio [5].

Furthermore, high strain rate dynamic mechanical properties shown as shear storage modulus (G_0) and shear loss modulus (G_∞), etc., for Nylon and GFRP composite materials is predicted based on linear extrapolation of logarithm of the rate of strain on the material properties to provide the data at high strain rates as discussed by Okoli et.al. [6,7]. For the data acquired from dynamic mechanical properties testing as shown in Table 1 and Table 2 of Nylon and GFRP Composite Materials. Selected testing temperature was very similar to the temperature during impact testing, around 25º C, its frequency were 10Hz and 100 Hz, due to limitation of experimental apparatus. In this case, required frequency used for determining the value of high strain rate properties is about 2500 Hz, which is related to contact duration between impactor and target material, about 40 micro-second for impact velocity of 200 m/s. As instance, the result of extrapolation can be shown in Fig. 1, Fig. 2 and Fig. 3, for Nylon material. The same technique of extrapolation were also performed for viscoelastic data of GFRP composite materials. Complete result of extrapolation can be seen in Table 3 below.

3. RESULT AND DISCUSSION

From the experimental result, as shown inTable 3 below that dynamic mechanical properties for Nylon and GFRP composite material increase from that at low strain rate (10 Hz) to moderate strain rate (100 Hz). For certain polymer materials, dynamic mechanical properties increase with increasing testing frequency due to occurrence of strain hardening [3)]. Dynamic mechanical properties at high strain rate (25000 Hz) is obtained from extrapolation technique. This technique of extrapolation is valid enough since it is very difficult to measure this properties at high strain rate experimentally due to limitation of experimental measurement. The inertia force problem during experiment of dynamic mechanical properties at high strain rate become main reason.

The data resulted from this extrapolation technique will be used for impact simulation using FEM. Contact duration resulted from impact simulation will be compared and discussed to that from impact testing. Impact simulation work is still underway right now.

Table 3, complete result of extrapolation for Nylon and GFRP composite materials

Mech. Properties	Nylon Material			GFRP Composite Materials		
	10 Hz	100 Hz	25000 Hz	10 Hz	100 Hz	25000 Hz
Go (Pa)	5.81E+08	7.00E+08	9.85E+09	3.57E+09	3.78E+09	4.28E+09
G∞ (Pa)	5.92E+07	6.92E+07	9.32E+07	5.62E+07	6.46E+07	8.47E+07
K (Pa)	1.26E+09	1.52E+09	2.14E+09	7.73E+09	8.18E+09	9.26E+09
β			1.06E+01			5.05E+01

Where *Go* is short time shear modulus in Pa, *G*∞ is long time shear modulus in Pa, K is bulk modulus in Pa and β is decay constant which is equal to *Go*/*G*∞.

4. CONCLUSION

From this research work, it can be concluded that extrapolation technique based on a linear relationship between several mechanical properties (visco-elastic data) and logarithm of its strain rate is valid enough. The value of dynamic mechanical properties at high strain rate i.e. at 25000 Hz, will be used in impact simulation.

ACKNOWLEDGMENT

ABSTRACT

PT "X" – Bandung is a state-owned companies and one of its products is vehicle. One of the important subassemblies of the vehicle is the airbrake. This paper is aimed at formulating an aggregate plan for the Machining Department for the production of airbrake for the upcoming scheduled three consecutive periods, namely period 1 (12 days), period 2 (12 days), and period 3 (27 days). The formulation of the aggregate plan began with rough-cut capacity planning to see whether the available resources would be able to meet the demand. It turned out that the available resources was unable to meet the demand. Therefore, we developed four alternatives. The first alternative was trying to meet the demand using the available resources by accepting the lateness in which penalty costs would have to be calculated based on the contract agreement. The second alternative was adding capacity through overtime and in this regard the overtime costs would be calculated. The third alternative was adding capacity by purchasing new machines in which the capital required would be calculated. And the last alternative was a mix of overtime and the addition of new machines and the related costs would be calculated as well. The alternative with the least cost would be selected. Based on our analysis, we conclude that the last alternative is the best aggregate production plan for the company in meeting the demand of airbrake for the upcoming three periods.

Keywords: *aggregate planning, rough cut capacity planning, airbrake*

1. INTRODUCTION

One of various products produced by a state-owned manufacturing company in Bandung was vehicle. One of important subassemblies for making vehicle is airbrake. The Machining Department had order of airbrake for three consecutive periods, namely period 1 consisting of 12 days, period 2 with 12 days, and period 3 with days. Each working day had eight hours. To make these orders, the department could use 18 machines as shown in Table 1. The objective of this paper is to propose an aggregate plan for the three periods.

Table 1. Type and number of machine

Machine	Number (units)
Regular lathe	9
Special lathe	6
Regular drill	3
Special drill	1
Regular mill	1
Special mill	1

2. METHODOLOGY

We adopt rough-cut capacity planning [1] to see whether the existing machines would be able to meet the orders or not. If the existing capacity could meet the demand, then we could show the calculation. If not, we would explore alternatives [2] in order to meet those orders. Based on our observation and discussion with the Machining Department in 2008 we finally came up with four alternatives: (1) fulfilling the orders using the existing capacity, but with lateness, (2) using possible overtime, (3) adding the existing capacity by purchasing new machines, and (4) a mix of overtime and adding new machines.

All required data were collected in the Machining Department in 2008. Data gathered include parts for making airbrake, routing data, overtime capacity, overtime wage, machine price. Recognizing the confidentiality of parts, we were allowed to use only part initials, instead of their full names.

It was stated in the contract that the buyer would terminate its orders if the company failed to deliver the orders at the maximum allowable lateness amounting to 5% of the contract value.

ISSN 114-1284

3. RESULTS

Rough cut capacity plan for nine regular lathes for the three periods are shown in Tables 1, 2, and 3. The required hours for period 1, 2, and 3 were 1,531.2; 2,692.2; and 3,692.8 hours respectively. The capacity of regular working hours for period 1 and 2 was 864 hours each and for period 3 was 1,944 hours. For the three periods, the total capacity available was 3,672 hours. Therefore, the existing capacity of regular lathes was less than the required one.

The existing capacity of special lathe for periods 1, and 2 was 576 hours each, and 1,296 hours for period 3. The required hours for the same periods are shown in Table 4, 5, and 6. The capacity of periods 1 and was less than the required one, while the capacity for period 3 was more than the required one. For the overall three periods, the total existing capacity (2,448 hours) was less than the required capacity (2,949.2 hours).

The existing capacity for special drill, special mill, and special mill was the same because each had one machine. The existing capacity for periods 1 and 2 was 96 hours each, and 216 hours for period 3. The required hours for special drill, regular mill, and special mill are shown in Table 10, 11, and 12 respectively. The required hours for special drill were higher that the existing capacity for all three periods. The required hours for regular mill were less than the existing capacity for all three periods. The required hours for special mill were higher than the existing capacity in period 3.

Because the existing capacity was unable to meet the order, we then explore and analyze possible consequences for each alternative. In this sense, we simply analyze the total capacity and required hours for the three periods. A summary of alternative 1, fulfilling the orders using the existing capacity, is shown in Table 13. As we can see, the total shortage of regular lathe was 4,245 hours. Using nine machines and eight hours per day, this shortage equals 59 working days late. For special lathe, the shortage was 501.2 hours or 11 days late. By the same calculations, the lateness for regular drill, special drill, and special mill were 16, 52, and 116 days respectively.
Alternative 2 sought to meet the orders using overtime. Each working day allowed four overtime hours. Therefore, using nine regular lathes, the shortage of 4,245 hours equals 118 days. With daily overtime wage of 60,000 rupiahs, the total overtime cost would be 63.72 million rupiahs. The similar calculations for the other machines are summarized in Table 14.

Alternative 3 is adding the existing capacity by purchasing new machines. For nine regular lathes with a total of 51 regular working days and hours per day, the shortage of 4,245.3 hours as shown in Table 15, equals 11 machines. The price of each machine was 100 million rupiahs. The new machines would require 11 new operators. There was not any problem with additional space required for the new machines. The remaining calculation for the other machines can be seen in Tables 15, 16, 17, 18, and 19.

Alternative 4 is a mix of overtime and adding new machines. We recognize that there many combinations of this mix and we did not enumerate them one by one. Instead, we firstly use the overtime during the 51 days and then the remaining shortage would be met by adding or purchasing new machines. For nine regular lathes as shown in Table 20, the overtime capacity for 51 days with 4 hours each day was 1,836 hours and thus the shortage after using the overtime would be 2,409.3 hours. This shortage could be fulfilled by adding four new machines and their overtime for 49 days. Adding three machines would result in overtime days more than 51 days, and adding five machines would be more expensive. The calculations for the other machines are summarized in Table 21 for regular drills, and Table 22 for special mill.

Overtime cost for 3 workers for 14 days	3,360,000
Total additional cost	84,480,000

4. DISCUSSION

Based on the analysis, we can see that alternative 1, operating with the existing capacity, would be unacceptable because the lateness exceeds the maximum allowable limits and this would result in termination of the contract which is unwanted by the company. The similar situation would occur with alternative 2, adding capacity using overtime in which shortages in regular lathe, special drill, and special mill would also cause lateness which would result in contract termination. Therefore, this alternative was unwanted as well by the company. Alternative 3, adding capacity by purchasing new machines can meet the required hours and therefore fulfill the order as scheduled. The total cost for this alternative was 1.641 billion rupiahs. The last alternative, adding capacity by using overtime and purchasing new machines could fulfill the order and the schedule. The total additional costs of this alternative would be 606.76 million rupiahs. Therefore, among the four alternatives, alternative 4 would be the best one. The summary of the four alternatives are shown in Table 23.

5. CONCLUSIONS

The orders for the three periods would be unable to meet either using the available capacity or using overtime. These orders could be fulfilled as scheduled through purchasing six new machines or a mix of overtime and purchasing four new machines. The best alternative would be the mix of overtime and purchasing four new machines. We acknowledge that this alternative might not be the optimal one. In addition, our analysis did not include holding costs since because of our inability to get the necessary data.

Table 23. Summary of all alternatives

Alternative	Cost (rupiahs)	Consequences
1. Operating with the existing capacity		
Regular lathe	0	Contract terminated due to lateness
Special lathe	0	Contract terminated due to lateness
Regular drill	0	Contract terminated due to lateness
Special drill	0	Contract terminated due to lateness
Regular mill	0	Contract terminated due to lateness
Total	0	Contract terminated due to lateness
2. Adding capacity using overtime		
Regular lathe	63,720,000	Contract terminated due to lateness
Special lathe	13,680,000	Can fulfill the order
Regular drill	5,580,000	Can fulfill the order
Special drill	6,360,000	Contract terminated due to lateness
Special mill	13,920,000	Contract terminated due to lateness
Total	103,260,000	Contract terminated due to lateness
3. Adding capacity by adding new machines		
Regular lathe	1,133,660,000	Can fulfill the order
Special lathe	309,180,000	Can fulfill the order
Regular drill	38,060,000	Can fulfill the order
Special drill	76,120,000	Can fulfill the order
Special mill	84,180,000	Can fulfill the order
Total	1,641,200,000	Can fulfill the order
4. Adding capacity through a mix of overtime and adding new machines		
Regular lathe	464,640,000	Can fulfill the order
Special lathe	13,680,000	Can fulfill the order using overtime
Regular drill	5,580,000	Can fulfill the order using overtime
Special drill	38,380,000	Can fulfill the order
Special mill	84,480,000	Can fulfill the order
Total	606,760,000	Can fulfill the order

HYDROGEN ABSORPTION PROPERTIES OF THE Mg-Ti ALLOY PREPARED BY MECHANICAL ALLOYING

Hadi Suwarno

Center for Technology of Nuclear Fuel– BATAN
Building 20, Puspiptek Area, Setu, Tangerang Selatan 15314, Banten, Indonesia

ABSTRACT

Metal hydrides are applied for reversible solid-state hydrogen storage at low pressures with high volumetric capacity, i.e. it should contain several kg of the metal hydride powder. Magnesium based has been researched for years due to the high hydrogen capacity. Although magnesium can absorb hydrogen up to 7.6 wt%, high operating temperatures and slow kinetics prevent them from practical application. Therefore, alloyed with other metals are being considered.

The synthesis and characterizations of Mg–Ti alloys prepared by mechanical alloying technique in toluene solution and the hydrogen absorption properties of the synthetic yielded have been performed. The Mg and Ti powders are milled with the variation of milling time 10, 20, and 30 h, in a Spex 8000 high energy ball mill. The milled specimens are analyzed with an X-ray diffractometer, Philip, type PW 1710, using Cu as the anode tube and = 1.5406 Å. Qualitative and quantitative analysis are calculated using Rietveld method developed by Fuji Izumi. The microstructure of the specimens after milling and hydriding are identified with a scanning electron microscope, Philip type 550.

The refinement analysis of the x-ray diffractions results show that the mechanical alloying of the Mg–Ti alloy under toluene solution result in the formation of four phases, namely Mg, Ti, TiH_2 and Mg_2Ti. Quantitative analysis show that the mass fractions of TiH_2 and Mg_2Ti phases are 62.90 wt% and 30.60 wt%, while the rests are Mg (2.6 wt%) and Ti (1.25 wt%). On hydriding at 300 ^oC, the milled powders are transformed into Mg_2TiH_4, TiH_2 and -MgH_2 phases with the mass fraction of 25.48 wt%, 64.0 wt%, and 10.52 wt%, respectively. Measured hydrogen capacity of the specimens is about 6.7 wt%.

INTRODUCTION

Magnesium is a promising material as hydrogen storage media because it can store 7.6 mass% of hydrogen. Various Mg-based alloys and compounds have been studied to improve its hydriding temperature and rate of hydrogenation. Among those materials, Mg_2Ni intermetallic compound is well known to form Mg_2NiH_4 hydride with high reaction rate, which has hydrogen storage capacity of 3.6 mass% [1-4]. Unfortunately the hydriding-dehydriding rate of the alloy is relatively at high temperature and therefore alloying of magnesium with other metal is considered.

Working with magnesium needs a special attention since it is difficult to cast at accurate desirable composition, especially by conventional melt-cast methods. The low melting point, the high vapor pressure, and the activity against oxygen are the most reason for magnesium when alloyed with other metals by melting methods. To solve the above problems, synthetic alloying with high energy ball milling has been introduced by many researchers. During mechanical alloying of two elemental powders, a binary mixture will be formed depends on the energy formation. An amorphous alloy powder will be formed if the heat of mixing in the liquid state has large negative heat and a crystalline powder will be formed if the heat of mixing is positive. The advantages of mechanical alloying in the synthesis of these powders can be defined as follows: (a) can be used to alloy elements having vastly different melting temperature, which cannot be easily done by conventional techniques such as arc melting, (b) is mature powder synthesis technique, and the method can be easily scaled from laboratory to industry.

In this paper magnesium alloyed with titanium with the atomic ratio of Mg:Ti = 2:1 prepared in a high energy ball milling in order to study the interaction of the alloy formed with hydrogen is discussed.

EXPERIMENTAL

The starting material consisted of elemental crystalline powders of titanium at purity of 99.5% and particle size of -100 mesh purchased from Aldrich and magnesium at purity of 99.7% and particle size of -325 mesh purchased from Merck. About 15 grams of Mg and Ti elements with the atomic ratio of Mg:Ti = 2:1 are mixed together with balls and then poured into a vial together with the toluene. The ball-to-specimen ratio is 8, and the milling is performed every 10, 20, and 30 h at room temperature in the toluene solution. The vial is made of stainless steel with a diameter of 5.1 cm and is 7.6 cm in length. The balls are also made of stainless steel with a diameter of 12 mm. The vial is then put into a high energy milling (HEM) Spex type 8000. One cycle of milling of the Spex type 8000 consists of normal blending speed of 4500 rpm, run time 90 minutes, and off time 30 minutes. This means that 10 h of milling needs 5 cycles of milling operation.

The hydriding experiment is conducted in a Sievert system that can be operated under high vacuum condition with a maximum operating pressure of 1000 mbar. The procedure of the experiment has been published

elsewhere[5]. About 3 gram of specimen obtained after milling is put into the hydriding system and then heated for 1 h at temperature of 430 oC for removing the toluene from the powder and recrystallization. After cooling down to room temperature the weight of Mg-Ti powder is measured. To avoid direct contact the powder with air during removing the powder from the system fro weighing purposes, hydrogen is admitted to the system. Hydrogen absorbed by the specimen can be calculated from the pressure changes during measurements.

The quality and quantity of the phases formed are analyzed using an x-ray diffractometer (XRD), Philip, type PW 1710, with Cu as the anode tube and □ = 1.5406 Å. Continuous scanning is conducted at 0.02° step size and 0.5 second/step. The scanning results are analyzed using *Rietveld method* developed by Fuji Izumi[6].

RESULT AND DISCUSSION

Figure 1 shows the XRD refinement result of the Mg-Ti alloy with the atomic ratio of Mg:Ti = 2:1 before milling, where only Mg and Ti peaks are identified. Quantitative analyses of the XRD refinement result yields a mass fraction of Mg and Ti are 62.76% and 37.24%. This result equals to the previous composition of the Mg and Ti metal powders.

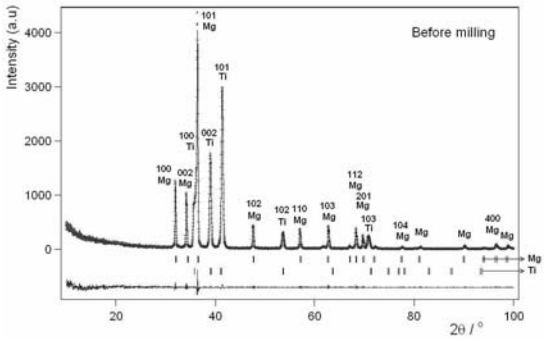

Figure 1. The XRD refinement result of the Mg and Ti before milling.

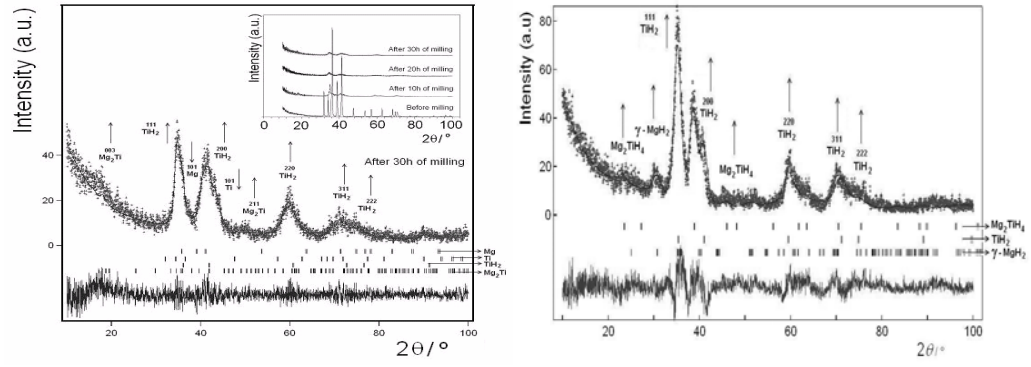
Figure 2 shows the XRD refinement result of (a) Mg-Ti alloy after 10, 20 and 30 h of milling and (b) after hydriding at temperature of 300 ^{o}C. Compared to the XRD of Mg-Ti before milling, it shows that the sharp peaks from Mg and Ti disappear and the new peaks formed. The low intensities of the new peaks formed are caused by a crystal structure changes of the specimens into amorphous state and a new phase formation. The refinement result of these new peaks appear at 2 . close to 19^{o}, 35^{o}, 40^{o}, 45^{o}, 59^{o}, and 70^{o} can be identified as Mg, Ti, TiH_2 and Mg_2Ti phases. Quantitative analyses on the XRD refinement result points out that the mass fraction of the Mg, Ti, TiH_2 and Mg_2Ti are 5.26 wt%, 1.25 wt%, 62.90 wt% and 30.60 wt%, respectively. The formation of TiH_2 in the specimen is suggested from the specimen preparation i.e. during removing the specimen from the hydriding system for weighing purposes, where hydrogen is used to avoid direct contact the specimen with oxygen. The grain sizes of individual crystallite calculated using Scherrer formula obtained that the Mg_2Ti, TiH_2, and Mg are 5.7 nm, 5.4 nm and 3.5 nm, respectively. The formation of binary Mg_2Ti informs us that mechanical alloying can be used to alloy elements having vastly different melting temperature, which cannot be easily done by conventional techniques such as arc melting. After hydriding, the elemental components of Mg_2Ti, Mg, Ti and TiH_2 are converted into new hydrided ones, i.e. MgH_2, Mg_2TiH_4 and TiH_2. Beside the peaks of TiH_2 incline, new peaks at 2θ = 31^{o} and 39^{o} can be identified as new phases from □-MgH_2 and Mg_2TiH_4 and the mass fraction of TiH_2, Mg_2TiH_4 and MgH_2 in the specimen equal to 64.0 wt%, 25.48 wt%, and 10.52 wt%, respectively.



(a) (b)

Figure 2. The XRD refinement results of (a) Mg and Ti after 30 h of milling and (b) after hydriding at 300 ^{o}C.

Figure 3 shows the *P-W-T* (pressure, weight gained, temperature) diagram represents the hydrogen sorption properties of the Mg-Ti alloy. From the figure in can be seen that only one plateau pressure is obtained, an indication that absorption on hydrogen into this alloy is very fast. Microstructure of the specimen also plays an important role in the performance of the material, where the fine microstructure increases the surface contact of the powder with hydrogen. The pressure versus wt% of

hydrogen in Fig 3 depicts that the hydrogen capacity is high, about 6,7 wt%. Compared to that of the Mg_2Ni[7,8], which absorbed hydrogen up to 3.6 wt% and Mg-Al, which absorbed hydrogen up to 3.2 wt% for □-phase and 4.9wt% for □-phase alloys [9,10], the Mg-Ti alloys looks more promising to be used as hydrogen storage material. For all Mg-based materials it is observed that mechanical alloying accelerates the hydrogenation kinetics of the magnesium based materials at low temperature, but a high temperature must be provided to release the absorbed hydrogen from the hydrided magnesium based materials. It is believed that the dehydriding temperature is largely controlled by the thermodynamic configuration of magnesium hydride. In addition, the rate of dehydriding is also depends on the milling time, where the longer milling time gives faster kinetics of dehydriding[12].

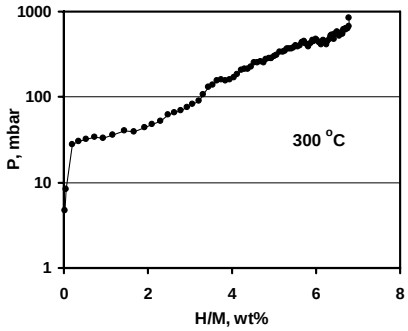


Figure 3. The *P-W-T* diagram of the Mg-Ti alloy at 300 °C.

Figure 4 shows the hydriding rate of the Mg_2Ti alloy measured at temperature of 300 °C. It is showed that maximum hydrogen content of about 6.7 wt% after 1270 seconds. Although the time needed to absorb hydrogen relatively long (21.16 min), the high capacity of hydrogen should be considered. Lomness et al. reported that in their experiment on Mg-Ni-Ti alloy they obtained the hydrogen capacity was about 11 wt% [13], almost twice as much as the present experiment. The high hydrogen capacity is closed connection to the nanosize particle used. Compared to other Mg-other metals alloy (Mg-Al, Mg-Ni, and Mg-Fe) the present result shows higher hydrogen capacity. Therefore, Mg-Ti can be considered in the future development of Mg-based material.

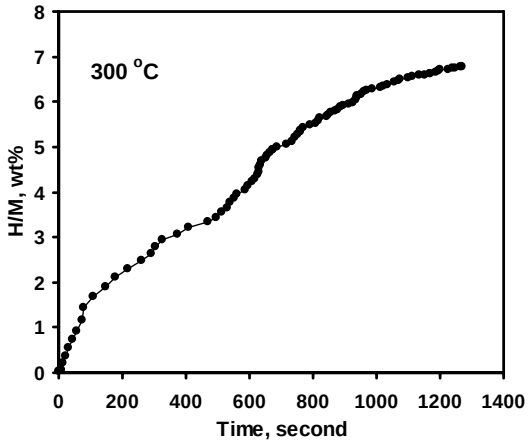

Figure 3. The hydriding rate of the Mg-Ti alloy at 300 °C.

CONCLUSION

Investigation on the hydrogen absorption properties of Mg-Ti alloy prepared by mechanical milling has been carried out. After 30 h of milling the elemental Mg and Ti powders can be synthesized into Mg_2Ti. The formation of TiH_2 is suggested from the use of hydrogen as media during alloy preparation. After hydriding, the specimens consist of TiH_2, Mg_2TiH_4 and MgH_2 phases with the mass fraction equal to 64.0 wt%, 25.48 wt%, and 10.52 wt%, respectively. Hydrogen capacity of the Mg-Ti alloy about 6.7 wt% is a good prospect for further investigation in developing Mg-based for hydrogen storage materials.

ABSTRACT

The present paper is devoted to an investigation of the problems of mass exchange behind the flame holder by utilizing a novel high-speed visualization technique based on laser sheet imaging. The experimental work was done in a flame holder model having a sudden expansion configuration in the form of a backstep. The model was placed in a horizontal small-scale wind tunnel and since the main objective is to determine the residence time, the experiment was done under isothermal (non reactive) flow. The visualization of the flow field was done with a laser-sheet based technique, where a planar image of the flow field, which was illuminated by a thin laser, was captured by a video camera. The visualization set-up consisted of a 4 W Argon-ion laser beam with a wavelength output of 514.5 nm (Coherent Innova 70-4) and a high-speed video camera (Motion scope HR series, Red Lake Imaging) which could be set to capture video images of 1000 frame/s. The continuous motion of the gas in the flow field could be visualized with sufficient temporal and spatial resolutions. Self-developed image processing software was used to conduct direct luminance intensity measurement on recorded image. The assessment of the residence time was done by analyzing the time history of the luminosity of recirculation zone on frame by frame basis.

Keywords: *Time residence, recirculation zone, high-speed visualization*

1. INTRODUCTION

Flame holding mechanism in a high speed air flow deals with maintaining the flame in the flow field at the condition that the flame which is formed is in the same degree as if it is in a low speed flow field. In order to hold a flame in a high speed and usually highly turbulent flow, one must either uses a small hot pilot flame or relies on recirculation holding. Of the standard flame holding techniques employed in subsonic combustion chambers, most involve the formation of recirculation zones in the flow field which assist in stabilizing flame structures. Strehlow [1] mentioned that these recirculation regions can be produced in a number of ways. These recirculation regions, which are typically formed behind bluff body (rod or sphere), V-gutter flame holders, by introducing a region of backflow using an opposed flow, or behind a sudden expansion of the duct area by introducing a step, are usually very low speed regions and provide conditions for a continuous source of ignition through the entrainment of hot combustion products. The diffusion flame then formed is mainly controlled by the mixing process of the utilized fuel and oxidizer (mostly air), as the time constant for mixing τ_{mix} is 5-6 orders of magnitude higher than the time constant for the chemical reaction τ_{cheml}. This means that mixing is the leading control parameter for the flame stabilization as well as for the efficiency of technical combustion process.

Furthermore, the stability of the process of combustion behind the flame holder greatly depends on the amount of heat received by the fresh mixture from recirculation zone. It is therefore advisable to investigate the flame holder operation with a study on the flow exchange between the zone and the outer flow. Proceeding from the peculiarities of the stream behind a sudden expansion, the exchange between the zone and flow has been usually assumed to take place mainly as a result of turbulent diffusion. However, there is no such effective way of directly determining the turbulent exchange coefficient for the recirculation zone. One of the possible methods is to determine it indirectly from the mean time of the presence of gas in the zone behind flame-holder. The residence time is then defined as mean time of exchange which describing the ratio of volume of the zone to that of the gas flowing through this zone per unit of time. Knowing the residence time and the dimension of the zone, it is possible to compute the mean coefficient of turbulent diffusion.

Bovina [2] mentioned that the connection between the zone diffusion coefficient D_z, the upstream flow diffusion coefficient D_f, flow velocity V_f and the size of the flame-holder d_{fh} is expressed by the following simple relationship

$$\frac{D_z}{V_z} = K_1 \frac{D_f}{V_f} + K_2 d_{fh} \quad (1)$$

In this case K_1 and K_2 are coefficients of proportionality. However, he did not succeed in finding away of directly determining the turbulent exchange coefficient for the recirculation zone and eventually proposed an indirect method based on the mean time of the presence of gas in the zone behind the flame holder (residence time, τ_{res}). Then in diffusion exchange

$$\tau_{res} = \frac{V_z r_m}{S D_z} \quad (2)$$

Where V_z , S and r_m are the volume, the surface and the mean radius of the zone respectively. The residence time and the dimension of the zone being known, it is possible to compute the mean coefficient of diffusion.

While there are abundant works devoted to determine the size of recirculation zone [3-6], to obtain the residence time was of considerable interest by itself. The dependence of its magnitude on various factors, such as the velocity and turbulence of the upstream flow, the dimension of the flame-holder and the composition of the mixture, have not as yet been comprehensively elucidated. The general physical consideration in determining the time residence is as follow. Some foreign admixture easily carried away by the turbulent displacement of the medium, whose presence can be fixed in some way is introduced into the zone behind the flame holder. After a stationary process between inflow and the discharge of the admixture has been established, its feeding is abruptly stopped and the change is recorded in its concentration in time from the equilibrium C_o to practically nil. The change in concentration occurs in accordance with the following equation:

$$C = C_0 e^{-\frac{t}{\tau_{res}}} \quad (3)$$

In the physical sense and numerically this value is equal to the mean time of the presence of gas during the stationary process (residence time). From Equation 3 we can obtain the magnitude of the residence time.

The present paper is devoted to an investigation of the problems of mass exchange behind the flame holder by utilizing a novel high-speed visualization technique based on laser sheet imaging. The continuous motion of the gas in the flow field could be visualized with sufficient temporal and spatial resolutions. Self-developed image processing software was used to conduct direct luminance intensity measurement on recorded image. The assessment of the residence time was done by analyzing the time history of the luminosity of recirculation zone on frame by frame basis.

2. EXPERIMENTAL METHOD

2.1 Apparatus and Test Condition

The present work was conducted in an experimental set-up as described in Fig. 1. The air was driven by a vortex blower into a horizontal small-scale wind tunnel and then flowed into a test section. The cross section of the test section upstream of the step was 50 x 80 mm2. The step height, H was 20 mm and the length of the test section was 300 mm. In the base wall, a gas injection port with 1 mm-slot exit spanned across the test section was installed at a distance lf from the step. Through the slot injection port, nitrogen gas from a high-pressure gas tank was injected upward into the test section after passing through a capillary manometer system for flow rate adjustment. The injected gas flow line was firstly passed through a particle seeding system, so that the injected nitrogen gas seeded with scattering particles entered the recirculation flow field in the test section. After a stationary process between inflow and the discharge of the seeded nitrogen has been established, the feeding is abruptly stopped and the change of luminosity of images is recorded.

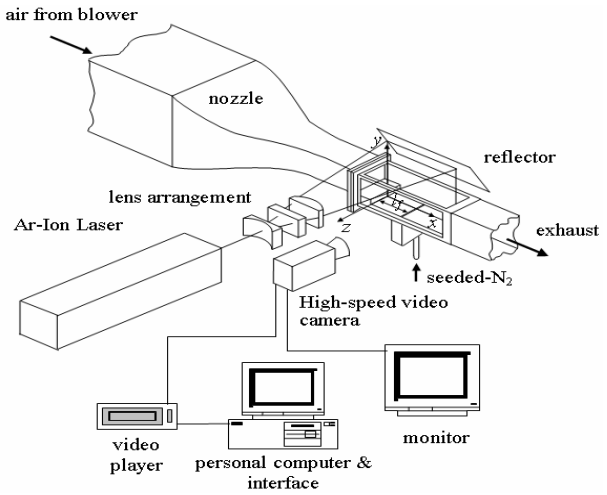

Figure 1. Sketch of Experimental Set-up

The test section was fixed to a transverse arrangement that allowed three-dimensional movement. Throughout the entire experiments of the present study, the upstream main airflow velocity was maintained constant at U_o = 10 m/s. In the experiments, the principal parameters were the ratio of specific momentum between the injected nitrogen and the main airflow ($I = \rho_{N2} V_{N2}^2 / \rho_o U_o^2$) and the stream wise

distance from the step to the injection slot (l_f). The specific momentum ratio of injection (I) was varied from 0.04 to 0.5 by altering the seeded-nitrogen injection velocity. Two locations of gas injection were selected within the recirculation zone, where the flow structure was different. In case (a), the nitrogen was injected at near step position ($l_f/H = 2$) where the recirculating flow was predominant. While in case (b) it was at near reattachment position ($l_f/H = 4$), where the shear turbulence was predominant.

The visualization of the flow field was done with a laser-sheet based technique, where a planar image of the flow field, which was illuminated by a thin laser, was captured by a video camera. The visualization set-up consisted of a 4 W Argon-ion laser beam with a wavelength output of 514.5 nm (Coherent Innova 70-4) and a high-speed video camera (Motion scope HR series, Red Lake Imaging) which could be set to capture video images of 1000 frame/s. The continuous motion of the gas in the flow field could be visualized with sufficient temporal and spatial resolutions, though images at the flow region with especially high local velocity would locally blur.

2.2 Assessment Method

Self-developed image processing software was used to conduct luminosity measurement on recorded image at a certain local point within the recirculation zone. Figure 2 represents an example of a captured image. To determine the residence time, the luminosity history at several points were tracked starting from the initial frame when the seeding is still introduced until several instants after the seeding is completely stop. In this method, images from about 2000 frames for each parameter condition were examined. The historical data of luminosity were then plotted into graphs to determine the magnitude of residence time.

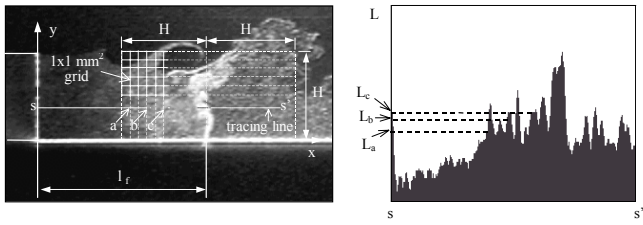

Figure 2. Assessment Method of Image luminosity

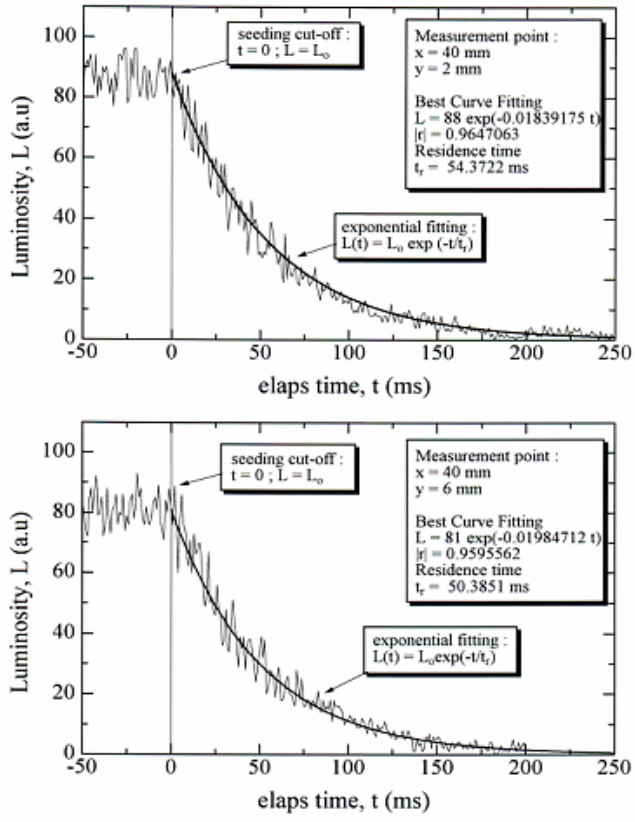
3. RESULTS AND DISCUSSION

Examples of luminosity signal history taken from image analysis are shown in Fig. 3 for the case of $l_f/H = 2$ and I = 0.04. From the figure it can be seen that the signal of luminosity indicates expected time history pattern for a recirculation region behind the step. The origins of the graphs show the cut-off point of the seeding process after a constant seeding. Afterwards, the graphs follow an exponential decrease until the intensity of luminance in the



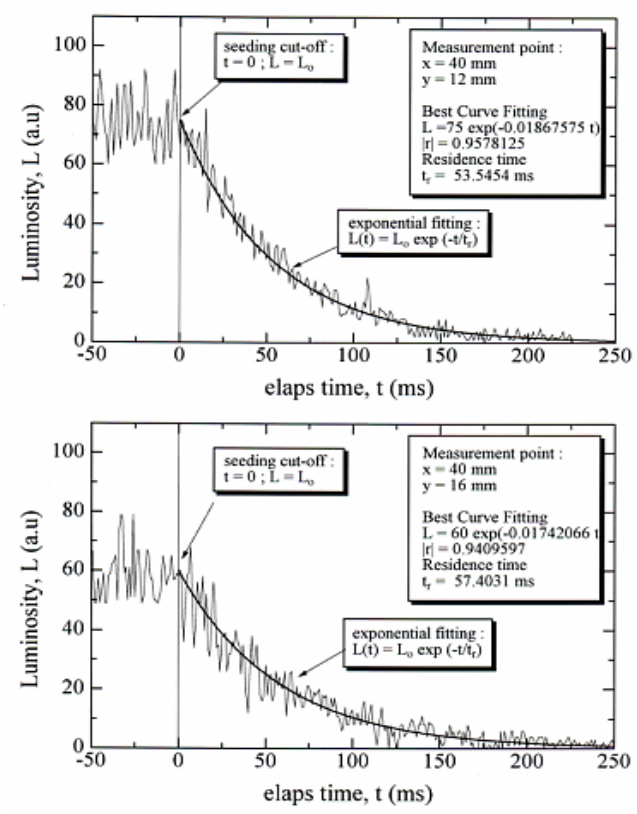


Figure 3. Example of luminosity signal history (U_o=10 m/s; l_f/H = 2; I = 0.04)

image vanishes. From the exponential fitting, the residence times are then determined.

Figure 4 summarize the residence times measured for all the case of specific momentum ratio of injection in the present study I = 0.04 – 0.5 when the nitrogen gas injection is at l_f/H = 2. For each case of specific momentum ratio, the measurements of luminosity is taken at several vertical position (y/H = 0.1 – 0.8) at horizontal position above the injection point (x/H = 2). The average magnitudes of residence times are also given. From the figure it can be seen that for the lowest momentum of injection (I = 0.04), local time residences are significantly scattered with standard deviation about 3 ms. However, for higher specific momentum of injection, the data show more constant value of residence time magnitude. Furthermore, the figure also indicates an obvious effect of the specific momentum injection to the shorten of residence time as the average magnitude drops about 27 % from 54 ms to 41 ms when the specific momentum is increased from 0.04 to 0.5. As implied by Equation (2), this result suggests that a higher specific momentum injection supports a faster flow exchange between the recirculation zone and the outer region.

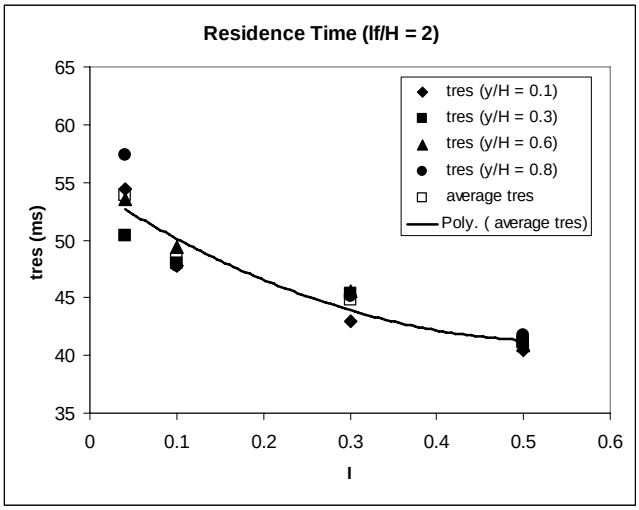

Figure 4. Effect of Injection Momentum to the Residence Time magnitue (U_o=10 m/s; l_f/H = 2; x/h = 2; I = 0.04-0.5)

Meanwhile, Fig. 4 summarize the residence times measured for all the case of specific momentum ratio of injection in the present study I = 0.04 – 0.5 when the nitrogen gas injection is at l_f/H = 4. Again, for each case of specific momentum ratio, the measurements of luminosity is taken at several vertical position (y/H = 0.1 – 0.6) at horizontal position above the injection point (x/H = 4). The average magnitudes of residence times are also given. From the figure it can be seen that shifting the injection position of the gas toward downstream direction and approaching reattachment point will shorten the residence time for the whole range of specific momentum of injection. When we compare the average magnitudes of residence times for the corresponding specific momentum injection in the previous case (l_f/H = 2), the decrease are ranging from 26 % for I = 0.04 to 11 % for I = 0.5. Moreover, it is apparent from the figure that injection near the reattachment point will make the influence of varying the specific momentum ratio becomes less significant. This result suggests a dominant effect of the shear turbulence with high intensity to the flow exchange between the recirculation zone and the outer region.

Furthermore, in a flame holding application those two trends could be the main aspect to be considered in maintaining the flame stability within the recirculation region.

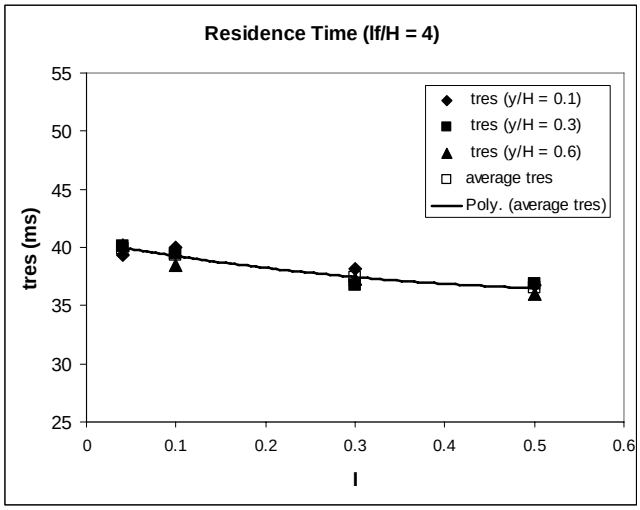

Figure 5. Effect of Injection Momentum to the Residence Time magnitue (U_o=10 m/s; l_f/H = 4; x/H = 4; I = 0.04-0.5)

4. CONCLUSION

In the present work, an investigation of the problems of mass exchange behind the flame holder has proposed a novel high-speed visualization technique based on laser sheet imaging to determine the residence time inside a recirculation flow region. The experimental work was done in a flame holder model having a sudden expansion configuration in the form of a backstep in which a seeded nitrogen gas is injected to simulate a fuel injection to a combustion chamber. The conclusions are as follows:

(1) The proposed method has been effectively used to measure the residence time which can be further analyzed to determine the turbulent exchange coefficient
(2) When the specific momentum ratio of the injection is increased, the time residence decreases which suggest a faster flow exchange between the recirculation zone and the outer region.
(3) Shifting the injection to approach the reattachment point will make the influence of varying the specific momentum ratio becomes less significant to the magnitude of time residence. This suggests a dominant effect of the shear turbulence with high intensity to the flow exchange between the recirculation zone and the outer region.

ABSTRACT

Flame lift-up phenomenon was proposed to overcome the overheating problem on burner tip. This phenomenon was initiated on the premix combustion using Bunsen burner built-in a ring above the tube burner. This work would be focused on measuring tip burner temperature. Temperature measurement was done utilizing two different method; platinum rhodium thermocouple and infra red thermograph. The infra red thermograph camera was connected to a computer to analysis the image using image processing software. It has been found that burner tip temperature of Bunsen flame was greatly influenced by the AFR or equivalent ratio. The highest burner tip temperature was nearly on AFR stoichiometric or equivalent ratio of 1. Burner tip temperature after flame lift-up indeed was lower than burner tip on Bunsen flame without lift-up. The proposition to apply this phenomenon seems appropriate to diminish the tip burner problem. However ring temperature look have yield on burner tip temperature due to the radiation heat loss. Simulation of heat loss from Bunsen flame based on flame temperature had been studied. This finding needs to be implemented on revealing the heat loss from flame lift-up phenomenon to clarifying burner tip temperature variation.

Keywords
Premixed combustion, flame lift-up, tip burner, temperature

1. INTRODUCTION

Damaged on burner tip due to high temperature stimulate the application of flame lift-up phenomenon on burner design. Flame lift-up phenomenon initially found on premix combustion using Bunsen burner slotted in a ring above the tube burner. This phenomenon was similar to lifted flame on diffusion flame. It retained the lifted flame using ring. The occasion when the flame jump to the ring was called lift-up phenomenon. So far a preliminary research on flame lift-up phenomenon had been done to investigate Air Fuel Ratio (AFR) for flame lift-up and the effect of ring position on AFR. Flame lift-up would appear on AFR above AFR blow-off without ring. It means that flame lift-up is on a lean combustion process. Position of ring or distance of ring from the exit tube burner was also play a part on determining AFR for lift-up. Closer ring position would provide greater AFR for lift-up [1].

In order to implement this phenomenon on design of burner, flame height had also been investigated. Research on flame height of flame lift-up has been done on the basis of AFR, position of ring, inside diameter of ring and material of ring [2,3,4]. Flame height was directly affected by AFR in reverse. This finding match up the Rokke correlation for premix flame that express flame height is proportional to mass fuel fraction and Froude Number [5].

Position of ring from the exit tube burner has also altered the flame height. It seems that flame height of flame lift-up was equivalent to position of ring. Research on flame height has also been done in term of inside diameter of ring employing 3 different inside diameter. It demonstrated that on low flow rate of fuel, inside diameter of ring nearly proportional to flame height. Nonetheless there was an optimum inside diameter that resulted in maximum flame height.

Further experimental study on material of ring particularly temperature of ring had also been carried out. Currently the impact of material ring has been investigated. Two different materials on the same dimension of ring have been applied [4,6,7]. For ring made of ceramic, AFR for lift-up was much lower contrast to ring made of stainless steel. Flame height would also vary. It has been found that flame height on ring made of ceramic was higher compare to flame height on ring made of stainless steel. Temperature of ring made of ceramic is lower than temperature of ring made of stainless steel when lift-up appeared. From AFR for lift-up, it seems that the raising of AFR is proportional to the raising of ring temperature. This result is match with the previous study, that lower AFR means lower flame temperature, and so was the ring temperature [7].

But, in the same burning load, it did not show the same thing. In the previous study it was found that AFR was defined by ring position on same burning load. Closer ring position means higher AFR. In term of the fuel flow rate, higher fuel flow rate did not affect the ring temperature when lift-up happened. On lower ring position, ceramic or stainless steel, show constant ring temperature. For stainless steel ring, on high position and high fuel flow, ring temperature is slightly raise, and this is in contrast with ceramic ring.

Correlation between ring temperature and flame length still cannot be defined since there is a jumping data for

those two materials. But for correlation between flame length and AFR for lift-up is match, for ceramic and stainless steel ring.

Measurements of burner tip temperature have never been reported to consider the phenomenon to be practically implemented. Therefore in this work burner tip temperature with and without flame lift-up phenomenon was measured using two different methods. The result can be used to estimate weather this phenomenon could be considered as the improvement on burner design. The experimental result was also evaluated based on simulation.

2. EXPERIMENTAL

This research was carried out using propane as a fuel. A Bunsen Burner Flame Propagation and Stability Unit which consist of air flow meter and gas flow meter, fan and AC motor were used to create flame and control the propane and air flow rate. The tube of Bunsen burner is 14 mm diameter and 38 cm height. A ring made of stainless steel AISI 304 with outside diameter of 30 mm and thickness of 5 mm was placed above the burner tube concentrically using a ring adjuster.

Thermocouple and infra red thermograph were used to measure the tip burner temperature. Infrared thermograph was directly connected to a computer so that the image can be analyzed using an image processing software as it is shown on Figure 1.

Flow rate of propane and flow rate of air were measured using rotameter and recorded whenever lift-up happened. The rotameter had been calibrated using a wet gas meter. Experimental was started without ring. Gas valve was open and it was kept on a fix value

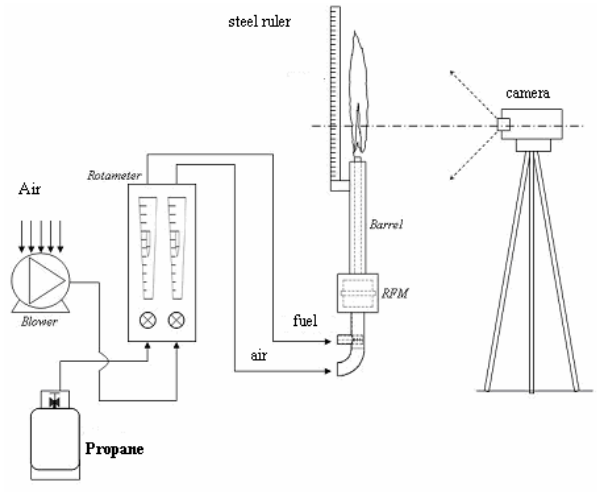

Figure 1. Experimental set-up

that can be seen from the rotameter. Ignition can be done and air valve was open slowly. Tip burner temperature and air flow rate was recorded. Air valve was further increased slowly until a fix value then tip burner and air flow rate was recorded. Experiment was done until flame was blow off.

Experimental expand with ring that put above the exit tube burner concentrically using ring adjuster. Gas valve was open and it was kept on a fix value that can be seen from the rotameter. Ignition can be done and air valve was open slowly until lift-off. Then within a few second flames will jump from the exit tube burner to the ring and 'sit on the ring'.

AFR was calculated based on regular propane flow rate. Air flow rate was regulated until the flame lift-up phenomenon came out. Air flow rate, tip burner temperature were recorded simultaneously.

Experiment was done on four positions of ring from the burner tube that is 10 mm, 20 mm, 30 mm and 40 mm respectively. For each position of ring, six variation of propane flow rate was carried out. The heat release of the flames studied ranges between 1.5 KW and 2.5 kW.

3. RESULT AND DISCUSSION

Image from the measurement of tip burner temperature without ring that had been done using infra red thermograph was presented on Figure 2. It shows that emissivity of the burner tip can be set on 0.44. The value for tip burner temperature was taken on the center of tip burner surface since this location is perpendicular to the infra red camera. AFR of each data was calculated and presented on Table 1.

43	62	42	50	40	50	39	50

Burner tip temperature on Bunsen flame without flame lift-up would be compare to burner tip temperature after lift-up. It is showed on the same chart as on Figure 4.

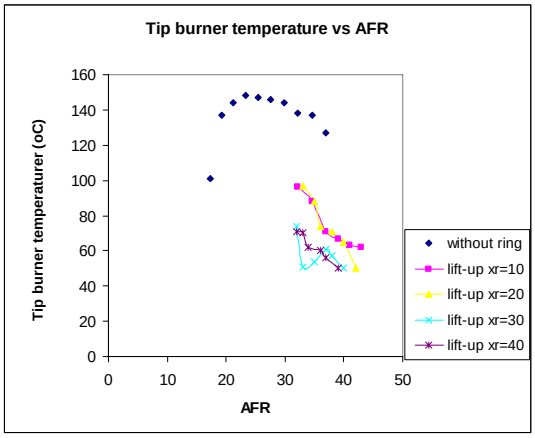

Figure 4. Tip burner temperature with and without ring or after lift-up

Tip burner temperature without ring followed flame temperature distribution that nearly maximum on AFR stoichiometric. In this experiment as propane was used as a fuel then the AFR stoichiometric was about 24.

However distribution of tip burner temperature after lift-up was hardly difficult to figure out. Definitely tip burner temperature after lift-up were lower compare to tip burner temperature without lift-up. Not only because the higher AFR that decrease the temperature, but also heat radiation to material of ring that absorb a certain thermal energy of combustion. This result was corresponded to previous experimental result on flame length of flame lift-up using two different material of ring [4].

Position of ring from the tip burner is also affected the tip burner temperature. The closer position of ring higher tip burner temperature will be. This result is consistent with the simulation result on tip burner temperature without ring that considers the standoff distance of the flame as it is shown on Figure 5 [10].

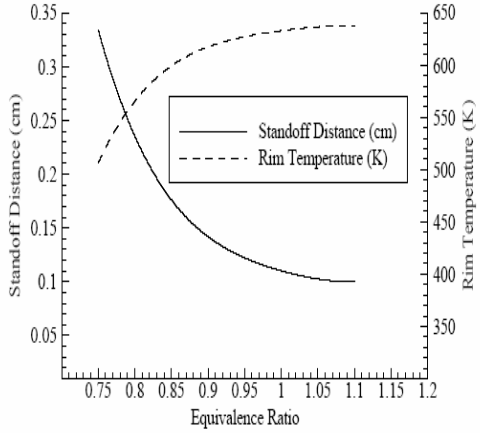

Figure 5: Rim temperature on equivalence ratio variation

4. CONCLUSION

Distribution of tip burner temperature on Bunsen flame was similar to the distribution of flame temperature. It depends on the AFR of equivalence ratio and it is the highest on its stoichiometric mixture.

Flame lift-up phenomenon was decrease the tip burner temperature. The longer distances of ring from the tip burner also decrease the tip burner. Therefore application of this phenomenon on burner design could be possible to overcome the overheating problem on premix burner.

ABSTRACT

Combustion of gas with diffusion system is generally used in industrial furnaces. Base flame of a diffusion flame usually departs from the burner tip. Such condition is called lifted-flames. The distance between base-flame to burner tip is called as lifted-distance. Lifted distance of diffusion flames generally increase linearly as the velocity of fuel gas injection from burner tip is increased. This is called as lift-off condition. The paper discuses the alteration of lifted-distance due to an air-injection around the jet flow of propane. Propane flowed through a 1.8 mm burner diameter with ejected combustor type and cone nozzle type at burner tip. The propane was burned in quiescence air until lift-off condition was reached. Furthermore air was injected around the jet of propane. The injection angles were 15^0, 30^0, 45^0, 60^0 and 75^0 from propane flow direction.
Lifted distance of a diffusion flames has strong correlation with characteristic of air diffusivity to the fuel. A shorter lifted-distance means greater air diffusivity to fuel gas. Injection of air around fuel flow at low flow rate produces flame with lower lifted distance than flames in quiescent air. Air injection with 45^0 direction gives the lowest lifted distance of diffusion flame.

Keywords: *diffusion combustion, base-flames, lifted-flames, lifted-distances*

1. INTRODUCTION

Combustion is process to convert chemical energy to thermal energy. There are two kind of combustion process: namely premixed combustion where fuel and oxidizer are mixed completely before their entering to combustion chamber and non-premixed or diffusion combustion where fuel and oxidizer flow into the combustion chamber separately.

Generally, the non-premixed combustion is preferred to be applied in industries for safety and reliability reasons, because in a diffusion flame, lifted phenomena often takes place early. With the base at a distance from burner tip, the flame gives an advantage to avoid thermal contact between the flame and the nozzle which would lead to erosion of the burner material. The disadvantage of this flame stabilization technique is that lifted flame blow off more easily than attached flame and therefore must continuously be controlled [1].

Liftoff distance defined as the distance between burner tip and base of flame will increase with additional velocity until the flame blows out [2]. The criteria for establishing the liftoff height are different for each theory and can be given as follows:

1. The local flow velocity at the position where the laminar flame speed is a maximum and matches the turbulent burning velocity of a premixed flame.
2. The local strain rates in the fluid exceed the extinction strain rate for laminar diffusion flame let.
3. The time available for back mixing by large scale flow structures of hot products with fresh mixture is less than a critical chemical time required for ignition.

Liftoff heights for free and confined jets at propane diffusion combustion have investigated by Cha M.S and Chung S.H. [3] and they found that the ratio of the liftoff height at blowout to the nozzle diameter maintains a near-constant value of 50 for free and confined jets. Result of observation indicates that liftoff heights x_f for free jets are proportional to the nozzle exit mean velocity u_i and are independent of the nozzle diameter and the data can be fit to equation (1):

$$\bar{x}_f = 0{,}002245u_i - 0{,}01663 \qquad (1)$$

While liftoff height for confined jets the data can be fit to equation (2).

$$\frac{\bar{x}_f}{d_i} = u_i\left(1{,}02 + \frac{0{,}0976}{d_d - 0{,}35}\right) \qquad (2)$$

Where d_i = nozzle diameter, d_d = shroud diameter.

L.K. Su et al. [4] investigated lifted jet diffusion flame by planar laser-induced fluorescence and particle image velocimetry. They delineate that there is high temperature region at the base of lifted flame.

Watson et al [5] performed simultaneous CH and OH PLIF measurements at the flame base. The CH radical is short-lived and is thought to mark the instantaneous reaction zone, while OH is removed by slower three-body reactions and marks regions containing hot combustion products. Maurey et al.[6] also observed high-temperature region outside and upstream of the reaction zones.

Some of research result suggested that at base flame has high temperature beside brightness; hence determination of base flame from flame photograph is determined as the position with highest brightness level.

2. EXPERIMENT

This research investigated the effect of air injection to alteration of lifted distance on a propane diffusion flame. Initially, propane was supplied to the quiescent air and a chemical reaction occurred. Flow rate of propane was increased gradually until liftoff condition reached. With propane flow rate at 69 ml/s, lifted distance reached 130 mm. Furthermore, air was injected around of propane flow through guide ring having various angles. Figure 1 shows the scheme of propane and air flow at the tip burner before entering the combustion chamber.

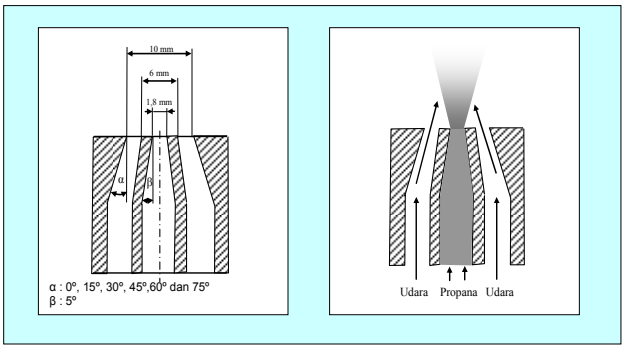

Figure 1: Scheme of propane and air flow at burner tip before entering the combustion chamber.

Propane flowed through cone nozzle type with exit diameter 1.8 mm and angle of cone nozzle 5^0. Air was injected around of propane through a gap between outer cone nozzles with outer diameter 6 mm and guide ring with inner diameter 10 mm. Guide ring has various angles of 0^0, 15^0, 30^0, 45^0, 60^0 and 70^0. Co-flow of air injected to propane occurred in case of the angles of guide ring was 0^0.

For each angles of guide ring, air injected was increased gradually and the alteration lifted distance was perceived. The sketch of experimental equipment is presented at Fig.2.

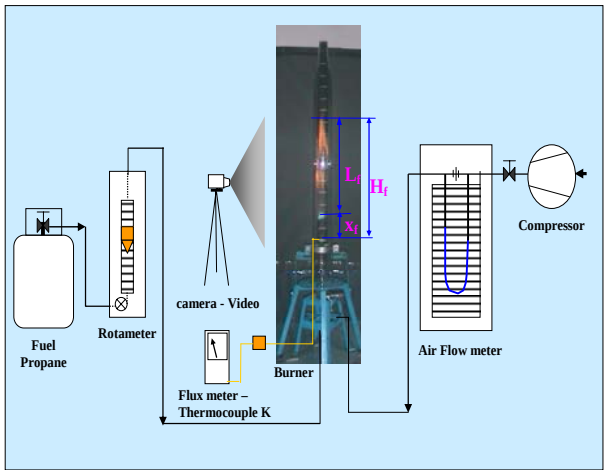

Figure 2. Schematic of experiment appliances

Propane flowed through a flow meter which has been calibrated by Wet Gas meter prior to the experiment. Flow of propane is controlled by a flow meter. Then, propane flowed into the nozzle burner for ejection into the combustion chamber. Air from compressor reservoir was delivered through orifice flow meter which have calibrated previously by Wet Gas meter before injected to the burner which passes through gap between guide ring and cone nozzles of burner tip.

Glass shroud with 82 mm of diameter and 1 m of length was installed to serve as the wall of combustion chamber for combustion with air injection. The image of flame was captured by camera, and then from the photograph some measurements of flame dimension were conducted including flame height, H_f , flame length, L_f, and Lifted distance, X_f.

3. RESULTS AND DISCUSSION

When Propane ejected to quiescence air and combusted at certain flow rate of propane, camera records the flame shape. From the captured images, the dimension of flame is determined. Figure 3 show lifted distance for propane's flame in quiescence air for some value of propane flow rate. Lifted distance is proportional to flow rate of propane. Lifted distance X_f (mm) is linearly dependent with flow rate of propane Q_f(l/s) as show as equation (3)

$$X_f = 2719.8Q_f - 59.698 \quad (3)$$

Meanwhile, Equation (5) present lifted distance X_f in meters and mean exit velocity of propane u_i in m/s when ejected from nozzle burner.

$$u_i = \frac{4.Q_f}{\pi.d_i^{\,2}} \quad (4)$$

$$X_f = 0.00691\,.u_i - 0.0597 \quad (5)$$

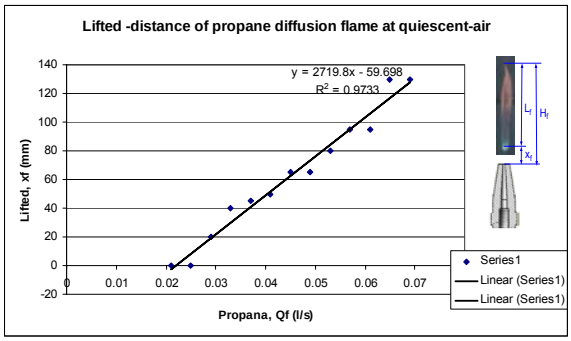

Figure 3. Lifted distance for Propane flame in quiescence air.

Equation (5) has similarity with observation result by Cha M.S and Chung S.H for free jet flames [3]. Hereinafter at propane flow rate is 69 ml/s air injected around propane stream, the alteration of lifted distance by air injection is presented in Figs. 4-9. It have the same tendency with the case of shortest lifted distance at low air injection flow rate and increases again when increased air injection. By gentle air injection, mixing between fuel and air is faster. Diffusion time become shorter than jet propane at quiescence air.

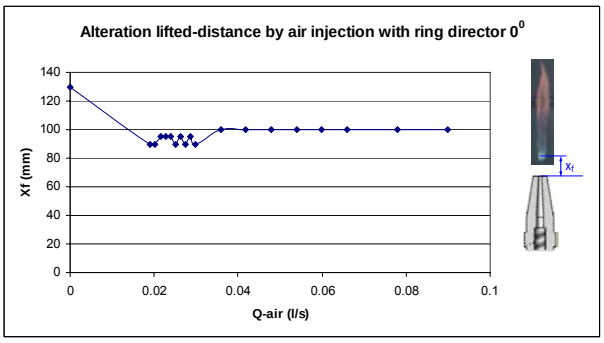

Figure 4. Alteration lifted distance by air injection through Ring director with angle 0^0.

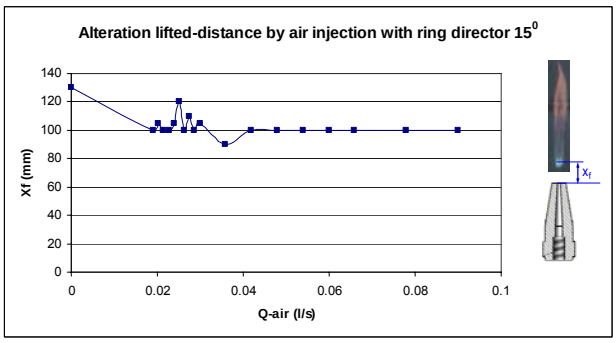

Figure 5.Alteration lifted distance by air injection through guide ring with angle 15^0.

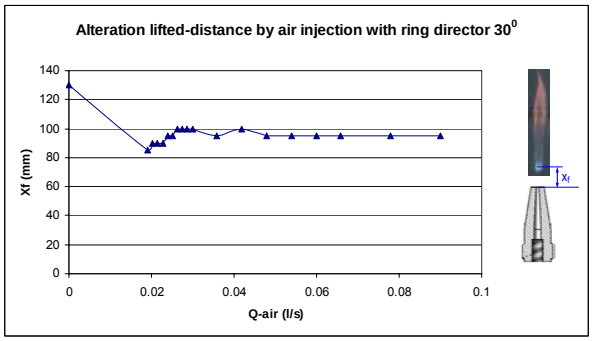

Figure 6. Alteration lifted distance by air injection through guide ring with angle 30^0.

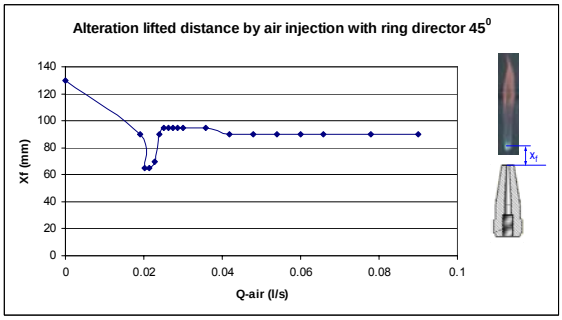

Figure 7.Alteration lifted distance by air injection through Ring director with angle 45^0.

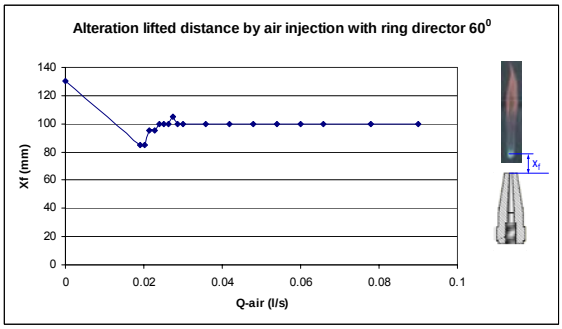

Figure 8. Alteration lifted distance by air injection through guide ring with angle 60^0.

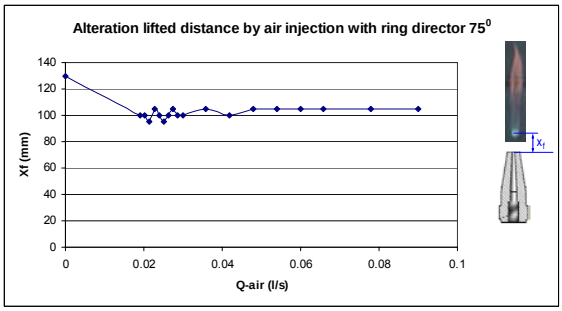

Figure 9. Alteration lifted distance by air injection through guide ring with angle 75^0.

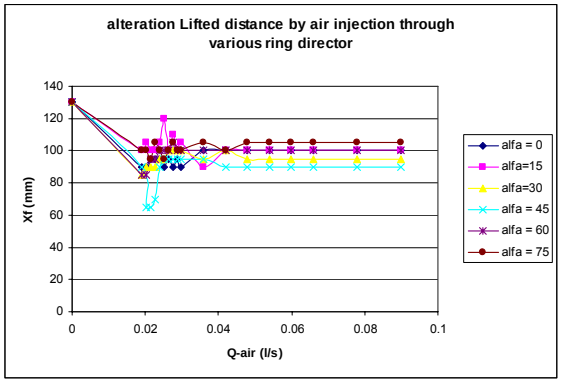

Figure 10. Alteration lifted distance by air injection through various guide rings.

The tendency of lifted distance decrease along with the increase of air injection reaches the maximum value for air flow rate 19.1 – 20.3 ml/s or air to fuel ratio is equal to 0.28 – 0.29. The decrease of maximum lifted distance decreases by air injection for various guide rings is presented at Fig. 11. Ring directors have 45^0 angles to propane stream give maximum value for alterations of lifted distance.

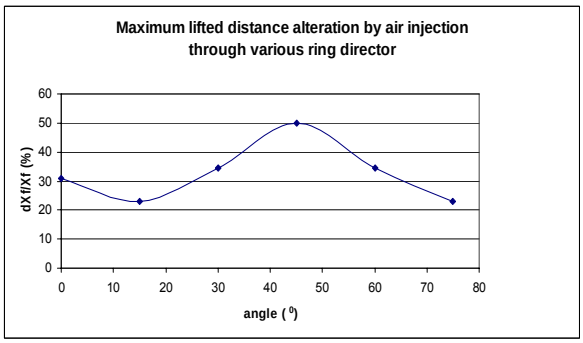

Figure 11.Maximum lifted distance alteration by air injection through various ring directors

Moreover, some numerical simulations were also conducted for propane jet injected into a combustion chamber with air injection through guide ring having various angles of 0^0, 30^0, 45^0 and 60^0. Figure 12, 13 and 14 show some results from the simulation in case of propane flow rate at 69 ml/s, and air injected flow rate at 20 ml/s. The numerical model solver is steady-state, axisymmetrical, viscous model is k-epsilon and species transport model inlet diffusion.

Figure 12 shows that mass-fraction of propane for guide ring with 45^0 angles decreases faster than the other ring. This proves that guide ring with 45^0 angles improves diffusion process of air into propane. Beside that Fig.13 shows that guide rings with angles 45^o produces highest turbulence kinetic energy compared to other angle.

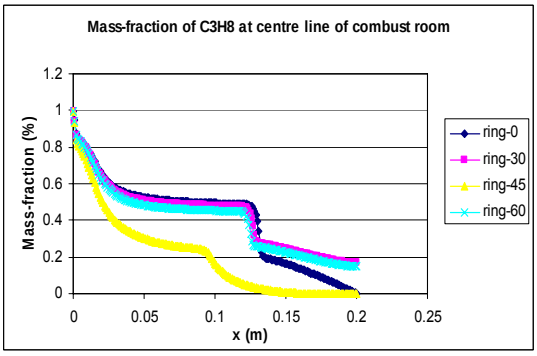

Figure 12.Mass Fraction of C_3H_8 at centre line of combust-room

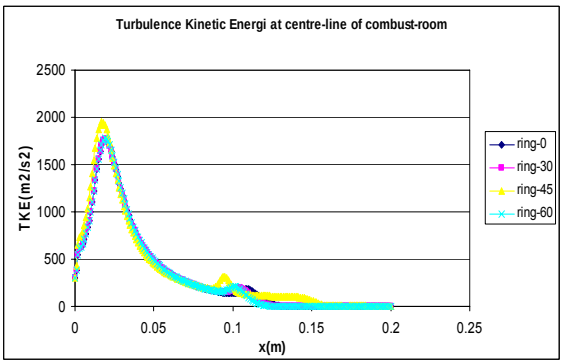

Figure 13.Turbulence Kinetic Energy at centre-line combust-room.

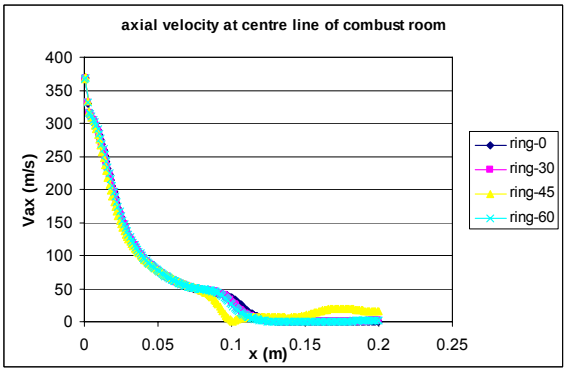

Figure 14.Axial velocity at centre-line combust-room.

Figure 14 shows axial velocity along the axis symmetry. In case of guide ring with 45^0 angles, the velocity initially reaches the minimum values which indicates that propane have radial flow, this support mixing between propane and air.

4. CONCLUSION

Air guide ring directors with angles of 45^0 to propane stream increases the diffusion process of air to propane. Numerical simulation proved that mass fraction of propane for 45^0 angles decreases faster than the other angle and the flow field has maximum turbulence kinetic energy distribution and reach minimum axial velocity earlier.

ABSTRACT

Air flow distribution and temperature in the hospital operating theater play a very important role in maintaining staff and patient comfort. Air temperature and velocity inside the older operating theater hospital are not matching with given standards. These limitations are due to the site constraint and also financial aspect.

The FLOVENT is one of the Computational Fluid Dynamics (CFD) software which has proven its validity in simulating airflow distribution in operating theaters. The engineering judgment has to be carefully selected to a successful CFD modeling job and must be taken to include all the relevant physics in the model.

Model visualization and simulation result shows that many factor has to be taken into account before using the software. The appropriate selection of the design parameters such as temperature, velocity and volumetric flow of fresh air have to be clearly defined to ensure accurate results.

A CFD model of airflow distribution is developed and its validation with the existing operating theater is already conducted. Furthermore, this model can be used as a reference in the earlier design of air flow modeling in operating theater.

Model analysis and thermal behavior in one of hospital operating theater in Indonesia will be explained specifically in this paper.

1. INTRODUCTION

One of the basic differences between the air conditiong systems for health care facilities including the operation room and that for other building types is the high risks of bacterial and viral infections into the rooms. Design and construction of the operation room have been regulated with some institutions in order to increase the hospital health management systems. Some technical specifications including other general requirements such as air conditioning system, ventilation and indoor air quality (IAQ) have been regulated with thoses institutions, but actually in some cases it is necessary to provide a specific design criteria for clean room or operating room.

The air conditioning system for clean room is designed for : maintaining the conditioned room temperature, relative humidity and filtering air to reduce the airborne particle contamination flowing into the room. The type of those airborne contaminants in the health care air conditioning system such as viable particle, which causes some infections and allergy for human. The examples of viable particle which are transported by air such as bacteria, fungi, spore and pollen. The airborne sources from outside air which could flow into the conditioned room are from air conditioning system, infiltration through window/door, piping system and hood. The viable particle could be controlled by air filtering system, positive pressure and isolation from all of infiltration sources. Meanwhile the particle sources from conditioned room/clean room itself are from human skin, breathing process, hair and cosmetic materials. The contaminated dust, particles control and air flow system are the main subjects to maintain the clean room conditions. The clean room performance conditions highly depend on quality and distribution of particle concentration, temperature, relative humidity, flow pattern and system construction.

The air conditiong and ventilation system for cleanroom which comply the medical and technical requirements is one the main aspects to improve public health services.

2. OPERATING THEATER

Operating room and operating theater are the special room which faciltitaed with some medical equipments to do some operations for the patient. Operating room is catagorized as cleanroom based on the guidelines and standards such as from US Federal Standard 209E (cancelled on November 29, 2001), BS 5295 and ISO 14644 Part 1 which can be defined as enclosed room where the airborne particle concentrations are controlled for a specific limit.

3. VENTILATION

The 100% fresh air system ventilation is normally required for health care facilities especially for cleanroom or operating theater. Air conditiong system could contribute to spread micro organisms. Normally in the healthcare air conditioning systems especially in cleanroom is equipped with some air filter with efficiency from 30%, 90% and 99.7% (HEPA). Air flow pattern inside the opearting room should flow from laminar flow canopy downward to operating table and then flows into return air grille and door. It is necessary to protect air change inside operating room with other rooms around the building. The air change factor is important for controlling temperature, relative humidity, to exhaust the anestetic gases dilluted in air, to reduce and remove bacterial contamination and also to control air movement in the mini zone, micro environment and sterilized zone.

ASHRAE has generally recommended for air ventilation in the cleanroom as follow : air change per hour between 20-30 times, air circulation inside the room is 80% of intake air volume, using filter with 90% and 99.7% efficiency which can filter particle with size 0.5 micron, positive air pressure inside the room 12.5 Pa (5 cm H_2O), relative humidity 40%-60% and inside room temperature around 20 $^oC \div 24\ ^oC$.

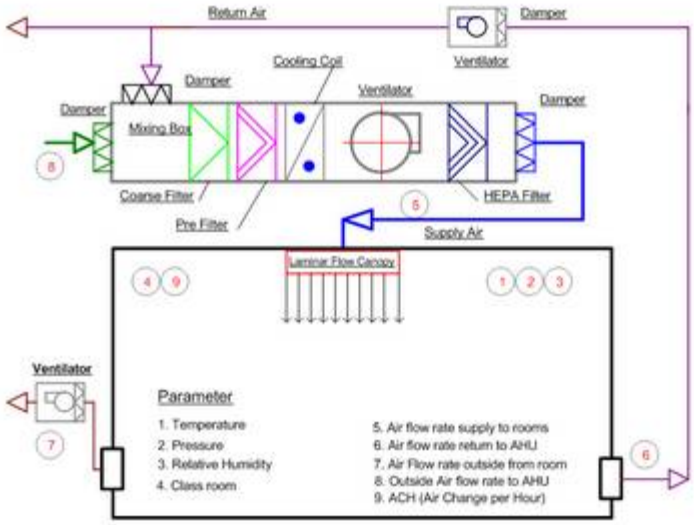

Figure 1. Typical Air Distribution system for Operating Theater

4. AIRFLOW MODELING

Flovent is 3D software using finite element method for *Computational Fluid Dynamics* (*CFD*) applications, developed by *The Mechanical Analysis Division of Mentor Graphics Corporation* from *United Kingdom* (former *Flomerics*).

This software usually uses as a simulation tool in the engineering design processes including heat transfer and fluid flow.

In air conditioning and ventilation system, Flovent could be used for temperature distribution optimization and contaminant control inside and outside the building. Air flow modelling could help the designer of air conditioning system for performance prediction of the air flow pattern in the clean room before the construction, the effect of room change architectural design and sufficient air change inside the room.

5. CASE STUDY

The temperature dan velocity distribution inside the operating room in one of the hospital in Jakarta is simulated by Flovent V7 with the following data :

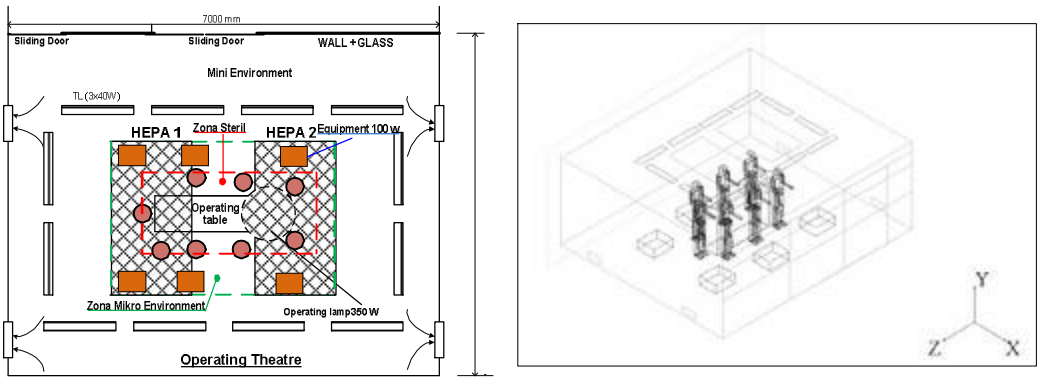

Figure 2. Operating Theater sketch and Model Visualisation

a) Room Dimension and Material
Operating room is located in the ground floor with volume 7 m x 6 m x 2.8 m.

Table 1. Dimension and item Operating Theater

Item	unit	Dimension
operating table	1	1900 mm x 500 mm x 1200 mm
operating lamp	1	300 mm x 300 mm x 100 mm
Doctor, nurse and patient	8	170 mm (5 ft 7 in) weight 77 kg (170 lb)
Overhead Lights	12	1000 mm x 200 mm
HEPA	2	2100 mm x 1200 mm
Exhaust	4	600 mm x 200 mm
others equipment	6	500 mm x 500 mm x 500 mm

b) Supply Air
Using 2 HEPA filters with the following specifications 1500 m^3/h with 25 ACH at temperature 20 °C

c) Exhaust
Four Exhaust with capacity 588 m^3/h.

d) Person
Three medical doctors, one anasthesist, one instrumention person, two nurses assistent (instrument), and one patient. Every person has average heat source 170 W

e) Lamp
Operating lamp 350 W and TL lamp 3 x 40W

f) Other electronic equipments
6 unit with 100 W/equipment

g) Operation table
Material alumunium

h) Cooling load estimation
Cooling load calculation is important to predict and estimate the heat generation inside the room and to select refrigeration equipments.

Table 2. Estimated of Cooling Load

item	unit	source (watt)	total source (watt)
Operating lamp	1	350	350
Overhead Lights	12	120	1440
People	8	170	1360
Others equipment	6	100	600
Total Cooling Load			3750

6. SIMULATION ANALYSIS

The initial data are collected from the operating room actual condition with assumption that outlet air distribution laminar flow canopy with unidirectional air flow and air temperature is same in all part of the room. Supply air intake flows into laminar flow canopy is designed for 3000 m^3/h at constant temperature 20°C.

From the above data, the simulated air flow velocity and air temperature are shown in the Figure 3 and Table 3.

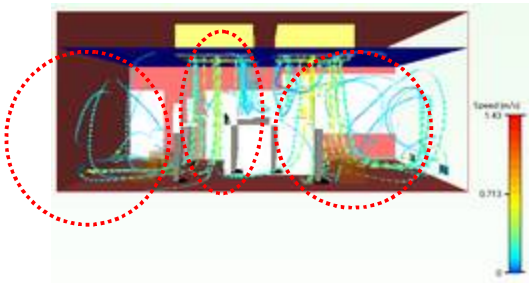

Figure 3. Flow distribution at first trial

Table 3. Mean temperature, pressure and velocity at the first trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur awal	20,5	20,9	21,4	22	23	23,3	23,2	22,6	21,8	21,6	22,03
pressure awal	39	39	38,9	38,9	38,9	38,9	38,9	39	39,1	39,1	38,97
velocity awal	0,275	0,175	0,107	0,0918	0,318	0,355	0,397	0,412	0,325	0,282	0,27

For the first simualation, the data are based on the actual conditions in the sample hospital with supply fresh air at 20^{o}C and debit 3000 m^{3}/h, with power for lighting 120 W.

The simulation result of air flow outside the laminar flow canopy (LFC) is shown that there are 3 parts of the flows : *non uni directional air flow* and even tends to form a *mixed flow* near the wall. It is because of the change of air flow after disturbance with some obstacles such as person, medical equipments, operation table, which cause turbulence around the wall. This phenomenon is possibly caused by the long distance between the two LFC and also mixed air flow. The outlet air velocity from LFC is around 0.30 ÷ 0.35 m/s and near the operating table around 0.27 m/s. Outlet average air temperature from LFC 20^{o}C and near the table is 22^{o}C. It is also shown that the pressure is 38.97 Pa inside the room but it does not comply with ASHRAE Standard which is 12.5 Pa at positive pressure.

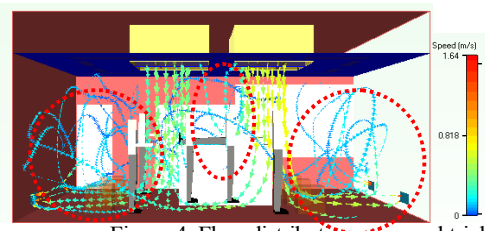

Figure 4. Flow distribution at second trial

Table 4. Mean temperature, pressure and velocity at the second trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur 1	20,5	20,9	21,6	22,3	22,9	23,1	23	22,9	22	21,9	22,11
pressure 1	28,9	28,9	28,9	28,9	28,9	28,9	28,9	28,9	29	29	28,92
velocity 1	0,29	0,185	0,11	0,091	0,215	0,216	0,297	0,329	0,33	0,37	0,24

In the second simulation we increased the outlet flow from exhaust and only 10% of return air. The result shows that air temperature and velocity tend to same as the first simulation but the pressure becomes 28.9 Pa. It is because the opening exhaust incraeses but not yet complied the ASHRAE Standard.

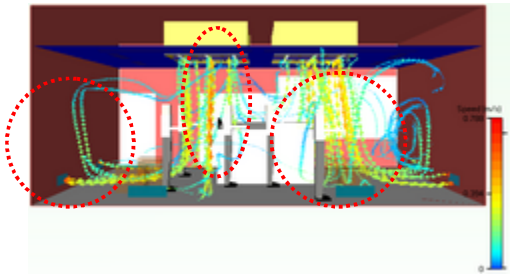

Figure 5. Flow distribution at third trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur 2	21	21,2	21,4	21,7	21,9	22	22,5	22,8	24,3	24,1	22,29
pressure 2	4,02	4,02	3.99	3.99	3.98	3,97	3,97	3,97	3,97	3,97	3,98
velocity 2	0,38	0,2081	0.18	0,172	0,19	0,215	0,32	0,153	0,104	0,09	0,20

Table 5. Mean temperature, pressure and velocity at the third trial

In the third simulation with increasing exhaust air flow and only 10% of return air and add the number of exhaust into 8 unit. It is shown that the flow is much better than before but the flow pattern is still *"non uni directional air flow"*, and average pressure inside the room decreases of 3.98 Pa.

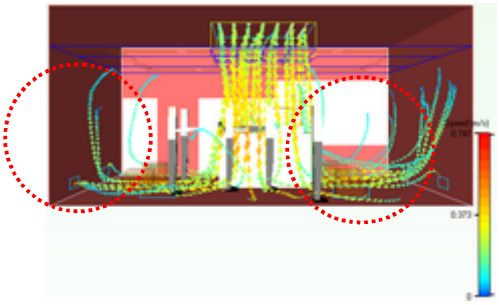

Figure 6. Flow distribution at fourth trial

Table 6. Mean temperature, pressure and velocity at the fourth trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur 3	20	20,1	20,8	20,5	21	21,1	22,1	22,3	25	24,4	21,73
pressure 3	72,7	72,7	72,6	72,6	72,6	72,6	72,6	72,6	72,6	72,6	72,62
velocity 3	0,29	0,247	0,19	0,192	0,2	0,218	0.31	0,208	0.189	0,106	0,21

In the fourth simulation with 1 HEPA, exhaust air flow with 20% return air and increasing exhaust into 8 unit. It shows that the flow pattern is *"uni directional air flow"* on the table surface where as the sterilzed place but still forms *"non uni directional air flow"* and average pressure 72.62 Pa.

Figure 7. Flow distribution at fifth trial

Table 7. Mean temperature, pressure and velocity at the fifth trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur 4	20	20,1	21	20,9	21,1	21,4	22,2	22,4	24,8	23,4	21,73
pressure 4	17,6	17,7	17,7	17,7	17,7	17,6	17,6	17,6	17,7	17,6	17,65
velocity 4	0,32	0,303	0,19	0,195	0,17	0,186	0,21	0,178	0,2	0,12	0,21

The fifth simualtion with 1 HEPA and exhaust air flow increasing, 10% return air and number of exhaust 4 unit. It is shown that flow pattern is "*uni directional air flow"* at the surface of the operation table and in the right hand side of the figure, but in the left "*non uni directional air flow"* and average pressure inside the room of 17.65 Pa where the ASHRAE Standard is 12.5 Pa.

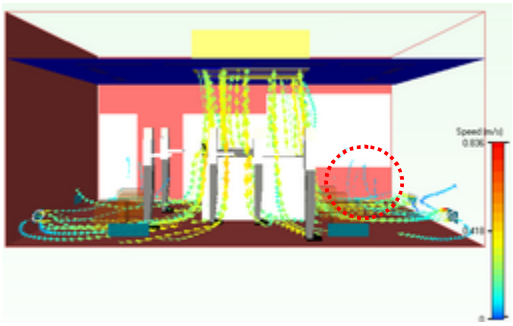

Figure 8. Flow distribution at sixth trial

Table 8. Mean temperature, pressure and velocity at the sixth trial

sumbu x	2,8	3	3,2	3,3	3,5	3,6	3,8	4	4,2	4,3	rata-rata
temperatur 5	20	20,1	20,3	20,4	20,9	21	22	22,3	24,2	24	21,52
pressure 5	11,7	11,8	11,8	11,8	11,8	11,8	11.8	11,7	11,7	11,7	11,76
velocity 5	0,302	0,245	0,2	0,196	0,301	0,219	0,301	0,205	0,57	0,134	0,27

In the sixth simulation with 1 HEPA and exhaust air flow, 10% return air and exhaust 4 unit. It shows that the flow pattern is "*uni directional air flow"* at all part of the room and average pressure 11.76 Pa as follows the ASHRAE Standard.

7. CONCLUSION

Model visualization and simulation using Flovent V7 as a CFD Model shows that pressure and temperature distribution in the operating room are not well confirmed with the requirements of any standard. The appropriate selection of the design parameters such as temperature, velocity and volumetric flow of fresh air have to be clearly defined to ensure accurate results.

The influence of difference design parameters on volumetric flow of supply air, layout of HEPA filter and position and number of return air grille can have a major impact on the air flow distribution pattern. It has been shown from the last trial that the flow has a type of unidirectional air flow.

ABSTRACT

The paper presents the study on a CAPP(computer-aided process planning) system that suggests optimal tool orientation with which positional five-axis machining of sculptured surface in a molding die manufacturing. The positional five-axis machining is operated on a five-axis NC machine, with the cutting tool orientation being fixed during the cutting operation. This type of machining operation is effective in machining separated areas (geometric features) on a molding die. The optimal tool orientation for a machining area is obtained through two steps: (1) the local optimal tool orientation on each cutter-contact point is obtained, which is based on the machinability condition, then the angular range of global tool orientation is obtained by the union of the local angles; (2) the tool length map for the indicated global tool orientation range is computed via interference check (collision and stroke-over), and the tool orientation with the minimum tool length is selected as an optimal tool orientation. The research was implemented on the basis of a commercial CAM system(I-Master) in the Windows XP environment, and was tested for positional five-axis machining of molding dies for automotive parts in a local company.

Keywords

Positional 5-axis machining, optimal tool orientation angle, CAPP

1. INTRODUCTION

Five-axis machining of molding dies has more benefits such as fewer set-ups and better machining accuracy resulting from shorter tool length [1,2]. It may be classified into positional five-axis and continuous five-axis depending on cutter orientation change (see Figure 1). The positional five-axis machining is a fixed-axis machining on a five-axis NC machine with the cutter-axis tilted, while the continuous five-axis machining is the conventional simultaneous five-axis machining.

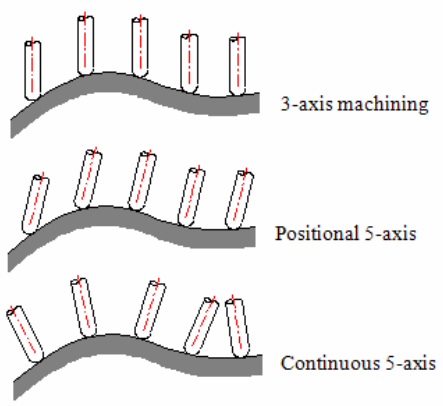

Figure 1: Machining types

Machining process of a molding die consists of several unit machining operations(UMOs), which is a combination of conventional three-axis, positional and continuous five-axis machining operations. An NC programmer determines most suitable machining type to each machining feature area.

Simultaneous five-axis machining can adaptively change cutting speed and tool posture at each CC(cutter contact) point by continuously varying tool-orientation, but it requires somewhat complicated interference avoidance and computing time. It should be noted that the positional five-axis machining is well applied to machining of molding die surface, due to consistent tool posture and simple interference avoidance compared to continuous five-axis machining [3].

According to a commercial CAM software developer [4], distinct machining types on a five-axis machine are: 73% of positional five-axis machining, 22% of multi-face three-axis machining, and 5% of continuous five-axis machining. It can be said that continuous five-axis machining operation using a five-axis machine may well be applied to where fixed-axis

machining is either infeasible or inefficient.

The tool length should be as short as possible without interference (e.g., collision) in order to enhance machining accuracy and surface finish, due to tool deflection and chattering. In positional five-axis machining of a certain surface area, it is imperative to select a tool orientation that minimizes tool length of the applied cutter but also causes no collision. A few existing commercial CAM systems provide such functionality, but requires complicated user interactions or fairly much computing time.

The research developed a system that computes the optimal tool-orientation with minimum tool-length for a ball-end milling case, given a surface area to be machined. Section 2 describes the key procedure, followed by an illustrated case in Section 3.

2. CONVENTIONAL PROCESS

A conventional process to determine the tool orientation and length by which a certain surface area is to be machined is described in figure 2. Tool orientation is usually designated by setting up a local coordinate system in a commercial CAM system. As shown in the figure, the process requires NC programmer's insight and experience, tool-path generation and collision avoidance through interactive as well as iterative operations.

The similar process should be repeated for each feature surface that needs positional five-axis tool-path generation, which is tedious and time consuming job. In addition, it does not always generate optimal tool orientation with minimum tool length, which may result in non-optimal machinability.

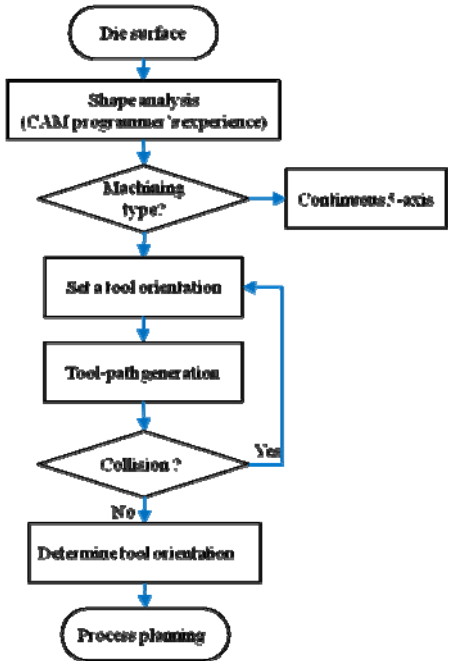

Figure 2 : Conventional process of work coordinate set-up

3. PROPOSED PROCESS

3.1 Overall view

Figure 3 depicts overall procedure of the proposed process, which is summarized as follows:

< Phase 1 >
(1) Sampling CC points on the defined surface area,
(2) For each CC point, determine preferred tool-orientation range,
(3) Obtain overall preferred tool-orientation range for all CC points,
< Phase 2 >
(4) Select feasible tool-orientation range from the preferred tool-orientation range for all CC points by checking stroke-over and collision,
(5) Determine the optimal tool-orientation angle with minimum feasible tool-length.

In the 1st phase, the preferred tool-orientation range for each CC point is determined based on a previous study which considered cutting force and surface finish in a ball-end milling case [5]. In the 2nd phase, the feasible tool-length for a specified tool-orientation is computed via interference check (i.e., stroke-over and collision check), the tool-orientation with minimum feasible tool-length is selected as an optimal tool-orientation. The collision check process considers cutter shank, tool holder, machine spindle, and machine table. Following sections describe more details about the process.

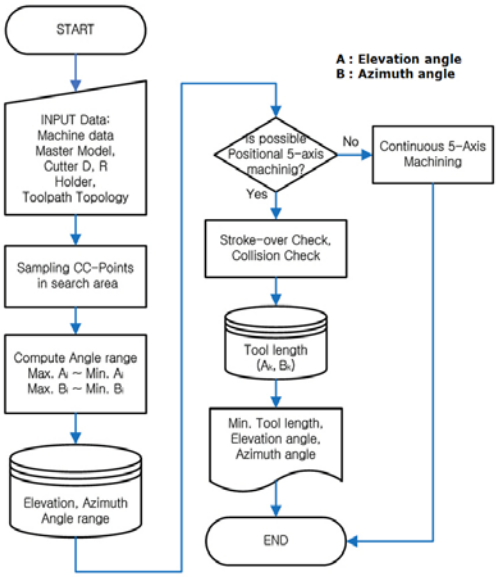

Figure 3 : Overall procedure

3.2 Phase 1: preferred tool-orientation

The 1st phase of the overall process determines preferred range of acceptable tool-orientation by aggregating each preferred tool-orientation at a single CC point. A previous study [5] depicted that the acceptable tool inclination angle (ball-ended milling) at a CC point should be 15˚ to 45˚ measured from the surface normal, which is based on cutting force and surface finish. This concept can be represented by a cone (see figure 4), since the applied cutter is a ball-ended mill. Being measured in the local coordinate system of a CC point, the tool inclination angle is converted to tool-orientation of the global coordinate system, which is represented by elevation and azimuth angles (see figure 5). The elevation and azimuth angles (A,B) corresponding to a tool inclination vector **n'** is represented by equation (1).

$$\text{A (elevation angle)} = a\tan 2(\sqrt{n'^2_x+n'^2_y},\ n'_z) \quad \text{(1a)}$$

$$\text{B (azimuth angle)} = a\tan 2(n'_y,\ n'_x) \quad \text{(1b)}$$

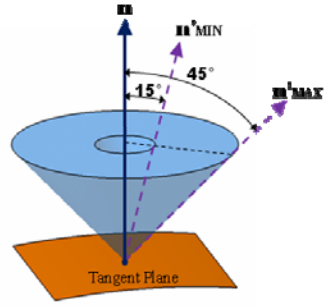

Figure 4 : Local acceptable range of tool-orientation

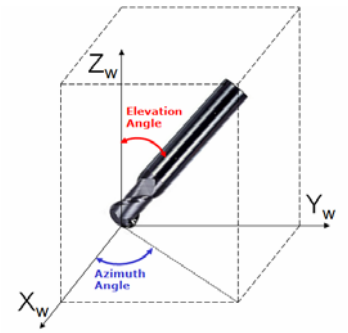

Figure 5 : Elevation and azimuth angles to define tool-orientation

The overall range of acceptable tool-orientation for all CC points is obtained by summing up each tool-orientation range of a single CC point, which is represented by ranges of elevation and azimuth angles such as $(A,B)_{MIN}$~$(A,B)_{MAX}$. Figure 6 depicts a schematic diagram of the phase 1.

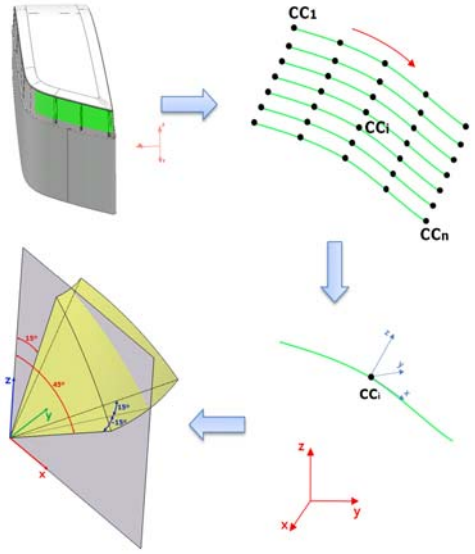

Figure 6 : Overall preferred range of tool-orientation

3.3 Phase 2: optimal tool-orientation

The overall preferred range of tool-orientation $(A,B)_{MIN}$~$(A,B)_{MAX}$ obtained in the 1st phase can be thought of as an initial filtering out process for efficient computation. The 2nd phase determines the optimal tool-orientation by computing minimum feasible tool-length at each tool-orientation among the given preferred range. The procedure is summarized as follows:

(1) For a tool-orientation $(A,B)_k$ among the overall range $(A,B)_{MIN}$~$(A,B)_{MAX}$, compute feasible tool-lengths for all CC points, and find the minimum tool-length L_k,
(2) Find the minimum tool-length L_m at $(A,B)_m$ among L_k, and set the optimal tool-orientation to be $(A,B)_m$.

The feasible tool-length at a tool-orientation $(A,B)_k$ at CC point is obtained via interference check including machine axis stroke-over, machine collision and tool collision. The machine axis stroke-over can be verified by considering inverse kinematics of the target NC machine. The machine and tool collision consider collisions between components such as machine spindle, table, cutter shank, and tool holder. The tool-length computation is based on the previous study [6]. Figure 7 describes overall procedure of phase 2.

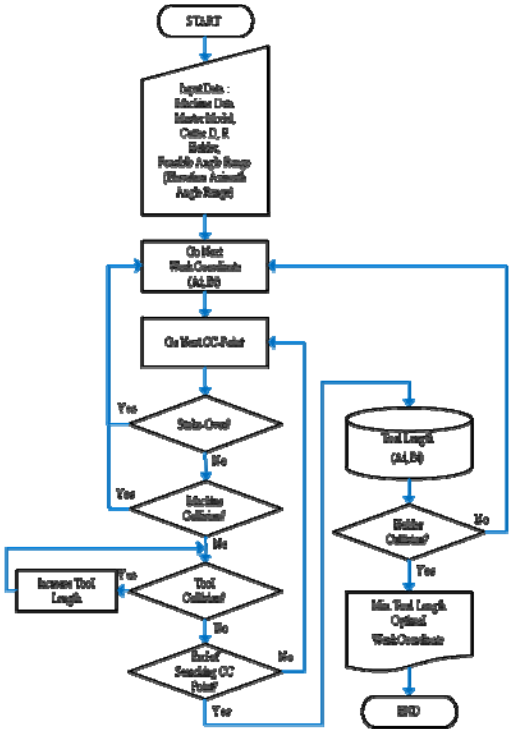

Figure 7 : Search of the optimal tool-orientation

4. ILLUSTRATED EXAMPLE

The proposed system has been implemented by Visual C++ and OpenGL in Windows XP environment. Figure 8 shows an example molding die surface, where the red colored face is the machining area. Figure 9a depicts preferred tool-orientation range (in elevation & azimuth angles), figure 9b illustrates the optimal tool-orientation.

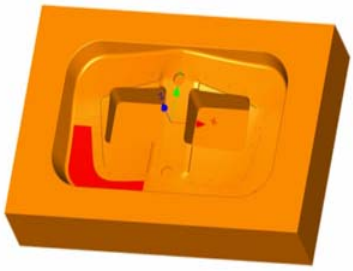

Figure 8 : Molding die surface and machining area

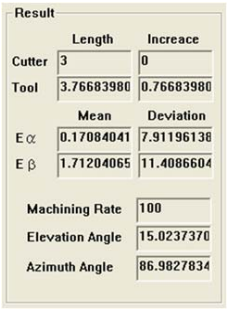
(a)



(b)

Figure 9: Preferred range of tool-orientation and search result

5. DISCUSSION

The research has developed a system that determines the optimal tool-orientation for positional five-axis machining of molding die surface. It provides a CAM programmer with an optimal work coordinate system and minimum tool-length information, thereby enabling objective and efficient process planning for five-axis machining tool-path generation.

It should be noted that the tool-length is not the only factor affecting machinability. As a previous study depicts [5], the tool inclination angle itself is an imperative machining condition. Therefore, another criterion including tool-length and tool inclination angle can be considered as an error function at a CC point as follows:

$$\varepsilon_T = \omega_\alpha\left(\frac{\varepsilon_\alpha}{\Delta a}\right) + \omega_L\left(\frac{\varepsilon_L}{\Delta L}\right);$$

where ε_α = angular deviation of inclination angle from given value,
ε_L = tool-length deviation (L_i-L_0, L_0 = minimum tool-length),
ω_α, ω_L = weighting factors,
$\Delta\alpha$, ΔL = scaling factors.

Considering the above combined error function at each CC point should be dealt in the further research.

ABSTRACT

One of biofuel which is possible to be used as a replacement fuel and as a mixture for gasoline is ethanol, due to its characteristics similarity with gasoline. This research purposed to know the performance of RON 88 gasoline and ethanol fuel mixture (bioethanol) at 20% (E-20) ethanol concentration on 4 stroke engine.

The research started with conducting the physical-chemical characteristic test of RON (Research Octane Number) 88 gasoline and bioethanol E-20. And then, the performance test conducted to those fuel using two motorcycles on 5000 km road test.

There were two cycles of 5000 km road test for each motorcycle, using RON 88 gasoline at the first cycle as reference and using bioethanol E-20 at the second cycle. In the beginning of each cycle, the overhaul and engine spare part replacement for each motorcycle were conducted to optimize the motorcycles engine. In each cycle, at 2500 km cover distances, the performance test to measure acceleration power, fuel consumption, and emission rate were conducted using chassis dynamometer test engine.

The result showed that the use of bioethanol not only affected the physical-chemical characteristic of gasoline but also affected the fuel performance test. The use of bioethanol E-20 had increase the fuel consumption by 27.15%. For the emission test, the use of bioethanol had decrease the CO emission by 35.80%. The CO_2 emission was also decrease by 22.27%. The hydrocarbon (HC) particulate emission was decrease by 18.5%, while the NOx emission was decrease by 53.7%. The bioethanol E-20 performance also showed by the acceleration and power, that in general, the use of bioethanol had decrease these two parameters of the motorcycles tested.

1. INTRODUCTION

During the past five years, Indonesian oil production has been declining due to the natural decline of oil reservoirs on production wells. On the other hand, the increase of Indonesian population has intensified the need of transportation means and industry activities that implies to the rise of national refined fuel oil (BBM) consumption and demand. In order to meet the fuel demand, the government has to import some fuel. According to the Directorate General of Oil and Gas, the import of petroleum keeps rising significantly from 106.9 million barrels in the year 2002 to 116.2 million barrels in 2003 and 154.4 million barrels in 2004 [1].

By the end of 2007, fuel consumption is estimated to have reached 1.189 million barrels per day and will continue to increase in line with the population growth rate reached 1.6% per year. Currently, the highest fuel consumption in Indonesia is in the transportation sector. Data from the Ministry of Energy and Mineral Resources (DESDM) as in Table 1 shows the consumption of gasoline for transportation in Indonesia

has a tendency to continue to increase in the period 2000 – 2007 [2].

Table 1 : Indonesian fuel consumption in the year 2000-2007

Year	Fuel Consumption (kL)
2000	12.059.026
2001	12.705.861
2002	13.323.304
2003	14.211.145
2004	15.928.928
2005	16.959.594
2006	17.068.237
2007	17.878.569

By means of those conditions, the government has disseminated a plan to reduce the dependence of Indonesia upon refined fuel oil by introducing President's regulation of Number 5, 2006 pertaining to National Energy Policy to develop an alternative energy as a substitution for refined fuel oil. Despite the fact that the policy stresses on the use of gas and coal, this policy also states the use of renewable energy resources such as biofuel as an alternative energy to replace fossil fuels. The Indonesian government has also given a serious concern of biofuel development by issuing President Instruction of No. 1, 2006 on 25 January 2006 about providing and using biofuel as an alternative energy.

In this study, fuel that examined is bioethanol for gasoline substitution. Bioethanol is an alcohol compound, in this case ethanol (C_2H_5OH), which is made from the fermentation agriculture products, so that become the renewable energy. Indonesia is rich with natural resources to produce ethanol, for example, sugar cane, maize, and cassava. We must learn this possibility so that it can produce profit as big as for the welfare of the Indonesian people.

From previous studies that have been done show that the performance of motorcycle using alcohol as fuel is close to the performance of the motorcycle using fuel gasoline [3]. The research purposed to determine the performance (acceleration, power, specific fuel consumption, and exhaust emissions) of gasoline RON 88 mixture with 20% ethanol (bioethanol) E-20 when used on a 4 stroke engine motorcycle.

2. EXPERIMENTAL METHODS

Research begins with the physical-chemical characteristics of RON 88 gasoline, the ethanol FGE with purity 99.5% volume, and gasoline-ethanol mixture in the percentage of 20% ethanol (E-20). Physical-chemical characteristics tested include distillation, water contents, oxygen contents, copper strip corrosion, oxidation stability, Reid vapor pressure, density, and octane number. Testing method used in this research accordance with the specification of gasoline in Indonesia, which is set by the government.

Further test is the 4 stroke engine motorcycle (as seen in Table 2) performance test using a static test bench chassis dynamometer. Prior to the performance test, those motorcycle were over haul and there were replacement of spare part to the new one. The expectation was the engine condition would have optimal performance [4]. After finished all the tests, the road test was been done for each motorcycle as far as 5.000 km.

Table 2 : Technical specification of fuel gasoline vehicles

No.	Description	Motorcycle 1	Motorcycle 2
1.	Engine Type	4 Stroke	4 Stroke
2.	Manufacturing Year	2005	2005
3.	Volume of Cylinder	125	110
4.	Capacity of Lubricant	0.8	0.8

Road test for each motorcycle consists of 2 cycle. First cycle, motorcycle is using RON 88 gasoline as its fuel. Second cycle, motorcycle is using bioethanol (E-20) as its fuel. After the distance cover 2.500 km, there were performance tests for both motorcycles using chassis dynamometer test bench.

***)** Indonesian RON 88 Gasoline Spesification [5]

Performance test conducted in the chassis dynamometer that has following technical specifications.

- Brand: Dynojet
- Type: 250i
- Year: 2004

Testing equipment with the above parameters is used to measure speed and acceleration, whereas specific fuel consumption (SFC) and emission levels conducted in the laboratory performance of Applications Product Research Program Group, LEMIGAS. Specific fuel consumption and emissions tests were conducted on the condition of the idle position (neutral gear).

Specific fuel consumption method test is explained as follows. Motorcycle switched on idle position. Measure the fuel that will be tested with a 100 mL cylinder graduate. Use a fuel hose to connect the cylinder graduate with motorcycles carburettor. Note the time that needed to make 100 mL of fuel in the cylinder graduate out. Specific fuel consumption is calculated with the formula:

SFC (L / hr) = 0.1 x 3600/time (seconds) [4]

Emission test conducted in a way to measure the actual CO, CO2, HC, and NOx in the motorcycle exhaust output using *Autocheck* exhaust gas analyzer.

3. RESULTS AND DISCUSSION

3.1 Physical-Chemical Characteristics

In Table 3 it can be seen the physical-chemical characteristics of RON 88 gasoline, bioethanol E-20, and pure ethanol. The distillation parameter of 50% distillate (T50) of E-20 did not meet the specifications set by the government. T50 distillation effect on the motorcycle acceleration. Since the T50 of E-20 was lower than gasoline, it was predicted that in the performance test, motorcycle using bioethanol would have lower acceleration than the one using RON 88 gasoline [6].

Furthermore, oxygen content exceeds the E-20 specification because ethanol is one of the oxygenat which can increase the amount of oxygen in the fuel. The presence of oxygen will affect the formation of deposits in the combustion chamber because the oxidation reaction will occur and resulted oxide in the form of a deposit. The formation of this deposit can only be viewed with the rating engine which is not done in this research.

In addition, oxidation stability is also outside of specifications related to the existence of oxygen in E-20. This states that the bioethanol is easier to oxydize than gasoline. The result is the same as the influence of high oxygen contents, which is the formation of deposits in combustion chamber [6].

On the other hand, the addition of ethanol gives a benefit as seen in the increasing of gasoline octane number. With the addition of 20% ethanol in RON 88 gasoline, research octane number of bioethanol become 96,3 equivalent to RON 95 gasoline. The increase of octane number can occur because ethanol has a higher octane number than RON 88 gasoline, which is > 118.

3.2 Acceleration

3.2.1 Acceleration Rate

Acceleration rate is measured from minimum torque (gear 1) until the motor reach maximum torque (gear 4) at a certain speed. Motor acceleration is measured by using chassis dynamometer test bench. The results showed 4.48% decrease in the acceleration rate. This is shown by Figure 1.

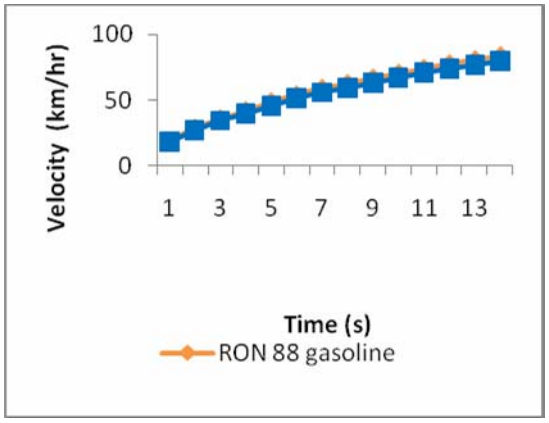

Figure 1 : Effect of bioethanol E-20 to acceleration time

3. 2. 2 Acceleration Power

Results from the chassis dynamometer test also indicate the decreasing of acceleration power in the motorcycle. The effect of bioethanol E-20 mixture in RON 88 gasoline decreased the acceleration power 2.24 % as showed in Figure 2.

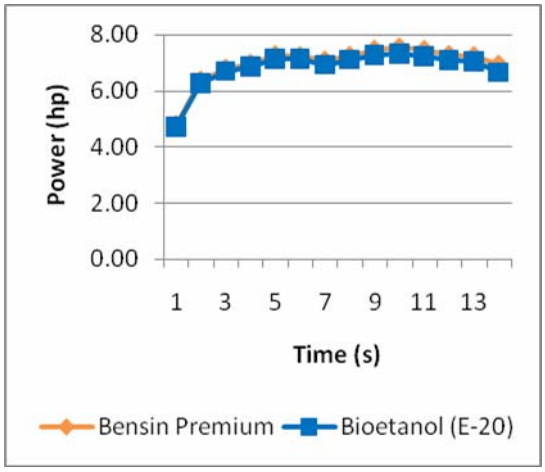

Figure 2 : Effect of bioethanol E-20 to acceleration power

3.3 Fuel Consumption

To see the effect of bioethanol (E-20) as a motorcycle fuel compare to RON 88 gasoline, the fuel consumption measurements carried out on the idle condition. This is to avoid the influence of external factors that can reduce the measurement accuracy. The results showed that the use of bioethanol (E-20) as a motorcycle fuel increase 27.15% consumption when compared to RON 88 gasoline. This is shown by Figure 3.

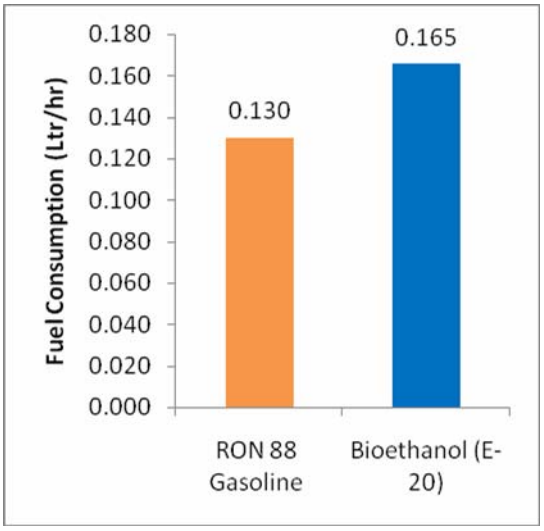

Figure 3 : Effect of bioethanol E-20 to specific fuel consumption

One of the causes of increased fuel consumption when using bioethanol is the calorie of bioethanol is lower then the calorie of gaoline. In addition, there are differences of physical-chemistry characteristics of the fuel such as viscosity and distillation.

3.4 Exhaust Gas Emissions

Exhaust gas emission tests on motorcycle were conducted on the condition of the idle position. Parameter of gas emissions that are measured consist of carbon monoxide (CO),carbon dioxide (CO_2), hydrocarbon (HC), and nitrogen dioxide (NOx). From the results of the test indicates the use of bioetanol gives a positive effect on the environment. There is a decline of bioethanol's exhaust gas emissions compared to RON 88 gasoline. CO emission is lower 35.8%, CO_2 emission is lower 22.26%, HC is lower 18.5%, and NOx is significantly decrease to 53.7%. This is shown in the Figure 4 to Figure 7.

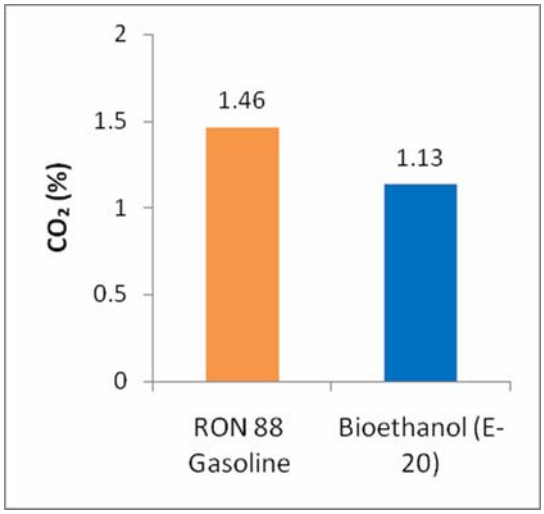

Figure 4 : Effect of bioethanol E-20 to the decline of CO_2

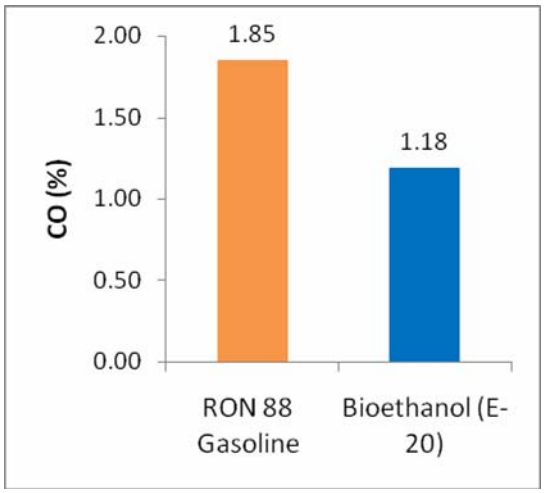

Figure 5 : Effect of bioethanol E-20 to the decline of CO

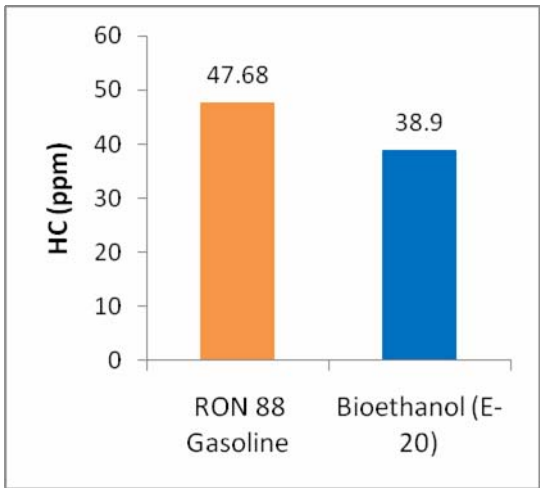

Figure 6 : Effect of bioethanol E-20 to the decline of hydrocarbon

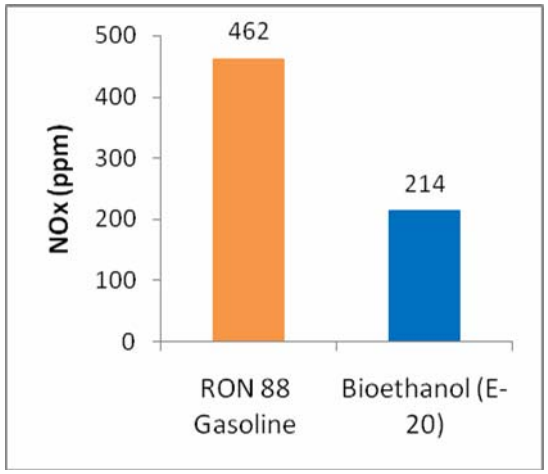

Figure 7 : Effect of bioethanol E-20 to the decline of NOx

4. CONCLUSION

1. Some parameters of phisycal-chemical characteristic of RON 88 gasoline were changed when mixed with ethanol:
   a. Octane number increased
   b. Distillation at T50 decreased
   c. Oxygen content increased and related to the decreasing of oxidation stability

2. Effect of ethanol addition in RON 88 gasoline to motorcycle performance can be defined into three parameters:
   a. Motorcycle acceleration :
      - Acceleration rate decreased to 4.48%
      - Acceleration power decreased to 2.24%
   b. Specific fuel consumption of motorcycle using E-20 is 27.15% higher than RON 88 gasoline.
   c. Exhaust gas emissions of E-20 compare to RON 88 gasoline is lower 35.8% of CO, 22.26% of CO_2, 18,5% of HC, and 53.7% of NOx.

ABSTRACT

Due to declining of oil and gas production and increasing the demand, in 2006, the Government of Indonesia issued Regulation Number 033/2006 to encourage the development of Coalbed methane (CBM) for alternative energy sources. Regarding to this issue, some specific terms and conditions must be applied for the CBM contract, therefore, an economic calculation model is needed to be used as a reference in evaluating or appraising CBM working area blocks in bid. In this study, a suitable model for CBM Production Sharing Contract (PSC) scheme is developed by modifying appropriate terms and conditions in economic model for oil and gas contract. CBM development scenario in South Sumatra is used for an example case with two base scenarios. In this case, total gas production during 23 years of operation is estimated to be 609,000 MMScf, while total expenditures is about US$ 745,130,000. In South Sumatra - Case I, where First Trenched Petroleum (FTP) is set 5% (shareable), Cost Recovery Ceiling (CRC) is 100% for 1-5 years and 90% for 6-end years, Split (after tax) is 55:45, Tax 44%, and Price of Gas is US$ 4.3 /MMBTU, the results show that Internal Rate of Return (IRR), Pay Out Time (POT), Net Present Value (NPV) @ 10% p.a and % profit for contractors are 12.9%, 15.4 years, US$ 44,000,000 and 41.87% respectively; while NPV @ 10% p.a and % profit for Government are US$ 160,000,000 and 58.13% respectively. Furthermore, our sensitivity analysis shows that yearly gas production and gas price are very sensitive economic parameters upon the change of IRR, NPV, and Government take, while Split and CRC are sensitive policy parameter upon the change of IRR and Government take. In order to make IRR close to 20%, the only way is to increase the wellhead price gas to be US$ 7.00/MMBTU. No policy parameters can be used to obtain this value.

1. INTRODUCTION

Indonesia possesses in place CBM resources potential to a number of 453 TCF [1,2,3]. Assuming 10% of this value, or as much as 45 TCF, can be produced, Indonesia will not be bothered anymore with the issue of increasing energy demand. Therefore, to boost the development of CBM for alternative energy sources, the Government of Indonesia issued Regulation Number 033/2006.

The regulation for CBM production is similar to the one applied in the production of oil and conventional natural gas, using a production sharing contract (PSC) scheme. The only difference is that in the CBM development, specific characters such as cost and longer time needed for production need to be considered. Therefore, an economic calculation model is needed as tool for the government to evaluate and to estimate the value of the blocks offered. This model can be developed from an economic calculation model usually used for conventional natural gas by modifying the model with specific requirement and characteristics for the CBM production. This model should be able to simulate the best scheme for the CBM production sharing contract that can satisfy both government and investor.

2. METHODS OF STUDY

The scheme of the study can be illustrated in Figure 1, and described as folllows.

a. Collecting data of typical CBM dewatering and gas production, estimated cost parameters which has been evaluated based on a pilot project. These data include the data obtained from the CBM field development in South Sumatra [4,5]. The cost parameters considered in this study include:
   - Number of wells
   - Annual gas production
   - Water gas production

- Production facilities (well facilities, piping network, future plan (compressor, process facilities, etc)
- Project investment cost, including:
  - Well drilling and related facilities
  - Gathering station
  - Low pressure compressor
  - Production tools and gas sales compression system
  - Tangible, intangible, capital and non capital project cost applied to the *PSC* accounting
- Depreciation schedule for tangible and capital cost according to *PSC*
- Operating Cost including:
  - Well maintenance
  - Production cost
  - Processing unit
  - Water treatment and Compression/ gas transportation

b. Reviewing the above data, and selecting appropriate production and development cost parameters
c. Modifying the model from oil and gas economic calculation by using appropriate parameters applied for CBM production
d. Economic evaluation of CBM field development including IRR, POT, and NPV.
e. Perform sensitivity analysis of economic calculation to obtain the most affecting variables upon economic parameters.
f. Making conclusions an recommendations

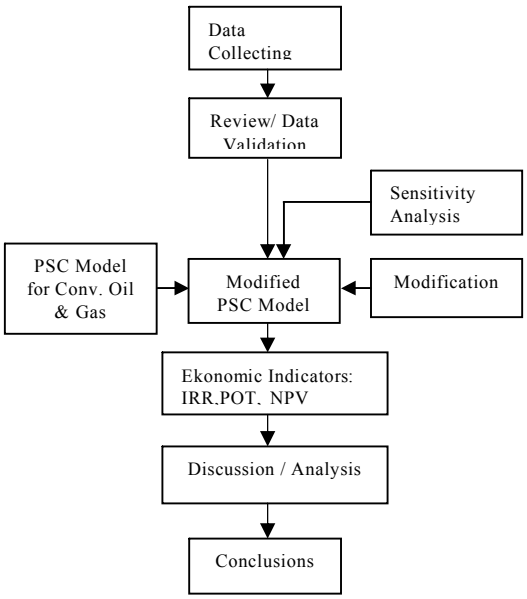

Figure 1. Research methods Scheme

3. RESULTS

Based on the cost components usually encounter in conventional gas development together with the data obtained from the CBM, the CBM field development, its production facilities and input data used in the economic evaluation can be described as follows.

3.1 Field Development

In this study, 367 wells will be drilled in two steps of development. In the first step, about 210 wells will be drilled. Pilot wells will also be used as a part of development system. Horizontal pilot scale wells will also be made in the development step. The main target of this development step is to obtain the optimum production.

In the second step, the number of wells is expanded. The main goal of this step is to maintain production rate during the contract time. The addition wells are around 10 to 24 wells annually. Horizontal drilling and special treatment might be applied to support gas production and sale.

Production Facilities

The CBM production facilities are slightly different from the conventional gas production. These include:

- *Well facilities*
  Well production system consists of *PCP screw* type pump moved by electrical motor set on surface to produce water from tubing and gas from annulus. This pump type is selected because of four reasons: (a) big capacity, (b) intermittent, (c) resist on high gas concentration and coal flakes and (d) cheaper than other types.
- *Piping Network*
  Gas compressor at capacity of 2-3 MMSCFD is needed near the well hole and set at the gathering station. Inlet pressure is 10 to 20 psig and the outlet is 150 psig to gather gas from 10 to 20 wells to the sales point. P*olyethylene* (PE) pipe is used at low pressure section to reduce investment cost.
- *Future Plan*
  Main compressor for gas sales will be set near the field. Several clusters with the capacity of 5 to 10 MMSCFD processing gas will be set up in the project area. Each cluster will serve 20 wells.

Input Data

Input data needed in the model includes investment data, annual gas and water production

, number of wells and number of production facilites needed. Furthermore, two cases are studied based on the specified above data.

***Case* I**

In this case, the following conditions are considered:

a. *FTP* = 5 % (shared for government and contractor)
b. *CRC* = 100 % for year 1 to 5, 90% for year 6 to the end of the contract
c. *Split* = 55 : 45 (after tax)
d. *Tax* = 44 %
e. Gas and water production is shown in Table 1 and Tabel 2.
f. Wellhead gas price is US$ 4.30/MMBTU

***Case* II**

In this case, the following conditions are considered:

a. *FTP* = 10 % (only for government)
b. *CRC*= 90 % for year 1 to the end of contract, or 80% for year 1 to the end of contract
c. *Split* = 55 : 45 and 60 : 40 (after tax)
d. *Tax* = 44 %
e. Gas and water production is shown in Table 1 and Tabel 2.
f. Wellhead gas price is US$ 4.50/MMBTU or US$ 5.00/MMBTU.

3.3.1 Production Rate

Annual gas and water production are estimated based on the reservoir simulation as shown in Table 1 and Table 2 [4,5].

Table 1. Annual Gas Production Estimation (MMSCFY)

Year	Gas Production	Year	Gas Production
2008		2023	32000
2009		2024	32000
2010		2025	32000
2011		2026	32000
2012	1500	2027	32000
2013	1500	2028	32000
2014	1500	2029	32000
2015	3000	2030	32000
2016	3000	2031	32000
2017	15000	2032	32000
2018	15000	2033	32000
2019	25000	2034	30000
2020	25000	2035	26500
2021	25000	2036	26500
2022	32000	2037	26500

3.3.2 Investment Cost and Operating Cost

In general, operating cost of CBM production is higher than a conventional gas production at the early stage. This is because CBM production has longer dewatering stage (5-7 years compared to 1 year in conventional gas). After this stage, the CBM production cost is estimated US $ 0.03/MCF lower than a conventional one. Exploration cost for one well in CBM is estimated about US$ 400.000 [6,7], lower than the one in oil or conventional gas (US$ 1 – 2 million).

Table 2. Annual Water Production Estimation (Thousand of Barrel)

Year	Water Production	Year	Water Production
2008		2023	20000
2009		2024	19000
2010		2025	17000
2011		2026	16000
2012	33000	2027	15500
2013	36500	2028	15000
2014	42000	2029	14500
2015	39500	2030	14000
2016	36000	2031	13500
2017	34000	2032	13000
2018	30000	2033	13000
2019	27500	2034	11000
2020	25000	2035	10700
2021	24000	2036	10600
2022	22000	2037	10500

Meanwhile, compression and power plant cost is about 2-8 % and 5 % of the total production respectively. Therefore, only 87-93 % of the total production can be sold. Transportation and distribution cost should be covered by *end user*.

Project investment starting from year 1 up to year 23 consisting of drilling related facility cost, gathering pipeline, low pressure compressor, production and sales compression system is described in Table 3.

Detail description of the above cost parameters is as follows:

a. Well and facilities
- Core and *coring* analysis is US$ 125.000 per well
- Well and facilities is US$ 425.000 per well consisting the following components:

- Access road, US$ 50.000. *Flow line,* US$ 25.000
- Drilling, completion and cracking, US$ 250.000 per well
- *PCP* pump and installation, US$ 100.000 per well.

b. *Pipelines* and production facilities (including water treatment)
- Low pressure gas gathering and compressor for each station consisting of modulo system @ 5-10 MMSCFD, US$ 1.200.000
- Water-gas separation system for 100 MMSCFD of gas, US$ 15.000.000

c. *Pipelines* and Compressor for gas sales
The following data is used for information only, and not used for calculation, because we use *wellhead price* in this study.
- Compressor with the capacity of 100 MMSCFD, US$ 45 million
- Piping, US$ 12 million, consisting of:
  - 25 km of 24 inch piping to send the gas to PGN & PLN pipe, US$ 9 million.
  - Piping for other market (5-6 location @ 5 MMSCFD), US$ 3 million.

Because CBM gas content high purity of methane (>90%) with N2 and CO2 impurities (without H2S), investment for gas treating facilities is not included [9,10].

Operating cost consists of existing well maintenance, production cost, water treatment cost, and gas compression/transportation. Those cost components are:
- Well maintenance and production cost, US$ 25.000 per well per year.
- Water production and treatment, US$ 0.30 per barrel.

Other cost component is US$ 15.000 for restoration per well per year.

3.4 Economical Calculation of CBM Contract

Economical evaluation of the CBM production is calculated based on the PSC model as shown in Figure 2 [8].

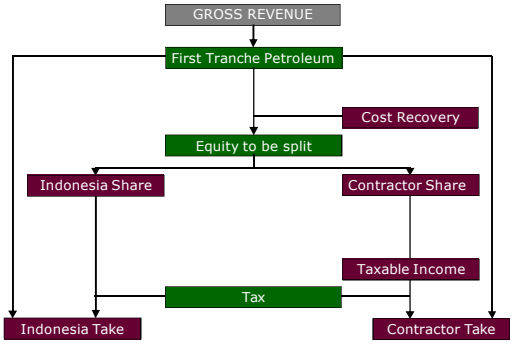

Figure 2. PSC Model for CBM Production

3.4.1. Results for *Case* I

Using conditions described in Case I, the following Tables 4 and 5 shows the economic indicators results.

Table 4. Economic Indicators of CBM Development on Case I

Economic Indicators	Value
Expenditure, MM US$	745.13
NPV @ 10% p.a, MM US$	44.00
% Gross of Revenue	30.00
Internal Rate of Return (% IRR)	12.90
Profit to Investment Ratio (PIR), Fract.	2.82
Pay Out Time (POT) Year	15.40
Contractor Take, % of Profit	41.87
GOI Take, % of Profit	58.13
NPV @ 10% p.a MM US$	160.00
% Gross of Revenue	41.59

Table 5. Revenue Distribution on Case I

Revenue Distribution	Contractor (MM US$)	Government (MM US$)
Gross Revenue	2618.70	
Net Cash Flow	784.48	1089.09
Cost Recovery	632.95	0
Total FTP Share	105.22	25.72

Table I shows that, based on Case I, contractor does not get reasonable IRR, i.e. 12.9%.

3.4.2. Results for *Case* II

Using conditions described in Case II (*CRC* 90%, Split 55:45 and Gas price US$ 4.50/MMBTU), the following Tables 6 and 7 show the economic indicators results.

Table 6. Economic Indicators of CBM Development on Case II

Economic Indicators	Values
Expenditure, MM US$	745.13
NPV @ 10% p.a, MM US$	29.00
% Gross of Revenue	25.9
Internal Rate of Return (% IRR)	12.00
Profit to Investment Ratio (PIR), Fract.	2.54
Pay Out Time (POT) Year	15.00
Contractor Take, % of Profit	35.52
GOI Take, % of Profit	64.48
NPV @ 10% p.a MM US$	194.00
% Gross of Revenue	46.95

Table 7. Revenue Distribution on Case II

Revenue Distribution	Contraktor (MM US$)	Government (MM US$)
Gross Revenue	2740.50	
Net Cash Flow	708.73	1286.64
Cost Recovery	625.38	0
Total FTP Share	0	274.05

As on Case I, the results shown in Table 6 also shows that, based on Case II, contractor does not get reasonable IRR, i.e. 12.0% (lower than Case I). For gas price US$ 5.00/MMBTU, IRR is obtained 13.4%.

3.4.3 Results on Sensitivity Analysis

Effects of economic variables on economic parameters are studied further to observe the sensitivity of each variable, following are the results.

a. Sensitivity Analysis on Case I

Figure 3 shows effect of gas production rate, gas price, Capex, and Opex on IRR. This figure shows that gas production rate and gas price give very sensitive effect on the IRR, while both Capex and Opex do not give significant effect on the IRR. For instance, increasing production rate or gas price by 20 % will increase the IRR from 12.9 to 15.3%.

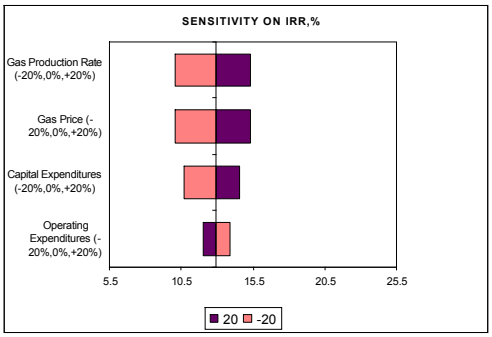

Figure 3. Effect of Gas Production, Gas Price, Capex and Opex on *IRR* in Case I

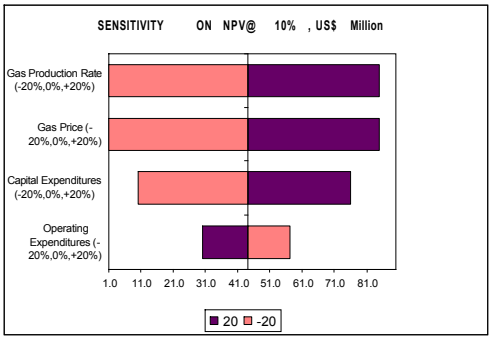

Figure 4. Effect of Gas Production, Gas Price, Capex and Opex on *NPV* in Case I

Figure 4 shows effect of gas production rate, gas price, Capex, and Opex on NPV for contractor. This figure shows that gas production rate and gas price give very sensitive effect on the NPV, while both Capex and Opex do not give significant effect on the NPV. For instance, increasing production rate or gas price by 20 % will increase the NPV from US$ 44 million to US$ 85 million.

Table 8 shows the sensitivity of the policy parameters on IRR. From the investor side of view, Split ratio is a very sensitive parameter on IRR. If the investor wants 19% of IRR, the Split ratio (Government: Contractor) should be 10 : 90, which is practically impossible, or the CRC is increased up to 120%, which is also impossible. Meanwhile FTP is not a significant factor on the change of IRR.

Table 9 shows the sensitivity of the policy parameters on Government Take. Similar to the above results, Split and CRC are important factors affecting the Government Take (in the reverse direction), while FTP is not a significant factor.

Tabel 8. Change of IRR on Policy Parameters In Case I

b. Sensitivity Analysis on Case II

Figure 5 shows effect of gas production rate, gas price, Capex, and Opex on IRR in Case II. As in Case I, gas production rate and gas price also give very sensitive effect on the IRR, while especially Opex does not give significant effect on the IRR. For instance, increasing production rate or gas price by 20 % will increase the IRR from 12.0 to 14.4%.

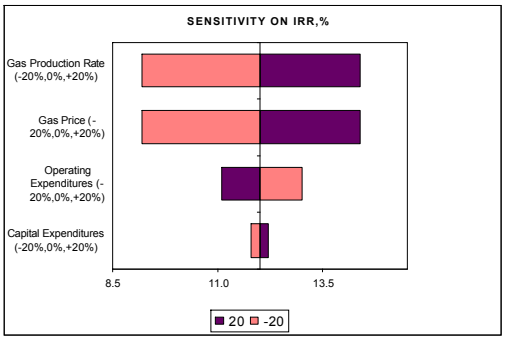

Figure 5. Effect of Gas Production, Gas Price, Capex and Opex on *IRR* in Case II

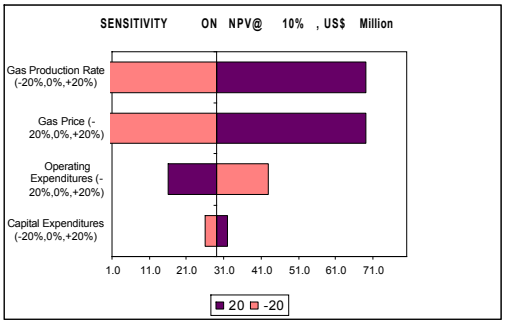

Figure 6. Effect of Gas Production, Gas Price, Capex and Opex on *NPV* in Case II

Figure 6 shows effect of gas production rate, gas price, Capex, and Opex on NPV for contractor. This figure shows that gas production rate and gas price give very sensitive effect on the NPV, while especially Opex does not give significant effect on the NPV. For instance, increasing production rate or gas price by 20 % will increase the NPV of contractor from US$ 29 million to US$ 65 million.

Table 10 shows the sensitivity of the policy parameters on IRR. As in Case I, split ratio is the most sensitive parameter on IRR for Case II. If the investor wants 19% of IRR, the government will gets nothing, or the CRC is increased up to 125%, which is also impossible. Meanwhile FTP is not a significant factor on the change of IRR.

Table 11 shows the sensitivity of the policy parameters on Government Take. Similar to the above results, Split and CRC are important

factors affecting the Government Take (in the reverse direction), while FTP is not a significant factor.

Table 10. Change of IRR on Policy Parameters In Case II

.

4. CONCLUSIONS

1. Base on Case I, IRR for CBM development in South Sumatra is 12.9%, and on Case II, IRR is obtained 13.4% at CRC = 90% and gas price US$ 5.00/MMBTU (the highest reasonable CRC and gas price).
2. Sensitivity analysis shows that Gas production rate and gas price give more significant effect on IRR and NPV, compared to the effect of Capex and Opex. Meanwhile, among the policy parameters, Split and CRC give significant effect on IRR, and FTP shows the least effect, both for Case I and Case II.

Tabel 11. Change of Government Take on Policy Parameters In Case II

SPLIT PEMERINTAH : KONTRAKTOR	GOV. TAKE (%)
0 : 100	13.73
10 : 90	22.96
20 : 80	32.19

3. From the government point of view, Split and CRC give significant effect on Government take, and FTP shows the least effect, both for Case I and Case II.

4. In order to get IRR = 20%, the following schenarios can be used:

Base Case I :

a. Gas price is increased to US$ 7,53/MMBTU, IRR = 20,6%
b. Gas price US$ 6,88/MMBTU, CRC = 100%, IRR = 20,2%

Base Case II :

a. Gas price is increased to US$ 8,10/MMBTU, IRR = 20,2%
b. Gas price US$ 7,65/MMBTU, CRC = 100%, IRR = 20,2%
c. Gas price US$ 6,75, FTP=10% (shared), CRC=100%, IRR = 20,0%

ABSTRACT

The increasing of demand for energy sources and the decreasing of fossil energy sources then needed new alternative energy sources. And from this research, the use of Thermoelectric Generator (TEG) is one solution for this issue. TEG is a module that can convert heat energy into electrical energy by utilizing the velocity difference between each electron of the two types of semiconductor which conduct different potential. This principle is known as Seebeck effect that reversing way of Peltier effect on Thermoelectric Cooling (TEC). And the focus of this research is to know the power generated efficiency of TEG by using exhaust waste gas of motorcycle as a source of heat. In this research, 100 cc 4 strokes motorcycle is applied, the 8 TEG modules were employed for generating electricity and the motorcycle will be simulated run steadily up to speed 20 km/ hour with 3 kinds of variations RPM. This research gives maximum power output 3.15 W at ΔT of 65.56 ^{O}C.

Keywords: *Heat Waste, Thermoelectric Generator, Energy Conservation, Hybrid Car, Differences Temperature.*

1. Introduction

It was realized that the need of energy day after day is increasing proportional to. Since energy sources have limited quantities, many researchers have been developing new method in order to increase the efficiency of energy utilization, especially in the field of transportation. And the Hybrid car was made to fulfill those demands.

A hybrid vehicle is a vehicle that uses an on-board rechargeable energy storage system (RESS) and a fuel based power source for vehicle propulsion. These vehicles use much less fuel than their counterparts and produce less emissions. In general hybrid vehicles recharge their batteries by capturing kinetic energy through regenerative braking. Some hybrids use the combustion engine to generate electricity by spinning a generator to either recharge the battery or directly feed power to an electric motor that drives the vehicle.

The hybrid car that used the electric motor as the support engine, use the electricity from the battery to run. The baterry is recharged when the driver manage the car to be decelerated, such as step off the accelerator lever or push the brake lever. Either the car is stop at the traffic light or traffic jam, it is also recharged. This condition reduces the fuel consumption that supports the combustion engine. For example, while the vehicle stops at the traffic lights, the combustion engine automatically turned off and change to electric engine.

Hybrid engine works with an additional sensor which is programmed to rechange automatically choosing between combustion engine or electrical engine. This is the preeminent engine from other conventional engines which more efficient because less gasoline are needed to reach the same distances.

Nowadays the hybrid car are still depent on the usage of regenerative breaking to produce the electricity, and the heat waste were not utilized. By using Seebeck principle of a thermoelectric generator, the waste heat energy from combustion of a hybrid engine can be converted into electrical energy which can be used for charging the battery. It was found out that the combustion temperature range from 100-250^{o}C, and the ambient temperature reach at 30-35

^{o}C. This condition makes a temperature difference that is required for Seebeck Principle to produce electricity[1].

The aim of this research is to develop a better way of utilizing the waste heat from combustion engine for generating electric power by using thermoelectric module.

2. Thermoelectric Generator (TEG)

Seebeck in 1822 discovered the thermoelectric effect. He observed an electric flow when one junction of two dissimilar metals, joined at two places, was heated while the other junction was kept at a lower temperature [2]. The electrical output produced was initially very small magnitude and there was no significant value in electric power generation. With the development of semiconductors material, it is founded that the output could be magnified significantly and this field began to be developed [3]. Renewable energy, such as solar energy, wind energy or hydropower is preferred, but it has limited use and is dependent on weather and topography. Thermoelectric Generator can convert heat energy to electrical power directly [4]. In additional, thermoelectric power generation has the advantages of being maintenance free, silent in operation and involving no moving or complex parts [5].

The available space to install a thermoelectric generator in an automobile is normally reduced because of the tendency to put more equipment in less space. There are mainly three possible locations for the TEG [6]:

1. Just behind the exhaust manifold
2. Between the manifold and the catalyst converter
3. After the catalyst converter

Figure 1 explained the TEG's structure which consist of type-n and type-p semiconductors. Those semiconductors are flanked between ceramic wafers where the cold and hot side will conduct and release heat. Heat source conducts heat on hot side and even though the cold side releases heat to environment. When temperature differences applied on this module between hot side and cold side, with the Seebeck Principle, it will produce electricity depend on its efficiency, called figure of merit. Iofee [2], who first studied thermoelectric module, found from the thermodynamic analysis that this ratio is function of the parameter called figure of merit (which is a function of only the thermoelectric material) and the temperature differences across the two parts of module. Generally, voltage is produced proportional to temperature gradient.

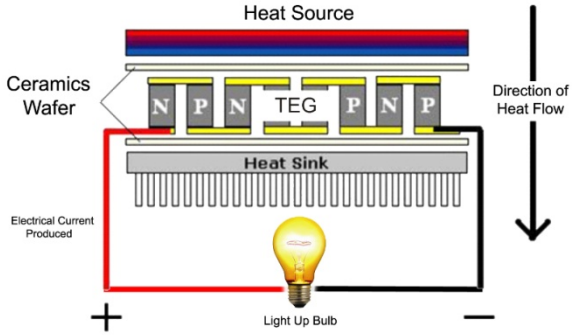

Fig 1. Thermoelectric Structure [6]

The efficiency of power generated by TEG depends on temperature difference. High power generated produced at higher temperature difference. When the temperature difference is getting wider, it effect to power income which is getting higher. So generally, a cooler such as heat sink, water jacket etc, applied together with TEG. Otherwise, increase the temperature of heat source. Thermoelectric generator can be connected each other as serial or parallel similar to a battery module to generate more voltage or current.

Many experiments have developed to explore the utility of thermoelectric power generator more widely. Rida Y. Nuwayhid et.al 2004 [7] developed a thermoelectric power generator using waste heat of a woodstove. Testing was undertaken under a controlled woodstove firing rate and temperatures, and open circuit voltages were monitored over extended periods. The maximum steady state matched load power was 4.2 W using a single module. The use of multiple modules with a single heat sink was found to reduce the total power output relative to single module case as a result of reduced hot to cold surface temperature differences. Because of this condition, higher voltages can be realized at some losses in available electric current, Eakburanawat et.al 2006 [4] developed a thermoelectric power generation to charge a battery with microcontroller based. The proposed system has maximum charging power of 7.99 W. That is better than direct charging by approximately 15%. This thermoelectric generation module is also applicable on notebook. Steven J W [8] presented Derivations and expressions for the optimal internal thermal resistance of a small ΔT thermoelectric generator with steady and time varying external thermal resistance.

Since the exhaust gas combustion as the heat source, it must be concern about the fluctuate amount of heat flux that transferred on hot side. So the temperature difference always changes during combustion. Because of that, the power generated is also become fluctuate as the temperature difference change each seconds. And when the maximum efficiency of TEG is reach at given temperature difference, the power income become a highest result for the TEG to generates power, even the temperature difference increasing. So, it's possible that when temperature difference is high, but the power income is remain low.

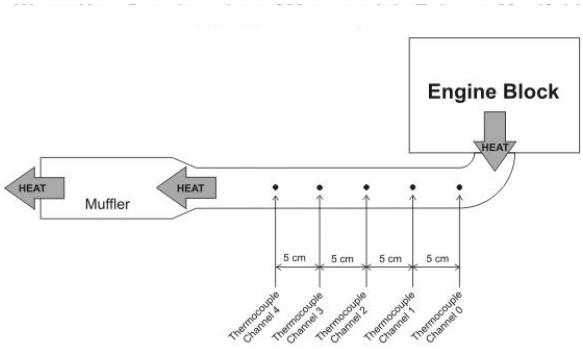

Fig 2. Scheme installation of thermocouple on motorcycle muffler

Figure 2 shows the placement of thermocouples on the muffler of motorcycle. It is done in order to know the temperature distribution of the muffler heated by the exhaust gas.

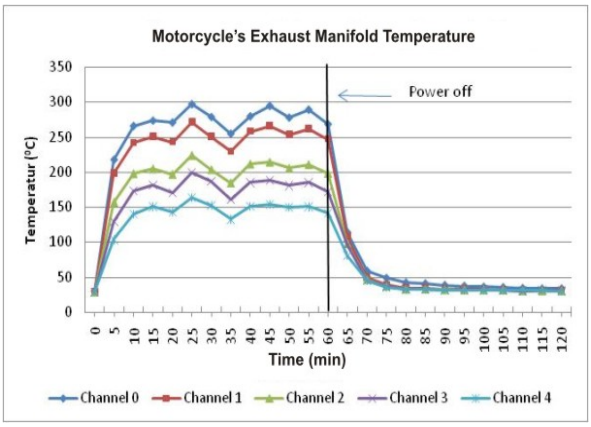

Fig 3. Temperature distribution on exhaust manifold of combustion engine

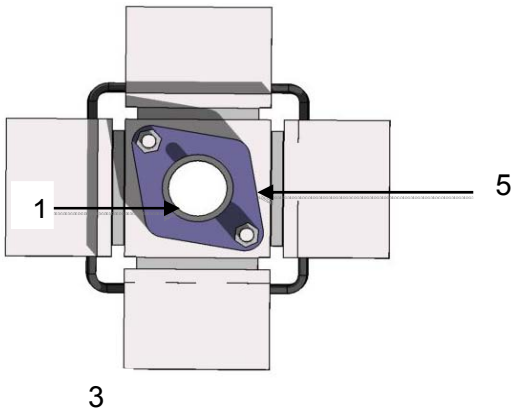
Figure 3 shows the temperature distribution on exhaust manifold, with the different position one and anothers to know about the temperature changes in any place as the comparison to placed the module for TEG. The experiment conducted on 110 cc motorcyle 4 strokes. Thermocouples are attached at given length on surface of the muffler.

The temperature distribution are range from 150 to 300 ^{o}C. The highest temperature is at the closest length to the exhaust manifold of the engine. And then it decrease until the tip of the muffler. Even when the engine is turned off, the muffler temperature is still higher than the ambient temperature. So, temperature difference still occur and produced electricity until the muffler temperature is similar to ambient temperature. But not as high as at higher temperature difference. This circumstance is another considerable for using TEG on muffler.

3. Design of Experimental Instrument for Thermoelectric Generator

In this research, it is realized that needs a support structure or bracket for TEG to be connected after exhaust manifold and before pipe or muffler. The bracket support structure is designed to be compatible with the exhaust manifold of the motorcycle engine and fit to the conventional muffler. Figure 4 shows construction of the designed bracket support structure where the TEG elements are placed.

The bracket is an aluminum block, which has dimension of 180 x 48 x 48 mm. The block was bored for flowing exhaust gas. The diameter of the hole is 30 mm that similar with diameter of pipe or muffler. In order to assemble easily the bracket into the exhaust manifold and pipe, the flans (5) are positioned on the top and bottom of the bracket.



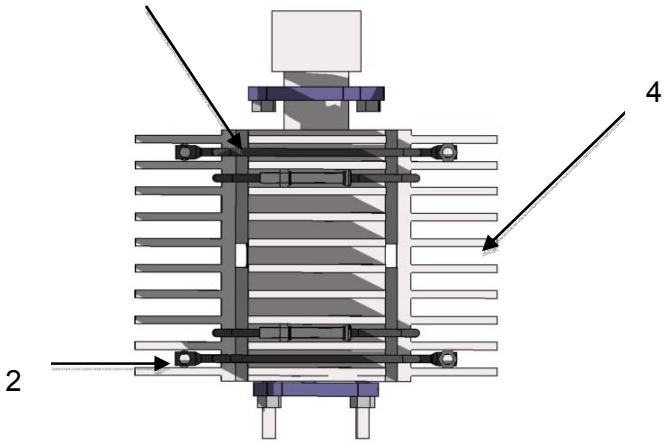


Fig 4. Bracket support structure

Eight TEGs (3) were used in this experiment. Each side of block was designed to hold two TEGs. The exhaust gas will flow through inside the bracket and heat will transfers to TEG. The heat will conduct through this aluminum bracket and reach the hot side of TEG. To have high temperature difference between hot and cold side of TEG, heat sinks (4) must be attached on the cold sides of TEG in order to absorbed heat and accelerated the released of heat to the environment. Fin heat sinks made of aluminum were used in this experiment

In this case, the using of bolts to tight heat sink and the TEG on the block is avoided in order to reduce heat conduction from the block to cold side of the TEG. These bolts will conduct more heat on cold side and affected decreasing of temperature difference between hot side and cold side. Rubber clams (1), clamps (2) are used to tight all TEGs and heat sink on the block.

4. Experimental Setup

The TEG system was tested with some variations such as electrical circuit analysis (serial, parallel, and series-parallel) and also based on the rotation of the engine (idle, middle, and high). This aims to represent the possible conditions of data logged with the conditions that might be faced when the motor run.

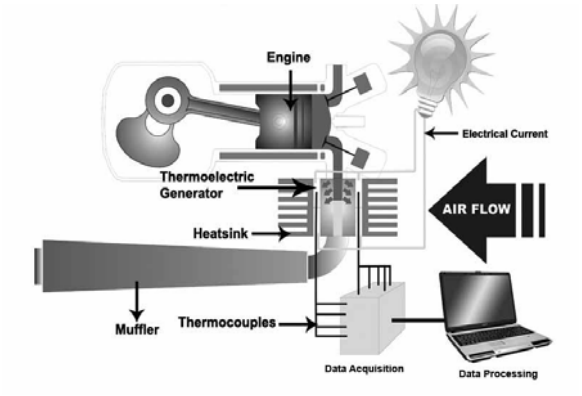

Fig 5. Schematic of experimental setup of TEG on motorcycle

The figure 5 shows the experimental setup of TEG on motorcycle. The bracket is attached after the exhaust manifold, to obtaining higher temperature on hot side.

To acquire temperature data, 11 thermocouples types K are employed, the thermocouples connected into PC based data acqusition system, (National Instrument Data Acquisition DAQ 9172). These thermocouples are placed on hot side and cold side of TEG, ambient temperature, and exhaust manifold.

All TEGs cable are connected with many kind of combination such as serial, parallel, and serial-parallel circuit module. Each experiment will conduct with different mode, in order to know the value of power which is generated by TEG. A multimeter is connected to the module to show voltage and current generated by TEG. In these experimental, 12 volt bulb is used as load.

The experimental is carried out on motorcycle which is simulated run. Therefore, to create this condition this experiment 160 watt, 30 inch fan is applied in order to blow the air similar to the situation when the motorcycle runs at 20 km/h. This air flow is to absorb the heat on heatsinks.

The test consists of a motor cycle with cylinder capacity of 100 CC – 4 strokes. Obtained data from experiment consists of output currents, output voltage, output power, the temperature data the heat and cold, are all comparable with the function of time. The data itself is done until the system is stable.

Beside the circuit combination, the experiment is also run in three kind of engine rotation, that's high RPM ranged from 3000-3500 RPM, middle RPM ranged from 2000-3000 RPM, and idle condition ranged from 1000-2000 RPM.

5. Result and analysis

Figure 6 shows the temperature distribution in each condition of RPM, as can be seen that the high RPM condition provided highest temperature difference. The change of temperature value is linear to the changes of RPM. The biggest temperature difference is 70 ^{o}C. It is clear that with high RPM, flow rate of exhaust gas will flow more gas through the block. Then the block will absorb more heat. As shown in fig 6 temperature difference was influenced by type of RPM. When the RPM was high, bigger temperature will occurred on hot side of TEG.

After several time, the engine was shouted down, then the difference temperature between hot side and cold side for all condition will decrease rapidly.

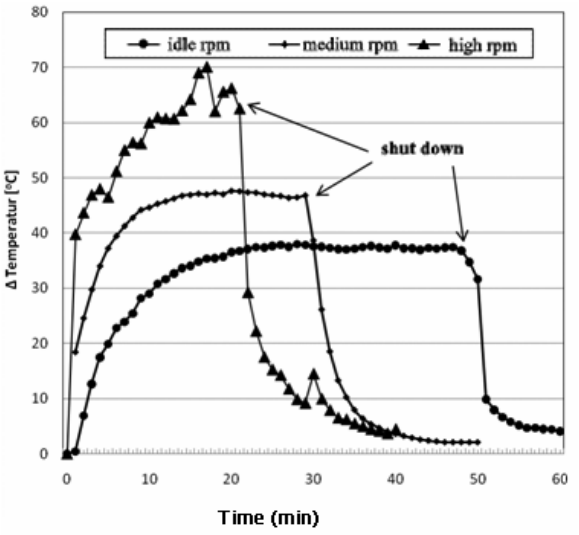

Fig 6. Comparison temperature difference versus time of TEG in each type of RPM

Figure 7 and 8 show the measurement of voltage and electric current as variation of circuits at high rotation of engine respectively. The serial mode electricity circuit gave highest voltage, it reached 7 volt. The parallel mode provided the lowest voltage. Meanwhile as depicted in Fig 8, the highest electric current is provided by parallel mode. In this research 3 Ampere was obtained in parallel mode. From the figure, it can be noted that even the engine has already been shouted down, the potential voltage and current still occurred because there are still temperature different on this system.

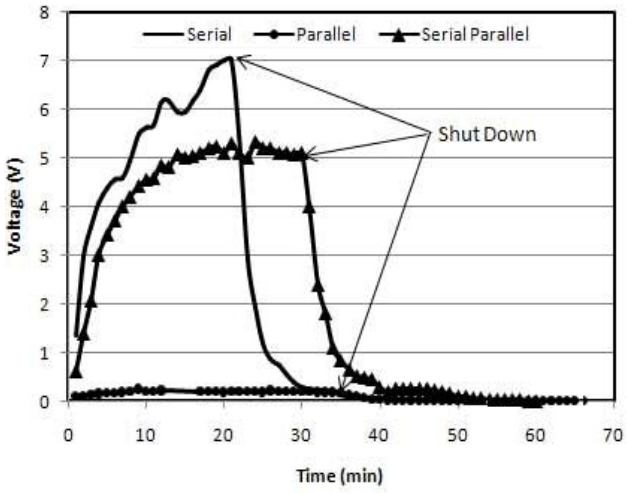

Fig 7. Comparison of voltage versus time in each circuit combination

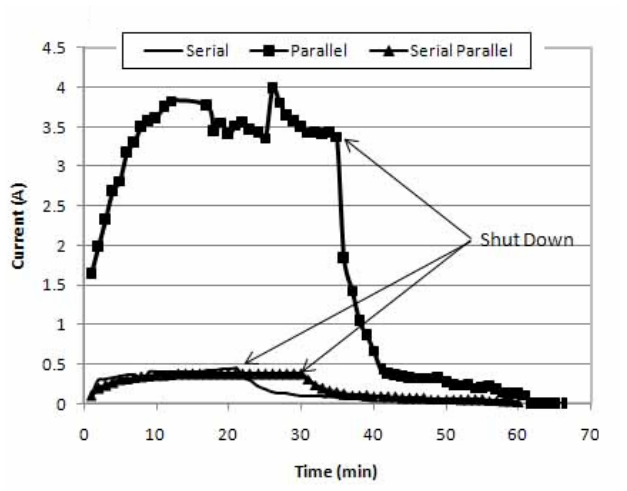

Fig 8. Comparison of current versus time in each circuit combination

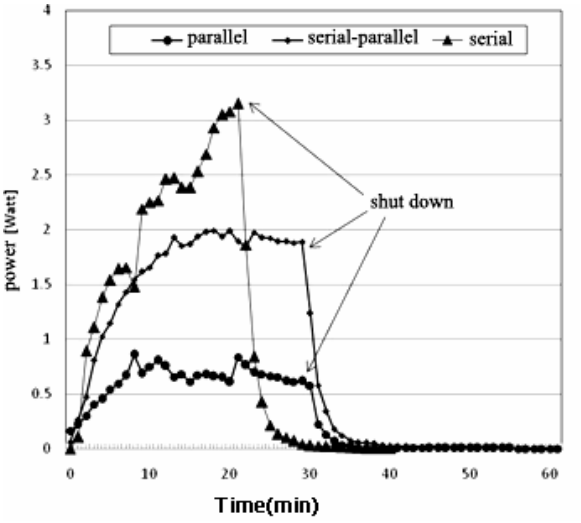

Fig 9. Comparison of power generated in high rpm on each type of module

Fig 9. is the comparison of the power that can be produce by each circuit in high RPM condition. The maximum power generated of this test is 3.2 watt in serial mode circuit and high rpm condition that produce 65^{o}C temperature differences. While at parallel and combination circuit, the power that produced is 0.9Watt and 2Watt, with 38^{o}C and 48^{o}C temperature difference.

Figure 10 displayed the comparison of power generated of TEG in serial module of thermoelectric generator at variation of engine rotation. It shows that the high electrical power will produce at the high rpm. As showed in Fig 6. High rpm acquire high difference temperature.

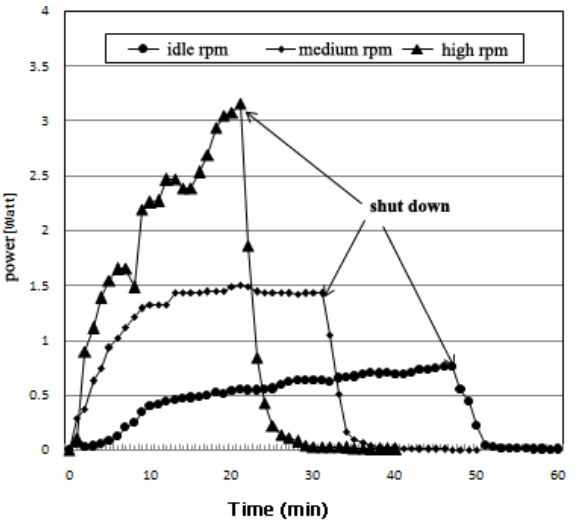

Fig 10. Comparison power generated versus time of TEG in each type of RPM in serial module

Nurwayhid et.al,[7] stated that the increasing of the amount of TEG may not be warranted that the power that can be produced will increase linearly too. On that research, one module produce 4W of electricity while when two modules is used only 3,8W that can be produced. This condition is also might be happen in this research, the increasing of TEG module is not influenced the amount of power that can be produced.

6. Conclusions

From the experimental results, it can be concluded that thermoelectric module is able to generate a number of electrical energy, utilizing the existing temperature difference. By using 8 TEG modules, it can produce power at about 3.2 watt at ΔT 62.5 ^{0}C (in serial circuit). The circuit can be adjusted by purpose, if needed to get a bigger current, parallel module circuit of TEG could be more effective. On the other hands, the serial circuit is used to obtain a bigger voltage. The experiment bought a result of high voltage in serial circuit in the high RPM condition. Meanwhile, high current was obtained in parallel module. The heat sinks on the cold side play an important role to obtain higher temperature difference and to produce higher electricity.

ABSTRACT

As the government's instruction about energy savings, some efforts need to be done to succeed this program. In household areas, energy savings can be done by so many ways, from turning off unused lamps until utilizing waste heat from air conditioning system to produce hot water which is known as Air Conditioning Water Heater (ACWH). ACWH is a heat recovery system that utilizes waste heat from refrigerant to produce hot water simultaneously through of a heat exchanger which is very suitable to be implemented at residence apartments. The existing ACWH system needs to be developed to reach an optimum result. Some problems of ACWH systems nowadays are low efficiency, insufficient hot water temperature, long period of heating, and increasing of evaporator temperature. The objective of this research is to maximize the performance of ACWH using Plate Heat Exchanger which has highest efficiency among all type of heat exchanger. The water flow rate and cooling load are variables to be tested. The result of ACWH system shows that the system with 2600W of cooling load can produce 50L/hr hot water with 46^{0}C temperature in open loop method.

Keywords *: Energy, Heat Recovery, Efficiency, Plate Heat Exchanger, Water Flowrate, Cooling Load*

1. Introduction

Indonesia has tropical climate which has high ambient temperature and humidity. Almost all houses, residences, and apartments in big cities use Air Conditioner (AC) to produce thermal comfort for human beings. Another demand for residences is water heater unit to produce hot water for many purposes such as bathing, washing, etc. System that is mostly used nowadays is the usage of 2 discreet systems, AC and water heater units, which each of those consume lots of energy.

Another alternative available is using water heater unit that doesn't consume any energy such as Solar Water Heater (SWH) and Air Conditioning Water Heater system (ACWH).

ACWH is not a new system. It has been developed for the last 50 years. ACWH recovers waste heat from air conditioning system to produce hot water. With this system, we can get 2 benefits simultaneously, cooling effect and water heating effect that consumes less power.

In subtropical climate (US), ACWH system are claimed to produce hot water with no additional energy at all [1]. Further studies shows that ACWH system will reach breakeven point with its initial cost in 2-3 years period [2].

Nowadays ACWH system has been developed in many countries, most of them in countries with tropical and subtropical climate. Ji et al [3] developed ACWH system that can produce hot water up to 50^{0}C in China (subtropical climate). In subtropical climate, ACWH system has another additional benefit as room heater. For tropical climate, ACWH system has been tested and developed by Techarungpaisan et al [4], and Putra et al [5, 6, 7]. In tropical countries ACWH is not used as room heater due to the high ambient temperature, so most systems developed in tropical countries only have 2 functions, as air conditioner and as water heater.

ACWH systems have several problems, such as temperature of hot water, long heating time, up to malfunction of cooling effect of the system itself. All of these problems made ACWH systems rarely used during 1980-1990 period.

As the technology developments, ACWH problems can be reduced and eliminated so that ACWH system is commonly used nowadays, especially in Europe [8]. By this research, the researchers want to develop an ACWH system that can be applied at residence apartments so that the energy consumption can be minimized.

2. Objective

The aim of this research is to develop, and optimize Split Air Conditioning Water Heater (S-ACWH) system with plate heat exchanger to produce better performance. S-ACWH performance is measured by 2 main parameters, hot water temperature and COP

3. System Description

Testing apparatus schematic can be seen at figure 1. Residence apartments is simulated as closed cabin with dimension 3 x 1,5 x 1,5 m. Cooling loads in the apartments such as humans, electric appliances, etc are simulated with lamps that can be varied from 0 – 2600 W. With this testing apparatus, we hope the testing condition resembles the real conditions at the apartments where the ACWH system is to be applied.

Main parameters to be measured in this testing are temperature (water and refrigerant) and pressure of the refrigerant.

Thermocouples (type K) are installed at inlet & outlet of working fluids of the Plate Heat Exchanger (PHE), outlet of condenser, inlet & outlet of evaporators. All thermocouples are connected to data acquisition module which connected to the computer. While pressure gauges are installed at inlet & outlet PHE (to measure pressure drop of PHE), compressor suction and evaporator inlet.

Thermocouples and pressure gauges are installed so that the information gained can be used to draw the system at P-h diagram.

4. Results and Analysis

Water flow rate variation has a significant effect to the hot water produced as seen at figure 2. Hot water temperature produced decrease as the water flow rate increase due to lesser contact time between water and PHE as water velocity inside PHE increased.

Another factor is gate valve opening. As water flow rate increase, gate valve is opened lesser. Gate valve can't be fully closed to maintain compressor suction pressure in its optimum range (60-70 psi). If the suction pressure decreases, the system will lose its cooling effect. Partially opened gate valve limits the amount of refrigerant flow to the PHE

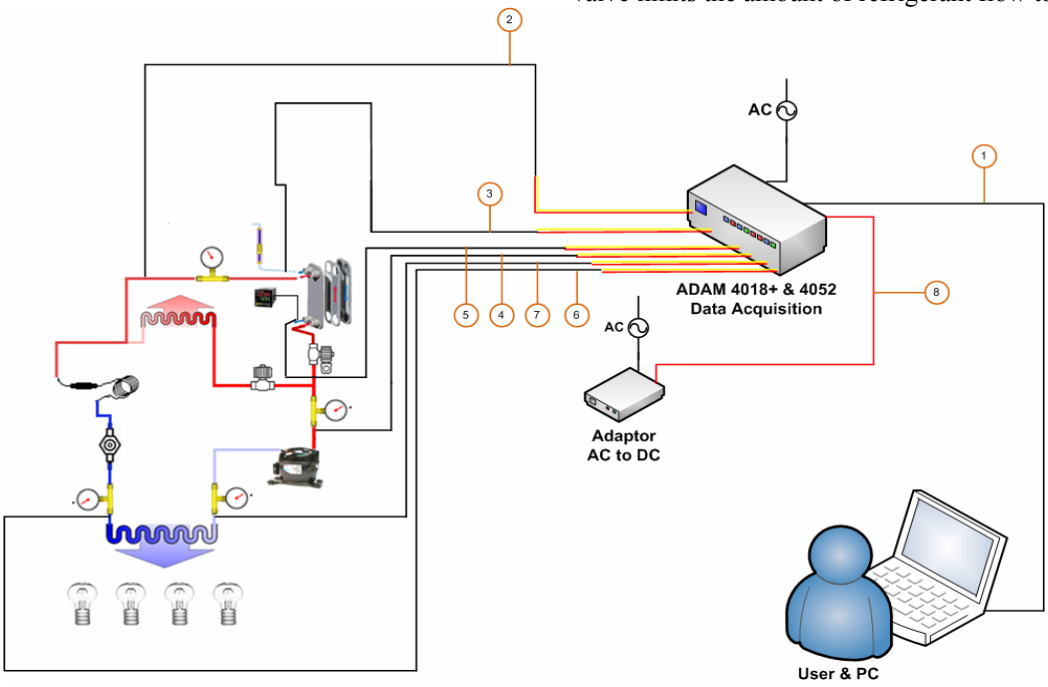

Figure 1. Testing apparatus schematic

ISSN 114-1284

Refrigerant inlet temperature also decreases due to increased heat recovery in the system. Enthalpy is a function of temperature. If the enthalpy of refrigerant decreases due to heat recovery, the temperature will also decrease.

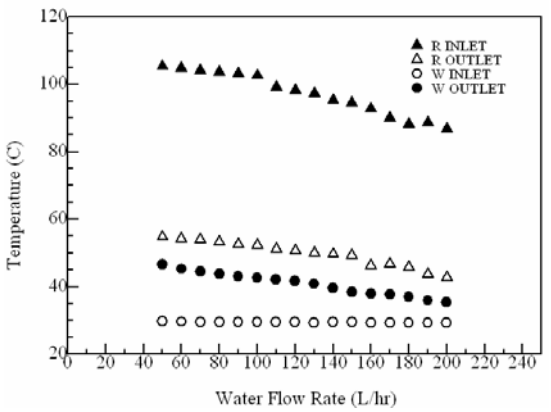

Figure 2. Working fluids temperature at PHE inlet & outlet

Decreasing hot water temperature produced doesn't indicate that the heat absorbed by water also decrease. Decrease of hot water temperature will decrease the temperature difference (ΔT). But the mass flow rate will increase. Mass flow rate increasing rate is bigger than temperature difference decrease rate. The result is an increase in heat absorbed by water.

Increased water flow rate will result in increased Renolds number (Re) of the flow. As the Re increase, the flow will switch from laminar flow into turbulent flow. Turbulence flow will result in higher heat transfer coefficient.

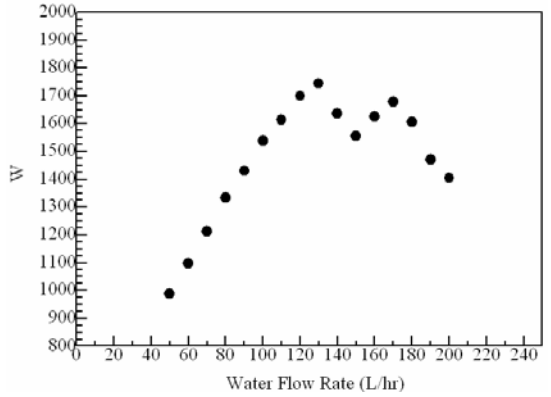

Figure 3. Heat absorbed by water

Heat absorbed by water can be maximized up to condenser capacity. As seen in figure 3, maximum heat absorbed by water is about 1750 W, much lesser than condenser capacity which is 3000W. Several developments will be done in the upcoming research to solve this problem.

In figure 4, we can see that the compressor work tends to decrease as the water flow rate increase. As stated before, heat absorbed by water increase as the water flow rate increase. The more heat absorbed by water, the more enthalpy of the refrigerant dropped. Refrigerant temperature will also decrease

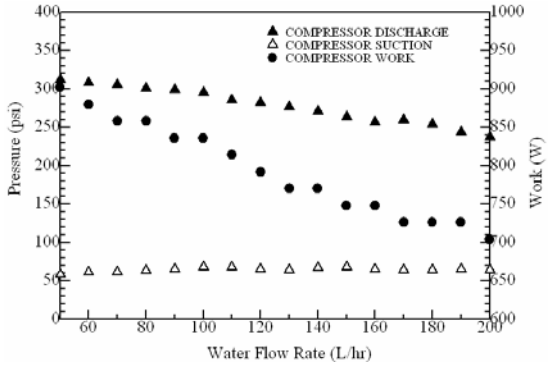

Figure 4. Compressor performance

The temperature of refrigerant at compressor inlet and outlet are decreasing. The decreasing rate of refrigerant temperature at compressor outlet ($\Delta T_{R,o}$) is greater than the decreasing rate of refrigerant temperature at compressor inlet ($\Delta T_{R,i}$) which results in decrease of refrigerant temperature difference ($T_{R,o} - T_{R,i}$). Lesser temperature difference means lesser enthalpy difference (Δh). Compressor work is a multiplication of refrigerant mass flow rate and enthalpy difference between compressor inlet and outlet refrigerant. Lesser Δh will result in lesser compressor work.

Decreasing compressor work is followed by decreasing discharge pressure due to heat recovery. Suction pressure is maintained constant by varying gate valve opening.

Overall system performance (COP_{ch}) increases as the water flow rate increase. COP is a ratio between effects gained compared to works done. In this system, the effects gained are the cooling effect and water heating.

Cooling effect is assumed constant as the cooling load is constant at 2600 W (heat transferred from the cabin is constant). System's cooling performance (COP_c) will increase as the compressor work decrease.

Water heating effect increases as water flow rate increase, which is shown by higher amount of heat absorbed by water. System's heating performance (COP_h) will increase due to higher heating effect gained and decreasing compressor's work.

Overall system performance (COP_{ch}) is addition of cooling performance and heating performance. Increased both performance will result in increase overall system performance. Overall system performance in S-ACWH increases 37,5% - 100% compared to normal AC system.

ISSN 114-1284

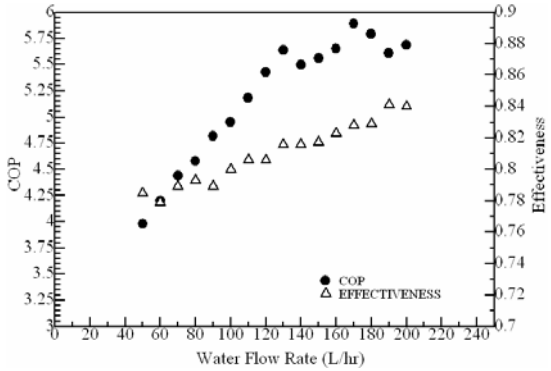

Figure 5. S-ACWH performance for water flow rate variation

PHE effectiveness in this system is not as high as normal PHE effectiveness. In calculation, refrigerant mass amount to the PHE is assumed same with refrigerant mass amount of the system. In fact, some refrigerant will flow to condenser (bypass) because gate valve is opened. This assumption is made due to the limited testing apparatus. In this testing, we were unable to get refrigerant flow meter. If refrigerant flow rate to PHE is decreased to its actual condition, PHE effectiveness will increase to its ideal condition (>0,9). PHE effectiveness increases due to increased heat absorbed by water as water flow rate increase. System's COP and effectiveness for water flow rate variation testing is shown at figure 5.

In figure 6, we can see that cooling load variation does have effect on hot water temperature produced, but the effect is not as significant as water flow rate variation in previous testing. Even there is increase in hot water temperature, the increase is very small, so that it can be considered constant.

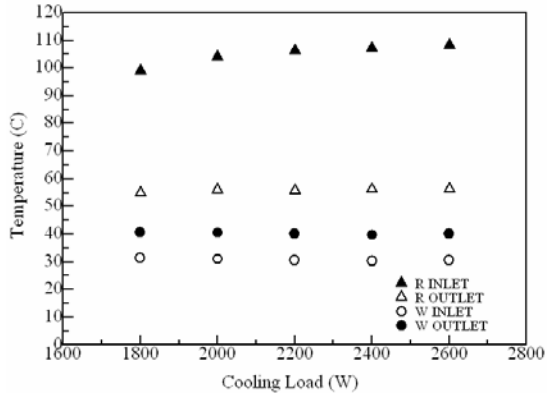

Figure 6. Working fluids temperature at PHE inlet & outlet

Increased cooling load means that more heat need to be transferred from the cabin and more heat to be rejected. More heat to be rejected means more heat available to heat the water.

Refrigerant temperature also increases as the cooling load increase. More cooling load will increase refrigerant enthalpy more, which result in higher refrigerant temperature.

Constant hot water temperature is followed by constant amount of heat absorbed by water. There is an increase, but quite small that in can be considered constant. In this testing, water flow rate is maintained constant at 100L/hr. Same water flow rate means same water flow which result in same Re and overall heat transfer coefficient. In this testing, heat absorbed by water tends to increase as cooling load increase. The amount of heat absorbed by water can be seen at figure 7.

As seen in figure 8, compressor's work tend to increase even the increase is not significant. The higher the cooling load, the enthalpy of refrigerant at compressor's suction will also increase which results in higher compressor's work.

Suction and discharge pressure tends to be constant during testing. There is increase in suction and discharge pressure, but again, not significant.

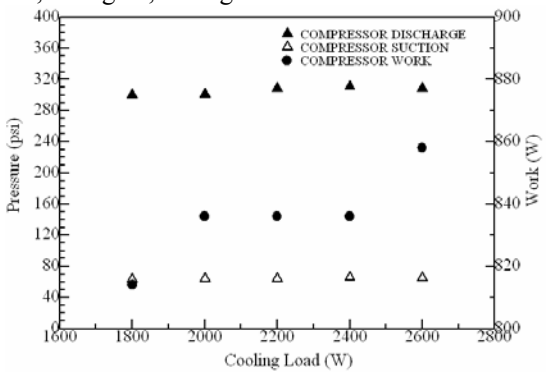

Figure 7. Compressor's performance

Discharge temperature increase as compressor's work increase and suction temperature increase as more enthalpy increase due to higher cooling load must be transferred from the cabin.

Overall ACWH performance (COP_{ch}) tends to increase as cooling load increase, but the increase is not as significant as in water flow rate testing. ACWH's overall performance for this testing can be seen at figure 9.

The cooling effect increase as the cooling load increased. But increased cooling effect is followed by increased compressor's work. This will result in increase in cooling performance (COP_c) but, the increase is not very significant.

The heating effect tends to be constant. The heating performance (COP_h) will decrease due to increase in compressor's work.

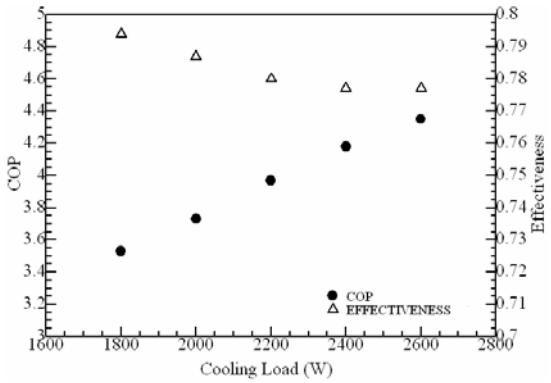

Figure 8. ACWH performance for cooling load variation

Increase in cooling performance and decrease in heating performance result in increase in overall ACWH performance. The increase rate in cooling effect is greater than the decrease rate in heating effect. ACWH performance increases 20 – 49,5 % compared to normal AC.

PHE effectiveness tends to decrease as water flow rate increase. Increase in cooling load is not followed by increase in hot water temperature produced.

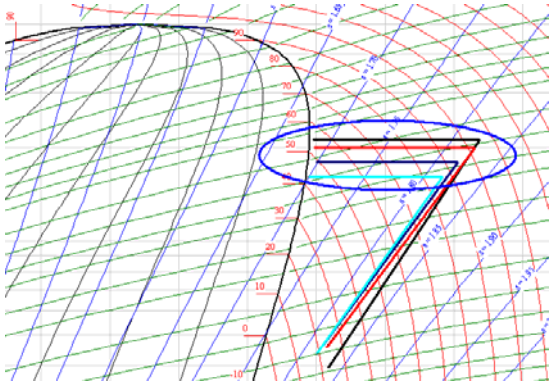

Figure 9. ACWH's Heat Recovery in P-h diagram (50L/hr, 100L/hr, 150L/hr, and 200L/hr)

As seen in figure 10, heat that should be rejected at the condenser is utilized to heat the water. The refrigerant used is the refrigerant which has highest enthalpy, at the compressor outlet. Refrigerant exiting the PHE is still at superheated phase. This refrigerant is mixed together with refrigerant exiting condenser before expanded together.

5. Comparison with existing ACWH systems.

As known, ACWH systems have been developed in the last 50 years. Many investigations have been done to have better ACWH's performance. Compared to previous research, modifications are done by modifying the testing schematic and changing the heat exchanger to gain best performance.

As seen in table 1, the highest heat exchanger effectiveness is gained using plate heat exchanger with this testing configuration. If the main parameter is hot water temperature, we can use helical triple shell pass heat exchanger to minimize the initial cost. Compared to plate heat exchanger, helical heat exchanger is cheaper. But as that heat exchanger's effectiveness is low, it may disturb the ACWH performances; especially it will decrease the cooling effect which results in higher cabin temperature.

Considering system performance and initial cost, the best option is using ACWH with plate heat exchanger. High effectiveness of heat exchanger will prevent malfunction of the system.

Table 1. Comparison of ACWH systems with various heat exchangers and testing schematic

Parameters	PHE	Triple Shell Pass [7]	Double Shell Pass [6]	Single Shell Pass [5]
T water in (^{0}C)	29.64	23	28	27
T water out (^{0}C)	46.59	60	47	47
ε (%)	78.5	59	22	27
COP	3.98	3.78	2.76	N/A

6. Conclusions

Based on data and analysis gained during testing, some conclusions can be concluded as the results of this testing:

- Using 1 PK rated Air Conditioner, water flow rate 50 – 200 L/hr and 2600 W cooling load, ACWH system can produce hot water with 35 – 47 ^{0}C. Higher water flow rate will result in lower hot water temperature
- With 100 L/hr water flow rate and 1800 – 2600 W of cooling load, the system can produce hot water at 39 – 41 ^{0}C temperature. The higher the cooling load, the higher hot water temperature produced.
- S-ACWH system will decrease compressor's work compared to normal AC system due to heat recovery
- S-ACWH system will produce higher performance than normal AC. Performance will increase 20 – 100 % compared to normal AC performance.

ABSTRACT

Since incipient damage in solid was in the state of microstructure disintegration and did not vibrate the body yet, therefore common practice to detect failures by detecting its vibration could not be applied. So there were 2 major efforts must be done in order to detect such incipient damage. Firstly was the designing and manufacturing of sensor which could sense the stress waves generated due to the microscopic disintegration of the solid material. Secondly was the developing of signal processing techniques which could enhance and show up the signals of the incipient damage, i.e. microscopic damage.
The propagating stress waves as the so called Acoustic Emissions were captured by a specially designed AE sensor. However, the signals were corrupted or buried under the background signals, i.e. noise. Many attempts to clean up such noise have been done in various researches were based on conventional adaptive noise cancelling that applying mathematical methods. The authors of this paper had researched the so-called equalizer which was a technique to reconstruct the convoluted signal into a delayed form of the original signal by implementing iterative process. However, some modification should be made in the routines of the common basic structure in order to suit with the characteristics of the stress wave. The simulation gave satisfactory results, as well as the tests with real data from real time experimental.

Keywords: *signal processing, blind deconvolution, vibration, condition monitoring.*

1. INTRODUCTION

In machines maintenance practice, the ability to detect the occurrence of early damage before a catastrophic failure happen will improve the utilization performance of the machines since its failures can be predicted better and the machines can be utilized most to the real limits.
Microscopic disintegration would be present first in the solid material of a machine element before fractures occurred. As the crystalline molecules started to disintegrate, energy would be released as wave of stresses. This wave would propagate throughout the solid material in a form of longitudinal Raleigh waves. Since the wave was propagating in same form of sound wave, this stress propagation was also called as Acoustic Emission. From vibration point of view, the stress wave had very high frequency but with very low amplitude. Therefore, the wave was not strong enough yet to vibrate the machine element or been detected by common sensors such as accelerometers or velocity transducer. Even though the stress wave was present but it was totally buried under other vibration signal sources as noise. If the presence of the stress wave could be detected, it means that the incipient damage was known since this wave was generated due to the disintegration of the crystalline molecules of the solid material prior the real sensible fracture occurred.
A specially designed sensor had been developed and successfully been used in this research to capture signals of incipient damage from the solid material of a machine element [1]. However, other means were still needed to reveal the real stress wave that originated from the incipient damage out of the noise. Many attempts had been done in various researches but still with unsatisfactory results. The main problem was the ability to differentiate between the real stress wave and the other wave as noise. Most researchers used mathematical methods directly as well as noise cancelling methods in trying to clean the noise from the real signal. Mathematical methods such as Hillbert Transform, Least Mean Square (LMS), Griffith algorithm, Estimation Maximization algorithm as well as the Auto Regressive methods were used as the core of the Adaptive Noise Cancelling technique. Many authors had reported

ISSN 114-1284

such researches for the noise removal process. However, the application of such methods were still not yet ready for real practice since many difficulties and unsatisfactory results were found [2]. Other techniques regarding noise removal or signal cleaning in other fields such as communication, mobile telephones etc. had been explored and studied in this research. In mobile communication there was the so-called equalizer for reconstructing convoluted signals. Basically it was a technique to reconstruct the convoluted signal into a delayed form of the original signal by implementing iterative process. The process involved a parallel Finite Impulse Response Filters, which were iteratively calculated and analyzed. By treating the signal, which captured by the specially developed sensor, as a digitized discrete time series then the original stress wave signal had been successfully revealed [3,4].

2. ANALYTICAL MODEL

In the real practical situation, the observed signal from a measurement was not the original input signal, but was the convolution result of the original input signal $x[n]$ with the impulse response system $h[n]$ plus corrupted by noise $s[n]$. The original input signal was inaccessible and the impulse response system was unknown. The system or the channel was comprised the physical transmission media and channel as well as the transmit and receive filters. In Digital Signal processing, convolution was the computation of the output signal $y[n]$, given knowledge of both the input signal $x[n]$ and the impulse response $h[n]$ of the system. Just the opposite, deconvolution refers to the determination of the impulse response of the system $h[n]$ or the input signal $x[n]$ whereas the output of the system $y[n]$ was typically accessible. With the availability of a reliable model of the system, the unknown input signal could be estimated. Since convolution was commutative, the deconvolution problems were mathematically equivalent and the solution was relatively straight forward [5,6]. In the efforts to enhance incipient damage signal from solid machine element, the original signal of the solid machine element was inaccessible directly, whereas the channel impulse response was unknown. To capture the original signal, this situation raised the need for a deconvolution process without any a priori knowledge of the channel/system or the original input signal. Since this process was performing "blindly", it was called as the blind deconvolution. Figure 1 below showed a basic configuration of a blind deconvolution. In order to reconstruct the original signal, a system that optimally removed the distortion that an unknown channel induced on the transmitted signal was needed .

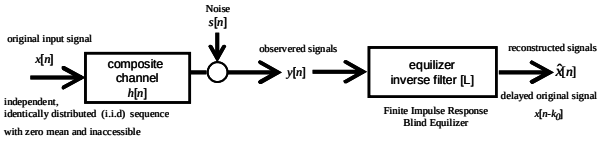

Figure 1 blind deconvolution system model for enhancing incipient damage signals

This system was classically known in mobile communication field as equalizer. Unlike the ordinary equalizer, this blind equalizer performed without access to the original input or any known training sequence, target or desired signal in terms of adaptive filtering. The objective was to deconvolve the receiver input $y[n]$ to retrieve the channel input $x[n]$. The output of the blind equalizer was denoted $\hat{x}[n]$. It could be restated as to find the Finite Impulse Response (FIR) of the inverse filter $e[n]$ that will give $\hat{x}[n]$ was as close as possible to the delayed original signal $x[n-k_0]$ in the Mean Square Error (MSE) sense [2, 3, 4] :

$$\mathrm{MSE}(e,k_0)\underline{\Delta}\sum\{|\hat{x}[n]-x[n-k_0]|\}^2 \Rightarrow \text{minimum} \qquad (1)$$

The process for enhancing the corrupted signals, involved a parallel Finite Impulse Response Filters, which were iteratively calculated and analyzed. Figure 2 below showed the block diagram of blind deconvolution (blind equalizer) iterative system model [7].

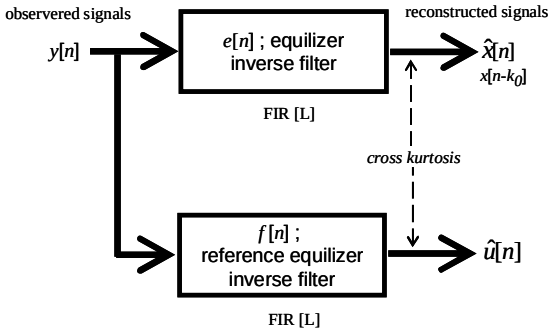

Figure 2 Block Diagram of Blind deconvolution iterative system

Basically by using the analog-digital signal acquisition, the total observed signals were digitized to be time series. Then it was processed as statistical cummulants as Shalvi and Weinstein higher order statistics operation methods. However, the algorithm required pre-knowledge of the excitation signal such as kurtosis and mean value and the convergence was generally slow because their method was based on stochastic gradient algorithm. To overcome those hindrances, beside an equalizer with $e[n]$ was the equalizer impulse response, was introduced to the channel output $y[n]$ to produce an output signal, a second parallel inverse filter with the same order was introduced as a reference system filter. The task of the second filter was to generate an implicit sequence of reference data for the iteration process. The impulse response of second filter was denoted by $f[n]$. The solution to blind deconvolution was based on the maximum "cross kurtosis" quality function [8]. Cross kurtosis between $\hat{x}[n]$ and $u[n]$ could be used as a measure of equalization quality. Using the convolution between the equalizer input and output signals, the cross-cumulant of the observed signal $y[n]$ and the reference signal $u[n]$, could be used to maximize the quality function [8,9]. Numerical techniques that been used to solve the iterative higher order

statistics operation were the Eigen calculation in Eigen Values determination method which was originating from the Blind Deconvolution method. The eigenvector algorithm (EVA) method originally developed by Kammeyer and Jellonek [9,10]. It based on cross kurtosis of two higher order cumulants and maximized the kurtosis criterion. Using this method, the characteristic of the inverse channel could be estimated directly from a number of samples of the observed signal. The iterative procedures consisted of calculating the blind equalizer impulse response and the outputs of the filters. After a certain number of iterations (based on the received data samples), both the reference and the equalizer systems will have a set of coefficients very close to the Minimum Mean Square Error equalizer [10].

Using the convolution between the equalizer input and output signals, the cross-cumulant of the observed signal $y[n]$ and the reference signal $u[n]$, can be used to maximize the quality function [10]. The cross cumulant of the output signal $u[n]$ and observed signal $y[n]$, denoted as C_4^{uy} could be calculated as written below.

$$C_4^{uy} = E\{|u(k)|^2 y_k y_k^*\} - E\{|u[k]|^2\}E[y\{y_k y_k^*\} - ..... \\ .....E\{u[k]y_k\}E\{u[k]^* y_k^*\} - E\{u[k]^* y[k]\}E\{u[k]y_k^*\} \quad (2)$$

" * " denoted the convolution operator.

As a Hermitian cross cumulant matrix, C_4^{uy} could be rewritten as scalar cross-cumulants where the symmetry property $C_4^{uy}(i_1,i_2) = [C_4^{uy}(i_2,i_1)]^*$ was exploited as:

$$C_4^{uy} = \begin{bmatrix} C_4^{uy}(0,0) & [C_4^{uy}(-1,0)]^* & ... & [C_4^{uy}(-l,0)]^* \\ C_4^{uy}(-1,0) & C_4^{uy}(-1,-1) & ... & [C_4^{uy}(-l,-1)]^* \\ ... & ... & ... & ... \\ C_4^{uy}(-l,0) & C_4^{uy}(-l,-1) & ... & C_4^{uy}(-l,-l) \end{bmatrix} \quad (3)$$

If R_{yy} represented the Toeplitz autocorrelation matrix of the observed signal $y[n]$, e was the equalizer impulse response and σ_d^2 denoted variance of the signals, then,

maximized $\left|e^* C_4^{uy} e\right|$ was subjected to $e^* R_{yy} e = \sigma_d^2$ (4)

$$C_4^{uy}{}_e = \lambda\, R_{yy}\, e \quad (5)$$

$$R_{yy}^{-1}\, C_4^{uy}\ e_{EVA} = \lambda\ e_{EVA} \quad (6)$$

Equation (5) and (6) were the Eigen Vector Algorithm EVA equations for determining the coefficient vector $e_{EVA} \underline{\Delta} [e_{EVA}(0),.....,e_{EVA}(l)]^T$. It could be obtained by choosing the eigenvector of $R_{yy}^{-1} C_4^{uy}$ associated with the maximum magnitude Eigen value λ, and was called the EVA-(l) solution to the problem of blind equalization. The e_{EVA} were calculated by choosing the most significant eigenvector of the estimated $R_{yy}^{-1}\, C_4^{uy}$. The calculation process gave the result as the MMSE (minimum mean square error) criterion was met in the iteration. These eEVA results were denoted then as $e_{EVA}^i[n]$ of the blind equalizer. Iteratively, load back the $e_{EVA}^i[n]$ into the reference system as a new estimation of $f[n]$. This iteration process produced the latest $e_{EVA}^i[n]$, until a sufficient equalization result was obtained (controlled by a relative error value set up), or the equalizer coefficient did not change anymore, i.e. the relative error is smaller than the set value [8,9,10]. The calculations routines were prepared and written on the Matlab® platform.

However, some modification should be made in the routines of the equalizer structure in order to suit with the characteristics of the stress wave. Since the method required a Bayesian type of series, a modification to remove the mean value or to shift the time domain signal to zero mean axis had been added prior the numerical processes stated above could begun. Numerical method steps for doing this were called as "remmean" subroutine, which was written in Matlab® as well. The maximum number of iteration was set to 120 times or the MSE value of 0.005 was reached whatever came first. This set up value was a reasonable value based on time, cost, affectivity and efficiency of an iteration operation with an acceptable result. Since the SNR were not known and with a variety due to the nature of the defects, a "moderate" value of 32 was taken for the FIR filter length [11,12]. The signals of the incipient damage could be detected as pulses showed in the time domain signal waves. This signal pulses, were defined as The Crest Factor, i.e. a ratio of the maximum peak of the signal over the RMS value. The Crest Factor could be regarded as a feature in condition monitoring or fault diagnosis.

$$\text{Crest Factor} = \frac{\text{Maximum Peaks}}{\text{RMS}} = \frac{X_{peak}}{\sqrt{\frac{1}{N}\sum_{i=1}^{N} X_i^2}} \quad (7)$$

The Crest Factors were good indicators to assess the property of the output signals. Even though a large amount of data is needed to be captured for accuracy, in the processing only some percentage of the total numbers was needed. This would be a significant saving in time and calculation efforts if the optimum percentage of samples could be determined first. The EVA approach in detecting signals had sensitivity in a range of SNRs in terms of Crest Factor and Energy. The signal energy levels stay relatively constant for SNRs less than 0.5 whereas the crest factors were hovering in a certain range. But at low SNR, interesting results were shown with a low Crest Factor and a high Energy. However, these relationships could not be used straightforward directly for determining the optimum number of samples data based on the high Crest factor since the Energy level could not be directly related to the number of samples [12,13]. The highest crest factor was appeared from processing an optimum percentage of data samples. For best practices, data samples should be captured at least twice the maximum frequency of interest times he capturing time, e.g. 3 revolutions. But it already revealed that by using too many samples data, i.e. more than 50%, the enhancement process would fail to show the original signals up. Therefore, the first step was to find the optimum percentage of the data sample points according to the

ISSN 114-1284

maximum crest factor value was found. Then after the optimum numbers of samples to be processed were determined, the real Blind Deconvolution full process were run to reconstruct or to enhance the original desired signals. So, the usage of all series data of the signal could be avoided to save the iteration time as well as to improve the result. Figure 3 on next page showed the Flow Chart of Digital Signal Processing for enhancing signal from incipient damage of solid machine element [13,14].

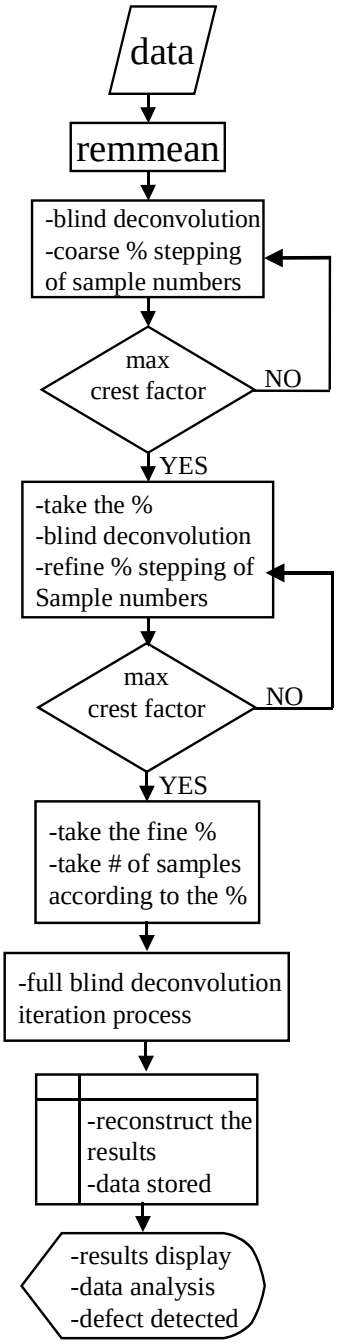

Figure 3 DSP flow chart to enhance signal of incipient damage from solid machine element

3. EXPERIMENTAL

Computer simulation data were firstly used to test the function ability and the reliability of the method. An experimental rig was constructed to test the feasibility of using the EVA blind deconvolution to detect a simulated rolling element bearing failure under controlled conditions. The bearing was set to rotate at a fixed rpm rate that gave its bearing defect frequency.). A schematic of the modeling process was shown in figure 4 below. A constant impulsive response $h[n]$ were provided by the machine element. Simulated noise signal data were generated using the series generator of a DSP software and sinusoidal wave generator via PZT actuator. Number of data points, spacing, values range, mean values and standard deviation were parameters that been set up when generating the simulated noise [12,13].

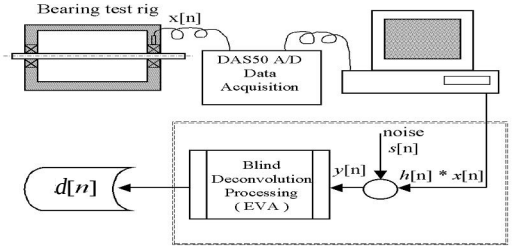

Figure 4 Schematic Diagram of the simulation experimental system set up

After that, real data from real time laboratory experimental tests were used as the experiment stage 2. Figure 5 below showed the real time experimental set up.

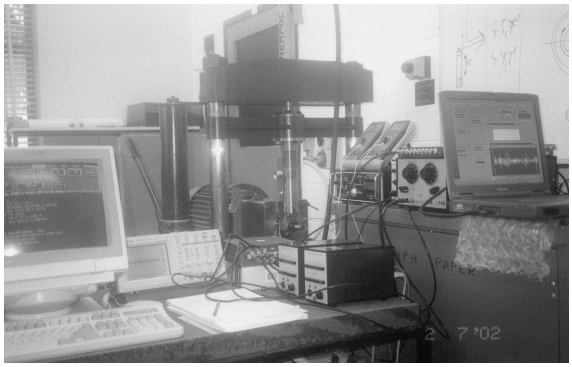

Figure 5 real time experimental and observation test rig

A test rig consisted of a hydraulic press and an electric motor and a set of sensors mounting were built. A new ball bearing, which installed on the output shaft of the electric motor, was loaded radially by the hydraulic jack and simultaneously was rotated at a normal operating speed by the electric motor. It was set up for a simulated extreme real operation condition. By using the bearing life/performance calculation procedures, i.e. from the manufacturer-operating manual, it was predicted that the ball bearing would last for 117 hours in that extreme operation condition. Specially designed AE sensor and common

accelerometer sensor were used to detect the signal and to compare the capability of both sensors in detecting incipient damage. With real time observation and offline signal processing, then the ball bearing condition was monitored and analyzed every hour. Reconstructed signals were extracted from the observed signal after the observed data were processed offline with a computer with the application of the Blind Equalizer Digital Signal Processing method. The method had succeeded to reveal the stress wave from the noise-corrupting signal [11,12,13,14].

4. RESULTS AND DISCUSSION

A numerical iteration procedure was executed with blind deconvolution calculation for refining number of samples in order to find the optimum samples numbers to be used in the Blind Equalization steps. These iterative calculation processes were based on the maximum Crest factor determination with regard to the optimum sample numbers been used. Figure 6 below showed that the optimum percentage of data samples were needed to enhance signal pulses, i.e. Crest Factor, significantly were in the range of 30% to 40%. The optimum percentage of data samples were the one that gave the highest crest factor value. It also showed that the enhancement process would fail to show the

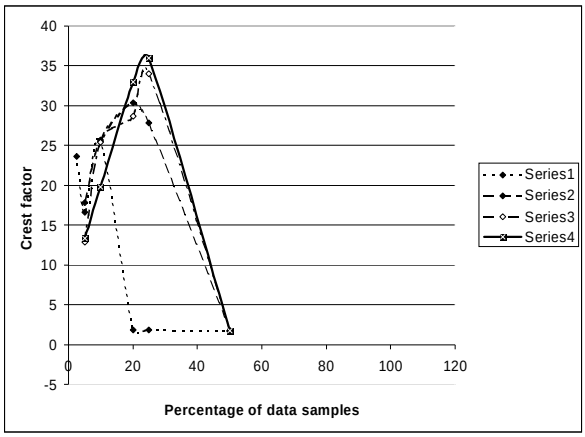

Figure 6 Percentage of data samples been used according to the maximum Crest Factor value

original signals up if using too many samples data [13, 14].

The simulation gave satisfactory results, as the reconstructed signal was so similar to the original simulated signal data. A number of tests were conducted to test the sensitivity of the technique in detecting a minute defect masked by a range of corrupting with varying SNRs. The amplitudes to mask the bearing signal were adjusted to give a range of signal-to noise ratios (SNR). It was evident that the generated noise has masked the bearing signal. However, higher SNR above 0.738 were not used in the test, as the bearing signal became more prominent and was clearly visible. Figure 7 showed the corrupted signal at low-level noise (SNR=0.738) and the reconstructed signal output after blind equalization process. Figure 8 showed the corrupted signal by high level noise (SNR=0.262) and the original signal after blind equalization reconstruction process. Both outputs, from low level noise and high level noise, distinctly showed the defective bearing signal with an impact rate corresponding to an outer-race bearing defect. Figure 9 showed the original signal from a simulated outer race defect bearing. From figure 7 and 8, it could be seen that the Crest Factors and signal energy levels of the reconstructed signals were similar to that of the original bearing as shown in figure 9.

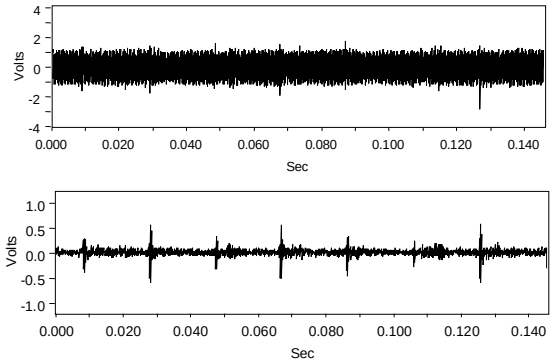

Figure 7 Corrupted signal at low level noise and result from blind equalization reconstruction process

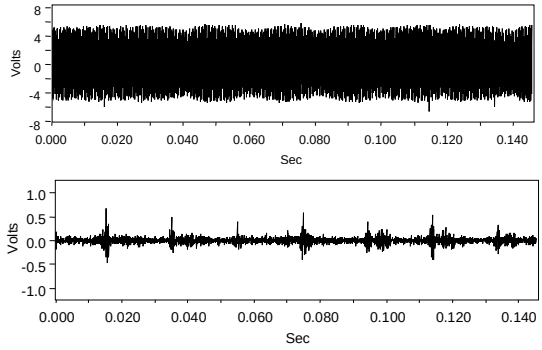

Figure 8 Corrupted signal at high level noise and result from blind equalization reconstruction process

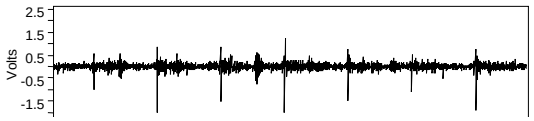

Figure 9 Original signals from simulated defect bearing

For the real practical tests, a new ball bearing which was installed on the output shaft of an electric motor and simultaneously rotated at a normal operating speed, was loaded radially by a hydraulic jack. With real time

ISSN 114-1284

observation and offline signal processing, then the ball bearing condition was monitored and analyzed every hour. Reconstructed signals were extracted from the observed signal after the observed data were processed offline with a computer using the blind equalization technique. Figure 10 on next page showed firstly the observed signal after 115 hours run, captured by the AE sensor, which contained the original signal of the microscopic defects, electric line noise as well as other noise, and secondly the reconstructed signal as a result from the blind equalization process. It was quite clear that all noise, including noise due to the electricity frequency were cleaned up and the little pulses were enhanced and appeared as the microscopic defect signals.

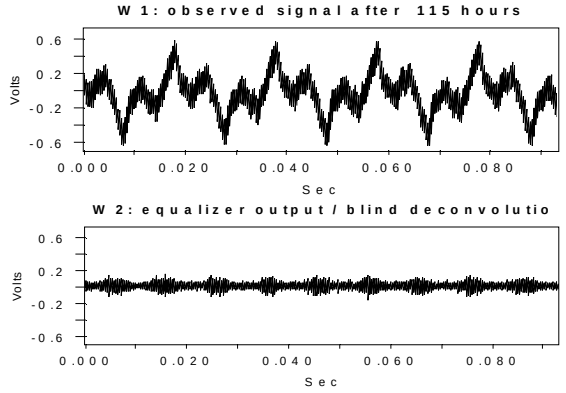

Figure 10 Corrupted signal after 115 hours test run and result from blind equalization reconstruction process

For next test, another new type of bearing was installed on the electric motor shaft and rotated, was extremely loaded to shorten its operating life hours in order to have efficient and effective observation time. 2 types of sensors were installed, i.e. AE sensor and common accelerometer sensor. Accelerometer sensor was used to get a comparison of the signals in order to prove that the signals which captured by the AE sensor were came from incipient damage, since incipient damage signal could not been detected by common accelerometer because the stress waves from such incipient damage were very low in amplitude so therefore had not vibrate the machine element body yet.

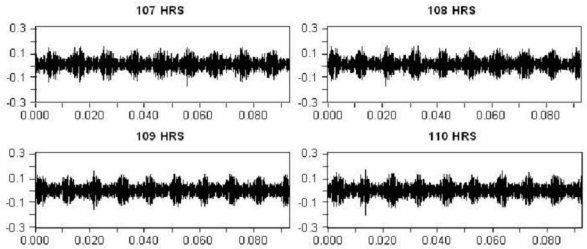

Figure 11 Reconstructed signals as result from blind equalization reconstruction process on observed signals after 107 to 110 hours test run

Figure 11 above showed that the blind equalization method had successfully eliminated the corrupting noise. The shape of the reconstructed time domain signal changed where signs of impacts clearly appeared. These impulsive signals were due to the AE signals from incipient damage in the bearing. These reconstructed bearing signals with pulses suggested that the bearing had a localized incipient defect. Whereas from figure 12, it showed the facts that the reconstructed signals were unchanged from that the observed or measured signals by the common accelerometer for the same bearing. No sign of impacts in the bearing that was detected by common accelerometer. This was due to the reality that the bearing was not vibrating since it had not had physical damage yet.

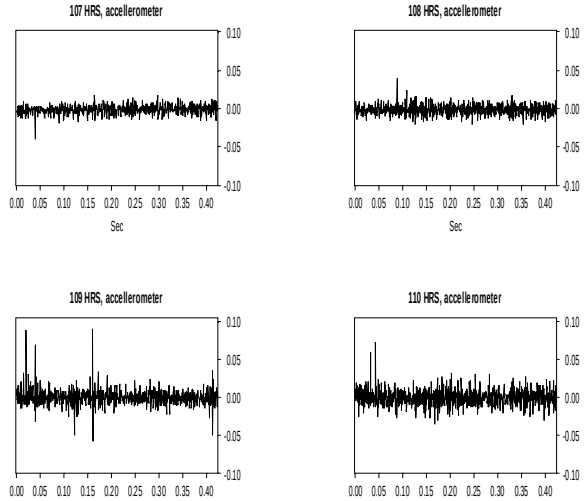

Figure 12 Reconstructed signals as results from blind equalization reconstruction process after 107 to 110 hours test run, from same bearing, detected by common accelerometer

Physical checks on the bearing showed nothing significantly to be the defect. This bearing was relatively still in a good condition, even the pulses in the signals were very clear. The number of pulses, which appeared in a certain time, would show the frequency of the impact/pulses. The vibration frequency told us that the incipient defect was in the outer race but still in a microscopic level since no significant sign of defect on the outer race could be seen visually. This was due to the facts that the frequency of the pulses in the time domain waveform was matched with the frequency of BPFO (Ball Passing Frequency Outer) of the test bearing. The reconstructed bearing signal with pulses suggested that the incipient defect was localized and in microscopic level, i.e. microstructure disintegration, in the solid material of the bearing outer race [13,14,15].

5. CONCLUSION

The advantages of blind equalization as a technique to recover the original signal of a typical faulty solid machine element, i.e. rolling elements bearing, which corrupted by noise and distorted by the transmission path were revealed. This technique that been developed with the numerical iteration method had shown its capability to enhance the

signal of incipient damage in the solid material of a machine element. The Blind deconvolution/equalization had been successfully developed based on Eigen vector approach (EVA) to enhance the incipient damage signals from the observed signals. The results showed the superiority of the technique in extracting the signals from a total observed signal that was corrupted by noise. It was found that there was a good agreement between the graph to determine the optimum percentage of sample numbers and the results of the blind equalization processes. The optimum values from the graph were matched with result from the preprocessing calculation which gave the values in a range of 30%-40% number of optimum samples. It was found that this procedure worked well and the incipient damage signals had been recovered from the observed signal. This technique clearly reproduced the original signal and worked very well with periodic noises, which could be very suitable from rotating machine elements. Since the characteristic frequencies contained very low energy, and usually are overwhelmed by noise and higher levels of macro-structure vibration, than it was difficult to identify them in the frequency spectrum. However, the defect could be detected directly from its time domain waveform, i.e. the equalizer outputs, even at an early stage of failure, still in microscopic level, far before the significant real defects could appear. The research would be developed later on to be a new technique in detecting very early damage, which no technique could do before. The most benefit of this method meanwhile was the contribution in improving the performance and the best practice of the vibration condition monitoring in the predictive or reliability centered maintenance.

6. ACKNOWLEDGMENT

The authors would like to acknowledge and appreciate highly the assistances and supports from Prof. Andy Tan of Mech. Eng. QUT, and the research facility supports from Dynamics and Vibration Laboratory of QUT, Brisbane-Australia, where most of the works regarding this research were done there. The authors would like also to acknowledge and appreciate highly the permission granted, via email, to explore, apply, adjust, enhance and/or improve the EVA technique for the Blind Deconvolution method as well as to use it in the authors' research for academic purposes; from Prof. Kammeyer and all his assistants at the University of Bremen West Germany.

ABSTRACT

As one of passive fire protection application in industry, fireproofing practice is quite beneficial to provide a degree of fire resistance for protected structures and equipment during emergency condition. Normally this practice was conducted at the design phase of constructing a new plant. However in an operating plant, fireproofing application shall be inspected regularly by conducting a fireproofing survey. From this survey, further evaluation is required to review the application.

During 2008 Full Risk Insurance Survey in PT Badak NGL, this practice was also highlighted. Since PT Badak NGL as widely recognized company is highly concern on safety for plant operation, therefore efforts to review the application and standardize the area required fireproofing at Process Trains was introduced. By using API 2218 as guidance, evident parameters and methods used to determine fireproofing area is stated. Methods used for determining the area in this paper consist of identifying type of fire that might occur, developing scenarios and analyzing consequences of each impact of scenarios on Process Train areas. Based on the result, a fireproofing required area mapping could be generated.

Keywords:

Passive fire protection, fireproofing, pool fire, consequence analysis, Process Train

1. INTRODUCTION

As like any other industries that deal in flammable liquids and gases, PT Badak NGL also concerns on the hazards of the fluid. These kinds of risk shall be managed to avoid undesired events such as explosions and fires. Therefore a system to protect the plant during emergency must be ready at all times. One of protection system which available in PT Badak NGL is fireproofing that could provide protection on equipment and structures to withstand fire exposure for certain amount of time.

During PT Badak NGL extensive experience, fireproofing practices which has been applied are maintained by conducting inspection, review and assessment. On fireproofing survey at Process Trains conducted internally, it was identified that several locations shall be determined whether those locations shall be fireproofed or not. Based on that purpose and also from external Insurance inspection recommendations in 2008, a review is needed on fireproofing requirements based on risk that exposed to the equipment or structures. The review is referred to API Publication 2218 – Fireproofing Practices in Petroleum and Petrochemical Processing Plants to generate the guidance and fireproofing mapping at Process Trains.

2. REQUIREMENTS

The term of Fire-Proof, as mentioned in the API Publication 2218, does not mean totally safe from the effects of fire. Fireproofing refers to the systematic process (including materials and the application of materials) that provides a degree of fire resistance for protected substrates, therefore it is also categorized as the passive fire protection. On the publication it is stated that to provide protection, the severity and duration of the fire scenarios shall be determined. However PT Badak NGL had determined that the fireproofing materials shall resist from fire for 90 minutes, referred to PT Badak NGL General Specification No. B.2.6 regarding Fireproofing.

This API document specifically addresses property loss protection for pool fires scenarios but not jet fires or vapor cloud explosions. Pool fires mainly selected due to intense and prolonged heat exposure that could cause collapse of unprotected equipment and lead to the spread of burning liquids. However the limit of the structures and equipment to withstand the heat radiation shall be determined.

Further consideration is derived from the publication that the computer modeling equates 300°C (572°F) to an exposure of approximately 12.5 kW/m^2 (4000 $BTU/hr\text{-}ft^2$) for exposure without fireproofing or water spray. This figure is applied for most of equipment, however since the other temperature limitation is higher and will be covered within the calculation, for instance for steel structure that can reach 538°C (1000°F), therefore heat flux of 12.5 kW/m^2 (4000 $BTU/hr\text{-}ft^2$) is selected for computer simulation.

In addition, related concern was also taken to generate mapping through layout of the plant rather than side view since it has already been covered in the standard. From all

above descriptions, it is obvious that this paper will emphasize on area required to be fireproofed rather than selection of fireproofing material.

3. METHODS

Since the fire type, heat flux and several considerations have been determined, the next step is to generate the fire scenarios. By considering pool fire as previously mentioned, the objective is searching the scenarios that provide intense and prolonged heat exposure of burning liquid. Several large lines, pressure vessel and tanks were then identified. Large pipelines were chosen since it could release tremendous amount of liquid hydrocarbon, while pressure vessels and tanks were selected by considering that they could hold level of flammable liquid. Vessels that were identified are shown on below table. Train H, as indicated in the table, was used in the calculation to provide the worst scenario effect since the Train has the biggest capacity among the others.

Table 1. Volume of Vessels Containing Flammable Liquid

Tag No.	Description	Tank Type	Total Volume (m^3)
H2C-1	Drier Separator Decanter	Vertical	26.18
H3C-1	Scrub Column	Vertical	14.80
H3C-2	Scrub Column Condensate Drum	Vertical	18.40
H3C-4	Deethanizer Column	Vertical	19.96
H3C-5	Deethanizer Condensate Drum	Horizontal	6.52
H3C-6	Depropanizer Column	Vertical	12.57
H3C-7	Depropanizer Condensate Drum	Horizontal	18.43
H3C-8	Debutanizer Column	Vertical	7.10
H3C-9	Debutanizer Condensate Drum	Horizontal	17.27
H4C-1	Propane Accumulator	Horizontal	149.08
H4C-2	High Level Propane Flash Drum	Vertical	89.63
H4C-3	Medium Level Propane Flash Drum	Vertical	72.71
H4C-4	Low Level Propane Flash Drum	Vertical	177.92
H4C-12	High Level Propane Knock Out Pot	Vertical	27.37
H4C-7	MCR First Stage Suction Drum	Vertical	42.64
H4C-8	MCR Second Stage Suction Drum	Vertical	71.59
H5C-1	High Pressure MCR Separator	Vertical	62.25
H5C-2	LNG Flash Drum	Vertical	47.08

During identification, vessels and lines on Plant 1 - CO_2 Removal Plant and Plant 2 - Dehydration Plant (except 2C-1 - Drier Separator Decanter) shall be excluded. Plant 1 was left out since the amine solution is not categorized as flammable liquid (as seen on its MSDS). As for Plant 2, there is no significant amount of hydrocarbon liquid observed that could stay for 90 minutes fire.

A release calculation then was performed to measure the size of liquid pools from various sources listed. During calculations, some assumptions were used such as using full bore release area for the leak size and 100% level of the flammable liquid in the vessel. At any instant in time, the rate of liquid spreading can be found by use of a simple hydrodynamic model,

$$\frac{dr}{dt} = \alpha\sqrt{h}$$

$$r = \alpha \int_0^t h^{1/2}\, dt \qquad (1)$$

where: r = pool radius at time t, m
t = time, s
α = constant = $\left[2g\left(\rho_s - \rho_{liq}\right)/\rho_s\right]^{1/2}$
h = pool height, m
g = gravitational acceleration, 9.8m/s^2
ρ_s = density of solid or ground, kg/m^3
ρ_{liq} = density of liquid, kg/m^3

The total volume of liquid released is measured with

$$V_{liq} = \int_0^t \frac{dV_{liq}}{dt}\, dt \qquad (2)$$

where: V_{liq} = volume of liquid in pool at any time t, m^3

Since the liquid pool size has been determined then the surface flux of the pool fire is calculated using the following equation,

$$q_{sf} = \dot{m}.\Delta H_c\left(1 - e^{-bD}\right) \qquad (3)$$

where: q_{sf} = surface flux of fire, kW/m^2
m = mass burning flux, kg/(m^2.s)
ΔH_c = the heat of combustion for the burning liquid, kJ/kg
b = extinction coefficient, dimensionless
D = diameter of the liquid pool, m

The surface of the flame is divided into numerous differential areas. The following equation is then used to calculate the view factor from a differential target, at a specific location outside the flame, to each differential area on the surface of the flame.

$$F_{dA_t - dA_f} = \frac{\cos(\beta_t)\cos(\beta_f)}{\pi r^2}\, dA_f \qquad (4)$$

where: $F_{dA_t - dA_f}$ = view factor from a differential area on the target to a differential area on the surface of the flame, dimensionless

dA_f = differential area on the flame surface, m^2
dA_t = differential area on the target surface, m^2
r = distance between differential areas dA_t and dA_f, m
β_t = angle between normal to dA_t and the line from dA_t to dA_f, degrees
β_f = angle between normal to dA_f and the line from dA_t to dA_f, degrees

The radiant heat flux incident upon the target is computed by multiplying the view factor for each differential area on the flame by the appropriate surface flux, atmospheric transmittance, then summing these values over the surface of the flame

$$q_{ai} = \sum_{A_f} q_{sf} \cdot F_{dA_t - dA_f} \cdot \tau \qquad (5)$$

where: q_{ai} = attenuated radiant heat flux incident upon the target due to radiant heat emitted by the flame, kW/m^2
A_f = area of the surface of the flame
q_{sf} = surface flux of fire, kW/m^2
τ = atmospheric transmittance, dimensionless

Equations (4) and (5) are repeated to achieve 12.5 kW/m^2 on each scenario.

4. DISCUSSION

All calculation was executed using Canary computer simulation as a supporting tool. By utilizing this software time required to calculate all scenarios was reduced significantly. Results of the calculation were sorted by scenarios that provided large impact. Summary of the top list results from the simulation are described in the table below.

Table 2. Major Impact Results of Pool Fire Cases for Heat Flux of 12.5 kW/m² (4000 BTU/hr-ft²)

No.	Source of Fire	Distance (Meters)
1	H4C-2	55.8
2	H4C-1	51.2
3	H5C-2	45.9
4	H4C-4	38.6
5	H4C-3	28.4
6	H5G-1A/B	28.1
7	H3C-1	25

From the table it can be seen that all of the results providing the largest impact were occurred from the vessels leak cases. It can be understood since vessels store large number of liquid that could sustain the heat radiation during 90-minute fire exposure. Therefore by these results, more attention on establishing and maintaining existing protection system on these vessels surroundings should be performed.

The last step was plotting those simulation results into plot plan of Process Trains. Each of the calculation was put together into one plot plan of Process Train and removed the similar overlapped radius of heat fluxes. The result of this plotting is shown below.

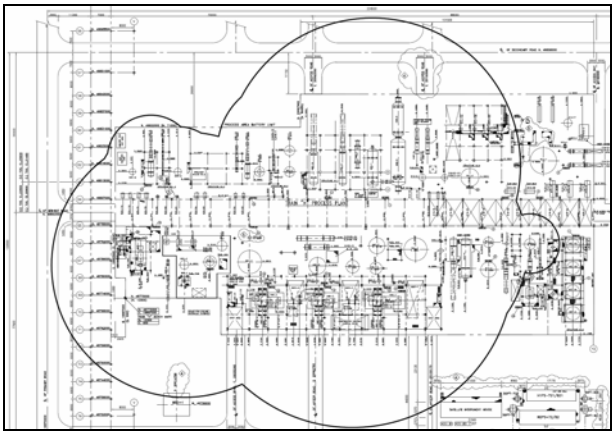

Figure 1. Fireproofing Required Area at Process Train

Hence as we can see, the area covered with radius of collective heat fluxes from all scenarios is the area that could be exposed to fire for at least 90 minutes, therefore fireproofing shall be applied within this area. In general, Plant 1 and Plant 2 (except 2C-1) as mentioned previously is not recommended to be fireproofed, however on the mapping, several areas (right side of the figure) at those plants still require fireproofing because those certain areas could also receive heat flux impacts from previous determined other scenarios.

Furthermore the result can be used as guidance for fireproofing application at other Process Trains. Besides the results, the methods used can be implemented to other areas such as storage tanks, loading docks and knock out drums at Storage & Loading areas.

5. CONCLUSIONS

The API Publication 2218 is a beneficial reference to determine fireproofing required area at the Process Trains, since some requirements have been clearly mentioned such as pool fire cases with heat exposure of approximately 12.5 kW/m^2 (4000 $BTU/hr\text{-}ft^2$). Therefore further sequential steps to identify and calculate the pool fire scenarios have been more structured.

From the calculation result, it can be deduced that the scenarios that provided large impact occurred on the vessels leak cases. Hence besides the fact that those vessels could hold certain amount of liquid which should

be well monitored, assessment on existing protection system at surroundings of the vessels shall be established and maintained.

Although the standard also provides guidance for fireproofing application on dimension of fire scenario envelope, the overall mapping on the plant could not be known directly from it. Through the mapping generated from all identified scenarios calculated in this paper, the required area to be fireproofed which in this case at Process Trains could be justified.

ABSTRACT

The chassis of trucks is the backbone of vehicles and integrates the main truck component systems such as the axles, suspension, power train, cab and trailer. The truck chassis has been loaded by static, dynamic and also cyclic loading. Static loading comes from the weight of cabin, its content and passengers. The movement of truck affects a dynamic loading to the chassis. The vibration of engines and the roughness of road give a cyclic loading. Next, the materials and methods should be explained briefly. The chassis used in the truck have almost the same appearance since models developed 20 or 30 years ago, denoting that they are a result of slow and stable evolution of these frames along the years. The manufacturers of these chassis, in the past, and some still today, solve their structural problems by trial and errors. Conducting experimental test in the early stage of design is time consuming and expensive. In order to reduce the cost, it is important to conduct simulation using numerical methods by software to find the optimum design. Determination of static, dynamic and fatigue characteristic of a truck chassis before manufacturing is important due to the design improvement.. This paper presents the Finite Element Analysis (FEA) of heavy duty truck chassis subjected by cyclic loading using Finite Element (FE) software. The out put of this analysis is useful for failure analysis of chassis and as a preliminary data for fatigue life prediction of chassis. The both analysis are the important steps in design of chassis.

Keywords:
Finite Element Analysis, Truck Chassis, Cyclic Loading, Component Design, Stress Analysis

1. INTRODUCTION

The chassis of trucks is the backbone of vehicles and integrates the main truck component systems such as the axles, suspension, power train, cab and trailer. The truck chassis has been loaded by static, dynamic and also cyclic loading. Static loading comes from the weight of cabin, its content and passengers. The movement of truck affects a dynamic loading to the chassis. The vibration of engines and the roughness of road give a cyclic loading. The existing truck chassis design is normally designed based on static analysis. The emphasis of design is on the strength of structure to support the loading placed upon it. However, the truck chassis has been loaded by complex type of loads, including static, dynamics and fatigue aspects. It is estimated that fatigue is responsible for 85% to 90% of all structural failures [1]. The knowledge of dynamic and fatigue behavior of truck chassis in such environment is thus important so that the mounting point of the components like engine, suspension, transmission and more can be determined and optimized.

Many researchers carried out study on truck chassis. Karaoglu and Kuralay [2] investigated stress analysis of a truck chassis with riveted joints using FEM. Numerical results showed that stresses on the side member can be reduced by increasing the side member thickness locally. If the thickness change is not possible, increasing the connection plate length may be a good alternative. Fermer et al [3] investigated the fatigue life of Volvo S80 Bi-Fuel using MSC/Fatigue. Conle and Chu [4] did research about fatigue analysis and the local stress-strain approach in complex vehicular structures. Structural optimization of automotive components applied to durability problems has been investigated by Ferreira et al [5]. Fermér and Svensson [6] studied on industrial experiences of FE-based fatigue life predictions of welded automotive structures.

ISSN 114-1284

The objective of the work in this paper is mainly to focuses on the application of FEA of cyclic loading on the heavy duty truck chassis. Sub modeling technique has been applied on the critical area in order to find the more reliable, more accurate and faster way of simulation.

2. MODEL OF TRUCK CHASSIS

The model is depicted in Figure 1. The model has length of 12.350 m and width of 2.45 m. The material of chassis is Steel with 552 MPa of yield strength and 620 MPa of tensile strength [7].

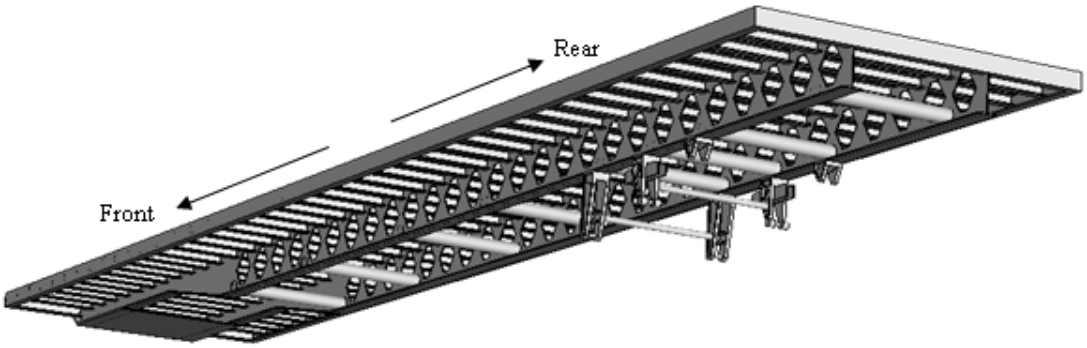

Figure 1. Model of truck chassis

The material properties of chassis are tabulated in Table 1. The truck chassis model is loaded by static forces from the truck body and cargo. For this model, the maximum loaded weight of truck plus cargo is 36,000 kg. The load is assumed as a uniform pressure obtained from the maximum loaded weight divided by the total contact area between cargo and upper surface of chassis. In order to get a better result, locally finer meshing is applied in the region which is suspected to have the highest stress.

Table 1: Properties of truck chassis material [7]

Modulus Elasticity E (Pa)	Density ρ (kg/m3)	Poisson Ratio	Yield Strength (MPa)	Tensile Strength (MPa)
207 x 109	7800	0.3	550	620

2.1 Boundary Condition of the Model

There are 3 boundary conditions (BC) of model; the first BC is applied in front of the chassis, the second and the third BC are applied in rear of chassis, as shown in Figure 2. The type of BC 1 is pinned (the displacement is not allowed in all axes and the rotation is allowed in all axes) that represent the contact condition between chassis and cab of truck. The BC 2 represents the contact between chassis and upper side of spring that transfer loaded weight of cargo and chassis to axle. In the BC3, the displacement and the rotation is zero in all axes on all of bolt's body. This condition is called fixed constrain. The bolt in BC 3 is assumed perfectly rigid. This assumption was realized by choosing a very high modulus Young value of the bolt properties.

2.2 Location of Critical Area

Based on the previous paper, The location of maximum Von Misses stress is at opening of chassis which is contacted with bolt as shown in Figure 3. The stress magnitude of critical point is 386.9 MPa. This critical point is located at element 86104 and node 16045 [8].

2.3 Submodeling Technique Application

Sub modeling technique is used to achieve efficiency in finite element analysis when details are required in sub-regions of a large structure. The sub modeling is also known as the cut boundary displacement method or the specified boundary displacement method.

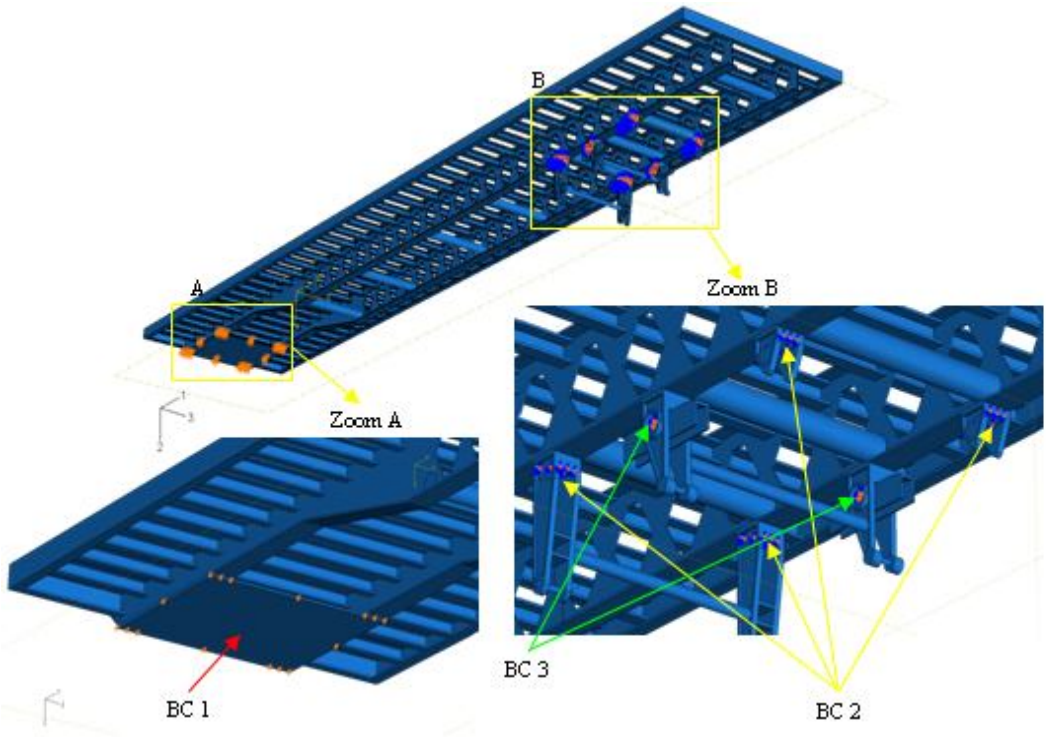

Figure 2. Boundary conditions representation in the model

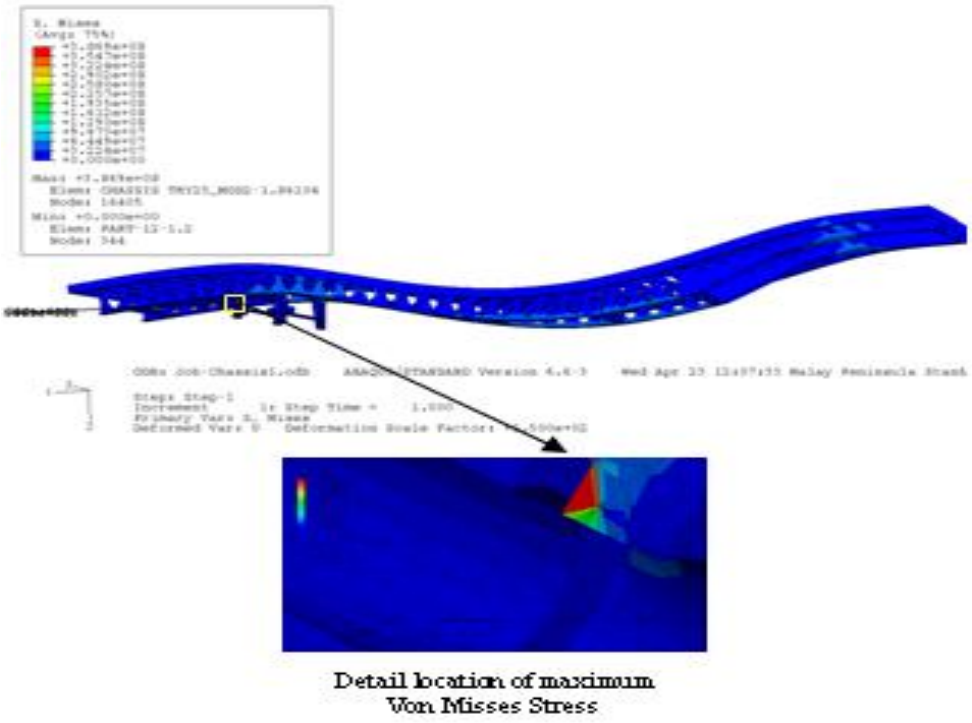

Figure 3. Von Misses stress distribution and critical point location

Based on the Von Misses highest stress area location obtained from previous paper [9], some part of chassis area is taken as a sub structure component where the cyclic loading from the roughness of road will be applied. The sub structure component is shown in Figure 4.

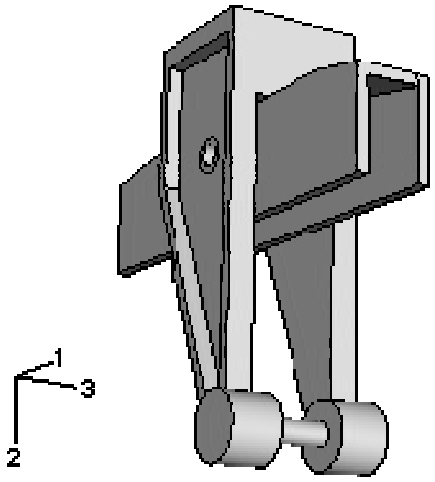

Figure 4. Sub structure Component of Truck Chassis

2.4 Cyclic Loading

Figure 5 – Figure 7 show the response of vehicle suspension due to roughness of road. These data are obtained from direct measurement of some accelerometer placed on the some point on the vehicle. These data converted to the force that will be applied on the sub structure component of truck chassis as cyclic loading .

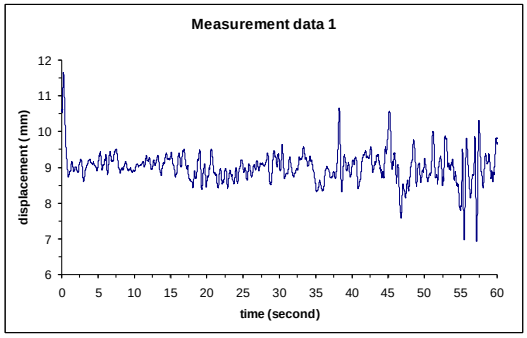

Figure 5. Response of sprung front left suspension of vehicle due to road roughness

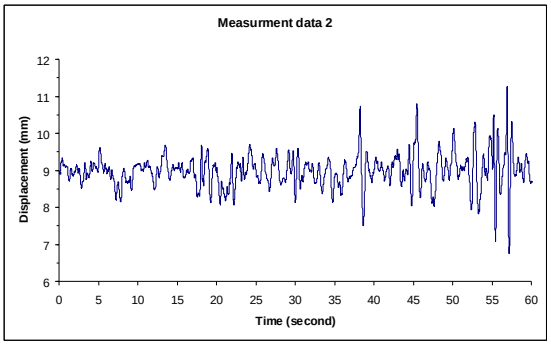

Figure 6. Response of sprung front right suspension of vehicle due to road roughness

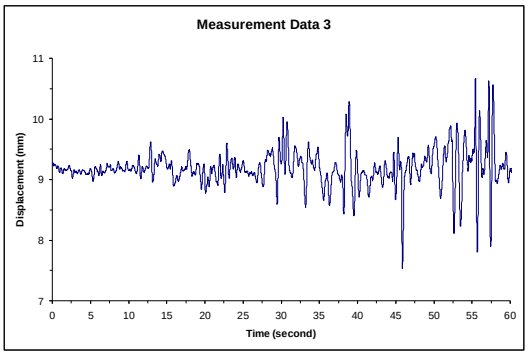

Figure 7. Response of sprung rear left suspension of vehicle due to road roughness

3. RESULT AND DISCUSSION

Figure 8 shows the Von Misses stress distribution of sub structure component subjected by static loading whereas Figure 9 shows the Von Misses stress distribution of the same model subjected by cyclic loading obtained by direct measurement from moving vehicle. The location of highest stress area for both model is same, namely at node 15951 whereas the magnitude of highest stress is little different, the stress of model subjected by cyclic loading is higher than the result of model subjected by static loading. The differences of highest stress magnitude of both model is not significant, just 0.05 %. It shows that the dominant loading on the truck chassis is comes from cargo and its content as static loading; the road roughness does not give significant effect to the stress of component.

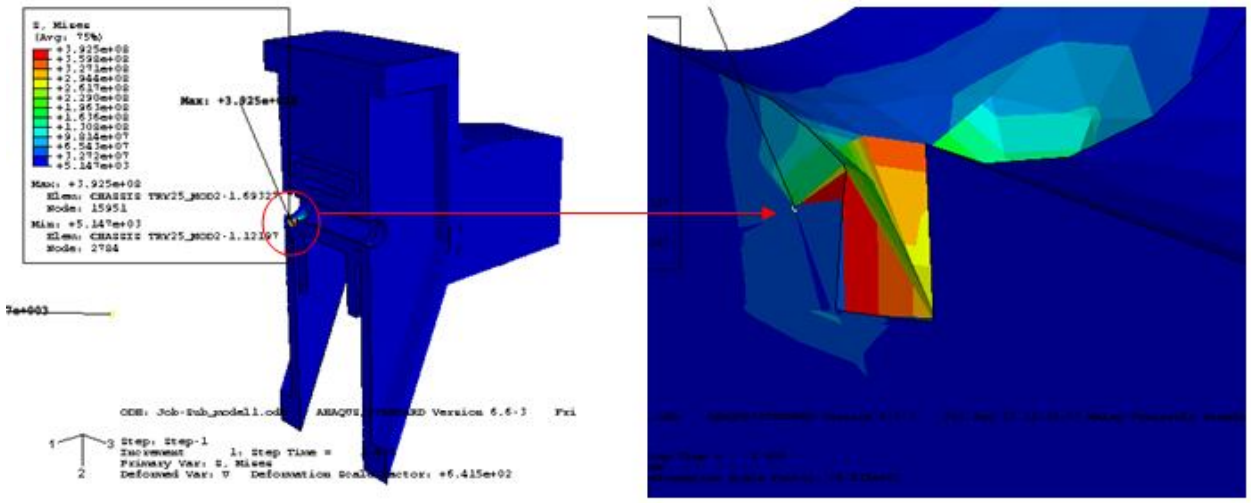

Figure 8. Von Misses result of sub modeling technique without cyclic loading

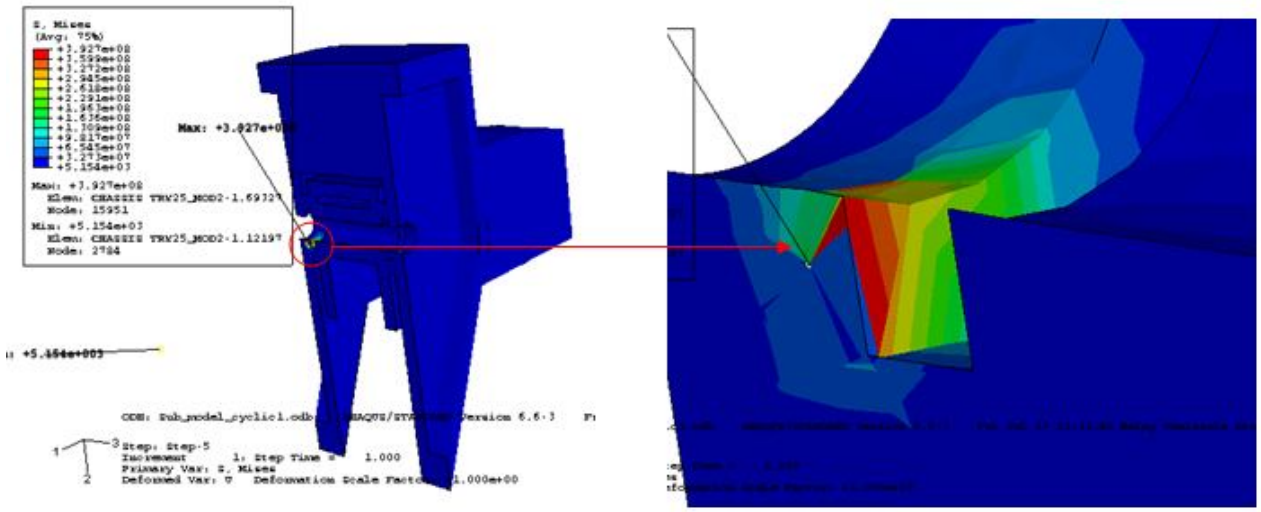

Figure 9. Von Misses result of sub modeling technique with cyclic loading

7. CONCLUSION

The finite element simulation of cyclic loading from the road roughness has been done successfully on the sub structure truck chassis component. The result shows that no significant effect of cyclic loading to the stress of the model, so it can be concluded that the static load is a dominant factor that cause a high stress in the truck chassis. The result need to validate by experiment and it is needed to do further research to look for other effect of cyclic loading to the failure of chassis such as effect of cyclic loading to fatigue life of component. The stress distribution of chassis can be used as preliminary data for fatigue life prediction of truck chassis.

.

ACKNOWLEDGMENT

The authors would like to thank the Ministry of Science, Technology and Innovation (MOSTI) for funding this research via project no. 04-01-06-SF0109. Our gratitude also goes to the members of Sound and Vibration Laboratory and Computational Solid Mechanics Laboratory of Universiti Teknologi Malaysia for their helpful discussions throughout the completion of this work.

ABSTRACT

Indonesian coal is unique among internationally traded coal for its low ash and sulphur contents. However, despite generally favourable quality characteristics, the majority of Indonesian coals have a relatively high moisture content and consequently low calorific value.Indonesia's domestic demand for coal is currently small relative to its production. In 2007, coal production was 213 million tonnes. Of this production, about 47 million tonnes was consumed domestically, mainly for power generation and for cement production. Today, due to extremely high price of oil in international market, it is believed that coal share in domestic electricity generation and cement production will follow an increased trend. Coal is becoming the most important choice among proven energy resources to sustain the required national economic growth in Indonesia. However, the utilization of the low rank coal fraction of Indonesian coal is depend on the ability to provide appropriate technologies for coal up-grading and efficient combustion processes

This paper presents the initial study of enrichment-combustion of non-carbonized briquette. The motivation of this work is that flame temperature of coal briquette by natural drag combustion is low and not enough to be used for heat source in manufactures processes. The flame temperatures could be increased by the increasing of oxygen concentration in the intake air, known as enrichment-combustion. The results are quite promising since coal temperatures above 1350 ℃ can be achieved.

Keywords
enrichment-combustion, flame mean temperature
non-carbonized coal briquette

1. INTRODUCTION

In domestic market, low rank coal which is from Bukit Asam South Sumatra is purchased in form of non-carbonized coal briquette. The proximate analysis of that is shown in Table 1.

Table 1. The proximate analysis data of Non-carbonized coal briquette

No	Parameter	Results
1.	Total Moisture	20.84 %
2.	Proximate Analysis	
	- Inherent Moisture	10.75 %
	- Ash Content	17.34 %
	- Volatile Matter	35.36 %
	- Fixed Carbon	38.55 %
3.	Sulphur	1.87 %
4.	Calorific Value	6214

Data from research before (*Diah .et.al, Sisest, UNSRI 2009*) shown that flame temperature maximum that can be reached by natural drag combustion is 1200 °C, for 2000 g of the briquette, but the increasing of the coal weight is not have significant effect for the char temperature. The temperature tend to constant (see Fig. 2).

This maximum char temperature of non-carbonized coal briquette is not enough as thermal energy resources for manufacturing industries. Because of that, for this application and to increase the char temperature until over 1000 °C, there is need to another technology for combustion processes.

According to According to *Kelly Thambimuthu* flame temperature can be increased over than dapat 1300 °C by oxygen-enrichment in the intake air to combustion chamber, Fig. 2.

ISSN 114-1284

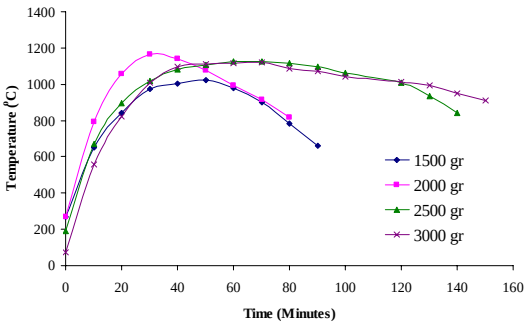

Fig. 1 Time-temperature history of a non-carbonised coal briquette combustion in a natural draft furnace for various coal loadings

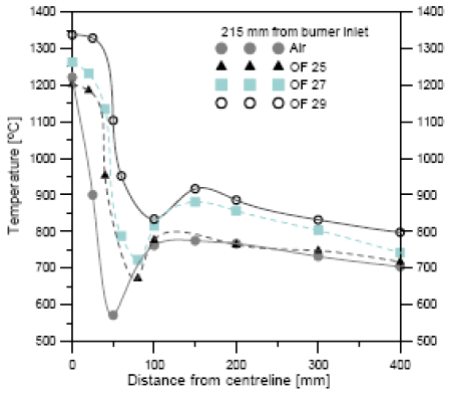

Fig.2. Temperature in combustion chamber

In order to look for the appropriate way to increase the char temperature, so this paper will presented about analytical study of South Sumatra non-carbonized coal briquette combustion by oxygen enrichment.

2. THEORITICAL REVIEW

In this study, intake air to combustion chamber from air tank is compressed air which is control by regulator at 0.5 atm pressure gauge. This is using natural air with 21 % oxygen and 79 % nitrogen and than oxygen composition is increased until 30 %.

For this study, the compressible gas formulas is using as basic equation about the relationship between pressure drop from compressed air in the tank and the air velocity that flow from nozzle to combustion chamber.

$$p_1 - p_2 = 2\rho^2 \frac{v^3 l^2}{\mu g d}$$

Where :
p_1 = air pressure in tank (Pa)
p_2 = air pressure discharge (Pa)
v = air velocity (m/s)
ρ = density (kg/m^3)
l = pipe length (m)
d = pipe diameter (m)
μ = kinematic viscocity

Than, air velocity flow from nozzle to combustion chamber ia :

$$v = \sqrt[3]{\frac{\Delta p.\mu g d}{2\rho^2 l^2}}$$

Than Mach Number is used to compute mass flow rate of oxygen from nozzle

$$\frac{1}{2}\rho v^2 = \frac{1}{2}\rho M^2 a^2$$

Where :
M = Mach Number
$v = Ma$
and

$$a = \sqrt{\frac{\gamma P}{\rho}}$$

Each of chemical composition in briquette will react with oxygen to perform combustion product and releases heat as the result of the combustion reaction process. However, if the process is carried out at a constant pressure or constant volume, it will determined only by the initial and final states of the system.The heat of reaction at standard state is follow :

$$\Delta H_{reac\,tan\,ts} + \Delta H_{r,T_2} = \Delta H_{r,T_1} + \Delta H_{product}$$

$$\Delta H_{reac\,tan\,ts} = \sum_{i=1}^{N} v_i' \int_{T_1}^{T_2} c_{p.M_i} dT$$

c_p *is* a constant average specific heat at constant pressure, M_i is total mass of species i, *v'* is stoichiometric coefficient for species i as a reactant and *v''* as a product.

$$\Delta H_{products} = \sum_{i=1}^{N} v_i'' \int_{T_1}^{T_2} c_{p,M_i} dT$$

Hence, the heat evolve from the combustion process is :

$$\Delta H_{r,T_2} - \Delta H_{r,T_1} = \int_{T_1}^{T_2} \sum_{i=1}^{N} (v_i'' c_{p,i}) dT - \int_{T_1}^{T_2} \sum_{i=1}^{N} (v_i' c_{p,i}) dT$$

By using those formulas, the chemical reaction of combustion will be simulated by using CFD (*Computational Fluid Dynamic).*

3. DISCUSSION

Simulation is conducted for fixed bed condition, where primary stream of air contain 30 % more oxygen composition than natural air with pressure inlet is 0.5 atm. Secondary stream is natural drag air with inlet velocity is 0.005 m/s. The pressure outlet of exhaust gas is 0 atm pressure gauge. Equipment is setting as Fig.3.

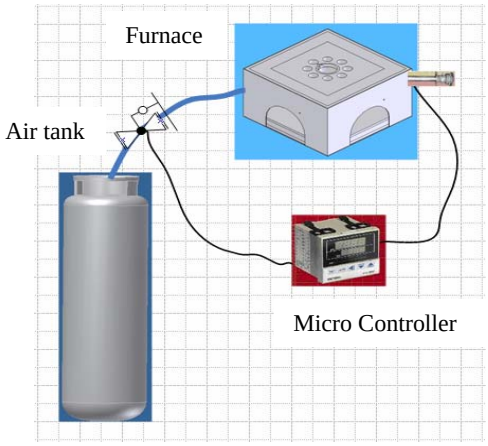

Fig. 3. Equipment set up for experiments

From simulation, the relationship between fuel mixture fraction and mean temperature char is shown on Fig. 4

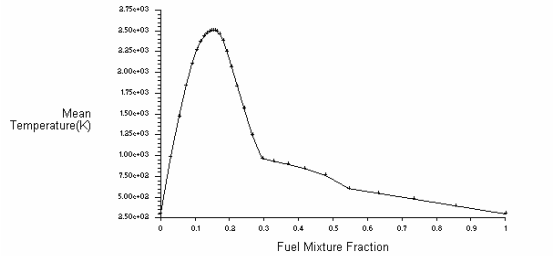

Fig.4.The relationship between *Fuel Mixture Fraction* of Non-Carbonized Coal Briquette with *Mean Temperature (K)*

On the Fig.4, mean temperature char max that could be reached is 2565 K at fuel mixture fraction 0.18. Than, the temperature will be decrease until fuel mixture fraction 0.3 at mean temperature 900 °C, and 1 at 300 K.

The CO_2 contains in exhaust gas will be max at fuel mixture fraction 0.18. This means that the combustion reaction will complete at this value and the composition of CO will be at minimum level., Fig. 5.

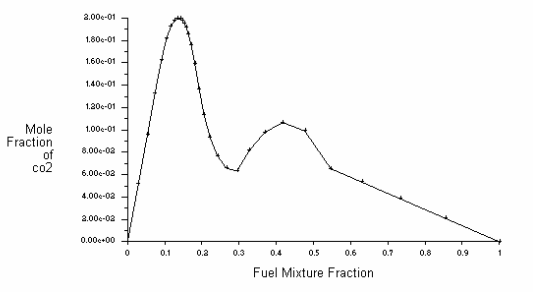

Fig. 5. The correlation of *Fuel Mixture Fraction with Mole Fraction of* CO_2

4. CONCLUSION

Data from analytical study of non-carbonized coal briquette combustion by oxygen enrichment in intake air, known that :

1. Briquette char mean temperature maximum at 2565 K will be reached at 0.18 *Fuel Mixture Fraction*
2. Composition of CO_2 will be at maximum level in the exhaust gas at 0.18 *Fuel Mixture Fraction*
3. The oxygen enrichment combustion technology for non-carbonized coal briquette is appropriate for manufacturing industries application.

ABSTRACT

The current energy demand and its dramatic rate of growth related to the increasing impact of developing countries, clearly indicate the necessity to consider renewable energy as a primary mean to alleviate the needs of a large number of communities around the world. One of those source with potentials opportunity is ocean current. Since unsteady hydrodynamics is the main source that drives the turbine into destructive vibration modes, it could lead to high cycle fatigue structural failures of the turbine after long exposure to unsteady loadings.

The current work presents preliminary analysis of unsteady load on a Vertical Axis Ocean Current Turbine (VAOCT) including changes of forces in its rotation. The work is conducted numerically, where the forces are created in every 5 degrees of turbine rotation at velocity variations of 0.5. The simulation results indicate the force fluctuation in its rotation which can cause unbalanced of turbine. NACA 0018 foil is used as straight rectangular blade model and simulated with nBlade=3 and shaft without pitch control. The comparison values of Cd and Cl of a blade was made, resulting the maximum error of 2.6411% for Cd and 0.7261% for Cl. Two phenomena of periodic dynamics force fluctuation pattern according to the vector resultant formed in a full 360^0 rotation. The result of the recent work will be developed and use as a tool to understand more the phenomena of fluid-structure interaction on VAOCT in order to minimize the effect of vibration according to its reliability.

Keywords: *ocean current, unsteady load, vibration, VAOCT*

1. INTRODUCTION

The motivation for this project arose from an expected vibration source of a small-scale vertical axis wind turbine currently undergoing field-testing. Vertical-axis turbine that is fully submerged and subject to an incoming flow caused by a marine current. Each blade has a straight rectangular, high-span plan form and it is connected to the rotor shaft by two arms. Conversion of streaming water energy into mechanical and electrical energy is based on a simple mechanism.

The hydrodynamic force acted by the incoming flow on the blades generates a torque that force blades, and hence the turbine, to rotate about its shaft. Using an electric generator, mechanical shaft power can be converted into electric power. An important aspect is that a vertical-axis turbine of this type can produce power regardless of the direction of the onset flow and producing force fluctuation subjected to fluid-solid interaction. From the above description it is apparent that production of power from water currents is primarily related to the hydrodynamic forces that are acted on blades.

Nonetheless, the global performance of the turbine results from an interplay of several components. Thus, a successful turbine design can derived only from a multi-disciplinary work, in which turbine hydrodynamics represent the first necessary step. Maximizing the turbine power output can be achieved only if the mechanism of generation of the hydrodynamic force on the blades is clearly identified and tools to design high-performance rotors are developed. In view of the complexity of physical aspects affecting the turbine performance, the most appropriate approach is to combine experimental activity and theoretical studies. This paper carry out a distinct investigation of assessing computational tools to understand more the hydrodynamic forces acting on vertical-axis turbine.

The turbine consists of 1 metre long vertically aligned blades each fixed to the central shaft by two horizontal arms and separated from one another by an angle of θ=120º. The blade profile is a NACA 0018 with a chord length of 0.1 metre fixed at zero angle of attack to the support arms. The turbine optimally operates at a blade-tip speed ratio (the ratio of the blade rotational velocity to the ambient wind velocity) of 2.3. As the blades turn about the central shaft, they encounter

an incident flow that is composed of the ambient flow and the flow due to rotation (Figure 1). This incident wind results in lift and drag forces on the blades resulting in both a thrust force and a radial force on the turbine arms. Note that in this paper, lift is defined as the force perpendicular to Uwind, and drag is defined as the force parallel to Uwind.

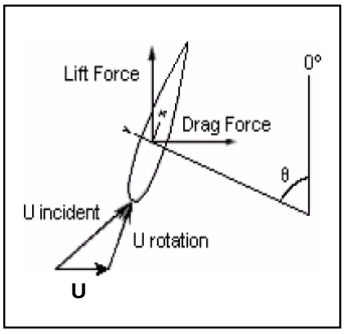

Figure 1: Lift and Drag components on the blade

It is evident that the lift and drag forces on the blade will then vary in time resulting in cyclic loading on the blades. There is also an expected decrease in flow momentum on the downwind side of the turbine as a result of the passing of the upstream blades.

Initial field tests on the turbine show the existence of significant vibration at three times the frequency of rotation, indicating that hydrodynamic loading on the blades may be the cause. In order to better understand the nature of this excitation source, a computational fluid dynamic (CFD) simulation was performed.

2. Fluid-Solid Interaction (FSI)

Structures in a fluid flow will generally induce fluctuating components. These fluctuating or flow-induced oscillations are important aspects of the flow pattern which may in turn excite natural modes of the structure. Such feedback loops in the fluid-structure system are highly nonlinear and under certain conditions may dominate the motion of the fluid-structure system. For each vibrational mode, data usually include the amplitudes of deflection, velocity and acceleration. These responses are linear and translational for bending modes and angular for torsional modes.

When each vibrational mode is independent, the system may be described by studying each mode separately. In general however, systems have two or more degrees-of-freedom and the response can be analyzed only by solving a system of simultaneous differential equations. As strongly emphasized by Naudascher [1] and Sarpkaya [2], the engineer is advised to carry out a detailed preliminary investigation in which all sources providing hydrodynamic loading are identified and their *effect* assessed., several classes of fluctuating hydrodynamic forces.

Naudascher develops a very workable scheme for distinguishing the sources of hydrodynamic loading and we use the terminology and classifications developed by Naudascher. There are four broad categories of fluctuating fluid forces, as shown in Figure 2.

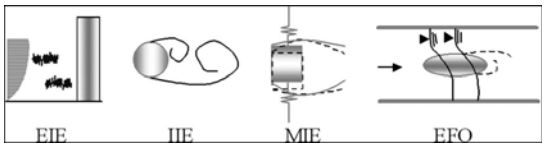

Figure 2. Examples of sources of excitation mechanisms (Naudascher [3])

These categories are fluctuations from:
1) Extraneously Induced Excitations (EIE);
2) Instability Induced Excitations (IIE);
3) Movement Induced Excitations (MIE), and
4) Excitations due to fluid oscillators (EFO)

From structural point of view, there are many research has explored the phenomena of rotating and vibration structure. Khader [4] investigating a simple structural model is adopted to study the stability of a rotating cantilever shaft with uniformly distributed mass, mass moment of inertia and stiffness, and make evaluation of effects of the gyroscopic moment associated with the mass moment of inertia of the rotating shaft-disk system, and of external damping forces and moments, which restrain the translation and tilting of the shaft's cross-section. The research continued by Behzad and Bastami [5] who investigated the effect of shaft rotation on its natural frequency. Apart from gyroscopic effect, the axial force originated from centrifugal force and the Poisson effect results in change of shaft natural Frequency.

Beedor and Qaisia [6] studies the forced vibrations of a flexible rotating blade under the excitation of shaft torsional vibration. A reduced order nonlinear dynamic model is adopted, wherein the torsional vibration degrees of freedom is substituted by a simple harmonic motion with a frequency that is function of the system rotating speed. The resulting system of second-order ordinary differential equation with harmonically varying coefficients is solved using the method of harmonic balance. The solution is useful for defining dangerous operating speed ranges and for quantifying the relationship between shaft torsional and blade bending natural frequencies.
Lau [7] conducted An analysis of a turbine blade fatigue life that includes the physics of fluid–structure interaction on the high cycle fatigue (HCF) life estimate of turbine blades. The rotor wake excitation is modeled by rows of Karman vortices

superimposed on an inviscid uniform flow. The vortex-induced vibration problem is modeled by a linear cascade composed of five turbine blades and the coupled Euler and structural dynamics equations are numerically solved using a timemarching boundary element technique. The analysis can be applied to any blade geometries; it is not limited to the blade geometry considered here.

Geometric analysis and flow characterization are performed together in making an assessment of potentials for flow-structural interaction. Unsteady fluid loads are either motion-independent or motion-induced *as* broken down in Figure 3. Motion-independent loads may be periodic or random, whereas motion-induced loads are primarily periodic. Periodic fluid forces include those resulting from vortex shedding. Random fluid oscillations include turbulence and acoustics.

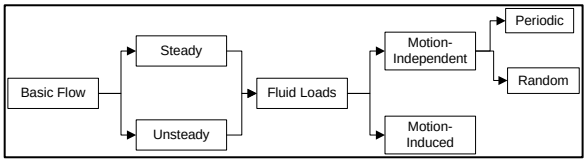

Figure 3. Characteristics of the Flow and its Interaction with Structure [8]

In some cases, the fluid forces are altered by the structural response, and motion-dependent fluid loads must be considered. These are cases of flow/structural interaction. Motion-induced unsteady fluid loads occur in the closed-loop feedback response of an elastic structure. Flow-structural interaction problems occur in specific regimes of reduced velocity. Quick estimates of Strouhal numbers at critical Reynolds numbers are possible to determined reference to basic geometry classifications and to fluid added mass. In many cases it is possible to quickly categorize the actual geometry in some design problem or some problem of high cycle fatigue in an operating system as being close to one of these basic fundamental geometries and thereby obtain the needed estimates.

4. Results

4.1. Numerical Model

The 3D numerical domain was designed to simulate the conditions of the turbine blade flow. A Steady State simulation with rotating wall was performed. Three turbine blade was then located within the domain at a radius of 0.5 metre from the axis of rotation (Figure 4). The inlet flow condition was fixed at U-flow = 0.5 m/s normal to the boundary, with turbulent intensity of 5%.

The outlet of the stationary domain was set at an opening. The upper and lower surfaces of the domain were also set with an opening. The surface of the blade and shaft was modelled as a smooth no-slip surface. The rotational velocity of the rotating wall was set at 2.3 rad/s giving a blade-tip speed ratio (TSR) of

$$TSR = \frac{\omega.r}{U} = \frac{1.15}{0.5} = 2.3$$

The initial conditions for the domain were the same as the inlet conditions.

Turbulence was modelled using the k-ω model near the blade and shaft.

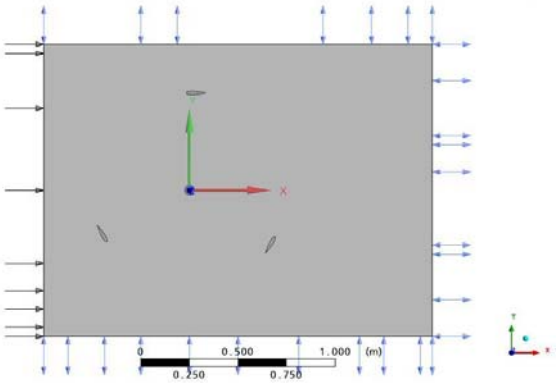

Figure 4. Numerical Domain showing the blade and shaft contained.

4.2. Force Fluctuation

The model was validated for theta of 0^0 to 12^0 and compared with literature results of a NACA 0018 airfoil [9]. As shown in Figure 5, the numerical results appear to match the literature data well.

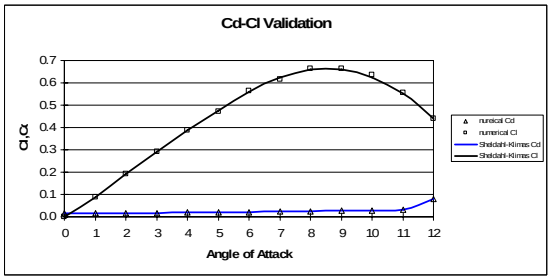

Figure 5. Validation of the model against literature [9]

There are differences dynamics behavior in comparison of force components on a foil in assembly (three turbine and shaft) and stand alone rotation.

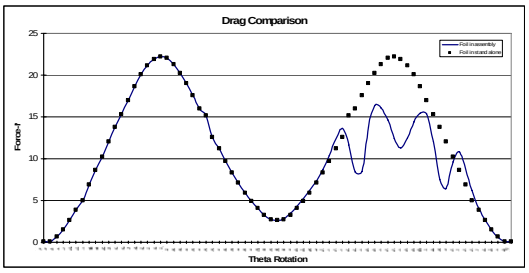

Figure 6. Drag Force Fluctuation on a foil at U:0.5 m/s and 22 rpm

The dynamics of drag and lift force characteristics shown in Figure 6 and Fig 7. There is no force fluctuation for stand alone condition along 180^0 of rotation as the foil to rotate without any disturbance in its upstream.

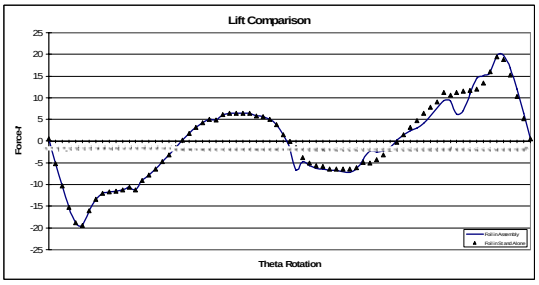

Figure 7. Lift Force Fluctuation on a foil at U:0.5 m/s and 22 rpm

Different behavior force fluctuations occurred for assembly condition at the position of rotation > 180^0. This fluctuation mainly because of the unstable flow pattern received which has been disturbed by others foil and/or shaft in its upstream. In the aspect of fluid force, this is subject to the increase of turbulence intensity by the movement of the body immersed and classified in Movement induced Oscillation [3].

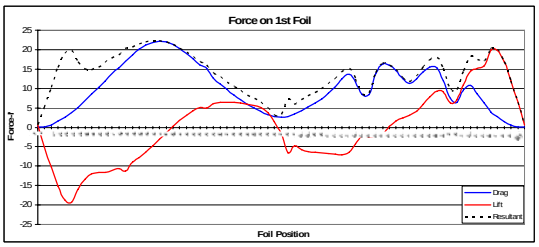

Figure 8. Force Fluctuation on a foil at U:0.5 m/s and 22 rpm

Complete forces fluctuation including its force resultant produce from of a foil and shaft at assembly condition in full 360^0 is shown in Figure 8 and Figure 9.

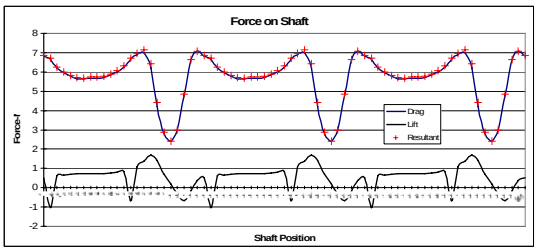

Figure 9. Force Fluctuation on shaft at U:0.5 m/s and 22 rpm

Optimization of total forces and the vector directions was made by estimate the total forced resultant acting on all of turbine components and describe in Figure 10.

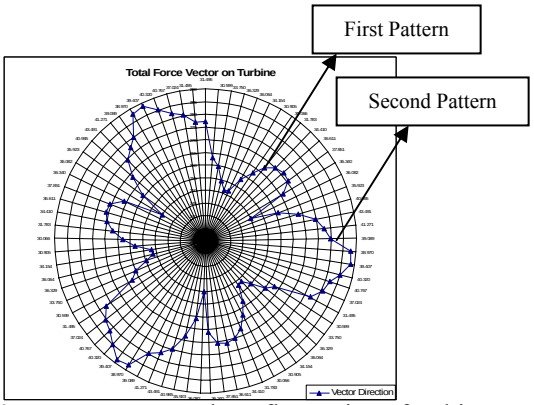

Figure 10. Force vector resultant fluctuation of turbine at U:0.5 m/s and 22 rpm

Two periodic dynamics force fluctuation pattern according to the vector resultant formed in a full 360^0 rotation, the first pattern occurred at Theta rotation of 25^0 - 65^0 , 145^0 - 185^0, and 265^0 - 25^0, while the second pattern occurred at Theta rotation of 65^0 - 145^0 , 185^0 - 265^0, and 305^0 - 25^0.

4.3. Torque Fluctuation

An intrinsic, mechanical phenomenon associated with the operation of ocean current energy conversion systems is given to the time variations
components of a ocean current turbine ideal conditions of a steady called “torque ripple”. Torque ripple is a name in torque which are transmitted through the various drive train ultimately to its load. Torque ripple in a vertical axis ocean current turbine is caused by continuously changing angles of attack between the apparent wind and the turbine blades [10,11]. Other events which contribute to the development of torque ripple include variations in ocean current magnitude and direction, blade dynamics, blade stall and torsional slack in the drive train.

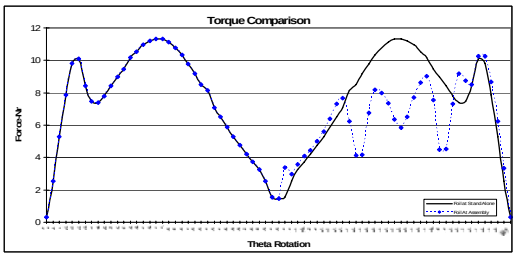

Figure 11. Torque Fluctuation on a foil at U:0.5 m/s and 22 rpm

As a consequence of force fluctuation, the resulted torque also experience the unsteady value and has direct impact to shaft which to be main load support since turbine will rotate 24 hours in ocean environment. The comparison of dynamic behavior of torque on a foil in full 360^0 is showing a similar phenomena with the force fluctuation and shown in Figure 11. Deviation of torque fluctuation between foil in stand alone and assembly condition also occurred at the position of rotation > 180^0.

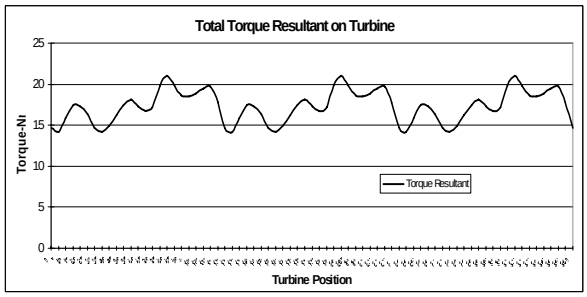

Figure 12. Total torque resultant fluctuation of turbine at U:0.5 m/s and 22 rpm

If sufficiently large, torque ripple may have a detrimental effect on fatigue life of various drive train components (such as shafts, couplings and transmissions) and on output power quality. It may also cause the generator pull-out torque to be exceeded, resulting in a sudden loss of load and possible turbine run-away. Torque ripple is clearly a concern of vertical axis ocean current turbine proponents, and deserves the attention of detailed investigations.

5. Conclusions

A CFD simulation of a vertical axis ocean current turbine blade has been developed and validated using static experimental data. Simulations then confirmed the existence of vibration driving forces generated from hydrodynamic forces. These results indicate that the majority of the force on the blade is in the radial direction. Furthermore, the dominant frequency of this vibration driving force is equal to the frequency of rotation, resulting in a driving force for all three blade and finally to the shaft as main support and mechanic power transmission.

Conversely, only a small portion of the force is actually used to drive the turbine and this is achieved in an unsteady oscillating manner. Future simulations with structural responds will be performed to study the effect of mode shapes generated by unsteady load. These simulations will be validated against experimental data obtained from the turbine prototype. Once validated, the CFD model will be used to predict hydrodynamic and vibration characteristics of future designs.

ABSTRACT

Analytical and experimental study on vibratory tillage by adding an external energy to tillage-tool has been widely applied. This method would significantly reduce soils resistance; unfortunately it uses a lot of energy. Self-excited vibration phenomenon on vibratory tillage has also been shown experimentally reduce soils resistance though not as much as the former. However, no analytical study of the latter method in detail can be found. This paper discusses analytical study of self-excited vibration of tillage-tool on vibratory tillage due to natural excitation of varying cutting forces. The Vibration of vibratory tillage was modeled as vibration with two-degree of freedom system, i.e. the motion of tillage-tool and the motion of swinging-mass arm. The tillage-tool is connected to an implement by an elliptic spring while the swinging-mass arm is connected to the tillage-tool by an elastic bar, which has functions as a spring. The natural excitation of varied cutting force was modeled as a periodic function, which can be expressed as a Fourier series. The elasticity of the elastic bar and the mass of swinging arm are optimized further, so that the tillage-tool vibrates violently at its resonant frequency. This condition will decrease both the soils resistance and the draft force needed for loosening soil density due to self-exited vibration during tillage operation.

Keywords: vibratory tillage, self-excited, vibration, soils resistance, Fourier series.

1. INTRODUCTION

Soil compaction reduces rooting, infiltration, water storage, aeration, drainage, and crop growth. To loosen the compact soil however high draft force and energy consumption is needed. It is well-known that tillage-tool vibration will reduces draft force during tillage operation if the maximum velocity of oscillation is higher than the velocity of the implement. Other advantages of this system is reduced clods size and increased number of crack in soil. This condition will facilitate penetration of plant roots, nutrients, water and air circulation in all soil that is necessary to plant growth.

There are two methods to oscillate tillage-tool. The first method is done by adding a mechanical energy while the second method is to take advantage of the elascity of tillage tolls combined with a varied cutting forced so that the tillage-tool will vibrate in accordance with self excited vibration phenomenon. The first method would reduce soils resistance significantly; unfortunately it uses a lot of excessive energy. The increase of energy consumption is caused by the amount of energy that is needed to drive inersia of tillage-tool and its mechanism.

The first method has been studied analytically [1-4] and experimentally [5-8]. Yow J. et.al. [1] investigated a substantial reduction in draught force about 30 % at velocity ratio about 2 and the overall power consumption will then only increase up to 50% above that for a non-oscillating tool. Butson et.al. [5] reported draft ratio about 0.58 at the velocity ratio about 3 but the power ratio increased until 3.2

The second method has been studied experimentally [9-11]. All author reported that this method will reduce the draft force though not as much as the former. Decreasing the draft force is depending only on the elasticity of the spring. Soeharsono *et al*. [12] conducted an analitycal study of self excited vibration on single-degree of freedom system of vibratory tillage. The excitation caused by varied cutting force was model as a periodic function which expands against as a Fourier series. The spring constant was varied and Soeharsono *et al*. [12] reported that the system will resonance at natural

frequency closed to twice the value of the excitation frequency.

This paper discusses analytical study of self excited vibration on a new model of vibratory tillage. The vibration of vibratory tillage was model as a vibration with two degree of freedom system i.e. angular rotation of tillage-tool θ_1 and angular rotation of swinging-mass arm θ_2. Tillage-tool was connected to main frame by a semi elliptic bar which has function as main spring while swinging-mass arm was connected to tillage-tool by elastics bar which had function as swinging spring. The natural excitation of varied cutting force was modeled as a periodic function, which can be expressed as a Fourier series and the graph was based on the quantitative data of unconfined test conducted in soil mechanics laboratory of agricultural machinery department IPB.

Differential equation of vibration shows that mass matrix $\boldsymbol{M}$ and stiffness matrix $\boldsymbol{k}$ will cause the coordinates θ_1 couples to coordinates θ_2. By modal analysis method, the coordinates θ_1 and θ_2 converted to new uncouple coordinates, namely η_1 and η_2. Thus, the solution becomes the solution of two vibration equation with one degree of freedom systems in η_1 and η_2 which transformed again into coordinates θ_1 and θ_2.

Elasticity of the main spring k_1 and inertia of the tillage tolls J_1 were kept constant while elasticity of connecting spring k_2 and mass of swinging mass m_2 were varied. This condition will effect to vibration of tillage-tool θ. This vibration will represent in graph of maximum displacement of the tillage-tool d_3 as function of time t and θ as function of m_2. At a certain condition, the tillage-tool will vibrate violently so the velocity ratio will greater than unity. There for the possibility of decreasing both soil resistance and draft force are visualized.

2. METHODOLOGY

2.1 Governing Differential Equation

The model of vibratory tillage is shown in figure 1. It consist of semi elliptic bar (which has function as main spring), tillage-tool, elastics bars which has function as connecting spring and swinging arm. A mass of m_2 is located on swinging arm. The model was installed on a carriage which has forward speed of V_0. The vibration of tillage-tool was induced by variation of soil resistance. During forward motion of carriage, tillage-tool press the soil and high resistance encounter, the tillage-tool displaces and the energy is store as potential energy in the main spring. When soil break up, soil resistance decreases, the restoring force of the spring return the tillage-tool to the original position and tillage-tool will be oscillated in accordance with self excited vibration phenomenon.

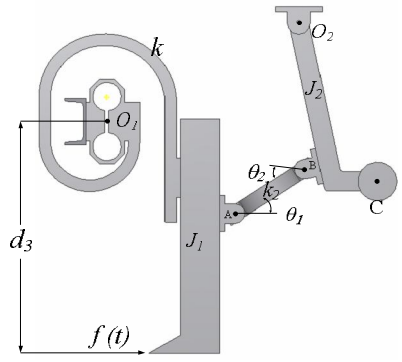

Figure1: Physical model of vibratory tillage

It is clear that the vibration of vibratory tillage could model as self excited vibration with two degree of freedom system as shown in figure 2. Due to soils viscous-elastics behavior, the soil was modeled as viscous damper c_s and soil stiffness k_s. All structure were made from steel therefore the damping coefficient are neglected. If θ_1 and θ_2 are angular displacement of tillage-tool and swinging arm, the differential equation of motion of the system is:

(1)

or

Where:

(2)

$f(t)$: draft force

J_1: mass inertia of tillage-tool and main spring

k_1: angular stiffness of main spring
k_2: linear stiffness on connecting spring
d_1: Distance from center of rotation of tillage-tool O_1 to point A
d_2: Distance from center of rotation swinging arm O_2 to point B
l_2: Distance from center of rotation swinging arm O_2 to point C
d_3: Distance from center of rotation tillage-tool to damping force of soil.

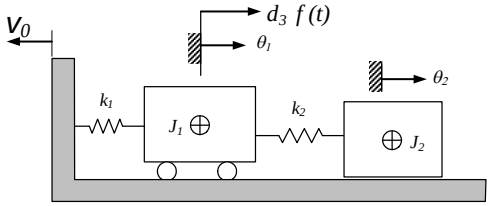

Figure 2: Vibration model of vibratory tillage

Equation 1 shows that coordinate θ_1 is coupled to coordinate θ_2, by modal analysis method, the coordinates θ_1 and θ_2 converted to new uncouple coordinates, namely η_1 and η_2. The natural frequency and eigen-vector of equation 1 are ω_{n1}, ω_{n2}, $\{Q\}_1$ and $\{Q\}_2$. Modal matrix $\boldsymbol{Q}$ defined as:

$$\boldsymbol{Q} = [\{Q\}_1\{Q\}_2] = \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & Q_{22} \end{bmatrix} \quad (3)$$

The orthogonal principle of $\boldsymbol{Q}$ to mass matrix $\boldsymbol{J}$ and stiffness matrix $\boldsymbol{k}$ written as:

$$\boldsymbol{Q^T J Q} = \boldsymbol{M} \text{ and } \boldsymbol{Q^T k Q} = \boldsymbol{\kappa} \quad (4)$$

Where $\boldsymbol{M}$ and $\boldsymbol{\kappa}$ are general mass matrix and general stiffness matrix respectively

$$\boldsymbol{M} = \begin{bmatrix} M_1 & 0 \\ 0 & M_2 \end{bmatrix} \quad \boldsymbol{\kappa} = \begin{bmatrix} \kappa_1 & 0 \\ 0 & \kappa_2 \end{bmatrix} \quad (5)$$

$$\kappa_j / M_{j=}\ \omega_{n,j}^2 \quad j = 1,2$$

Modal analysis method requires transforming the couple coordinate $\boldsymbol{\theta}$ to new uncouple coordinate $\boldsymbol{\eta}$

$$\theta = Q\eta \qquad \eta = \begin{Bmatrix} \eta_1 \\ \eta_2 \end{Bmatrix} \quad (6)$$

Substitute equation (5) and (6) to equation 1 and pre multiply by $\boldsymbol{Q^T}$ obtained two equations of vibration with one single degree of freedom system:

$$M_1\ddot{\eta}_1 + \kappa_1\eta_1 = Q_{11}M(t),$$

and

$$M_2\ddot{\eta}_2 + \kappa_2\eta_2 = Q_{12}M(t) \quad (7)$$

$M(t)$ is a periodic function with period of T and frequency of ω expresses as a Fourier series [13-14]:

$$M(t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} a_n Cos(n\omega t) + b_n Sin(n\omega t) \quad (8)$$

Where:

$$a_0 = \int_0^T M(t)dt, \ ,$$

$$a_n = \frac{2}{T}\int_0^T M(t)Cos(n\,\omega t dt$$

$$b_n = \int_0^T M(t)Sin(n\omega t)dt$$

$$\eta_1 = \frac{a_0}{2\kappa} + \sum_{n=1}^{\infty} \frac{a_n Cos(n\omega t) + b_n Sin(n\omega t)}{\kappa_1(1-(n\omega/\omega_{n1})^2)}$$

$$\eta_2 = \frac{a_0}{2\kappa} + \sum_{n=1}^{\infty} \frac{a_n Cos(n\omega t) + b_n Sin(n\omega t)}{\kappa_2(1-(n\omega/\omega_{n2})^2)}$$

Thus the response of $\boldsymbol{\theta}$ is:

$$\theta_1 = Q_{11}\eta_1 + Q_{21}\eta_2 \quad \text{And} \quad \theta_2 = Q_{21}\eta_1 + Q_{22}\eta_2 \quad (9)$$

Equation 8 and 9 show that the system will vibrate violently if $(n\omega/\omega_{n2})^2$ closed to unity.

2.2 Dynamical Parameter

The dynamic parameters of vibratory tillage in figure 1 are as follow: Angular stiffness of main spring k_1 was 32086 *Nm/rad* and the mass inertia of tillage-tool J_1 was 2.486 *N-m*^{2} inertia mass of swinging arm j_2= *0.404 kg-m*^{2}. Other parameters are d_1 = 0.4 m, $d2$ = 0.38 m, $d3$ = 0.6 m, l_2 = 0.448 m, angle $\theta_1 = 28^0$ and $\theta_2 = 21^0$. Two different connecting springs were used for simulation, i.e. connecting spring with stiffness k_2 = 70312.5 N/m and k_2 = 132629 N/m. swinging mass m_2 was varied and depending on connecting spring used for simulation. Both main spring k_1 and connecting spring k_2 were made from alloy steel which have yield strength about 400 MPa, other material were made from structural steel. Substituted above dynamical parameter to equation 1 will obtain differential equation of vibration as:

$$\begin{bmatrix} 2.486 & 0 \\ 0 & 0.363 + 0.18m_2 \end{bmatrix}\begin{Bmatrix} \ddot{\theta}_1 \\ \ddot{\theta}_2 \end{Bmatrix} + \begin{bmatrix} 32086 + 0.353k_2 & -0.355k_2 \\ -0.355k_2 & 0.337k_2 \end{bmatrix}\begin{Bmatrix} \theta_1 \\ \theta_2 \end{Bmatrix} = \begin{Bmatrix} d_3 f(t) \\ 0 \end{Bmatrix} \quad (10)$$

Draft force $f(t)$ was modelled as a periodics function as shown in figure 3. The draft force is devide into 4 step. The vibration cycle starts point 1 (t= *0)* with the tillage-tool stationary and about to move forward. From point 1 to point 2 the tillage-tool moves forward through tilled soil (loosen soil) and from point 2 to point 3 the tillage-tool move forward cut the untilled soil (dense soil). From point 3 to point 4 and 5 the tillage-tool moves backward through tilled soil. For each step, the model of draft force was based on the qualitative data of unconfined test which had conducted in soil physics laboratory of agricultural machinery department IPB.

- For tilled soil (loosen soil), the draft force is constant and closed to zero.
- For untilled soil (dense soil) the draft force is in the form of three order polynomial of t.

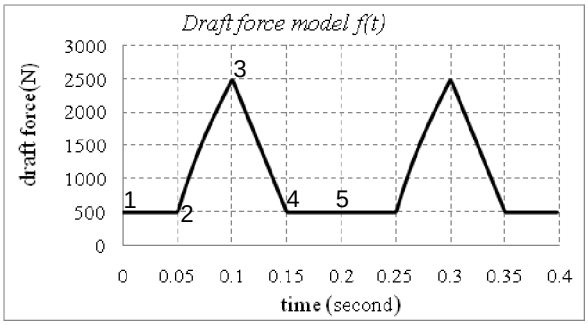

Figure 3: Draft force model for depth tillage of 0.25 m

Maximum draft force (point 3) was calculated with Gill model [15], for tillage depth of 0.3 m, the draft force is about 2500 N. Assumed that the period of draft force is

0.2 second (excitation frequency fe = 5 Hz) so the draft force is modeled as:

$$f(t) = 500\ N \qquad 0<t<0.05$$
$$= 3.2E6\ t^3 - 960000\ t^2 + 128000\ t^2 + 3900\ (N) \qquad 0.05<t<0.1$$
$$= -4000\ t + 6500\ (N) \qquad 0.1<t<0.15$$
$$= 500\ N \qquad 0.15<t<0.2 \qquad (11)$$

2.3 Simulation Procedure

Simulation was based on equation (1) to equation 9 and focused on steady state response of tillage-tool. Detail of simulation is shown in table 1. For spring stiffness k_2= 44762 N/m, swing mass m_2 was varied from 1 kg to 3 kg while for spring stiffness k_2 = 132629 N/m, swing mass m_2 was varied from 2 kg to 4 kg

Fable 1 Dynamics parameter used for simulation

Stiffness k_1 Nm/rad	Inertia J_1 Kg-m^2	Inertia J_2 Kg-m^2	Stiffness k_2 N/m	Swing mass m_2 kg
32086	2.486	0.404	70312.5	0 to 3 kg
32086	2.486	0.404	132629	0 to 4 kg

Displacement of tillage-tool, swing mass and connecting spring is plot as functions of swing mass and plot in time domain. For high displacement, the stress of spring is check again. This is important to avoided excessive strain in the spring and to avoid the spring going to plastic. All graphs are analyzed further to determine the possibilities of draft force reduction during tillage operation.

3. RESULT and DISCUSSION

Frequency was calculated first, for excitation period about 0.2 second, the excitation frequency f_e is 5 Hz. As swinging mass varied, the fundamental frequency is varied too. For k_2 = 70312.5 N/m, the fundamental frequency f_{n1} is varied from 16.42 Hz (m_2=0 kg) to 14.17 Hz (m_2 = 3 kg) while k_2 = 132629 N/m the fundamental frequency f_{n1} is varied from 16.54 Hz (m_2=0 kg) to 14.11 Hz (m_2=4 kg).

For maximum force about 2500 N, Statics deflection of tillage-tool is 29 mm. Contribution of swinging arm and swinging mass m_2 to statics deflection is very small and can be omitted. The graph of maximum deflection of tillage-tool, swinging mass and connecting spring as function of m_2 caused by varied cutting force *f(t)* is shown in figure 4 (for k_2 = 44762 N/m) and in figure 5 (for k_2 = 132629 N/m).

For k_2 = 70312.5 N/m, high displacement of tillage-tool is encounter in range of swinging mass m_2 from 1.5 kg to 2.0 kg or in the range of fundamental frequency f_{n1} from 15.24 Hz to 14.87 Hz while maximum tillage-tool deflection about 75 mm occurred at m_2 about 1.8 kg or at resonance frequency f_r about 15.02 Hz. For m_2 = 1.5 kg the displacement of tillage-tool is 34.4 mm while the displacement of connecting spring is 19.6 mm. At this condition, the equivalent stress in main spring is 180 MPa while the equivalent stress in connecting spring is 400 MPa closed to yield strength of material. For m_2 = 2.0 kg, the displacement of tillage-tool is 35.2 mm while displacement of connecting spring is 22 mm. At this condition, the equivalent stress in main spring is 182 MPa while the equivalents stress in connecting spring is 406 MPa higher than yield strength of material.

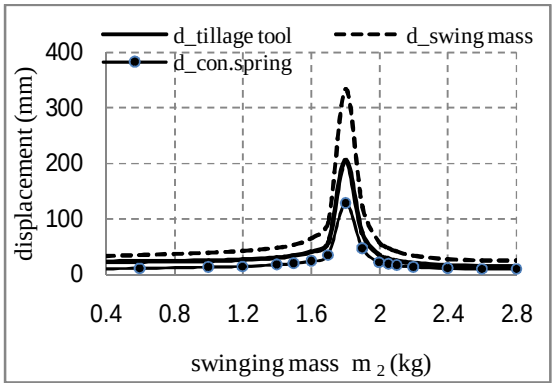

Figure 4: Maximum displacement for k_2 = 70312 N/m

For k_2 = 132629 N/m, high displacement of tillage-tool is encounter in the range of swinging mass m_2 from 2.1 kg to 2.6 kg or in the range of fundamental frequency from 15.15 Hz to 14.88 Hz while maximum tillage-tool deflection about 148 mm occurred at m_2 about 12.4 kg or at resonance frequency about 15.0 Hz. For m_2 = 2.1 kg the displacement of tillage-tool is 42 mm while displacement of connecting spring is 17 mm At this condition, the equivalent stress in main spring is 220 MPa while the equivalent stress in connecting spring is 375 MPa. For m_2=2.6 kg, the displacement of tillage-tool is 40.2 mm while the displacement of connecting spring is 17 mm. At this condition, the equivalent stress in main spring is 218 MPa while the equivalents stress in connecting spring is 375 Mpa. All stress conditions is lower than yield strength of material.

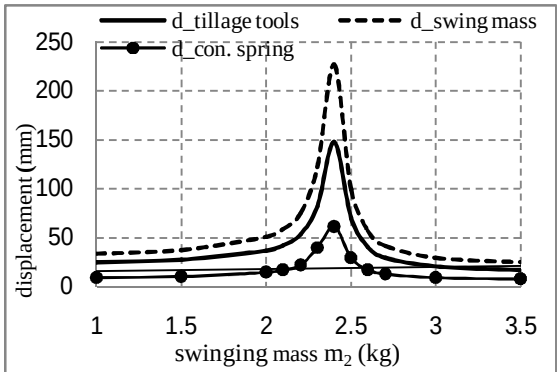

Figure 5: Maximum displacement for k_2 = 132629 N/m

Condition of velocity ratio greater than unity or condition of draft force reduction is correlated to high tillage-tolls deflection, thus simulation is continuing with two conditions (table 2). First is simulation with connecting spring k_2 = 70312 N/m and swing mass m_2 = 1.5 kg and m_2 = 1.5 kg, others is simulation with connecting spring k_2 = 132629 N/m and swing mass m_2 = 2.1 kg and m_2 = 2.6 kg. Possibilities of draft force reduction during tillage operation are investigated by analyzing time response of tillage-tool for both conditions.

Table 2: Condition of simulation

Spring stiffness k_2 (N/m)	Swing mass m_2 (kg)	Condition
70312	1.5	$f_{n1}>f_r$
	2	$f_{n1}<f_r$
132629	2.1	$f_{n1}>f_r$
	2.6	$f_{n1}<f_r$

Time response for *k2* = 70312 N/m is shown in figure 6 while time response for *k2* = 132629 N/m is shown in figure 7. All graph shows that tillage-tool vibrates in excitation frequency and in its fundamental frequencies. Fundamental frequency of graph 1 and graph 3 is higher than its fundamental frequency while fundamental frequency of graph 2 and graph 4 is lower than its resonance frequency.

From t = 0 s to 0.05 s, tillage-tool retract tilled soil, all graph shows that tillage-tool vibrates in half cycle. The importance thing in this step is the tillage-tool cut the clod in a smaller size.

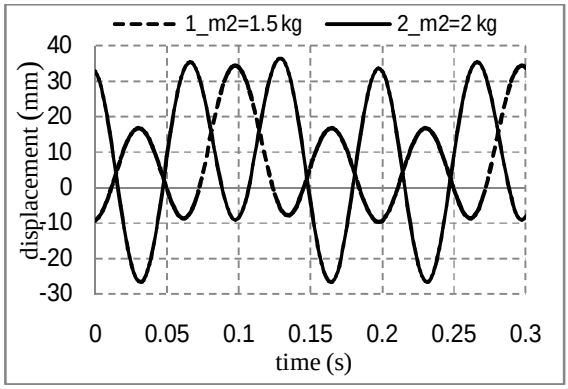

Figure 6: Displacement of tillage-tool for k_2 = 70312 N/m

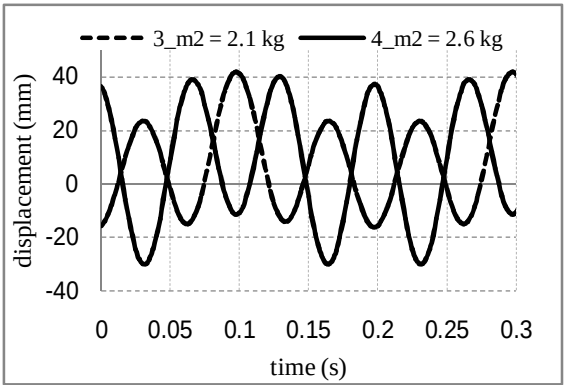

Figure 7: Displacement of tillage-tool for k_2 = 132629 N/m

From t = 0.05 s to 0.1 s tillage-tool cut untilled soil. For vibration with frequency higher than its resonance frequency (graph 1 and graph 3), the tillage-tolls vibrates in low energy level. Compact soil presses the tillage-tool to move backward until the soil break up. This phenomenon is similar to phenomenon on conventional tillage that's why no draft forces reduction in this step. For vibration with frequency lower than its resonance frequency (graph 2 and graph 4), the tillage-tolls vibrates in high energy level in half cycle. First, compact soil presses the tillage-tool to move backward until the soil break up, soil resistance decreases and the restoring force of the spring pushed the tillage-tool to move forward. This phenomenon is similar to vibratory tillage resulting draft force reduction [1]

From t = 0.1 to t = 0.2, all graph shows that the tillage-tool vibrates pass through tilled soil. This is important for tillage-tool to cut the soil clod to smaller size.

4. CONCLUSION

In this work, the simulation of self excited vibration phenomenon on vibratory tillage has successfully been demonstrated. The vibration of vibratory tillage was modeled as vibration with two degree of freedom system

while the excited force was modeled as periodic function. The tillage-tool was vibrated periodically at excitation frequency and at its fundamental frequency. The value of resonance frequency was found three times than that the value of excitation frequency.

The possibilities of high displacement of tillage-tool or the possibility of draft force reduction is happen if the system vibrates around its resonance frequency. In this case, two important conditions were note:

- For vibration with frequency higher than its resonance frequency, there were no draft force reduction were predicted but the quality of soil were increased i.e. the size of soil clod become smaller.
- For vibration with frequency lower than its resonance frequency, both draft force reduction and smaller size of soil clod were predicted

ABSTRACT

The new algorithm based on Modified Particle Swarm Optimization which is robots could change its niche membership is investigated. Then, ODE (Open Dynamics Engine) library is used for physical modeling of the robot like friction, balancing moment and others. This research has a purpose of validation for that MPSO in previous result is applicable in real robot. Simulations prove that newly proposed algorithm can solve diversity lackness problem in multi source problem.

Keywords

Example:
Modified Particle Swarm Optimization (MPSO), Open Dynamics Engine (ODE), Niche Characteristics

1. INTRODUCTION

This research has a purpose to improve MPSO algorithm proposed in the previous research by A. Nugraha [1]. This research also upgraded simulator created which was still in 2D. The 3D simulator developed in this research, its program based on the 2D simulator from the previous research as its result shown in Figure 1. It used ODE library to make the 3D version. This purpose is to reduce gap between software and real hardware. In 2D simulation, robot's movement is drawn by drawing a circle which represents the robot from one coordinate to another. And where there is a collision between 2 robots, these robots do not need to change their direction. Robots are just colliding like if they are balls in pool table.

Algorithm proposed in this research is called Draft Niche-PSO. The word "draft" here is taken from the new behavior of niche that now neutral robots and charged robot could draft from 1 niche to another. For this drafting behavior, there is new robot, main robot which has an attract area. This purpose is to increase the divergence of MPSO algorithm.

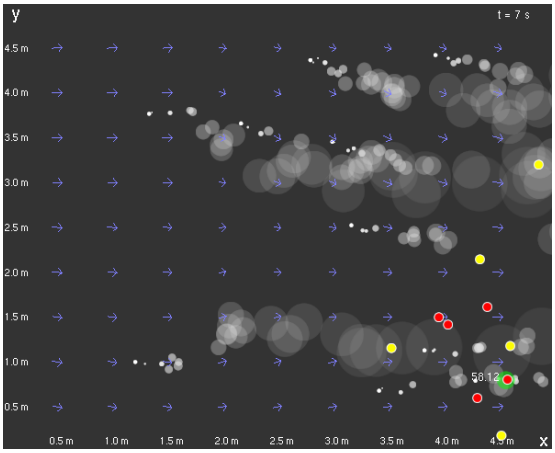

Figure 1: 2D Version Simulator

In Figure 1, neutral robots are the red robots and charged robots are the yellow robots. Main robots did not exist in the previous research.

2. ODE MODELING

Robot(s), field, odor source(s), and plumes are here to be modeled with ODE.

2.1 Robot Modeling

Robot's design is shown in Figure 2 and Figure 3. Robot's principal of changing direction is shown in Figure 4 that robot has to turn each wheel in opposite direction. Robot's changing direction has pivot which is the center of the robot itself. Robots here do not changing their direction while moving forward, they are spinning.

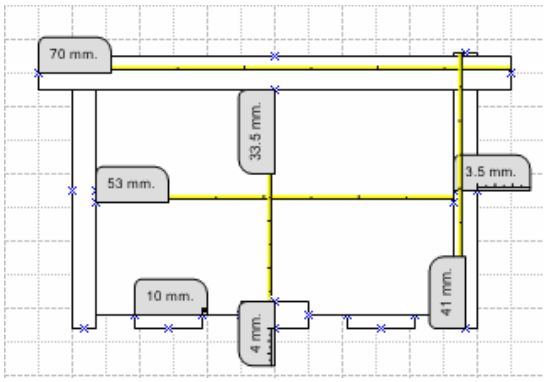

Figure 2: Robot Design (Front)

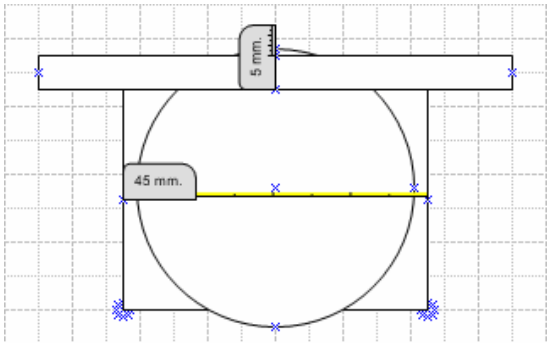

Figure 3: Robot Design (Side)

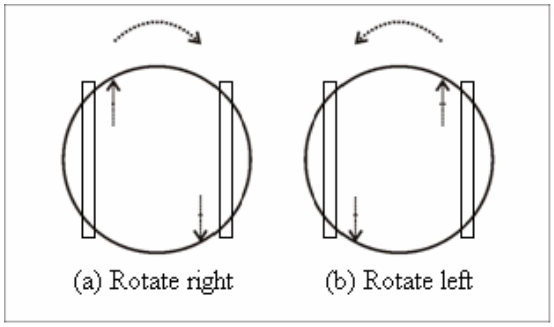

Figure 4: Robot Rotation

The result of robot modeling is shown in Figure 5. Color for each neutral, charged and main robot are shown in Table 1.

Table 1: Robot Color

Robot	Color	RGB
Neutral	Red	(1.0, 0.0, 0.0)
Charged	Yellow	(1.0, 1.0, 0.0)
$CHCl_3$	Purple	(0.8, 0.2, 1.0)

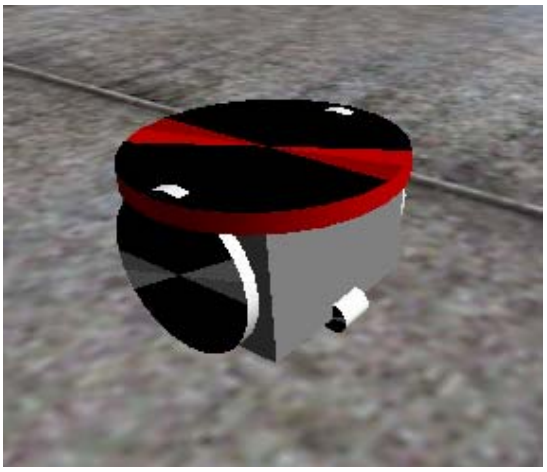

Figure 5: Robot in ODE (Neutral Robot)

2.2 Field Modeling

Field are design as square if viewed from right above. It is build with 4 block with each edge connected as shown in Figure 6. Field has transparency so that robots, odor source(s) and plumes can be seen from side.

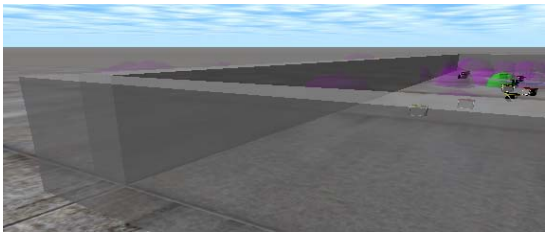

Figure 6: Field in ODE

2.3 Plumes Modeling

Plumes in this research has characteristic as:
[1]. Transparent
[2]. Do not have any collision with any other objects
[3]. Drawn as a sphere
Plumes will become more and more transparent as time running. By the time it has just emitted from its source it transparency is 0, and this transparency will increased until its value is 1 and plumes will become invisible. Plumes are gas material so that it does not have any collision with any other objects. Plumes are drawn as a sphere. Plumes in real life are an enormous number of dust particles for that it is nearly impossible to draw. The size of the sphere will become bigger and bigger as time running. Plumes design result is shown in Figure 7.

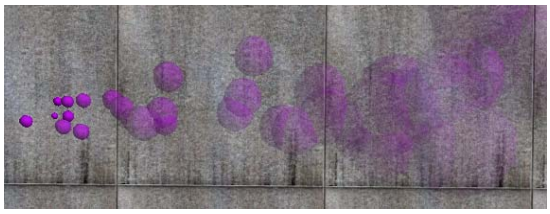

Figure 7: Plumes

2.4 Odor Source Modeling

Odor source in this research simply modeled with half sphere. Actually it is a full sphere, but half below part is under the ground so that it could not be seen. Odor source's color is purple, the same with plumes' color. Odor source model is shown in Figure 8.

Figure 8: Odor Source

Odor source once it had been found by a robot, it will be closed. Odor source closing is illustrated with changing its color into grey as shown in Figure 9.

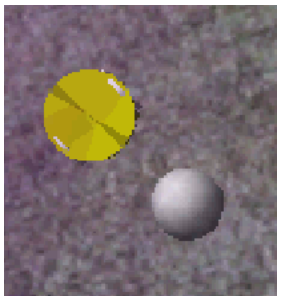

Figure 9: Odor Source Declaration

3. DRAFT NICHE-PSO

Newly proposed algorithm in this research is called Draft Niche-PSO. In Draft Niche-PSO there is possibility for neutral or charged robot to draft to another niche, to change its membership of niche. Robot newly introduced here is main robot which control drafting procedure.

3.1 Main Robot

Main robot has an attract area where other niche's neutral or charged robot whom entered this area will become its niche member. Unlike neutral robots or charged robots, main robots only have local best, and like charged robots, they have charge, too, but only effects with other main robots. Main robot design is shown in Figure 10. The blue circle shows the attract radius. The R Core line in the simulator will not be drawn.

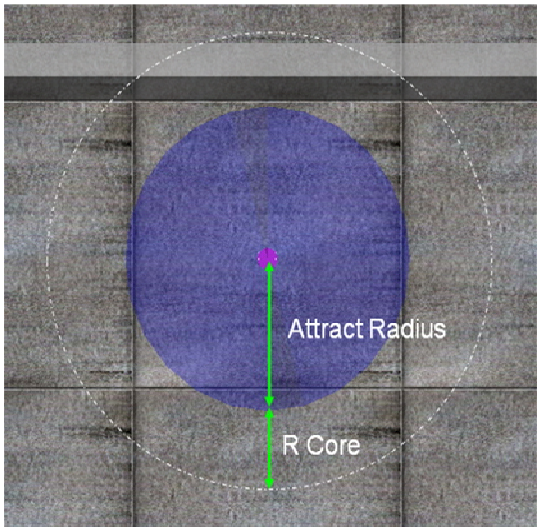

Figure 10: Main Robot

Main robot will reject other main robot if their R Core limit intercepted. The amount of rejection is shown in equation (1).

$$u_{jk}(t) = \begin{cases} \dfrac{Q_j Q_k (x_j(t) - x_k(t))}{(AttractRadius + RCore)^2 \left\| x_j(t) - x_k(t) \right\|} \\ 0 \end{cases} \quad (1)$$

Where μ is the amount of rejection, Q is the amount of charge.

μ will become 0 or main robot do not reject any other main robot if their R Core radius is not intercepted.

4. RESULT

After implementing robot and its environment in 3D simulation including physical model, we utilized MPSO algorithm for searching multiple odor source in dynamic environment. Its results show that MPSO is applicable in real situation.

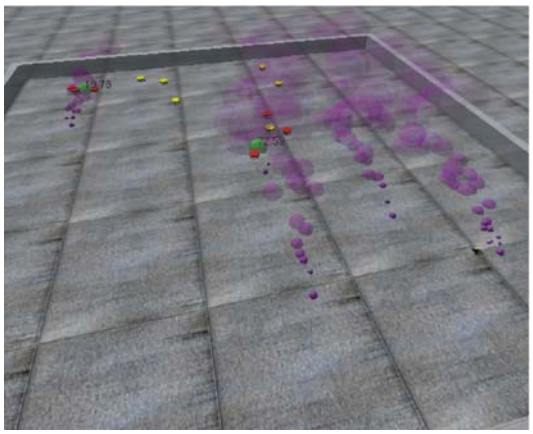

Figure 11: MPSO with ODE

Draft Niche-PSO also shows a good result for increasing the diversity of previous PSO algorithm. Now, we see the comparison of them with initial condition shown in Figure 12 and Figure 13.

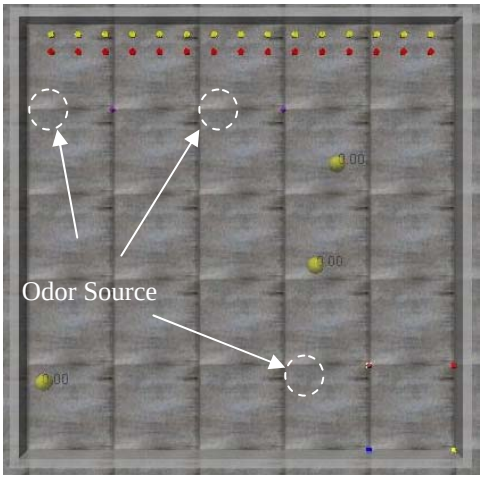

Figure 12: Original MPSO (Initial)

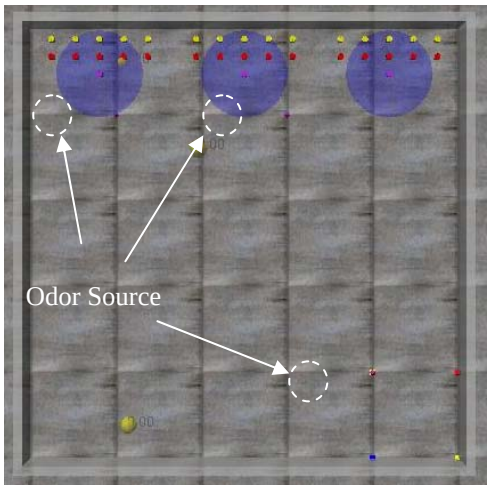

Figure 13: Draft Niche-PSO (Initial)

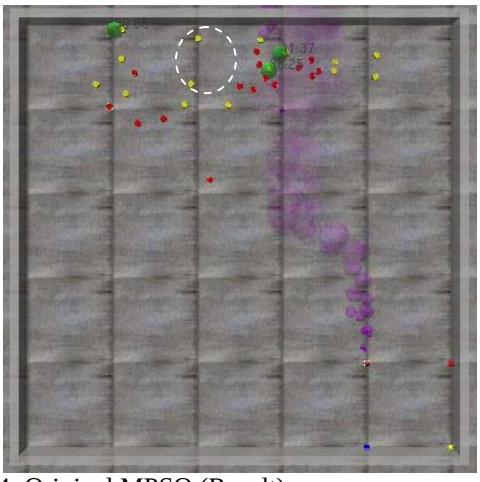

Figure 14: Original MPSO (Result)

Figure 14 shows the result of original MPSO. We can see that 2 niche still toward the same odor source with their global best near each other.

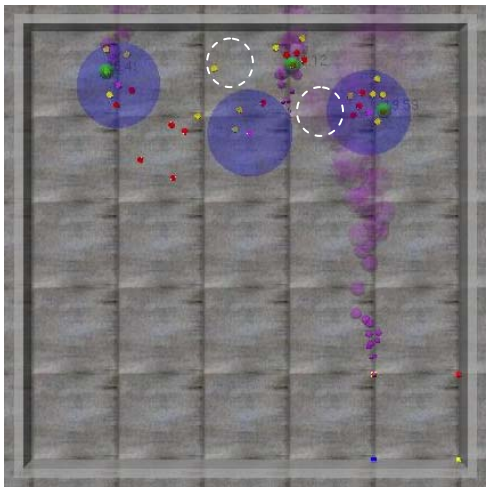

Figure 15: Draft Niche-PSO (Result)

Figure 15 shows the result of Draft Niche-PSO. We can see that middle niche and right niche were moving toward the different odor source.

7. CONCLUSION

We have implemented MPSO algorithm in 3D environment in order to model robot movement and environment in searching multiple odor sources. We have moved one step further to implement MPSO in real robot for searching odor source in real world. The result of this simulation is not analyzed yet. Furthermore, this simulation must be analyzed in order to assess its effectiveness.

ACKNOWLEDGMENT

This work was supported in part by the Science and Technology 2007 by Indonesia Toray Science Foundation and the Incentive Research Program 2008-2009 by the Ministry of Research and Technology Republic of Indonesia.
The authors also are grateful to Prof. J. A. Farrell from the University of California, Riverside, U.S.A., for his support in advanced turbulent-environment source-code.

ABSTRACT

The paper presents the study on a CAPP(computer-aided process planning) system that suggests optimal tool orientation with which positional five-axis machining of sculptured surface in a molding die manufacturing. The positional five-axis machining is operated on a five-axis NC machine, with the cutting tool orientation being fixed during the cutting operation. This type of machining operation is effective in machining separated areas (geometric features) on a molding die. The optimal tool orientation for a machining area is obtained through two steps: (1) the local optimal tool orientation on each cutter-contact point is obtained, which is based on the machinability condition, then the angular range of global tool orientation is obtained by the union of the local angles; (2) the tool length map for the indicated global tool orientation range is computed via interference check (collision and stroke-over), and the tool orientation with the minimum tool length is selected as an optimal tool orientation. The research was implemented on the basis of a commercial CAM system(I-Master) in the Windows XP environment, and was tested for positional five-axis machining of molding dies for automotive parts in a local company.

Positional 5-axis machining, optimal tool orientation angle, CAPP

1. INTRODUCTION

Five-axis machining of molding dies has more benefits such as fewer set-ups and better machining accuracy resulting from shorter tool length [1,2]. It may be classified into positional five-axis and continuous five-axis depending on cutter orientation change (see Figure 1). The positional five-axis machining is a fixed-axis machining on a five-axis NC machine with the cutter-axis tilted, while the continuous five-axis machining is the conventional simultaneous five-axis machining.

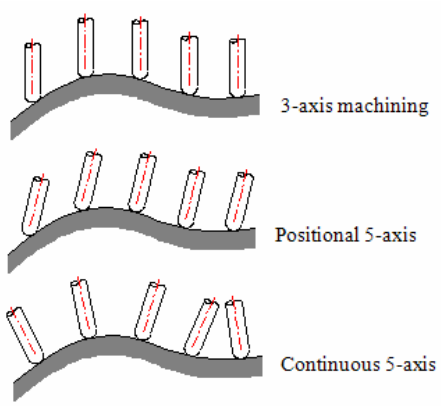

Figure 1: Machining types

Machining process of a molding die consists of several unit machining operations(UMOs), which is a combination of conventional three-axis, positional and continuous five-axis machining operations. An NC programmer determines most suitable machining type to each machining feature area.

Simultaneous five-axis machining can adaptively change cutting speed and tool posture at each CC(cutter contact) point by continuously varying tool-orientation, but it requires somewhat complicated interference avoidance and computing time. It should be noted that the positional five-axis machining is well applied to machining of molding die surface, due to consistent tool posture and simple interference avoidance compared to continuous five-axis machining [3].

According to a commercial CAM software developer [4], distinct machining types on a five-axis machine are: 73% of positional five-axis machining, 22% of multi-face three-axis machining, and 5% of continuous five-axis machining. It can be said that continuous five-axis machining operation using a five-axis machine may well be applied to where fixed-axis

machining is either infeasible or inefficient.

The tool length should be as short as possible without interference (e.g., collision) in order to enhance machining accuracy and surface finish, due to tool deflection and chattering. In positional five-axis machining of a certain surface area, it is imperative to select a tool orientation that minimizes tool length of the applied cutter but also causes no collision. A few existing commercial CAM systems provide such functionality, but requires complicated user interactions or fairly much computing time.

The research developed a system that computes the optimal tool-orientation with minimum tool-length for a ball-end milling case, given a surface area to be machined. Section 2 describes the key procedure, followed by an illustrated case in Section 3.

2. CONVENTIONAL PROCESS

A conventional process to determine the tool orientation and length by which a certain surface area is to be machined is described in figure 2. Tool orientation is usually designated by setting up a local coordinate system in a commercial CAM system. As shown in the figure, the process requires NC programmer's insight and experience, tool-path generation and collision avoidance through interactive as well as iterative operations.

The similar process should be repeated for each feature surface that needs positional five-axis tool-path generation, which is tedious and time consuming job. In addition, it does not always generate optimal tool orientation with minimum tool length, which may result in non-optimal machinability.

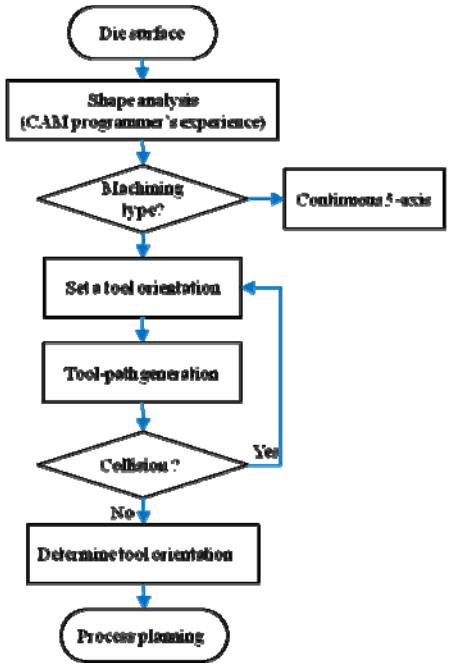

Figure 2 : Conventional process of work coordinate set-up

3. PROPOSED PROCESS

3.1 Overall view

Figure 3 depicts overall procedure of the proposed process, which is summarized as follows:

< Phase 1 >
(1) Sampling CC points on the defined surface area,
(2) For each CC point, determine preferred tool-orientation range,
(3) Obtain overall preferred tool-orientation range for all CC points,
< Phase 2 >
(4) Select feasible tool-orientation range from the preferred tool-orientation range for all CC points by checking stroke-over and collision,
(5) Determine the optimal tool-orientation angle with minimum feasible tool-length.

In the 1st phase, the preferred tool-orientation range for each CC point is determined based on a previous study which considered cutting force and surface finish in a ball-end milling case [5]. In the 2nd phase, the feasible tool-length for a specified tool-orientation is computed via interference check (i.e., stroke-over and collision check), the tool-orientation with minimum feasible tool-length is selected as an optimal tool-orientation. The collision check process considers cutter shank, tool holder, machine spindle, and machine table. Following sections describe more details about the process.

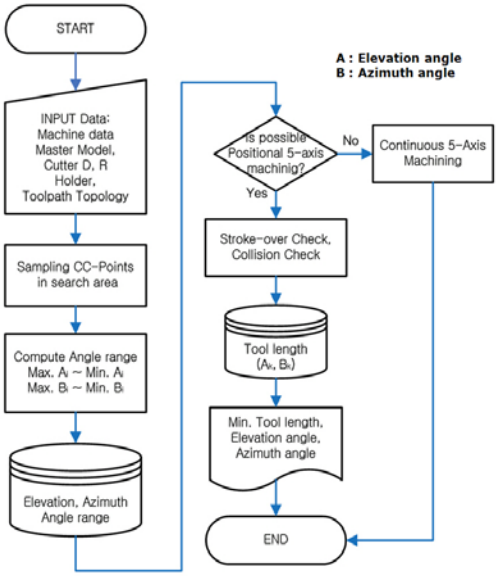

Figure 3 : Overall procedure

3.2 Phase 1: preferred tool-orientation

The 1st phase of the overall process determines preferred range of acceptable tool-orientation by aggregating each preferred tool-orientation at a single CC point. A previous study [5] depicted that the acceptable tool inclination angle (ball-ended milling) at a CC point should be 15˚ to 45˚ measured from the surface normal, which is based on cutting force and surface finish. This concept can be represented by a cone (see figure 4), since the applied cutter is a ball-ended mill. Being measured in the local coordinate system of a CC point, the tool inclination angle is converted to tool-orientation of the global coordinate system, which is represented by elevation and azimuth angles (see figure 5). The elevation and azimuth angles (A,B) corresponding to a tool inclination vector **n'** is represented by equation (1).

$$\text{A (elevation angle)} = a\tan 2(\sqrt{n'^2_x + n'^2_y},\ n'_z) \quad (1a)$$

$$\text{B (azimuth angle)} = a\tan 2(n'_y,\ n'_x) \quad (1b)$$

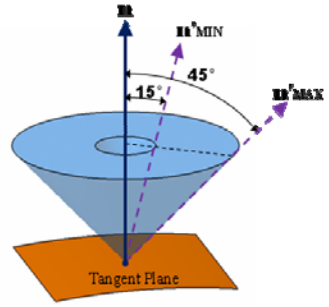

Figure 4 : Local acceptable range of tool-orientation

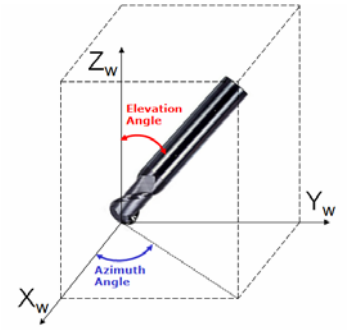

Figure 5 : Elevation and azimuth angles to define tool-orientation

The overall range of acceptable tool-orientation for all CC points is obtained by summing up each tool-orientation range of a single CC point, which is represented by ranges of elevation and azimuth angles such as $(A,B)_{MIN}$~$(A,B)_{MAX}$. Figure 6 depicts a schematic diagram of the phase 1.

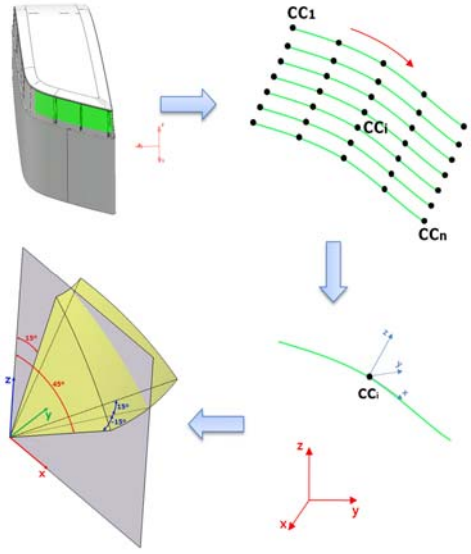

Figure 6 : Overall preferred range of tool-orientation

3.3 Phase 2: optimal tool-orientation

The overall preferred range of tool-orientation $(A,B)_{MIN}$~$(A,B)_{MAX}$ obtained in the 1st phase can be thought of as an initial filtering out process for efficient computation. The 2nd phase determines the optimal tool-orientation by computing minimum feasible tool-length at each tool-orientation among the given preferred range. The procedure is summarized as follows:

(1) For a tool-orientation $(A,B)_k$ among the overall range $(A,B)_{MIN}$~$(A,B)_{MAX}$, compute feasible tool-lengths for all CC points, and find the minimum tool-length L_k,
(2) Find the minimum tool-length L_m at $(A,B)_m$ among L_k, and set the optimal tool-orientation to be $(A,B)_m$.

The feasible tool-length at a tool-orientation $(A,B)_k$ at CC point is obtained via interference check including machine axis stroke-over, machine collision and tool collision. The machine axis stroke-over can be verified by considering inverse kinematics of the target NC machine. The machine and tool collision consider collisions between components such as machine spindle, table, cutter shank, and tool holder. The tool-length computation is based on the previous study [6]. Figure 7 describes overall procedure of phase 2.

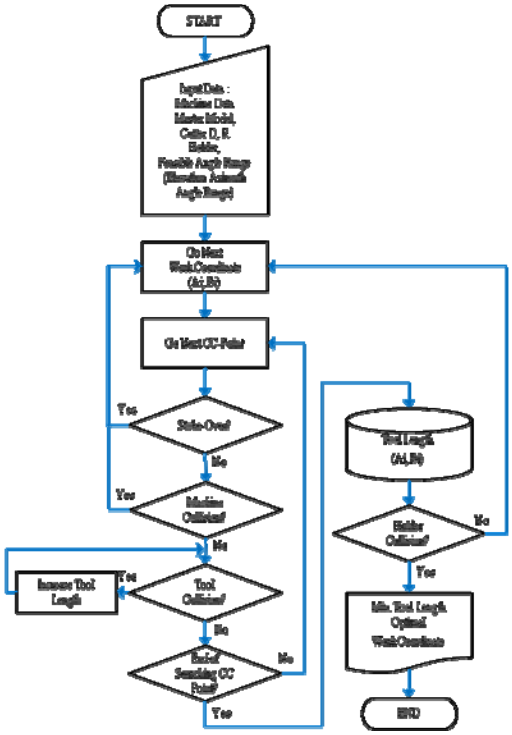

Figure 7 : Search of the optimal tool-orientation

4. ILLUSTRATED EXAMPLE

The proposed system has been implemented by Visual C++ and OpenGL in Windows XP environment. Figure 8 shows an example molding die surface, where the red colored face is the machining area. Figure 9a depicts preferred tool-orientation range (in elevation & azimuth angles), figure 9b illustrates the optimal tool-orientation.

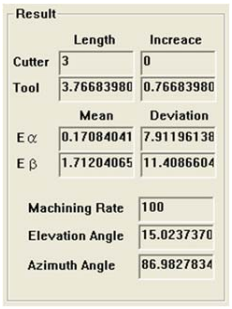
(a)



(b)

Figure 9: Preferred range of tool-orientation and search result

5. DISCUSSION

The research has developed a system that determines the optimal tool-orientation for positional five-axis machining of molding die surface. It provides a CAM programmer with an optimal work coordinate system and minimum tool-length information, thereby enabling objective and efficient process planning for five-axis machining tool-path generation.

It should be noted that the tool-length is not the only factor affecting machinability. As a previous study depicts [5], the tool inclination angle itself is an imperative machining condition. Therefore, another criterion including tool-length and tool inclination angle can be considered as an error function at a CC point as follows:

$$\varepsilon_T = \omega_\alpha\left(\frac{\varepsilon_\alpha}{\Delta a}\right) + \omega_L\left(\frac{\varepsilon_L}{\Delta L}\right);$$

where ε_α = angular deviation of inclination angle from given value,
ε_L = tool-length deviation (L_i-L_0, L_0 = minimum tool-length),
ω_α, ω_L = weighting factors,
$\Delta\alpha$, ΔL = scaling factors.

Considering the above combined error function at each CC point should be dealt in the further research.

ABSTRACT

When ferroelectric materials are subjected to repeated reversal of polarization, the magnitude of the reversed polarization is observed to decrease. This phenomenon is referred to as fatigue and is generally ascribed either to space charge effects or to the pinning of domain walls at defects.

In recent times several techniques have been developed which allow the study of polarization profiles in thin, insulating films. In the present work, the polarization profiles in fatigued ferroelectric polymers were measured using the laser intensity modulation method (LIMM).

The polymers studied were polyvinylidene fluoride (PVDF) and its copolymers with trifluoroethylene (TrFE). The polymers were fatigued by reversing the polarization many times using a cyclic field with an amplitude above the coercive field. For some of the polymers, this leads to a decrease in the magnitude of the reversed polarization, while for others, the magnitude remained reasonably constant.

It was found that those polymers which showed most fatigue in their hysteresis loops had a more symmetrical distribution of polarization after fatiguing. The lack of fatigue and asymmetrical polarization profiles seem to be associated with materials which contain the non-polar α crystal form.

Keywords:

Polarization, Fatigue, Ferroelectric, Pyroelectric, LIMM

1. INTRODUCTION

This year marks the fortieth anniversary of the announcement of the piezoelectric properties of the ferroelectric polymer polyvinylidene fluoride [1]. In the period since this announcement, there has been a large amount of research into the ferroelectric nature of PVDF and some of its copolymers. Ferroelectrics find applications in a range of electronic devices, arising from their high dielectric constant, piezoelectric, pyroelectric and switching properties. In the case of switching an important property is fatigue; the reduction of the observed reversed polarization with repeated cycling of the applied electric field. This property is of particular importance in the recent application of ferroelectrics in memory chips [2].

In order to better understand the causes of fatigue, polarization profiles were prepared for ferroelectric polymer films which had been fatigued. The method used was the LIMM technique [3-5]. In this technique light, with periodically varying intensity is directed onto the surface of a sample. The frequency of variation determines the spatial distribution of temperature fluctuation in the sample and hence the magnitude and phase of the pyroelectric current. Deconvolution of the current allows the extraction of the polarization profile in the sample.

2. BACKGROUND THEORY of LIMM

A complete description of the theory underlying LIMM is readily available in the literature [3-8]. For completeness, a brief outline is given here.

The basic arrangement for LIMM is shown in figure 1. It consists of a free standing pyroelectric film, with electrodes on both surfaces. The distance through the sample is denoted x. The back surface (x=d) of the film is thermally isolated, while the front surface (x=0) is illuminated by a modulated laser beam.

ISSN 114-1284

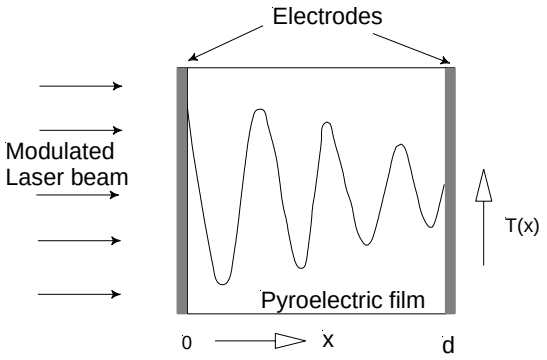

Figure 1: Thermal wave inside a pyroelectric film. Sample is heated from x=0, while the other surface (x=d) is thermally isolated.

The temperature fluctuation $\Delta T_\omega(x,t)$ at the point x, is given by [4]:

$$\Delta T_\omega(x,t) = \frac{\eta W_\omega}{\mu G_t}\frac{\cosh[\mu(d-x)]}{\sinh(\mu d)} e^{j\omega t} \qquad (1)$$

where $\mu = (1+j)\sqrt{\frac{\omega}{2\delta_t}}$, δ_t is the thermal diffusivity, W_ω is the laser beam power, η is the emissivity and G_t is the thermal conductivity and ω is the frequency of the thermal wave.

The thermal waves generated by the optical excitation create a pyroelectric current ($I_p(t)$) between the two electrodes of the sample. There are several mechanisms contributing to the pyroelectric effect [7], such as the temperature dependence of the dipolar polarization (primary pyroelectric effect), thermal expansion of the crystallites (secondary pyroelectric effect), thermal expansion of the amorphous regions, temperature dependence of the crystallinity, and temperature dependence of the space charge distribution. In LIMM measurements, it is not possible to separate the effects of these contributions [4].

If permanent dipoles are compensated by an appropriate charge density, the time dependent pyroelectric current, I(t), is given by [3,8]:

$$I_p(t) = I_{p\omega} e^{j\omega t} = \frac{\alpha_p A}{d}\int_0^d P(x)\frac{\partial \Delta T_\omega(x,t)}{\partial t}dx \qquad (2)$$

where P(x) is the unknown, spatially dependent polarization distribution and $\alpha_p = \frac{1}{P}\frac{dP}{dt}$ is the relative temperature dependence of the polarization. The product of α_p and P(x) is the spatial variation of pyroelectric coefficient (p(x)). Inserting the temperature profile from equation (1) into equation (2) yields the pyroelectric current:

$$I_{p\omega} = \frac{A\alpha_p \eta W_\omega}{\rho c d}\frac{\mu}{\sinh(\mu d)}\int_0^d P(x)\cosh[\mu(d-x)]dx \qquad (3)$$

In a LIMM experiment the pyroelectric current is measured as a function of modulation frequency ω. To obtain the spatial polarization distribution equation (4) has to be deconvoluted. A convolution integral is given by:

$$g(y) = \int f(x) r(y-x) dx \qquad (4)$$

where the function f(x) is convolved with a response function r(x). The convolution theorem states that:

$$G(y)=F(y)R(y) \qquad (5)$$

where F, G and R are the Fourier transforms of the functions in equation (4). The Fourier transforms of g(y) and r(y) can be calculated by dividing G(y) by R(y), and an inverse Fourier transformation is calculated. Mathematically, this calculation is readily done. In practice however, this is an ill-posed problem. Since g(y) always contains some experimental noise, there exists an infinite set of function, f(y), which after convolution with r(y), agree with g(x) within the uncertainty.

Several deconvolution techniques, each with its own advantages and disadvantages, have been developed [4,5]. The first is a Fourier filtering method. By expanding the solution of the heat conduction equation (3) as a Fourier series, the distribution P(x) can be calculated from the measured pyroelectric current [5].

The second method is the regularization method [6]. In this method, in order to get a reasonably smooth polarization profile, it is necessary that the integral over the second derivative should be minimised, i.e.

$$\int_0^d \left|P''(x)\right|^2 dx = \min \qquad (6)$$

A disadvantage of this method is that one has to find the right compromise between suppressing unphysical oscillations and smoothing out the solution too much [7]. In practice, one often encounters a strong polarized layer near the surface, giving rise to a rapidly changing P(x), and a much smoother distribution deep inside the sample.

Both Fourier filtering and regularization methods often produce artefacts and require a large computational effort. Ploss *et al*. [7,8] proposed an approximation technique. Near the surface of the sample, an approximate solution of the heat conduction can be used to obtain an analytical expression for the polarization distribution. Referring to equation (1) the

spatial temperature change at high frequencies ($\omega > 2\delta_t/d^2$) is approximated as [7]

$$T_\omega(x) = \frac{\eta W_\omega}{\mu G_t} e^{-\mu x} \quad (7)$$

From equations (2) and (7) the pyroelectric current at high frequencies can be written as:

$$I_{p\omega} = \frac{\eta \alpha_p A W_\omega}{\rho c d} \int_0^\infty P(x) \mu e^{-\mu x} dx \quad (8)$$

The difference between the real ($I_{p\omega re}$) and imaginary (I_{pim}) components of this current is given by [8]

$$P_a(x_t) = \int_0^\infty P(x) \frac{2}{x_t} \sin(x/x_t) e^{-x/x_t} dx \quad (9)$$

where $P_a(x_t)=I_{p\omega re}-I_{p\omega im}$ and $x_t(=2\delta_t/\omega^{-1/2})$ is the thermal diffusion depth. Ploss *et al*. [7] defined the function $[2\sin(x/x_t)/x_t]e^{-x/xt}$ as a thermal scanning function ($f(x,x_t)$). Based on the analysis of the properties $f(x,x_t)$ they found that the temporal derivation of the temperature amplitude has all the properties of a scanning function for the pyroelectric profile. The function $P_a(x_t)$ which is calculated from the measured pyroelectric current is an approximation of the pyroelectric distribution $P(x_t)$ for small x_t. Therefore, the approximation $P(x_t) \approx P_a(x_t)$ is only valid near the heated surface of the sample. With the approximation method the component of the measured pyroelectric spectrum gives an approximation for the pyroelectric profile without the necessity for a mathematical inversion [8]. This enables LIMM to be used as an on-line procedure, where the pyroelectric coefficient at a given depth on the sample is obtained directly from the current measured at a particular frequency.

The strength of the approximation method is its accuracy in showing the polarization profiles near the heated surface [8].

3. EXPERIMENTAL

The polymers used were PVDF and its copolymers with trifluoroethylene (TrFE). The samples were of two types. The first type consisted of commercial films of 25 μm thickness. 25 μm films of PVDF were obtained from Kureha and Solvay, and 65/35 and 75/25 mol% VDF/TrFE copolymers in 25 μm thickness were obtained from Solvay. The second type of sample were sub-micron films, prepared by spinning a solution of the polymer onto a metallised glass substrate. Such spun-cast samples typically had a thickness of the order of 0.1 μm. It may be possible to produce samples with thickness less than 0.1 m. [9,10].

Hysteresis loops for the films were generated in conventional Sawyer-Tower type circuits. The 25 μm films required maximum voltages around 2 kV in order to generate the loops. For these films, the period of cycling of the field could not be reduced below a few tens of seconds, because of slew rate limitations in the high voltage supply. For the spun-cast films, the required voltages were much lower, and readily supplied by an ordinary signal generator. The period used was normally less than a second. If the period was greater than one second, then the loops tended to balloon in shape - presumably as a result of leakage in the films.

LIMM measurements were made by illuminating the samples either with a modulated IR laser diode or with a chopped laser beam. The pyroelectric current thus generated was measured using a lockin amplifier. The currents were measured over the frequency range from 10 Hz to 10 kHz.

4. RESULTS

The effects of fatigue on the hysteresis loops of the commercial 25 μm films are illustrated in Figures 2 and 3. Figure 2 shows the effect of repeated cycling on the loops of the Kureha 25 μm PVDF films. The period of these loops was 100 s. Neither of the PVDF films (i.e. Kureha and Solvay) showed a significant reduction in reversed polarization with repeated cycling. Both materials produced loops which were reasonably symmetric about the zero polarization axis.

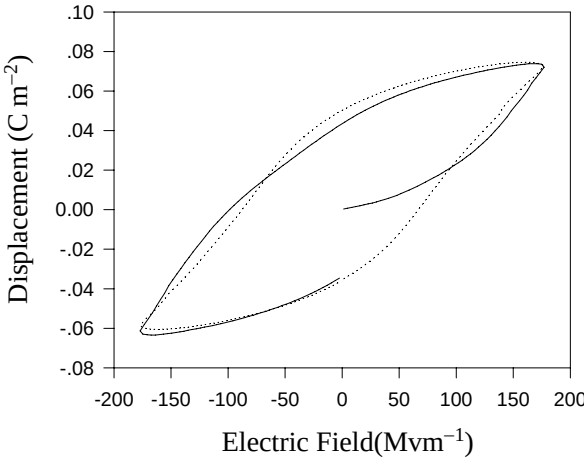

Figure 2: The first (solid) and 100th (dotted) loops for 25 μm Kureha PVDF. The loop period was 100 s.

In contrast, both the 65/35 and 75/25 copolymers displayed fatigue, which was clearly evident even during the first couple of cycles. The copolymers would normally display a large initial loop, lying entirely above the polarization axis, (Figure 3) and subsequent loops would maintain this initial offset.

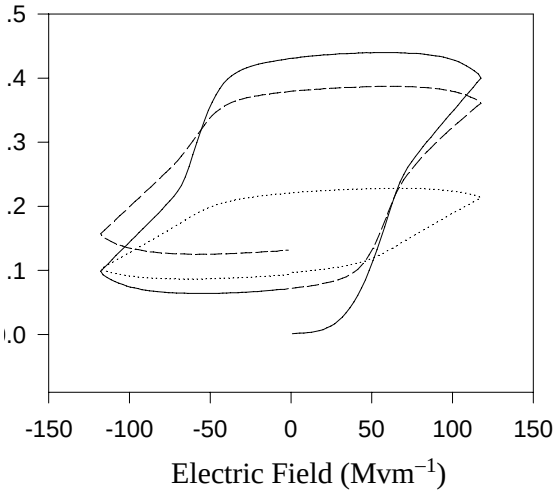

Figure 3: The first (solid), second (dashed) and tenth (dotted) loop for a 25 μm Solvay 65/35 copolymer film. The loop period was 100 s.

Figure 4 shows the loops for a 230 nm spun-cast film of the 65/35 VDF/TrFE copolymer. The sample was initially cycled 9×10^4 times, then left for eight days with short-circuited electrodes, after which another 4×10^4 loops were run. The period of the loops was 0.03 s. Figure 4 shows the shape of the first and the 9×10^4th loop obtained from the initial run on this sample.

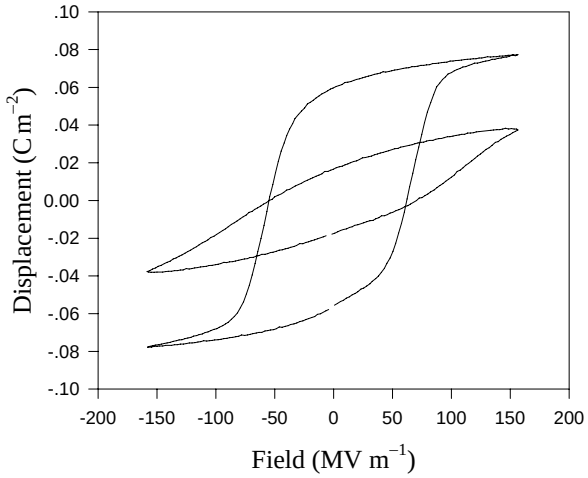

Figure 4: Hysteresis loops for a 230 nm film of 65/35 VDF/TrFE copolymer. The larger loop was the initial loop, the smaller one is the 90,000th loop. The loop period was 0.03 s.

Figure 5 shows the magnitude of the switched polarization obtained in the initial run of 9×10^4 loops and in the subsequent run of 4×10^4 loops run after eight days resting. The spun-cast films displayed a fairly constant polarization for the first thousand or so loops, then a steady decrease in the amount of reversed polarization. If a sample was rested for some time, then re-cycled, the reversed polarization continued at a value close to that of the last cycle in the previous run.

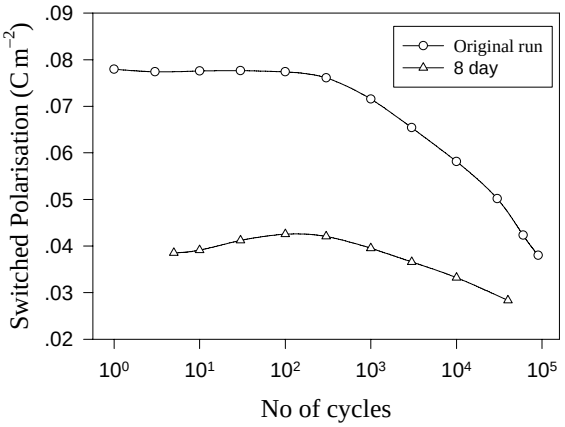

Figure 5: The switched polarization, as measured from the hysteresis loops, for the sample of figure 4. The upper plot shows the polarization observed in the initial 90,000 loops. The lower plot shows the polarization observed after eight days resting.

Because of the limitation in resolution of the LIMM measurement, it was only possible to obtain meaningful polarization profiles in the 25 μm samples. The polarization profiles in the Kureha and Solvay PVDF and both copolymer films, before any poling treatment, is shown in Figure 6.

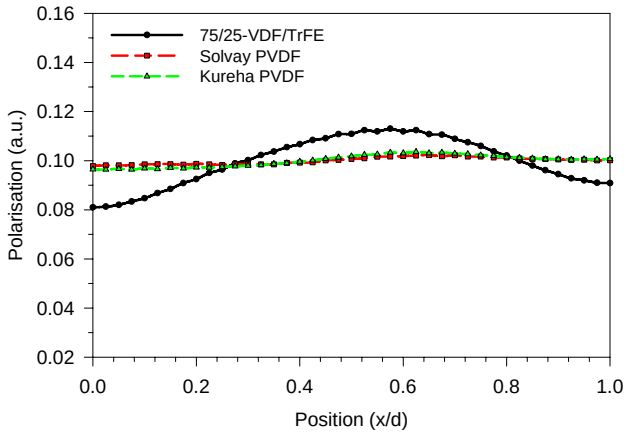

Figure 6: Polarization profiles in unpoled 25 μm films of PVDF and DVF/TrFE copolymers.

The horizontal axis in this plot represents the position through the thickness of the film as a fraction of the total thickness. The Solvay 25 μm PVDF film showed similar behaviour to the Kureha film and is not shown separately.

In the deconvolution process the mean polarization is set to 0.1 and the polarization fitted around this value by a least-squares fitting [3]. Thus the vertical scale in figures 6 and 7 has an unknown offset and only the variation of the polarization through the thickness can be inferred from these plots.

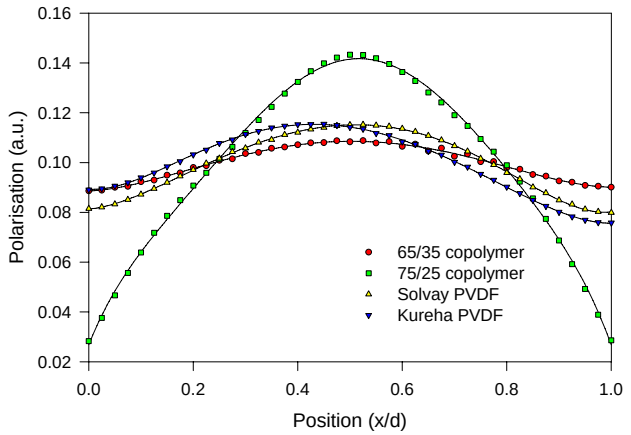

Figure 7: Polarization profiles in PVDF and copolymer films which have been exposed to several cycles of poling.

The polarization profiles obtained for samples of unpoled, half, one, ten and two hundred cycle poled Kureha PVDF films, with thickness of 25 μm, are shown in figure 8. Poled or fatigued samples were subjected to a maximum field 180 MVm^{-1}. While the polarization profiles for unpoled, poled and fatigued 65/35-P(VDF/TrFE) films are shown in figures 9. For the copolymer, the field amplitude was 140 MVm^{-1}.

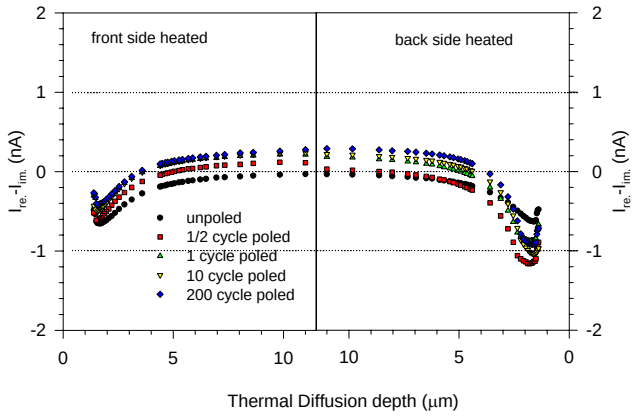

Figure 8: Polarization profiles near the heated surfaces of unpoled, poled and fatigued Kureha PVDF.

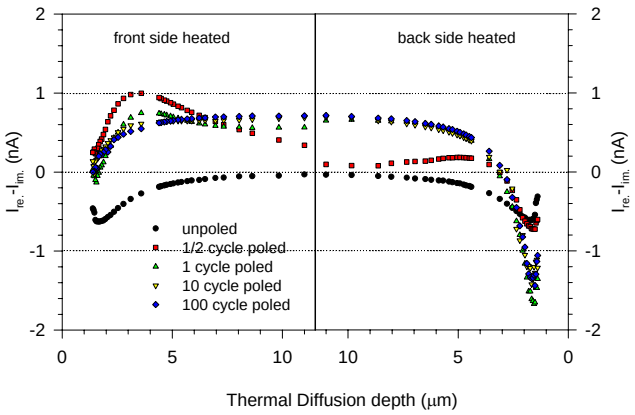

Figure 9: Polarization profiles near the heated electrodes of unpoled, poled and fatigued Solvay 65/35-P(VDF/TrFE) samples.

It is seen from figures 8 and 9 that all of the unpoled polymer films had some initial polarization. The nature of this initial polarization was similar for all films; it was symmetrical and was located near the electroded surfaces. It is assumed that this initial polarization arises from a diffusion of electrons from the metal electrodes into the surface regions of the polymers. This migration would result in regions of space charge accumulation near the electrodes and would be the same for both surfaces of the polymers. As the samples were poled, the effects of these space charge regions remain visible, however they become quite asymmetrical. The space charge region on the left in the figures, becomes much less prominent and, for the copolymer samples, virtually disappears with large numbers of field cycles. This is the surface of the film which becomes positive when the field is first applied. On the right hand side, the space charge layer becomes more prominent and also becomes much narrower, meaning that it is much more localized in the vicinity of the electrode. These effects are much more noticeable in the Solvay PVDF and the copolymers than they are in the Kureha PVDF. It can be recalled that the Kureha PVDF is the film with the highest content of the α crystal form.

The polarization in the bulk of the polymers, before the application of the field, was essentially zero. This is as expected, suggesting that there is random orientation of the dipoles in the bulk of the polymer. As the samples became poled, the net polarization in the bulk increased and was always largest and most uniform after several hundred field cycles. In the early stages of poling there was often some non-uniformity in the profiles, especially in the copolymers. The results for the 65/35 copolymer, shown in figure 9 show this effect very prominently. For most samples there were occasional discontinuities when the two halves of the plots were joined. This is a result of the poorer resolution of the approximation method for positions deep within the films.

ISSN 114-1284

5. DISCUSSION

The thin polymer films exhibit similar fatigue behaviour to that observed in ceramic ferroelectrics [11]. The polarization remains reasonably constant for about one thousand cycles, then drops with repeated cycling. In ceramics the number of cycles before the reduction is usually more than this, and indeed for memory applications efforts are directed towards reducing fatigue. The effects of fatigue appear to be reasonably permanent, in that the switched polarization did not recover after resting the sample for eight days.

In the 25 μm films the situation appears more complex. In the 25 μm PVDF films it appears at first that there is no fatigue. However these films contain significant amounts of the non-polar α crystal form. IR spectroscopy [12] indicates that continued reversal in these films leads to a steady conversion of the α form to the polar β form. It is the β form which is thought to be responsible for the reversible polarization, and an increase in β content would increase the switchable polarization. Thus in the PVDF films it may be that the increased β content masks the effects of fatigue. In copolymer films with VDF content in the range from 70% to 80%, the crystal form is almost entirely β [13]. Thus it appears that the films with significant β content and little, if any, α content are the ones which display fatigue.

The pre-existing polarization in the films, as shown in fig. 5, is similar to that observed by others [14]. In ref. [14] this initial polarization was found to be independent of electrode material and to have a magnitude in the range from 0.01 to 0.02 Cm^{-2}. In previous studies the variation in poled films, even those which have been poled in one direction, then reverse poled, show distinct asymmetries [13,14]. In the case of copolymer films studied here (figure 9), the polarization is quite symmetric after several reversals, while that in the PVDF films is not. After fatigue, we might expect that the polarity of the last half cycle would be evident, but the fatigued copolymer samples all display a final polarization which is quite symmetric.

Since fatigue appears in the first few loops if the loop period is large (figure 3), but does not appear for several hundred loops if the period is small (figures 4 and 5), it would seem that the important factor is the time of exposure to the field, rather than the actual number of reversals. This would tend to indicate a space charge migration as being the underlying cause, rather than domain wall effects. Space charge has been thought to inhibit the switching in PVDF and a model of space charge attachment to the polar crystals has been used to explain this inhibition [14]. If space charge is the cause of the fatigue, then it seems that presence of the α crystal form in a sample may inhibit the motion of space charge, hence prevent it moving to the β crystals.

To date, equipment limitations have prevented running loops of the same period on both thick and thin films, although it is hoped to be able to do this in the near future. It would also be very interesting to be able to look at the polarization profiles in the sub-micron films. Unfortunately at the moment it seems that no techniques are available to probe polarization with the precision required.

6. CONCLUSION

The polarization distributions in ferroelectric polymer films, with 25 μm thickness, have been presented in this chapter. The polarization was generated by applying a cyclic field for up to several hundred cycles. The effects of differing numbers of field cycles have been observed.

The most reliable measurements of the polarization distributions are felt to be those proposed by Ploss *et.al*. [8], obtained by the approximation method. This is in spite of the poor resolution of this method in the central regions of the films.

It is apparent that when electrodes are deposited on unpoled films, some charge diffusion occurs, leading to space charge regions in the vicinity of the electrodes. Cyclic poling of the films leads to the development of significant polarization in the bulk of the films and also has an affect on the space charge regions. While this suggests that space charge is involved in the fatigue process, the mechanism by which it operates is not obvious.

In the present context, the results of this chapter indicate that cyclic poling produce films with a uniform distribution of pyroelectric activity through their thickness, although there are significant surface charge layers at the negative electrode.

ACKNOWLEDMETS

I acknowledge support for this work from the Macquarie University Research and am thankful to Adventist University of Indonesia for the support to join this QIR seminar.

ABSTRACT

This research is to study the effect of firing and holding time on characteristic of SiC/Al Ceramic Matrix Composite produced by Directed Metal Oxidation (DIMOX). The firing temperature and holding time used were various from 900°C to 1300°C for 10 and 20 hours respectively. The characteristic of composites were examined such as density, porosity, hardness, and microstructure analysis. The results showed that SiC preform has been infiltrated by Al liquid and occurred optimally at 1100°C for 20 hours. This ceramic composites possess highest density of 3,54 gram/cm^3, while porosity tents to increase with increasing firing temperature. Porosity within the channels is associated primarily with insufficient Al flow to feed the solidification shrinkage. The highest hardness obtained at 1300°C for 10 hours i.e. 1820 VHN. The distribution of SiC particles spread over SiC/Al composites and new phases present containing of spinel ($MgAl_2O_4$), Al_2O_3 and Mg_2Si analyzed by EDS.

Key words *: CMC's, firing temperature, holding time, DIMOX*

1. INTRODUCTION

Ceramic Matrix Composite (CMC's) of SiC/Al is one of the important candidate materials for use in airplanes, automobiles and the first wall of fusion reactors[1]. Directed metal oxidation (DIMOX) is one of the methods to produce CMC's which have high toughness and good thermal shock resistance, as well as high stiffness, good wear resistance and high temperature stability. Further more, the method allows production of near net shape at a low cost. The process has been developed commercially by the Lanxide Corporation[2,3] . The process involves the oxidation of a bulk molten metal by a gas through a directed growth process to produce an interconnected ceramic reaction product that may contain several percent of residual metal. This process mostly used for some space application[4]. Solid-liquid interface energy reduces by holding time for all of ceramic particle-Al alloy system. Some of the surface energy change and occurred faster interface reaction at higher temperature. Decomposition of oxide coat in the solid ceramic phase either physically or chemically has also been considered as one of influencing factor that affect the wetting kinetics[5]. Molten metal start to infiltrate when the solid-liquid interface energy decreasing.

In many cases, the great improvement of wettability can be observed in the 900°C temperature for ceramic/Al-alloy system[6,7]. This behavior has been explained by decomposition of thin coating of Oxide on the ceramic surface[7,8] and also by the change of the Oxide coating on the liquid metal surface. Temperature will affect the viscosity, and the viscosity effect of molten Alloys Al to the infiltration is shown by intrinsic parameter (Φ) that is developed by Martins[9] and expressed as:

$$\Phi = \frac{(\gamma \cos \theta)}{2\mu} \quad \text{.....(1)}$$

For which : γ = Surface energy (mNm^{-1})
θ = Liquid-Solid contact angle
μ = molten viscosity

High intrinsic parameter value is used as the description of infiltration speed improvement for the lower viscosity of molten Alloys Al.

Although the stability of ceramic phase in the Metal-Ceramic system is usually only allowing a few solubility, but the small amounts of solution can reduce solid-liquid interface energy. Adsorption is a surface reaction that is depends on concentrate, temperature and diffusivity. The relationship between the adsorption, temperature, surface energy, and concentrate is expressed by the Gibbs equation:

$$\Gamma = -\frac{1}{RT}\frac{d\gamma}{\ln dX} \quad \text{.....(2)}$$

For which:

Γ = Adsorbs (m/^{o} mol)
R = Gas constant (8.3144 joules /^{o} mol
γ = Surface energy (mNm^{-1})
X = Solute Mole faction .

The greater the adsorption more the solute tends to lower the surface energy. The time dependence of wetting can be explained in terms of reaction kinetic in ceramic-metal system, for a system of high reactivity interfacial reaction proceed quickly after physical contact between liquid and solid phases.

Generally, wetting ability is poor and wetting process is slow for less reactive system, so that needed by the longer time to reach the wetting. Analyzing of the oxide layer on the ceramic phase considered one of the factors affecting the kinetics of wetting[7,8]. The liquid metal starts infiltration if decrease of the solid-liquid interfacial energy.

Almost linear decreasing of wetting angle with time for the SiC/Al system was observed by Halverson et al[10]. Aghajanian in its research prove that detention time influence the kinetics infiltrate, the longer holding time with the same process give the greater kinetics infiltrate[11].

2. Experimental Procedure

Materials used are Al alloy block with composition showed in **Table 2.1**, analyzed by Spectrometer, SiC powder (94,23%) and Mg powder (98,5%). All these materials then were arranged as in **Figure 2.1**. The prepared samples were heated in muffle furnace at temperature of 900, 1100 and 1300^{o}C with ramp temperature of 10^{o}C/minute. This temperature was maintained for 10 and 20 hours then furnace cooled.

Tabel 2.1. Chemical Composition of Al alloy (%wt).

Al	Si	Cu	Mg	Zn	Fe	LOI
86,3	9,91	1,56	0,23	0,405	1,01	-

The characterization of composites produced was examined such as density and porosity (ASTM C 373-88), micro hardness Vickers (ASTM E 384), and microstructural analysis by SEM link to EDS..

3. Result and Discussions

3.1. Effect of Firing Temperature and Holding Time on Density

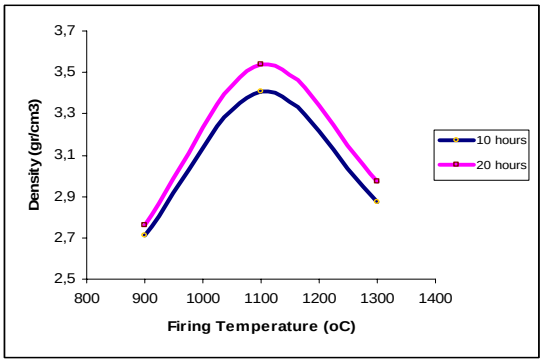

Figure 3.1 Effect firing temperature and holding time to density

The density increase significantly from temperature 900^{o}C to 1100^{o}C with value from 3,2 gr/cm^3 to 3,6 gr/cm^3, while after 1100^{o}C the density decrease for both holding time as shown in **Fig. 3.1**, but the value is still higher than 900^{o}C. This is indicated that Al alloy block mostly has been infiltrated into ceramic powder at higher temperature, as we know that the density of Al was lower than the density of SiC (2.7 kg/m^3 Vs 3.12 kg/m^3 respectively). This higher value than that of the matrix SiC might be caused by Al_2O_3 product created as the effect of Al oxidation.

At higher temperature and longer holding time create molten Al more infiltrate because Mg which is mixed with SiC has oxidized with air to form MgO. Interdiffusion MgO with alumina layer on the surface of Al changed MgO into un protective spinel ($MgAl_2O_4$) so that it can be wetted by molten Al[12-14].

3.2 Effect Firing Temperature and Holding Time on Porosity

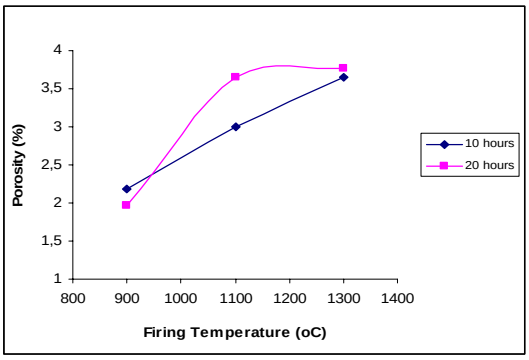

Figure. 3.2 Effect firing temperature and holding time to porosity

At higher firing temperature and longer holding time generated higher porosity, it seems that the value slightly odd. It should be the porosity content tends to decrease with higher temperature. Microstructural observation showed that porosity locate dominantly on the interface of Al block or on the base of CMC's. Area around interface is an area of pre-form which poor contain of oxygen so that according to Manor et al.[15] the growth of matrix initiated by spinel ($MgAl_2O_4$) formation. $MgAl_2O_4$ which does not occur will give the space amongst pre-form particles which then cause such a porosity formation. Three dimension interconnected ceramic structure also can cause the formation of porosity on the product caused by interconnected ceramic structure, so that Al can not fill all remain space on ceramic matrix.

3.3 Effect Firing Temperature and Holding Time on Hardness

The hardness of CMC's is shown in **Fig. 3.3.** The micro hardness of CMC's will decrease with longer holding time. The highest hardness value is obtained at firing temperature of 1300°C and holding time for 10 hours.. Increasing hardness due to less porosity and high density. At 1300°C for 10 hour, the phases present giving increasing hardness due to the formation of $MgAl_2O_4$. The spinel is form on the outer layer of SiC as the product of reaction

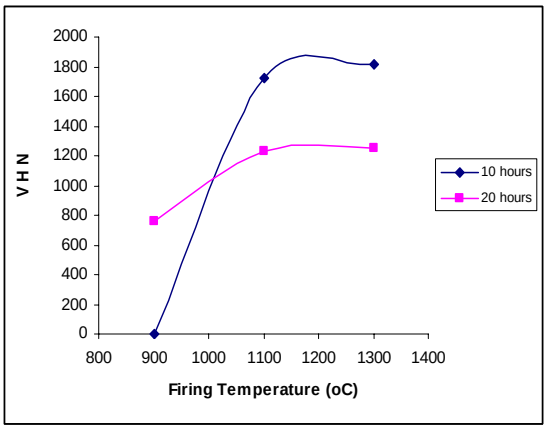

Figure. 3.3. Effect firing temperature and holding time to hardness

At firing temperature of 1100°C and 1300°C for 20 hours, the hardness were decrease due to increasing porosity and more molten Al infiltration to perform.

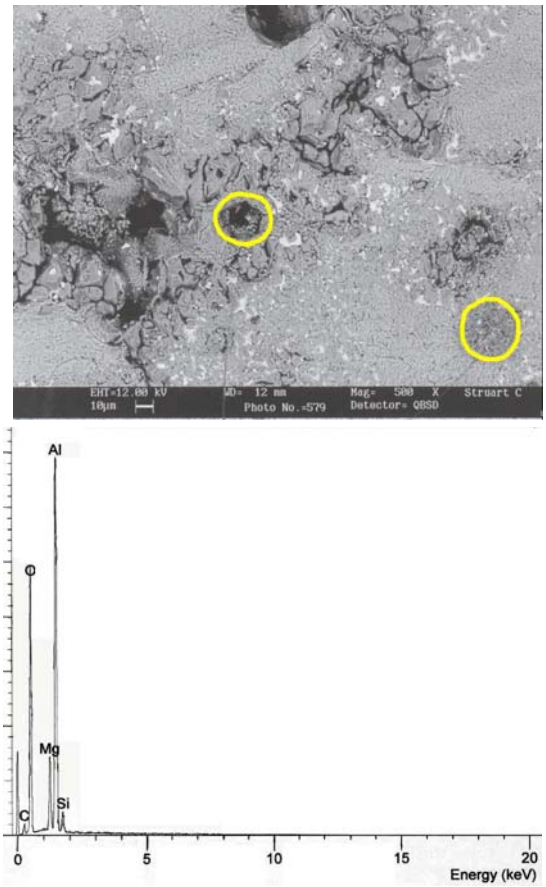

Figure 3.4. SEM link to EDS indicated the phases present on CMC's product during firing at temperature of 1300°C for 10 hours.

CMC's produced in this research has hardness in the range between 1200VHN (1100 °C for 10 hours) and 1800VHN (1300 °C for 10 hours) as

mentioned above that increasing hardness also is affected by a new phase present in CMC's such as Al_2O_3 (possess hardness between 1500 – 1650 VHN).

3.4. Microstructural Analysis

The formation of Al_2O_3 on the SiC surface due to oxidation of SiC at temperature 1100°C react with Al analysed by EDS (**Fig. 3.5**). The particles SiC seem to be uniform distribution on the microstructure (**Fig. 3.6**).

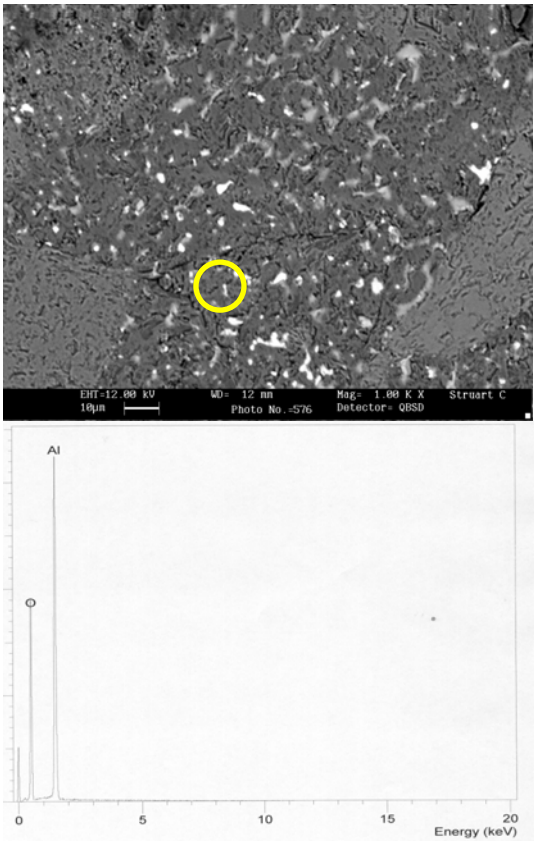

Figure 3.5. Microstructure of CMC's after firing at 1100°C for 20 hours, Al_2O_3 zone is found in the structure analyzed by EDS

The present of Cu might be originated from Al alloy block with light phase can reduce the Mg_2Si solution in SiC/Al system.[16]. Mg content in this CMC promoted the formation of spinel ($MgAl_2O_4$) and also present in the formation of Mg_2Si. These new phases occurred after firing at 1100 °C for 20 hours.

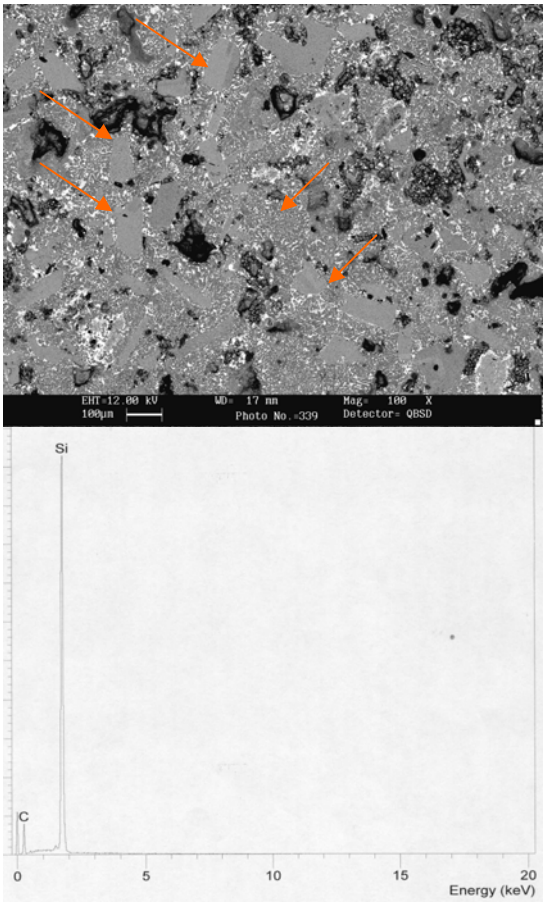

Figure 3.6. SiC distributed uniform and the light phase is channel Al. after firing at 1100°C for 20 hours**.**

4. Conclusions

- The optimum properties of CMC's found at condition of firing temperature at 1300°C for 10 hours..
- The distribution of SiC particles spread over SiC/Al composites, and microstructural analysis found new phases produced during firing containing Al_2O_3, $MgAl_2O_4$ and Mg_2Si analysed by SEM link to EDS.

ABSTRACT

Polypropylene-clay nanocomposites were prepared. A commercial homopolymer polypropylene was melt blended with commercial nano-clay masterbatch at different concentration using Laboratory Mixing Extruder (LME). The influence of three different concentrations of nano-clay on the morpholofy structure, the non-isothermal crystallization, and the viscoelastic properties were investigated. These properties were characterized using Scanning Electron Microscope (SEM), Differential Scanning Calorimetry (DSC), and Dynamic Mechanical Analysis (DMA). The results show that the melting temperature of the PP-clay nanocomposites were not significantly affected by the presence of nano-clay material. However, the dispersion of nano-clay in the PP matrix increases the crystallinity of PP- clay nanocomposites, which reached maximum crystallinity at 5 wt% nano-clay loading. DMA curves show an increase in storage modulus of nanocomposite material, which indicate that the incorporation of nano-clay into PP matrix remarkably enhances its stiffness and thermal stability.

Nanocomposites, polypropylene, nano-clay, masterbatch, melt blend

1. INTRODUCTION

Polypropylene (PP) is one of the most widely used polyolefin polymers. It is used in different applications as automotive parts, and cable insulation. The properties of polypropylene are significantly enhanced using different fillers. Although, traditional fillers such as $CaCO_3$ and talc improve PP properties, there are many limitations as poor fillers dispersion. The use of fillers in nano-scale is believed to overcome such limits.

Polymer nanocomposites consist of a polymeric and a reinforcing nanoscale material. Because the nano-materials are so small, limited amounts are sufficient to enhance the polymer properties. Thus, the use of such materials has no effect on polymer density, transparency and processability compared to the traditional composites. This feature counterbalanced the negative effect of high cost of nanofillers [1,2,3].

Recently, commercial nanocomposite masterbatches have been already manufactured. Using commercial masterbatch becomes a promising alternative in the production of polymer-nanocomposites compared with using bulk nano-materials. Besides dust free, masterbatch also has a less healthy and safety risks. Another advantage of masterbatch is the elimination of difficulty in dispersion process and also easy handling because the nano-materials are bounded inside the polymer matrix. Therefore, masterbatch process is considered to be one of the simplest and most economical methods in processing of polymer-nanocomposites. However, literature survey revealed that the investigation reports which studied polypropylene-nanocomposites using masterbatch are limited compared to direct incorporation of nano-material into polyolefin that makes it an attractive area for research [4,5].

Among the entire potential nanomaterials, nano-clay (layered silicate) has attracted great interest among researchers, because clay materials are easily available, environmentally friendly, and their intercalation chemistry has been investigated for a long time. This make nano-clay one of the most widely accepted and effective nano-reinforcements [1,3]. One of the most widely used methods to prepare PNs is melt intercalation method. This method is compatible with current industrial processes as extrusion and injection molding. Besides, it is environmental friendly because no solvent is used [1,6,7].

In the present work, two series of PP-clay nanocomposites were prepared. The aim of this work will be studying the influence of composition (nano-clay content) on the properties of PP-clay nanocomposites. We will investigate the morphology by SEM , the crystallinity with DSC analysis, and viscoelastic behavior in a wide range of temperature using DMA tests.

2. MATERIALS AND METHODS

2.1. Materials

A commercial homopolymer polypropylene (PP) were used as matrix materials for the polyolefins nanocomposites which were investigated in this work. The polypropylene was acquired from the local market (product name : PP70) which has MFI 8 g/10 min. The melt flow index (MFI) was measured at 230 ^oC at a load of 2.16 kg, according to ASTM-D1238. Commercial PP nano-clay masterbatch with 50 wt% concentration of nano-clay (product name : NanoMax, from Nanocor) was used for the preparation of the nanocomposites. The nano-clay is organophillic montmorillonite (MMT)

which has been modified with dimethyl-dihydrogenated tallow ammonium.

2.2. Preparation of polypropylene-organoclay composites

In this work, polypropylene/nano-material composites were prepared by diluting highly concentrated nano-material masterbatch pellets in polypropylene matrix using melt blend technique. Laboratory Mixing Extruder (LME), made by Dynisco, was used at constant chamber temperature of 260 ^{o}C, die temperature of 265 ^{o}C, and rotor speed of 250 rpm. The melt blend process was done in two steps. The first step was the pelletization step where the nano-material masterbatch was blended with polypropylene matrix then pelletized. The next step was to use these pellets to extrude ribbons. These two steps were necessary to avoid the lack of mixing that was observed on the ribbon surface when the masterbatch was used directly to produce ribbons without the pelletization step. Prepared polypropylene nanocompostie materials (both pellets and ribbons) were characterized. The specimen will be called PP70-5 for the sample obtained using PP70 and nano-clay 5 wt%, etc.

For the morphology of the nanocomposties, scanning electron microscopy (SEM) images were obtained using a JEOL JSM-6360A scanning electron microscope operated at an acceleration voltage of 15 kV. Calorimetric measurements were carried out using a differential scanning calorimetry DSC-60 from Shimadzu. The samples used here were the pellet extrudates from LME. They were cut into small pieces and maintained at the weight of about 5-10 mg. All materials were treated in the same way : For 1st heating scan, they were heated with a constant heating rate of 10 ^{o}C/min from ambient temperature up to 200 ^{o}C, to erase their previous history, they were held for 10 min at 200 ^{o}C, subsequently cooled down to 30 ^{o}C with the cooling rate 10 ^{o}C/min. Then for the 2nd heating scan, the samples were heated again at rate of 10 ^{o}C/min up to 350 ^{o}C, and the corresponding thermogram was recorded. The melting temperature, T_m was taken as the maximum in the transition endotherm. The non-isothermal crystallization analyses were carried out from the melt at 150 ^{o}C with a cooling rate of 10 ^{o}C/min down to 50 ^{o}C. The crystallinity of the specimen may be calculated from the experimental heat of fusion ΔH_m and the literature value of 100% crystalline polymer material, ΔH_m^o and for PP, ΔH_m^o is 207 J/g [17]. In order to estimate the percentage of crystallinity (Xc), the following equation was used :

$$X_c = \frac{\Delta H_m}{\Delta H_m^o} . 100\ [\%] \qquad (1)$$

Dynamic Mechanical Analysis (DMA) was performed using AR-G2 instrument made by TA Instruments. The analysis was carried under torsion mode at a controlled angular frequency of 1 rad/s and 1% strain. The samples were heated with intervals of 3 ^{o}C from 30 ^{o}C up to 140 ^{o}C. The specimens used here were the ribbon extrudates from LME machine which has a thickness about 0.3 mm.

3. RESULTS AND DISCUSSIONS

3.1. Dispersion of the organoclay in polypropylene

Figure 1(a),(b) and Figure 2(a),(b) shows the SEM micrographs of PP70-clay nanocomposites respectively with nano-clay content 5% and 15% with different magnification. The study of the SEM images revealed that all the samples showing a good dispersion of both nano-clay loading in polypropylene matrix. It is because the processing conditions like high screw speed rotation which generated high shear forces. Additionally double cycle processing were used at sample preparation which generated more shear forces. As for the extent of intercalation or exfoliation of the nanocomposites still need further investigation.

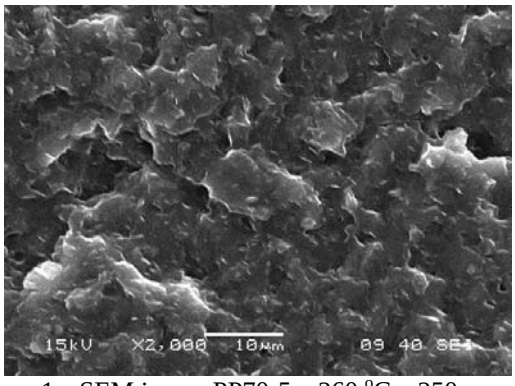

Figure 1a. SEM image PP70-5 – 260 ^{o}C – 250 rpm

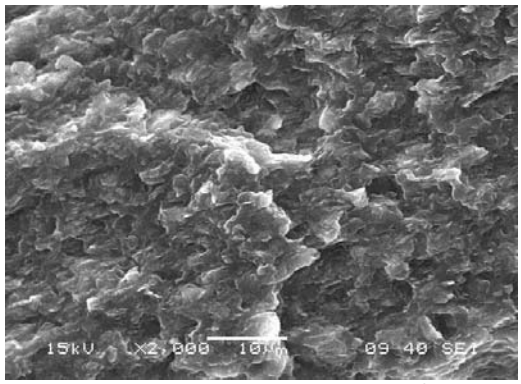

Figure 1b. SEM image PP70-15 – 260 ^{o}C – 250 rpm

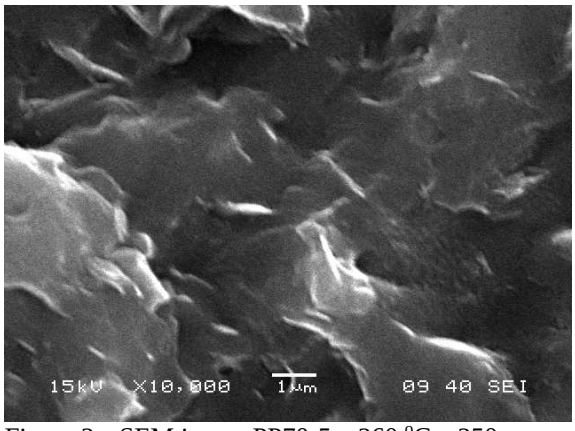

Figure 2a. SEM image PP70-5 – 260 °C – 250 rpm

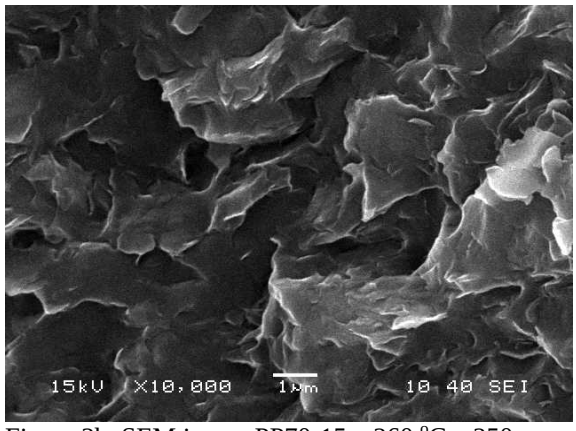

Figure 2b. SEM image PP70-15 – 260 °C – 250 rpm

4.2. Thermal properties

The heating thermograms of the PP-clay nanocomposites are presented in Figure 3. The DSC results in terms of melting temperature (T_m), heat of fusion (ΔH), and the percentage of crystallinity (X_c) are summarized in Table 1. The corresponding cooling thermograms of the non-isothermal crystallization are presented in Figure 4. The DSC measurements show that the melting peak of PP-clay nanocomposites is not significantly affected by the changes in the nano-clay content in PP matrix. While, the heat of fusion (attributed to crystallinity content) of PP70-clay nanocomposites increased up at 5% wt nano-clay loading but then decreased at higher loading (see Figure 3 – see also Table 1), but still most of them higher than the pure PP. There were also the shifting of the crystallization temperature to higher temperatures (from 11 up to 13 °C) of the corresponding exotherm of Figure 4.

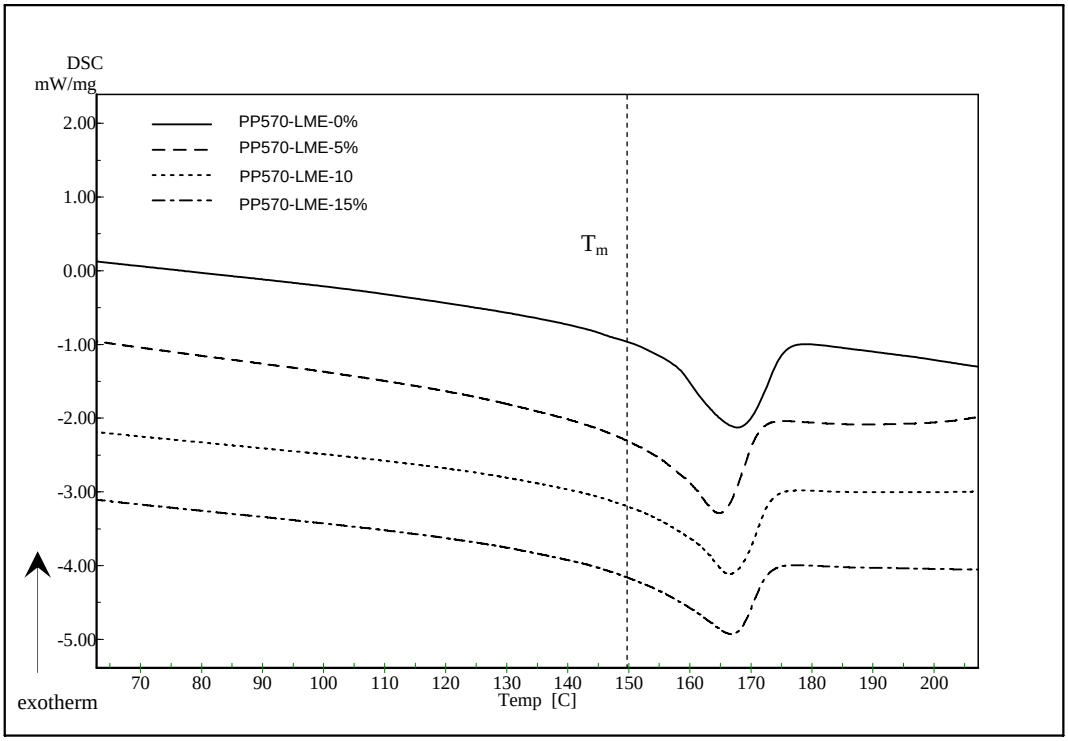

Figure 3. DSC thermograms of PP70-clay nanocomposites at a heating rate of 10 °C/min. The curves have been shifted in the *y*-direction to make them distinguishable

The explanation of this phenomena is that the presence of nano-clay platelets dispersed in the PP matrix significantly reduce the crystallization time of PP. It was proposed that clays enchance the nucleation process of the matrix by acting as heterogenous nuclei during the crsytallization of PP [8]. Thus making the crystallinity to increase and crystallization temperature shifting to higher temperature (see Table 1). But, there is no further increasing of crystallinity in PP-clay nanocomposites at nano-clay loading higher than 5 wt% (it reached maximum of 72.96 %). The decreasing of the crystallinity degree can be explained by the presence of an excessive number of nano-clay platelets which can hinder the motion of the polymer chain segments and thus, retard crystal growth [9].

It was proposed that the explanation above also describe another peak (beside Tc_1) which appear on the crystallization diagram of both PP-clay composite materials (see Figure 4 - Tc_2). If we observe carefully, most of Tc_1 for all the samples (pure and the nanocomposites – both of PP) are almost same (110 – 113 ^oC). But, in nanocomposite samples there is Tc_2 with higher temperature of Tc_1. It is proposed that Tc_2 could be attributed to heterogenous crystallization caused by the presence of nano-clay, while Tc_1 could be attributed to homogeneous crystallization by PP itself. So, in the crystallization diagram of nanocomposite samples we found two populations of crystallites. This postulation needs further investigation.

Table 1. DSC results for PP70-clay nanocomposites

Sample (nano-clay)(wt%)	T_m (°C)	Heat of Fusion (J/g)	X_c (%)	Tc_1 (°C)	Tc_2 (°C)	T onset (°C)

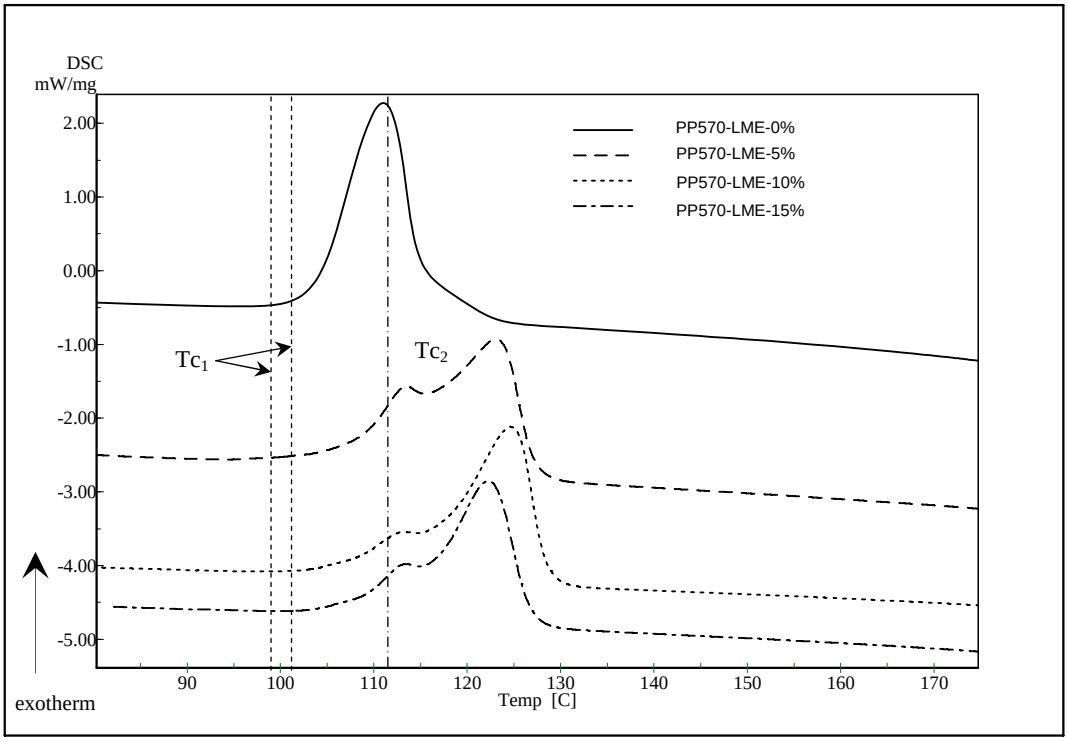

Figure 4. DSC thermograms of non-isothermal crystallization for the PP570-clay nanocomposites at a cooling rate of 10 ^oC/min.

4.3. Viscoelastic properties

To study the reinforcing effect of nano-clay material in a wide temperature range, dynamic mechanical analysis (DMA) of nanocomposites has been carried out at a fixed frequency 1 Hz, 1 % strain in the temperature range 30 – 140 ^oC. The dynamic mechanical results were obtained in terms of storage modulus (G') and plot of storage modulus (G') versus loss modulus (G''). In Figure 5, the temperature dependencies of the dynamic storage modulus G' are shown for the neat PP and PP-clay nanocomposites containing 5%,10% and 15% wt of nano-clay. It can be observed that the storage modulus G' of the nanocomposites were higher that those of the corresponding neat PP. This behavior can be explained as follows :

The matrix of the composites can be assumed that consists of two parts. One of them is the free part, where the state of the macromolecular chains is the same as that in the pure PP matrix. The other is the interphase. The larger the interfacial area and the stronger the interaction between the matrix and the fillers, the greater the volume of the interphase. Because the macromolecular chains of the interphase are restricted to the surface of the fillers, the molecular motion is greatly limited. As a result, the storage modulus of the interphase is higher that of the free part. It was proposed that increasing of nano-clay material enlarges the interfacial area and results in an increasing volume of interphase which improves the storage modulus of the materials [9].

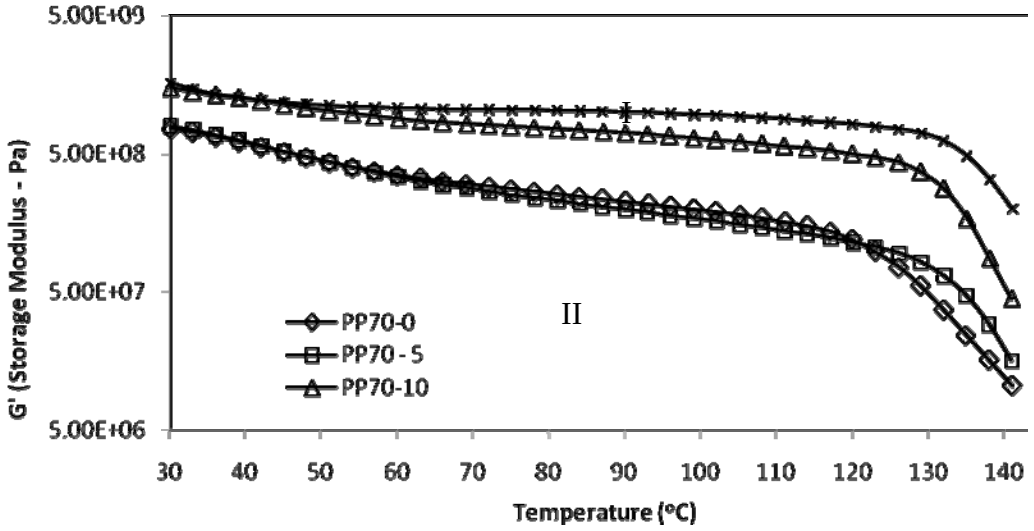

Figure 5. Storage modulus (G') versus temperature of PP70-clay nanocomposites at frequency 1 Hz.

If we observe again in Figure 5, there are two different types of curve, curves I (PP70-10 and PP70-15) and curves II (PP70-0 and PP70-5). In each of the curves we divided into two region, flat region and steep region. From the flat region we calculate the slope of the curves. And in the steep region we calculate the "softening temperature", the temperature where the storage modulus start to fall, by using tangent. If we observe carefully the curve of neat PP falling steeply than the nanocomposites. The curve of nanocomposite materials looks like more flat. It shows us that the presence of nano-clay gives a good thermal stability on the resulting nanocomposite materials. And also the "softening temperature" of the nanocomposites material are higher than the neat PP. It shows us that the addition of nano-clay material made the resulting nanocomposite material has a wider range temperature of usage than neat PP.

From the Figure 6. (G' versus G" curve), it can be observed that there are two different types of curve. The neat PP and PP70-5 curves are similar. However, in the higher loading of nano-clay (PP70-10 and PP70-15) the curves look different and have greater value than before. It shows that the presence of nano-clay material in higher loading made the resulting nanocomposite materials have different molecular structure that the neat PP, as results of interaction between nano-clay and PP matrix [10].

Table 2. DMA results of PP70-clay nanocomposites at different loading of nano-clay

Sample	G' (@51 °C), Pa	G' (@75 °C), Pa	G' (@102 °C), Pa	Slope of the flat region x E-2	Softening Temp, °C
PP70-0	4.31E+08	2.75E+08	1.89E+08	-1.84	123
PP-70-5	4.30E+08	2.52E+08	1.62E+08	-2.06	130
PP-70-10	1.02E+09	7.82E+08	6.30E+08	-1.09	131
PP70-15	1.11E+09	1.04E+09	9.47E+08	-0.513	133

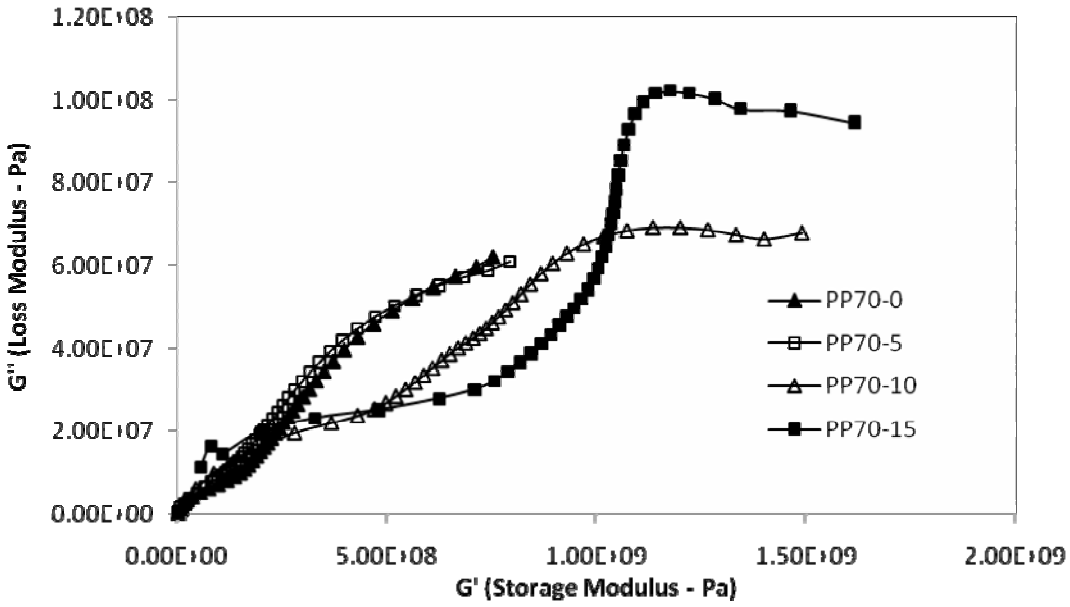

Figure 6. G' (Storage Modulus) vs G" (Loss Modulus) of PP-clay nanocomposites at different nano-clay loading

5. CONCLUSIONS

Melt blended PP-clay nanocomposites were obtained using different compositions, in order to study the effect of nano-clay loading on the thermal behavior, viscoelastic properties and morphology of the nanocomposites prepared. The presence of organo-clay nano-material cause a great enhancement of the crystallinity because the nano-clay act as nucleating agents, thus promoting heterogeneous crystallization. Furthermore, there was also shifting of crystallization temperature to a higher temperatures. While, any significant effect of the clay loading on the dispersion of the clay in the composites properties was not revealed. DMA curves show marked improvement of storage modulus of the nanocomposites; the increase is affected by the presence of nano-clay, especially at higher loading. It is also found that the addition of nano-clay material gives a good thermal stability and wider temperature range of usage on the resulting nanocomposite materials.

ABSTRACT

We developed a new concept of biocatalytic microreactor for continuous transesterification by utilizing the pores of membrane as a matrix for enzyme immobilization. Microreactors have become a promising technology in biotechnology and chemical engineering field. The membrane pores as a kind of microreactor was modified by simple adsorption with lipase from **Pseudomonas sp** *which is suitable for a highly efficient biocatalytic transesterification. A lipase solution was allowed to permeate through the Biomax™ membrane with NMWL 300,000 made of polyethersulfone (Millipore). The performances of biocatalytic membrane microreactor (BMM) have been studied in biodiesel synthesis through transesterification of triolein with methanol. Transesterification was carried out by passing solution triolein and methanol through porous of the membrane. The degree of triolein conversion using these microreactors was about 80% with a reaction time 19 minute. The stability of BMM system showed very good results, with no activity decay during 3-days period of continuous operation. This BMM system might be suitable for triglycerides transesterification (commercial production of biodiesel), which produce no waste stream.*

Microreactor, Immobilization, Biodiesel, Biocatalytic, Membrane

1. INTRODUCTION

Development in biocatalyst application (enzymes, whole cells, antigens or antibodies) requires continuous reactor to be used. In such operations immobilization is necessary. Common immobilization techniques include physical adsorption onto a solid support [1], covalent bonding to a solid support [2] and physical entrapment within a polymer matrix support [3]. The synthetic utility of lipases can be greatly improved when lipase are adsorbed onto micropores membrane due to the special characteristics of a membrane which separates the two phases thus avoiding emulsion formation; it also provides a means for immobilizing the lipase thus enhancing enzyme activity, stability and recyclability of lipase [4].

A simple method of immobilizing enzymes onto porous membranes modified using long time adsorption has been suggested. Support for the enzyme is achieved by using a sponge layer and porous asymmetric membrane made of polyethersulphone. Permeation of the substrate solution through the membrane minimizes diffusional mass-transfer resistance of the substrate to the immobilized enzyme, and hence enhances the overall biocatalytic reaction. To our knowledge, biocatalytic membrane reactor for applications in synthesis of methyl ester (biodiesel) has not been reported.

Among various studies on lipase catalyzed for biodiesel production, two main problems have been reported. First, inactivation of the enzyme due to methanol excess during reaction [5] and adsorption of glycerol on the enzyme surface[6]. A second problem is correspond to the reaction time is still unfavourable if compared to the alkali catalyzed homogeneous processes, in order to achieve product yield of ≥ 90% it was necessary to utilize reaction time greater than 40 hours [7]. Therefore several attempts have been made to develop an effective system to commercialize the lipase-catalyst process in biodiesel industrial application.

In this study, a new concept of biocatalytic membrane microreactor is developed for synthesis of methyl ester. By utilizing the pores of membrane as a kind of microreactors was prepared by a simple surface modification. The nanostructure formed by simple adsorption of membrane porous with lipase. When an immobilized enzyme adsorbed on the inner wall of the membrane pores is used for transesterification reaction, the activity of immobilized enzyme is predicted to increase because the pores act as microreactor.

The objective of this study were twofold: (i) to immobilize lipase originating from a *Pseudomonas sp* onto porous membrane using long time adsorption; and (ii) to evaluate of conversion degree of substrate during permeation of triolein solution dissolved in methanol. The membrane pores could function as microreactors and as nanocatalist system to produce a high rate of transesterification reaction.

2. MATERIAL AND METHODS

2.1. Materials

Commercially available disk membranes made of polyethersulphone (PES) with NMWL 300 kDa were used as matrix for enzyme immobilization and then act as a kind of microreactors. The membranes were supplied by Millipore Inc. (USA). Lipase D from *Rhizopus oryzae* was purchased from Valley Research (South Bend, India), Lipase Y from *Candida rugosa* were purchased from Sigma-Aldrich (Japan). Lipase PS and Lipase AK from *Pseudomonas sp* were purchased from Amano Enzyme (Nagoya, Japan). Triolein from Sigma-Aldrich (Belgium) were used as substrate triglyceride. All the chemicals were analytical grade and used without further purification.

2.2. Immobilization

0.5–0.75 g of crude lipase were dissolved in 50 ml of 50mM phosphate buffer (pH 7.0) and the solution was gently stirred using a magnetic stirrer for 2 h. Afterwards the solution was centrifuged at 3000 rpm for 10 min to remove the insoluble substances. Enzyme immobilization onto membranes was carried out following the two main steps: (i) simple adsorption on the support layer and (ii) permeation through the membrane. Firstly, a membrane sample 63.5 mm diameter was fixed in filtration cell (Amicon, model 8200, Fisher Scientific, Loughborough, UK) so that only sponge layer was in contact with the lipase solution while the membrane layer was placed upside down prevented from contact by the enzyme solution.

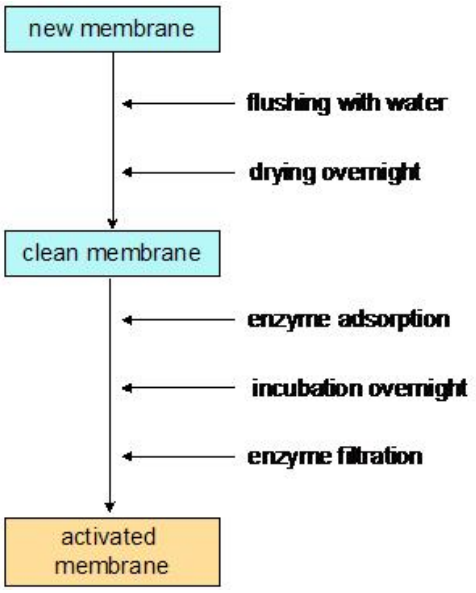

Fig 1. General procedure for the preparation of active membranes with immobilized enzymes

20 ml of lipase solution in phosphate buffer (pH 7.0) was poured in to filtration cell. Membrane samples were incubated with lipase solution for 18 h at 20°C. After incubation overnight the lipase solution was permeated through the sponge layers of the membranes in dead-end filtration cell under a pressure of 2 kPa without stirring. A lipase solution was allowed to permeate through the membrane, and lipase molecule adsorbed on the inner wall of the membrane pores. After immobilization, membranes were rinsed with 50mM phosphate buffer (pH 7). The amount of lipase adsorbed onto the sponge layer and retained in the membrane pores was determined as the amount of protein in solution before and after permeation and in washing using Lowry method. The amount of lipase adsorbed in the membrane was calculated as follows:

$$E = (C_0 - C)v \qquad (1)$$

where C_0 and C are the concentrations of lipase solution before and after filtration (mg/L), respectively. ν is the volume of lipase solution.

2.3. Transesterification reaction

Figure 2 is a diagram of experimental setup, which consisted of a stirred cell, a hot plate magnetic stirrer and peristaltic pump to provide driving force (vacuum) for permeation.

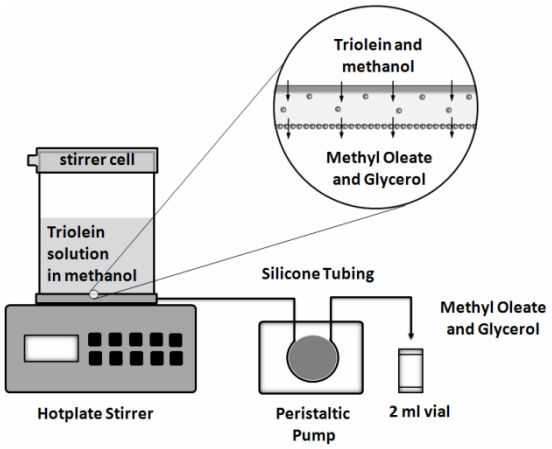

Fig 2. Experimental setup of microreactor for transesterification reactor

Continuous agitation was provided just above the membrane surface by a magnetic spin bar suspended from the cell top and driven by an external magnetic stirrer. The membrane microreactor was designed on a base of utilize a membrane pores as microreactor. The 300 kDa membrane consists of immobilized lipase in the pores (40 nm) with an effective area of 28.7 cm2. The disk membranes were placed in Amicon filtration cell. Enzyme-loaded side of membrane sponge was placed at the bottom side therefore no direct contact with feed solution. The peristaltic pump was used for driving forces (vacuum) of permeate streams at a flow rate of 5 ml/min. Fifty millilitres of solution containing of triolein in methanol used as a feed stream.

The feed and receiving reservoirs were kept at a constant temperature of 35±1 °C.

Transesterification started by forcing the solution phases through the membrane microreactor. Triolein solution in methanol was diffuse through the biocatalytic membrane microreactor then converted to methyl oleate and glycerol. Trans-esterification reactions occurred as a result of catalytic action of immobilized lipase in the membrane pores.

2.4. Analysis

The concentrations of FAMEs in the reaction mixture were determined using HPLC with a UV detector at 205 nm. The analytical HPLC system consisted of two Shimadzu LC-9A pumps and a SPD - 10A variable - wavelength UV detector (Shimadzu, Kyoto). For this analysis, a LiChroCART RP-C18 analytical column of 2504 mm (Merck, Darmstadt, Germany) was employed. The mobile phase consisted of three different components: hexane, isopropanol and methanol. Reservoir A contained methanol and reservoir B contained a mixture of isopropanol and hexane (5:4, v/v). The gradient went from 100% A to 50% A 50% B linearly over 30 min. The flow rate of the mobile phase was 1 ml/min and the sample injection volume was 10. This nonaqueous RP-HPLC method was modified from the method reported by Holcapek et al. [8].

3. RESULTS AND DISCUSSION

3.1. Types of Lipase

Lipases were screened for their ability to transesterification triolein with short-chain alcohols to alkyl esters. The lipase from *Pseudomonas cepacia* (PS) was most efficient for converting triolein to methyl oleate with primary alcohols, whereas the lipase from *Candida rugosa* (AY) was not efficient for transesterification triolein with primary alcohols to give methyl oleate.

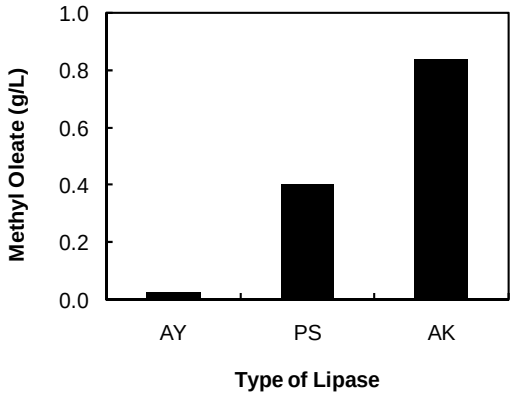

Fig 3. Lipase screening on transesterification

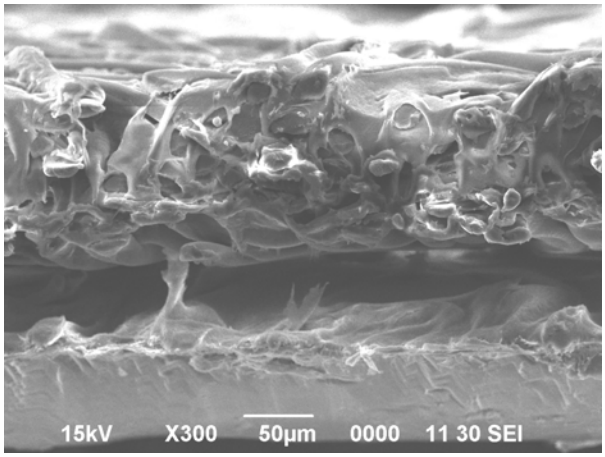
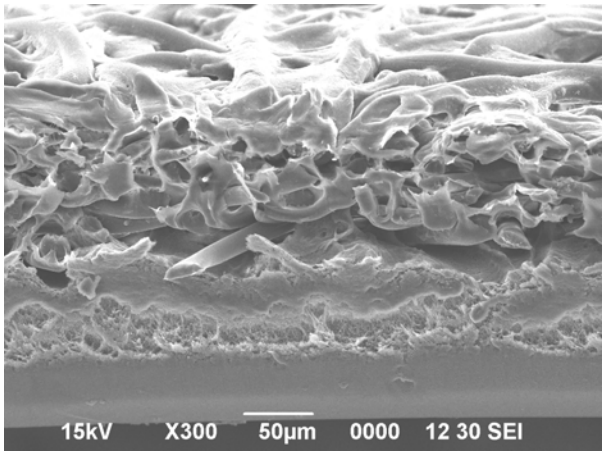
Reactions were carried out in erlenmeyer glass (100 ml) containing mixture of 10 g triolein, 3 x 0.37 g methanol (methanol to oil molar ratio of 3), and 0.25g dried lipase. The reaction mixture was incubated at 40°C, 220rpm, and 24h reaction time in a shaker incubator. The screening results for the tested lipase are presented in Fig. 3. Reaction products are presented as g/L of methyl oleate in the reaction mixture.

3.2. Lipase Immobilization

Physical adsorption of lipase for immobilization is one the most widely used methods [Balcao 1996]. The lipase was immobilized into the sponge layer of PES 300 kDa membrane by long time adsorption and filtration of 50 g/l of lipase in buffer solution (pH 7.00) at room temperature. In this way, lipase becomes adsorbed on the sponge layer and in the membrane pores. Consider a protein (lipase) with diameter d and a pore of diameter d_p. When $d << d_p$ the protein can enter most pores, deposit on the pore walls, and thus increase enzyme loading [9]. Scanning Electron Microscopy (SEM) was used to produces images of cross section of both new membrane and lipase immobilized membrane (Fig 4).



(a)



(b)

Fig 4. SEM micrograph of new mwmbrane (a) and lipase immobilized membrane (b)

3.3. Influence of permeate flux

The conversion of triolein to methyl oleate occurs within membrane pores, where act as microreactors, during the

permeation of the substrate solution through the membrane. In this type of operation mode, the permeate flux is an important parameter. In fact, high flux means low residence time of substrate solution within the microreactor. The reaction were carried out using triolein 10 gram in 3 g methanol, the value of vacuum pump scale were between 1-3, corresponding to permeate flux 0.5 to 2.2 litre/m^2.h, respectively. The value of permeate fluxes were then plotted versus conversion as illustrated in Fig 5. The amount of immobilized enzyme is another important parameter to consider. According to Fig 5, the best performance was attained using a concentration of protein within membrane pores of about 3.2 g/m^2.

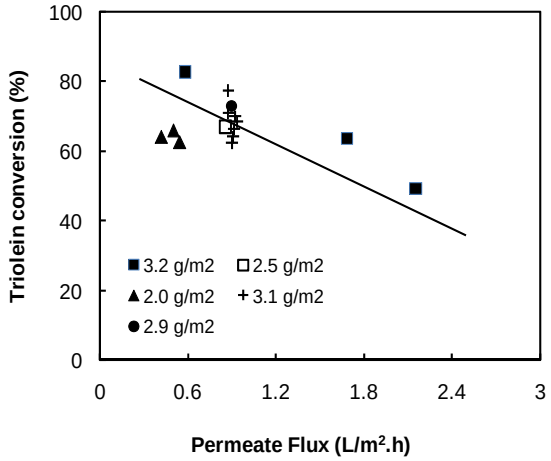


Fig 5. Experimental setup of microreactor for transesterification reactor

Fig 5 also demonstrate that, at the higher flux (lower residence time) conversion decreased, and this effect was particularly significant for 3.2 g/m^2 of immobilized enzyme. From these values the corresponding residence time were calculated and reported that the degree of triolein conversion using these microreactors was about 80% with a reaction time 19 minute. The results clearly show that reaction time of enzymatic transesterification in membrane microreactor system was faster than in conventional system., in order to achieve product yield of $\geq$ 90% it was necessary to utilize reaction time greater than 40 hours [7].

3.4. Stability of biocatalyst membrane microreactor

The stability of enzyme was measured using 2.042 g/m2 and 3.115 g/m2 of immobilized enzyme. Experiments were carried out continuously for 3 days. During the experiments there was no evidence of activity decrease in the microreactor and the conversion was constant at about 65% for 1st stage and 85% for 2nd stage (Fig. 6). In order to calculate the half-life experiments will need to be carried out for a longer time; nevertheless the results show that microreactor maintained good stability for at least 3 days.

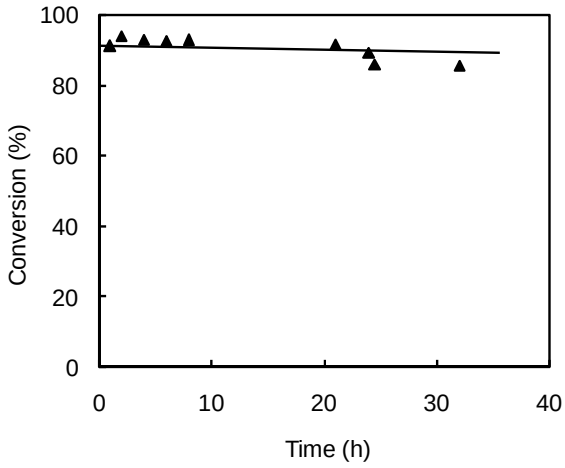

Fig 6. Stability of lipase immbilized membrane during transesterification reaction

4. CONCLUSIONS

In this study, a new concept of membrane microreactor is developed for trans-esterification reaction. The influences of various parameters such as permeate flux, enzyme loading and stability was investigated.

The degree of triolein conversion using these microreactors was about 80% with a reaction time 19 minute. Most significantly, the enzymatic microreactor exhibited far superior activity than the crude enzyme. The stability of enzymatic microreactor system showed very good results, with no activity decay during 3-days period of continuous operation. This system might be suitable for triglycerides transesterification (commercial production of biodiesel), which produce no waste stream.

ABSTRACT

Liquid coal is a future energy which keeps being developed to replace fossil based unrenewable energy source. One of the most important factor to run this process is the role of catalyst. This requirement leads to question how to provide low cost catalyst in abundant.

In this research, pyrite mineral (iron-sulfide) from gold mining waste has been employed. Pyrite which its content has been increased to 92%, was measured its activity by sulfidazing test. The product, active compound pyrhotite ($Fe_{1-x}S$) was characterized by XRD and crystal size was determined by Scherer equation. This pyrite sulfidazing test at coal liquefy's temperature (400 ^0C) resulted pyrhotite crystal with size 33.13 nm.

Next investigation, pyrite mineral activation was conducted at temperature 400, 500 and 600 ^0C to obtain hematitee. This hematitee then was milled by HEM (high energy milling) resulted 50-300 nm in size. After sulfidazing test at temperature 400 ^0C, active compound pyrhotite was acquired with crystal size 24 nm. Crystal size of pyrhotite affects coal liquefy's rate and yield. Smaller the sizes, the better influence to coal liquefy conversion process. Finally, hematitee as a nano catalyst used for coal liquefaction process and reached the conversion up to 91.05%.

Keywords: *nano catalyst, pyrite, sulfidizing test, pyrhotite crystal, coal liquefaction.*

1. INTRODUCTION

As a big country, Indonesia was faced with a big problem in fuels supplies, especially from oil resources where the deposition was predicted only for 30 years later. Coal liquefaction is one of technology wich keep being developed to gain liquid fuel from coal. It is very important to change fossil fuel from petroleum where the deposition is growing decrease.

On coal liquefaction process, catalyst has important roles to increase the yield product and speed up the convertion process. It used for assist hydrogen put into coal or coal-solvent mixtures to increase active hydrogen availability. Hydrogen has function for hydrogenize aromatic compound, promote cracking reaction and stabilize free radicals. Figure 1 gives ilustration for coal hydrogenation mechanism.

Synthetic catalist such as Co-Mo is the most effective catalyst for this pupose since it's reactivity but the price is very expensive. Another source wich has eligible low price and good ability for coal liquefaction is catalyst based on iron (Fe). This catalyst has better activity when transform to pyrhotite coumpound ($Fe_{1-x}S$), which occured when added together with sulfur in liquefies reaction condition.

This research aimed to prepare catalyst in nano scale for coal liquefaction pupose from gold mining waste, pyrite (FeS_2) rich, which has not been used optimaly.

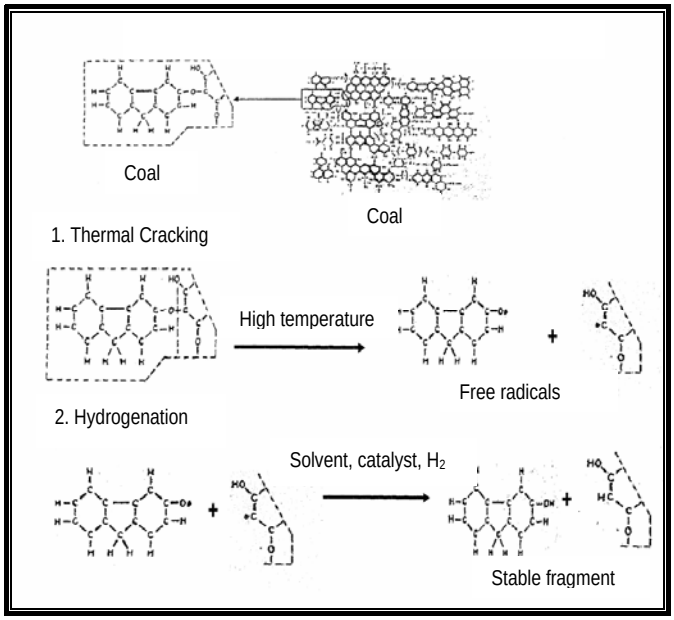

Figure 1. Coal hydrogenation mechanism

2. EXPERIMENTAL

Experimental steps shown in figure 2 below.

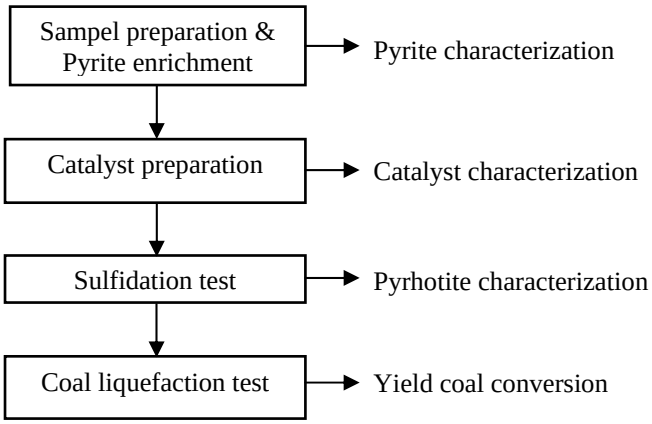

Figure 2. Flow diagram of the research

Preparation of raw materials from bulk size by crushing and milling using jaw crusher and ball mill until -200 mesh in size (76 micron). After that, pyrite enriched by flotation method with two variation, i.e. solid percentage and collector value.

Catalyst synthesized by roasting pyrite at several temperatures: 400, 500 and 600 ^{0}C. The resulted material then milled with high energy milling (HEM) to get higher surface area.

To obtain the catalyst convertion to pyrhotite, processed in sulfidazing test using autoclave unit, mix together catalyst, sulphur, antracen oil, without coal, and injected with hydrogen gas (100 bar), set at 300, 350, and 400 ^{0}C. To measure the size of pyrhotite crystal formed, used XRD and calculated with Scherer equation.

Finally, to confirm the liquefaction conversion conducted by coal liquefaction test using apparatus and the same condition with sulfidation test, using coal from Berau - East Kalimantan.

3. RESULTS AND DISCUSSION

3.1 Sample Preparation and Pyrite Enrichment

Table 1 shows chemical composition of raw materials.

Table 1. Chemical composition of raw material (%wt)

Si	Al	Fe_{Tot}	Ca	Mg	K	Na	S	LOI
10.70	1.24	33.7	0.11	0.028	0.49	0.041	38.0	25.2

From that composition, Fe_{Tot} 33.7%, it is potential used pyrite for coal liquefaction catalyst based on iron (Fe). To enrich the pyrite value, it was done by flotation method with two variations, solid percentage and collector value. Table 2 shows the flotation condition.

Table 2. Flotation condition

Condition	% Solid variation	Collector value variation
Feed size	-200 mesh	-200 mesh
Collector (Xanthat)	200 g/ton	-variation-
Frother	Phini oil	Phini oil
% solid	-variation-	20%

The optimal condition occured at 20% solid and 200 g/ton collector value, gained 91.50% pyrite value with 93.80% recovery.

3.2 Preparation and Characterization Catalyst

Catalyst for coal liquefaction was prepared from pyrite which has already enriched. Activation was done at several temperatures: 400, 500 and 600 ^{0}C as long as 2 hours, regarding TGA/DTA test result (Figure 3).

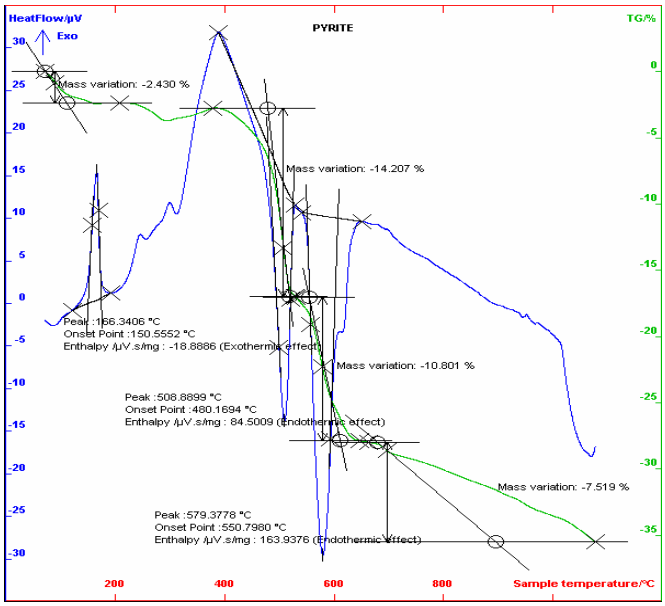

Figure 3. TGA/DTA curve of pyrite

Regarding information from TGA/DTA analyzed at 500 ^{0}C pyrite significantly transform to hematite, shown by the most extreme slope. This phase transformation phenomenon effects in it's physical properties, i.e. surface area and pore size. Table 3 shows the value of spesific surface area and avarage pore size of hematite (pyrite activated) measeured by BET method.

Tabel 3. Spesific surface area and avarage pore size of hematite

	T=400 ^{0}C	T=500 ^{0}C	T=600 ^{0}C
Spesific Surface Area	1,75 m^2/g	4,57 m^2/g	2,51 m^2/g
Avarage Pore Radius	108 nm	133 nm	110 nm

As catalytic puposes, surface area is one of the most important factors which influence the effectivness process. The highest surface area, the highest effectivness of catalyst's role. Therefore, to increase the surface area can be done by size reducing by using high energy milling apparatus (HEM) in several hours. The result can be measured by SEM as shown in figure 4.

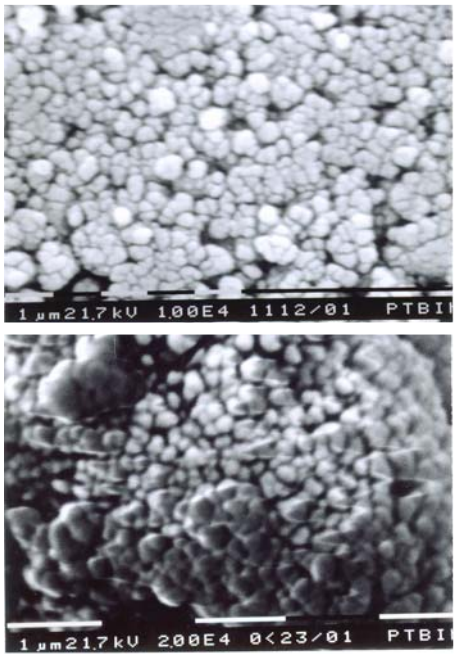

Figure 4. SEM photograph of hematite milled in 18 hours by using HEM

From above picture shows that the smallest particle size about 50 nm and the biggest about 300 nm.

3.3 Sufidazing Test

Sulfidazing test used hematite as catalyst succesfully formed pyrhotite crystal ($Fe_{1-x}S$), shown by pyrhotite peak in XRD difractogram (figure 5). While using pyrite as catalyst, only a few has converted to pyrhotite but the rest still in pyrite (FeS_2) phase (figure 6).

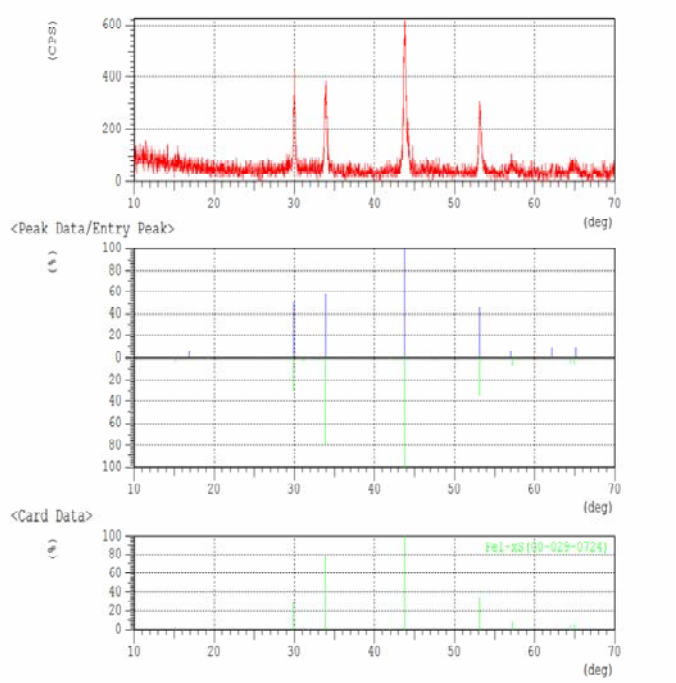

Figure 5. XRD difractogram of sulfidazing test result using hematite as catalyst

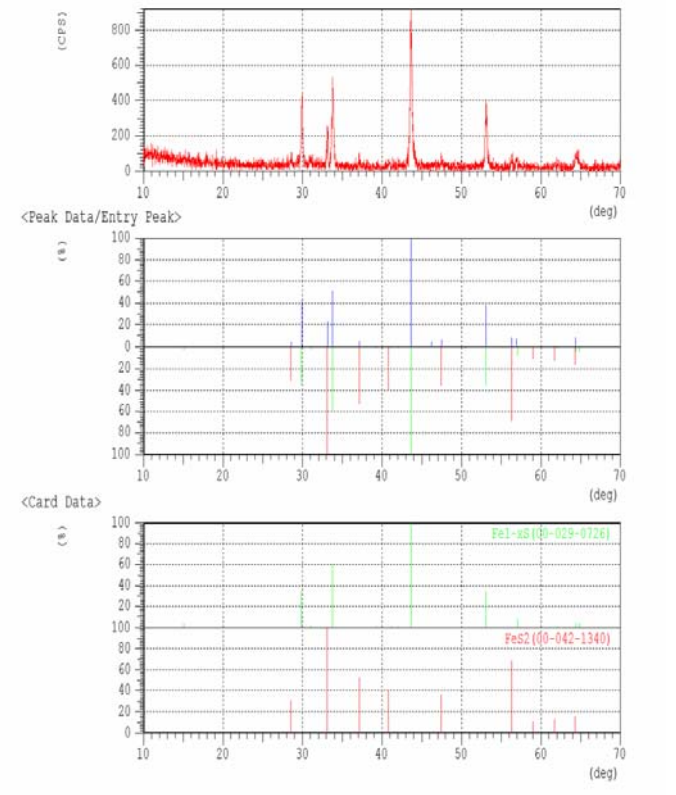

Figure 6. XRD difractogram of sulfidazing test result using pyrite as catalyst

By using Scherer equation, the size of pyrhotite crystal can be obtained as shown in figure 7.

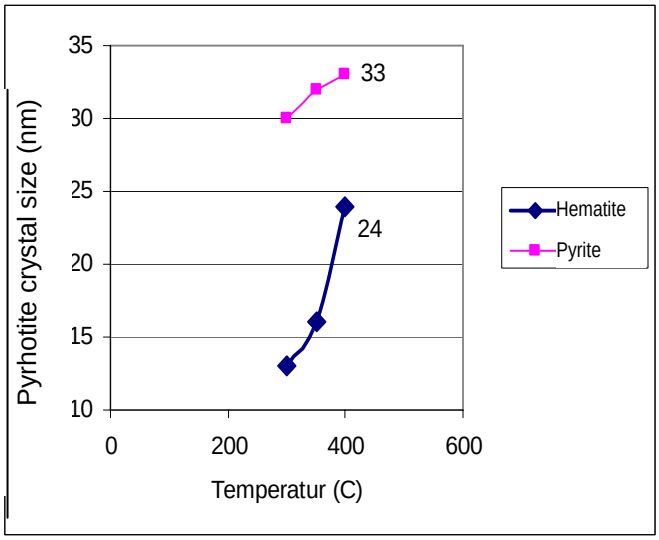

Figure 7. The growth of pyrhotite crystal resulted from sulfidazing test by using hematite and pyrite as catalyst at 300, 350 and 400 ^{0}C

As the result, hematite catalyst able to form pyrhotite crystal with the better size (24 nm) than by using pyrite (33 nm) at 400 ^{0}C. That caused Fe in hematite (Fe_2O_3) has oxidation number +3 so easier formed pyrhotite than Fe in pyrite (FeS_2) which only has oxidation number +2. Beside that, surface area in hematite is higher than pyrite, by milling treatment until sub-cron/nano scale.

3.4 Coal Liquefaction Test

The result of coal liquefaction using hematite catalyst shown in table 5 below.

Table 4. Yield coal conversion to liquid

Product	% Conversion
Liquid coal	91,05
Unreacted coal	8,95

From the data above, liquefaction coal from Berau-East Kalimantan gained total liquid coal 91.05% consist of light oil , water and gas reached up to 45.77%, asphalten 23.03% and preasphalten 22.25%. The rest is unreacted coal 8.95%.

4. CONCLUSSION

Preparation of catalyst hematite was carried out by activing pyrite at 500 ^{0}C and milling using high energy milling (HEM) apparatus resulting hematite with particle size 50-300 nm from 76 micron. By using this catalyst in sulfidazing test formed pyrhotite crystal 24 nm in size, and succesfully convert solid coal into liquid coal reached up to 91.05%.

ABSTRACT

In this research, the nanostructural evolution of TiO_2 crystallite upon in situ sol−gel process of titania–polymethyl methacrylate (TiO_2–PMMA) nanocomposites was systematically investigated. The main objective is to understand the mechanisms responsible for the amorphous nature of the sol−gel derived TiO_2−polymethyl methacrylate (PMMA) nanohybrids. For this purpose, two sol−gel parameters i.e. the coupling agent concentration, water content or hydrolysis ratio (rw), and pH value of the titania precursor solution were varied. On the basis of XRD analysis, it has been found that the modification of those parameters can enhance the nanocrystallinity of pure TiO_2 phase. However, this could not be applied when the titania precursor was mixed with the PMMA segment. On the basis of XRD and FTIR analyses, it was found that the largely amorphous TiO_2 state is related to the fast development of stiff Ti−OH networks during the hydrolysis and condensation stages in sol−gel process, worsened by the entrapment of the rigid PMMA matrix.

Keywords

Example:
Nanohybrids, TiO_2, PMMA, hydrolysis ratio, pH, nanostructural evolution.

1. INTRODUCTION

Poly(methylmethacrylate) or PMMA is well-known as an excellent optical polymer for use in optical fibers, optical disks and lenses [1]. However, the refractive index (n_o) of PMMA is limited to only 1.49. On the other hand, titanium oxide (TiO_2, titania) has been recognized as an inorganic material having high refractive index, *i.e.* ~2.45 (anatase) and ~2.70 (rutile). Therefore, an incorporation of TiO_2 nanoparticles into PMMA has been considered for preparing high-refractive index polymers. Accordingly, titania-poly(methyl methacrylate) or TiO_2-PMMA nanohybrids have been studied previously by several researchers. Zhang *et al*. [2] synthesized TiO_2-PMMA nanohybrid using chelating ligand as a coupling agent. A further study on preparation and optical properties of PMMA-titania thin films was performed by Chen *et al*., [3,4] who synthesized thin film TiO_2-PMMA nanocomposites by *in situ* sol-gel process of trialkoxysilane-capped PMMA-titania combined with spin coating and multi-step annealing process. The refractive indices of thus prepared films were reported in the range of 1.505-1.867, provided the loading of titanium alkoxide in the precursor solution was up to 90 wt%.

In our previous works, it has been shown that the TiO_2−PMMA nanohybrids derived from *in situ* sol-gel polymerization exhibits a very fast recovery time of ~1.5 picosecond and a large third order nonlinear optical susceptibility, $\chi^{(3)}$, as observed [5,6]. Therefore, the nanocomposites are promising for several potential applications in optoelectronic devices such as nonlinear optical switching devices in photonics and real-time

coherent optical signal processors [7,8]. However, it is realized, that TiO_2−PMMA nanohybrids are limited by the occurrence of amorphous TiO_2 nanoparticles, which cannot be avoided under the conditions tolerable by the polymer matrix upon the low temperature sol−gel process. Therefore, it is thus of our main interest to investigate the factors causing the amorphous nature of TiO_2 phase in PMMA matrix. For this purpose, two synthesis parameters involved in the *in situ* sol−gel polymerization, including the water content or hydrolysis ratio (*rw*), and pH value of the titania precursor solution were systematically investigated.

2. EXPERIMENTAL

In this work, we used an *in-situ* sol-gel polymerization technique, which is basically a thorough mixing process between a pre-hydrolyzed TiO_2 precursor (titanium isopropoxide, Ti-iP) and pre-polymerized PMMA. First, the monomers, methyl methacrylate (MMA, 99%, Acros) and coupling agent 3-(trimethoxysilyl)propyl methacrylate (MSMA, 98%, Acros), and initiator benzoyl peroxide (BPO, 98%, Acros) in solvent tetrahydrofuran (THF, 99%, Acros) were added into a reaction flask and polymerized at 60°C for 1 hour. The molar ratio of MSMA to MMA+ MSMA was controlled at 0.25 and the amount of BPO added to the mixture was fixed at 3.75 mol%. Furthermore, a TiO_2 based sol solution was prepared by mixing titanium isopropoxide (Ti-iP, 98%, Acros) with ethyl alcohol (EtOH, 95%, Merck) in a container and stirred for 30 minutes. A mixture of de-ionized water and hydrochloric acid (HCL, 36%, Ajax) was then added under stirring condition into the transparent solution to promote hydrolysis. The Ti-iP concentration in the solution was controlled at 0.4 M. It should be noted that for investigation purposes, first we varied the coupling agent concentration since this agent governs the interaction between inorganic and organic moieties in nanohybrids. For further investigation, three different sols with different pH value i.e. 3.08, 1.08 to 0.33 were prepared under the same ratio of water to Ti-iP (*rw*) or hydrolysis ratio of 0.82. At the same time, other sols with varying hydrolysis ratio of 0.82, 2.00 and 3.50 under the same pH value of 0.78 were also synthesized. All of these parameters were thoroughly varied while maintaining the stability of sol solutions to be clear and transparent. Finally, this transparent sol solution was carefully added drop by drop over a duration of 30 minutes into the partially polymerized monomers with rigorous stirring to avoid local inhomogenities. The reaction was allowed to proceed at 60°C for another 2 hours. In this study, the weight ratio between the inorganic and organic precursors in the reaction mixture was fixed at 60:40.

The fabrication of thin film was performed by spin coating the hybrid solution onto glass substrates at 3000 rpm for 20 seconds. The coated films were then annealed in two stages of curing temperatures, *i.e.* at 60°C for 30 minutes and 150°C for 3 hours. The nanohybrids characterization was carried out with X-ray diffraction (XRD) measurements on Bruker AXS θ–2θ diffractometer using Cu K-α radiation (1.5406 Å) operated at 40 kV, 40 mA and with a step-size of 0.02° and time/step of 20 seconds. The incidence angle between the beam and film plane was fixed at 1.5°. Further analysis was performed using Fourier Transform Infrared (FTIR) spectroscopy at room temperature in the range of 4000-400 cm^{-1} using Bio-Rad model QS-300 spectrometer, which has a resolution of $\pm$ 8 cm^{-1}.

3. RESULTS AND DISCUSSION

Effect of coupling agent concentration. In the present study, 3-(trimethoxysilyl)propyl methacrylate (MSMA) is introduced as a coupling agent between the inorganic titanium alkoxide precursor and the organic MMA matrix. In our previous work [5,6] a constant MSMA/(MSMA+MMA) molar ratio of 0.25 was used in the nanohybrid preparation. Thermal gravimetric analysis (TGA) and FTIR studies confirmed that the thus derived nanohybrids demonstrated a strong interaction between the inorganic and organic moieties. For optical properties, this can be beneficial since the resulting nanohybrid is transparent in the visible region. On the other hand, however, such a strong bonding may have a reverse effect on the TiO_2 formation, *i.e.,* the strong hindrance experienced by the hydrolyzed titanium alkoxide (Ti−OH networks) in PMMA gave rise to largely amorphous TiO_2 phase. Therefore it is of further interest to investigate whether an incorporation of a lower concentration of coupling agent at the solution preparation stage can provide a higher flexibility for the hydrolyzed titanium alkoxide to undergo densification in the PMMA matrix during the subsequent annealing process. By having so, it is expected that Ti−O−Ti bonds will be able to

develop a long-range order, such that nanocrystalline TiO_2 particles can be formed. The amount of MSMA/(MSMA+MMA) molar ratio was reduced down to 0.05 and the resulted nanohybrid was compared to that derived from 0.25

Figure 1 is the XRD traces for both nanohybrids showing two broadened phase peaks at 2θ angles of 25.35 and 48.12° that can be assigned to (101) and (200) crystal planes of anatase phase. The nanohybrid derived from the coupling agent ratio of 0.05 shows slightly stronger diffraction peaks than those derived from the coupling agent ratio of 0.25.

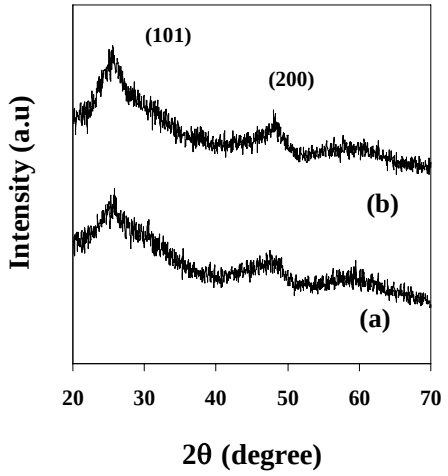

Figure 1. XRD traces of nanohybrid derived from ratio MSMA/(MSMA+MMA) ratio of (a) 0.25 and (b) 0.05.

For further confirmation, FTIR spectroscopy of the two nanohybrids was investigated. The stretching vibrations for both samples are shown in Figures 2 and 3, for both low wavenumber range (1100−400 cm^{-1}) and high wavenumber range (4000−2400 cm^{-1}), respectively. Figure 2 shows the occurrence of absorption bands located at 450 and 650 cm^{-1} which can be assigned to Ti−O and Ti−O−Ti stretching vibrations, respectively as the characteristic of nanocrystalline TiO_2 in short and long range order [9,10]. In addition, there is an additional band at 910 cm^{-1}, corresponding to the stretching vibration of Ti−O−Si bond [11]. Although the two nanohybrids show similar intensities, however a careful comparison reveals that there occurs a considerably higher band intensity in the range of 1000−1200 cm^{-1} in spectrum "(b)", in comparison to spectrum "(a)". This band, with the strongest absorption peak located at ~1080 cm^{-1}, is assigned to the Ti−O−C stretching mode originated from the remaining unhydrolized alkoxy groups [12,13]. Although there is a possibility of overlapping with C−O−C bonds originated from the PMMA matrix in the range of 1039−1192 cm^{-1} [3], however the same amount of MMA monomer was incorporated into both nanohybrids. This was further confirmed by checking the stretching vibration of C−H bond at 2950 cm^{-1} as shown in Figure 3.15. Both spectra "(a)" and "(b)" are very similar in intensity. Therefore it can be concluded that the enhanced intensity at ~1080 cm^{-1} in spectrum "(b)" of Figure 3.14 is related to the higher number of Ti−O−C bonds in the nanohybrid derived from the lower coupling agent ratio.

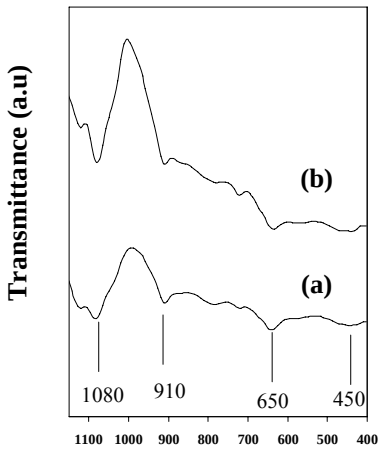

Figure 2. FTIR spectra of the nanohybrid derived from MSMA/ (MSMA+MMA) ratio of (a) 0.25 and (b) 0.05, respectively, in the low wavenumber range of 1100−400 cm^{-1}.

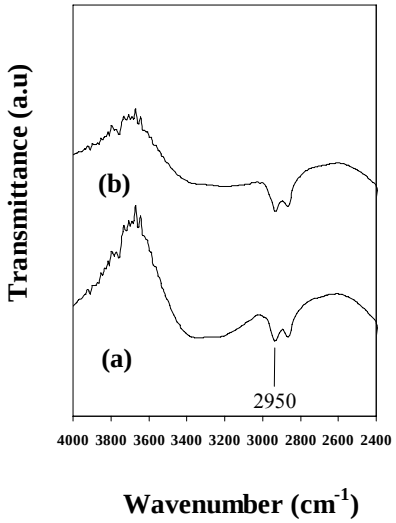

Figure 3. FTIR spectra of the nanohybrid derived from MSMA/(MSMA+MMA) ratio of (a) 0.25 and (b) 0.05, respectively, in the high wavenumber range of 4000−2400 cm^{-1}.

It is of further interest to investigate the reason behind the enhanced nanocrystallinity shown by the nanohybrid derived from the lower coupling agent ratio. One approach is to look at the three absorption bands, *i.e*. Ti−OH at ~3400 cm^{-1}, Ti−O−C at 1080 cm^{-1} and Ti−O−Si at 910 cm^{-1}. As seen in Figure 3, the intensity of Ti-OH band for the nanohybrid derived from the coupling agent ratio of 0.05 is lower than that derived from 0.25, while a higher intensity of Ti−O−C band (Figure 2) is demonstrated by the former. In contrast to these differences, both nanohybrids show more or less the same intensity for Ti−O−Si band. As proposed by Brinker and Hurd [14] and Langlet *et al.* [15], the largely amorphous TiO_2 thin films obtained at low temperatures is due to the formation of stiff Ti−OH networks resulted from the fast condensation of titanium alkoxide precursor, which in turn hinder the densification of crystallite TiO_2 phase. In this connection, therefore, the low intensity of Ti−OH observed for the nanohybrid derived from the lower coupling agent ratio suggests a reduced amount of amorphous phase. On the other hand, the high intensity of Ti−O−C stretching mode from the unhydrolized alkoxy groups in this sample is related to the high number of interfacial sites for TiO_2 nucleation. The interfacial bond is not as stiff as Ti−OH network and is therefore sufficiently flexible to take part in the densification of TiO_2 phase, *i.e*., by the arrangement of Ti−O−Ti bonds in the long-range order and thus an enhancement in TiO_2 nanocrystallinity was resulted, as detected by XRD. Zhang *et al.* [13] has reported that Ti−O−C bond, together with Ti−O and Ti−OH, can lead to connected networks of TiO_2 nanoparticles in titania-poly(phenylenevinylene) or TiO_2−PPV nanocomposites. The interfacial phase plays an important role in providing the necessary dispersion function and thus preventing the agglomeration of TiO_2 nanoparticles in polyvinyl alcohol (PVA) matrix [16].

The effects of different coupling agent concentrations on nanohybrids were further investigated by TGA. Figure 4 shows that both samples have similar response upon heating up to 850 ^oC. It is clearly demonstrated that the nanohybrid derived from the lower coupling agent ratio decomposes at a lower temperature than that derived from the higher coupling agent ratio. This can be accounted for by the high number of interfacial Ti−O−C bonds of unhydrolized alkoxy groups in the former, as has been confirmed by FTIR spectroscopy. On the other hand, the similarity in TGA behavior up to 300 ^oC shown by both samples can be related to the similar intensity of Ti−O−Si band at 910 cm^{-1} shown in Figure 2. With further heating beyond 300 ^oC, however, the difference in mass change becomes more remarkable when both samples underwent the second stage of mass loss. This suggests that once the unhydrolized alkoxy groups had been decomposed, there occurred a higher number of organic segments, dissociated from the inorganic networks in the former. This is further supported by the reduced amount of char yields at 850 ^oC produced by this sample, suggesting a lower number of remaining organic moieties that could be trapped in the inorganic network. Based on this observation, it is confirmed that a lower concentration of coupling agent can lessen the binding strength between the inorganic and organic moieties upon heating, particularly at temperatures beyond the decomposition temperature T_d of PMMA matrix (345 ^oC).

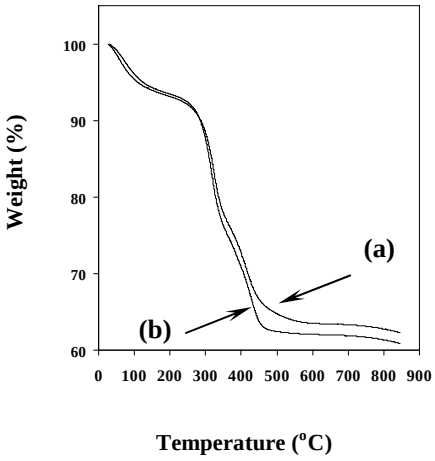

Figure 4. TGA curves of the nanohybrid derived from MSMA/(MSMA+MMA) ratio of (a) 0.25 and (b) 0.05, respectively.

Effect of pH value. Brinker and Hurd [14] and Langlet *et al.* [15] proposed that the amorphous state of TiO_2 was caused by the formation of stiff Ti−OH arising from fast condensation. In line with this understanding, Yoldas [17] also suggested that if the rate of condensation process is faster than hydrolysis, the alkyl groups are incorporated into the structure and sterically hinder the formation of

ordered structure. Therefore, in order to enable the precursor to crystallize into an equilibrium structure, the condensation should proceed slowly after the completion of hydrolysis. Lowering the pH value of the titania solution has been considered effective in enhancing the rate of hydrolysis and to inhibit the condensation [18]. This is made possible since the −OR groups in alkoxide are protonated by H^+ ions, making their charges more positive. Being positively charged, the metal ions repel the −OR groups and prefer to be attached to the −OH groups. Consequently, this promotes the hydrolysis process and at the same time decreases the rate of condensation significantly since the protonated species reduce their interaction by repelling each other. Yoldas [19] and Kallala *et al.* [20] have shown a difference in the inhibition ratios can lead to sols, transparent gels, turbid gels or precipitates. Accordingly, Gopal *et al.* [21] and Watson *et al.* [22] have reported the formation of anatase and rutile TiO_2 synthesized directly from an acid-catalyzed solution at temperatures close to room temperature. For the nanohybrids investigated in this study, however, a question remains as to whether a slow condensation rate of the protonated titanium hydroxide can lead to the densification of TiO_2 during the subsequent annealing process, while at the same time polymerization of the MMA monomers takes place effectively. The latter is responsible for the fast trapping effect causing a largely amorphous TiO_2 phase in the polymer matrix. Therefore, it will be of further interest to investigate the effect of pH value on the nanocrystallinity of TiO_2 phase in nanohybrids. For the investigation, TiO_2−PMMA nanohybrids were derived from TiO_2 sol solutions of pH value varying in the range of 3.08 to 0.33. This was done by adjusting the amount of hydrochloric acid (HCl) added, the function of which is to control the hydrolysis and condensation rates of titanium alkoxide [20,23]. The water to titanium alkoxide ratio (r_w) in each solution was kept at 0.82. Prior to mixing with the organic constituent, the sols were stirred at room temperature for 72 hours, aimed at providing sufficient time for the protonation of titanium alkoxide to take place, in accordance with the amount of hydrochloric acid added into the sol precursors. The XRD traces of the thus derived nanohybrids are given in Figure 5. It is shown that the nanohybrid derived from the inorganic sol solution of pH 3.08 (trace "(a)") is highly amorphous as indicated by the occurrence of two broadened humps in the 2θ ranges of 20−35° and 40−55°. By contrast, diffraction peaks at 2θ of ~25 and 48° corresponding to (101) and (200) crystal planes of anatase titania were observed for the nanohybrids derived from the inorganic sol solution of pH 1.08 and 0.33 (traces "(b)" and "(c)").

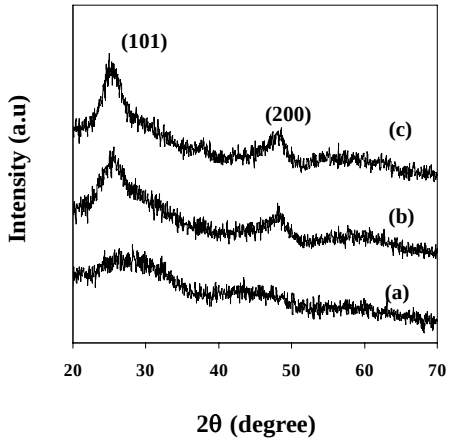

Figure 5. XRD traces of the nanohybrid derived from inorganic sol solution with pH value of (a) 3.08, (b) 1.08, and (c) 0.33, respectively.

The results observed above can be interpreted by considering the role of H^+ ion in providing repulsion forces among the protonated inorganic species. It is known that a highly acidic protonation leads to a stronger repulsion force and thus formation of extended structure from the hydrolyzed alkoxide [24]. By using small-angle X-ray scattering (SAXS), Xiong *et al.* [25,26] investigated the structure of inorganic species in trialkoxysilane-capped acrylic-titania hybrids derived from titania sols under three typical pH values of 4.4, 7.0 and 8.8, representing acid, neutral, and basic conditions, respectively. They observed that under the basic condition the inorganic domains can reach a radius of gyration (R_g) and fractal dimension (D) of 7.3 nm and 1.35. However, under the acid condition, the values were only 2.4 nm and 0.18, respectively. The smaller sizes in the latter were associated with the restriction of inorganic chain-like structure into open regions of the mesh produced by the crosslinked polymers [25,26]. This was more or less similar to the situation of the amorphous nanohybrid derived from titania sol with a pH value of 3.08 investigated in the present work (trace "(a)" in Figure 5). On the other hand, however, the notable diffraction peaks in the XRD traces "(b)" and "(c)" for the nanohybrids derived from titania sols with a much lower pH value

(1.08 and 0.33) suggest a rather different mechanism in comparison to what has been proposed by Xiong *et al.* [25, 26] for acid catalyst condition. In the system investigated in this project, the linear chain-like structures of hydrolyzed inorganic precursors were able to perform further self-densification in the solution stage. It proceeded up to the stage when the nanohybrid sample was annealed, whereby a rigid organic PMMA network was formed. The nanocrystallinity of the sample derived from the sol solution with a much lower pH value, *i.e.*, 0.33 (trace "(c)") is slightly higher than that of 1.08 (trace "(b)"). It suggests that the stronger repulsion force created among the protonated species at lower pH values can induce a better densification for titania phase in the TiO_2−PMMA nanohybrid system.

Effect of water to alkoxide ratio. The water to alkoxide (R_w) or often called as *hydrolysis ratio* determines the potential functionality of inorganic monomers in building the network [27]. In the previous investigation, a R_w of 0.82 was consistently used for the titania sol which is stable and did not turn into a gel, prior to mixing with polymer matrix. However, this ratio is less than the required stoichiometric value, *i.e.*, 4. As a result, the alkoxide precursor experienced an incomplete hydrolysis process. It is therefore of interest to find out whether the amount of water during sol preparation can favor a more completed hydrolysis and thus provide a higher nanocrystallinity for the titania phase in nanohybrid. For investigation, three different sols with R_w of 0.82, 2.00 and 3.50 under the same pH value of 0.78 were prepared. All the titania sol solutions were transparent and stable. An attempt to increase R_w to 4.00 led to the formation of immediate gel which could not be incorporated homogenously into pre-polymerized PMMA. Therefore, the first three compositions were used for further investigation. The XRD traces of the resulting nanohybrids are given in Figure 6. It is shown that when R_w is 0.82, the resulting nanohybrid (trace "(a)") demonstrates two broadened diffraction peaks at 2θ of ~25.35° and 48.12° corresponding to (101) and (200) crystal planes of anatase titania phase. An increase in R_w to 2.00 did not lead to a significant enhancement in nanocrystallinity for the respective nanohybrid (trace "(b)"). However, there was an onset of additional two peaks at 2θ of 38.63° and 55.08° corresponding to (112) and (211) crystal planes. Further increase of R_w to 3.50 gave rise to an un-expected occurrence of amorphous titania phase.

The above observation can be analyzed by considering that an increase in R_w gives rise to a stronger nucleophilic reaction between water and alkoxide species, and thus more −OR groups bonded to metal were substituted by −OH network structure. A larger and more compact structure of inorganic domains, as a result of the formation of a three-dimensional network structure, is therefore expected with the completion of −OH network [25,26].

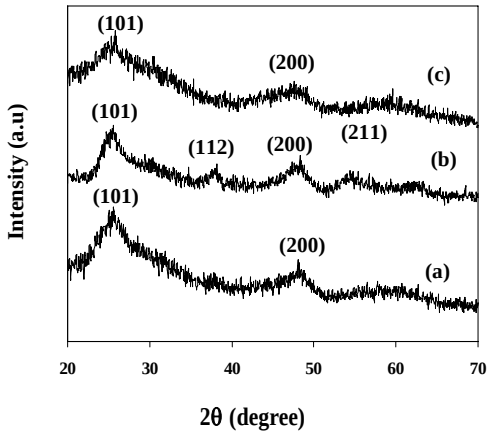

Figure 6. XRD traces of the nanohybrid derived from inorganic sol solution with R_w of (a) 0.82, (b) 2.00, and (c) 3.50, respectively.

Based on the XRD results, however, such increase in the inorganic domain size to form bigger nanocrystallites was not clearly indicated when R_w was increased from 0.82 to 2.00, as shown by diffraction peaks intensity at 2θ of ~25.35° and 48.12°. Yu *et al.* [28] has proposed a transition model of the inorganic domains in TiO_2−SiO_2 nanohybrid whereby chain-like structures transformed into particle-like clusters when R_w was varied from a value below the stoichiometric ratio (<4) to that of above the critical value (>4). The appearance of two additional peaks at 2θ of 38.63° and 55.08° suggested that the high number of −OH groups generated at R_w of 2.00 had provided more TiO_2 nuclei which furthermore grew as nanocrystals of different directions in addition to what has been formed at R_w of 0.82. It is of interest to compare the current result with a previous work performed by Xiong *et al*. [29] who employed SAXS technique to investigate the effect of water content on the structures of thermoplastic acrylic resin−titania hybrids. They

observed that hybrids derived from R_w of 1 and 2 demonstrated shallow linear regions in the Guinier and Porod plots, indicating little phase separation. Besides, the difference in scattering intensity between hybrids derived from R_w of 1 and 2 was small. This is very similar to the nanohybrids with R_w of 0.82 and 2 in the present study, as revealed by XRD results in Figure 6. However, at high R_w, a discrepancy occurs between the current result and what has been observed by Xiong *et al.* [29]. In their case, further increase of R_w up to 4 led to a denser inorganic phase with a larger size. In contrast, the nanohybrid derived from the hydrolysis ratio, R_w of 3.50, is highly amorphous when compared with those of derived from 0.82 and 2.00. Again, this is associated with the trapping of the hydrolyzed alkoxide groups by rigid PMMA network during and after annealing at 150 ^{o}C. It is highly possible that although a great number of –OH groups were generated through the relatively complete hydrolysis, however due to the strong constraint effect by organic polymer matrix, they failed to proceed to the subsequent densification and hence nanocrystalline TiO_2 phase was not achieved. In connection with the discrepancy observed between the two studies, it should be noted that Xiong *et al.* [25,26,29] relied on the SAXS scattering patterns in order to determine the sizes of inorganic phase in the hybrid composition. Indeed, several variations in their synthesis process such as pH value, water content and solvent mixture which led to different levels of hydrolysis and condensation for titania precursor could result in different levels of phase separation and thus scattering patterns accordingly. It was not confirmed whether the inorganic network formed in the hybrids were amorphous Ti−OH, nanocrystalline TiO_2 or a mixture of both. Therefore, the observed scattering pattern can be considered as a response from cumulative quantity of inorganic phases, regardless of their amorphous or crystalline nature. As a result, the SAXS studies of Xiong *et al*. [25,26,29]were not affected by the trapping mechanism of titania phase by the polymer matrix, as encountered in the nanohybrids investigated in the current study.

4. CONCLUSION

In an attempt to understand the mechanism responsible for the largely amorphous nature of the TiO_2 phase in the nanohybrids, several processing parameters involved in sol−gel and *in situ* polymerization were investigated, including coupling agent concentration, pH value and water to alkoxide ratio. Variation of these processing parameters did not effectively lead to a significant enhancement in the nanocrystallinity of TiO_2 phase in the nanohybrids. They were not adequately effective to compete with the formation of stiff Ti−OH structures, which were trapped by the rigid network of polymerized PMMA matrix. This mechanism has resulted in a largely amorphous structure for TiO_2 phase in nanohybrids.

ABSTRACT

Fe-Al coating on steel has been fabricated by mechanical alloying method using high energy milling HEM-E3D. The resulted will be utilized in carbon steel coating process in order to improve its corrosion resistance and its resistance of both chemically and mechanically degrading environment. The properties of its compound were predicted to be improved by the addition of Cr in Fe-Al coating process. Mixture composition of Fe-40at.%Al and Fe-40at.%Al-3at.%Cr was used as initial coating agent of steel plate. Stainless steel vial of 100 ml was used for milling process under argon condition for 32 h. The grinding media were stainless steel balls of 10 mm and 5 mm in weight composition of 1:5. Milling speed was maintained at 263 rpm. To observe coating evolution, carbon steel substrate were also milled in milling process. The ball to powder ratio was 8:1. The microstructure of milling results was characterized using SEM-EDS, XRD and micro hardness tester. SEM results showed the coating exist after 8 hours of milling time. The thickness of coating is depending on milling time, the coating will become thick as longer milling time.

Keywords: *High Energy Milling, Coating, Fe-Al, Cr addition.*

1. INTRODUCTION

Fe-Al alloys known have a structural superiority in high temperature condition because their resistant to oxidation, sulphidation and corrosion [1-4]. This alloys posses a high strength because a high attractive force between element composer [5]. On the other hand, the mixing of this powders become intermetallic alloys with various combination. Because their superiority, this alloys is hoped to assume substitute the use of stainless steel and Ni base superalloys in several case [6-13]. The lack of this alloys are brittle in room temperature and strength decrease when the temperature above 600^{o}C. Several approaches has been developed to decrease the lack of this alloy, one of the approach is adding element like Cr [14-15]. The other approach is nanostructured material that can be increase the ductility of intermetallic [16].

Coating Fe-Al with nanostructured on steel has been done by Grosdidier *et al*. [16], Ji Gang *et al*. [17] and Guilemany [18]. The temperature is used for thermal spray as high as 2350^{o}C [16]. Intermetallic FeAl was formed on coating and have a nanostructured [16-18]. The recent research showed combination of ball mill and pack cementation was used to coating the steel [19]. Intermetallic Fe_2Al_5 was formed after 15-120 minute at temperature 400-600^{o}C. This result is faster if compare with the conventional pack cementation. Ball mill was used is responsible to form the nanostructure coating.

This research is to investigate the intermetallic Fe-Al coating on structural steel. Beside that, this research was investigated the form of nanostructure powder and coating of Fe-Al powder.

2. EXPERIMENTAL METHOD

Materials used in this research are Al (purity above 90%) and Fe (purity more than 99% with size 10 µm) obtained from Merck Co. Ltd. Cr powder (purity above 99% with size -200 mesh) obtained from Soekawa Chemical. Composition of powder are Fe-40at.%Al and Fe-40at.%Al-3at.%Cr.

Coating conducted by using high energy milling HEM-E3D for 32 hours in inert condition by using argon gas with the speed determined at 263 rpm. Milling use the vial with the volume 100 mL made from stainless steel. Ball mill was used are made from chrome steel with size 10 mm and 2 mm. The comparison between big ball and small ball is 1:5 with the ball to powder ration (BPR) is 8:1. To keep the temperature during milling is lower (25-50^{o}C), every 5 minute HEM-E3D taken a rest for 1 minute. Result of the milling was characterized using SEM Leo 430 and XRD Philips with anode tube CuKa.

3. RESULT AND DISCUSSION

Figure 1 showed the XRD patterns of substrate surface is coated the powder mixture of Fe-40at.%Al in the initial state and after different milling times. From Figure 1, one can perceive coated layer occurring in the powder samples during milling. From Figure 1, it can be seen that at the early stage of MA process (0–8 h), only Fe peaks can observed and no Al peak. After milling for 16 h, Al peaks was observed with small intensity. On further milling, Al peaks was disappear and only small intensity of Al (111) was observed. This indicates that solid solution is formed since Al atoms dissolves into Fe lattice [20].

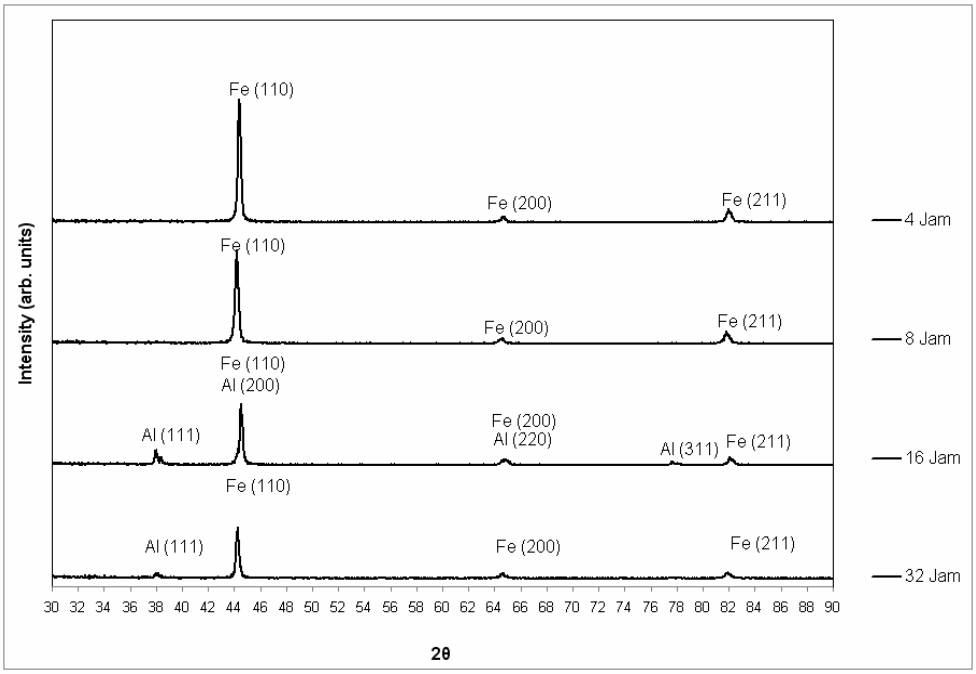

Figure 1. XRD Result of Substrate surface was coated with Fe-40at%Al powder

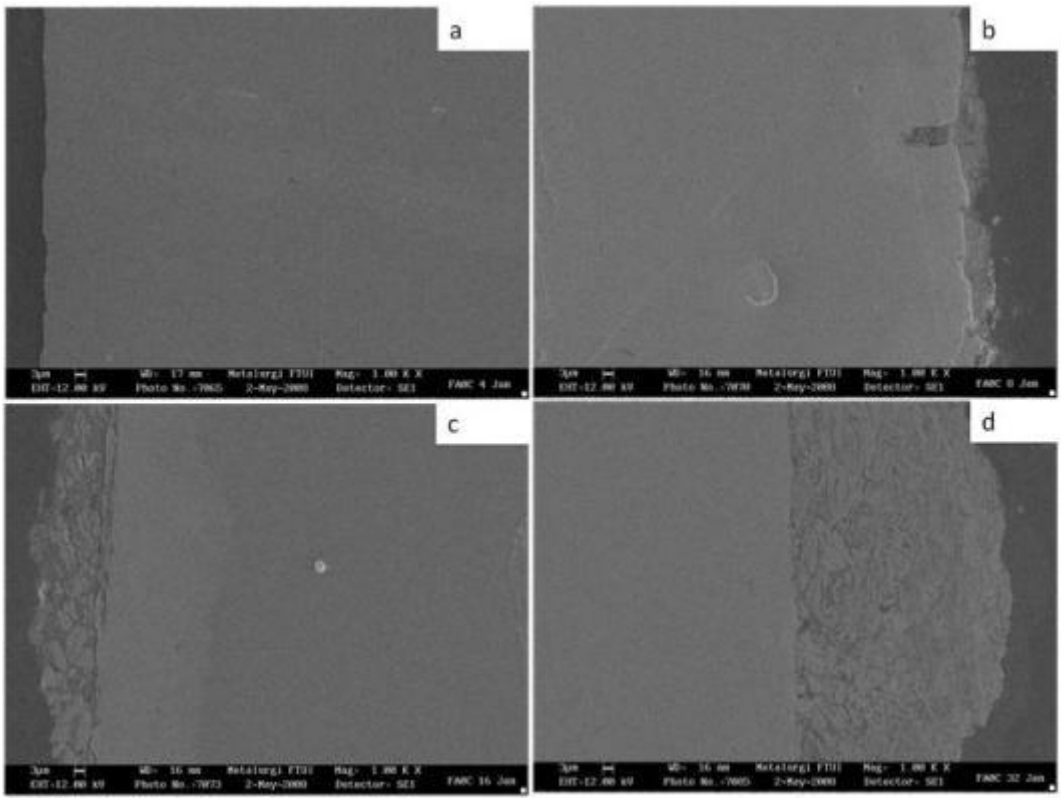

Figure 2. SEM Image of Substrate was coated with Fe-40at.%Al (a) 4 hours, (b) 8 hours, (c) 16 hours and (d) 32 hours

Figure 2 showed the cross section of substrate with Fe-40at.%Al coating. This result was appropriate with XRD result. In the early time of milling (0-8 h), there is no coating layer. Only small of powder stick on substrate found at milling time 8 hours. According to XRD result, this powder is Fe. On further milling (16 h), the coating layer is formed. The powder was coated still rough and have a big size. After milling time 32 h the coating became thick and the structure of coating smooth than before.

Figure 3 showed XRD result of substrate surface was Coated with Fe-40at.% Al-3at.% Cr. On the addition 3at.% Cr, MA process seen more quickly. This indicated with the shift to the left at the peak of the Fe (110) starting from milling time 16 h. This shift of peak indicated phase transformation of Fe-Al to FeAl or Fe_3Al. In addition, the peak Al (311) is not appear on the milling time 16 hours. This is different with Fe-40at.%Cr in which the Al (311) peak still observed in milling time 16 hours.

Cr addition effects have observed on layer thickness as showed in Figure 4. The coating layer became thickness on further milling time. There is different between Cr addition and without Cr addition. Coating layer with Cr addition thicker than without Cr addition.

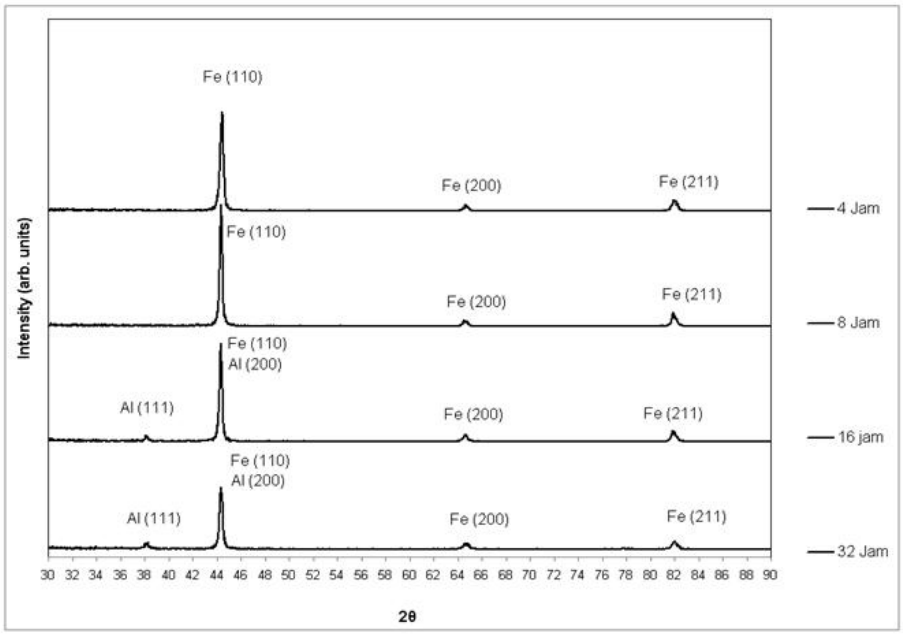

Figure 3. XRD Result of Substrate surface was coated with Fe-40at%Al-3at.%Cr powder

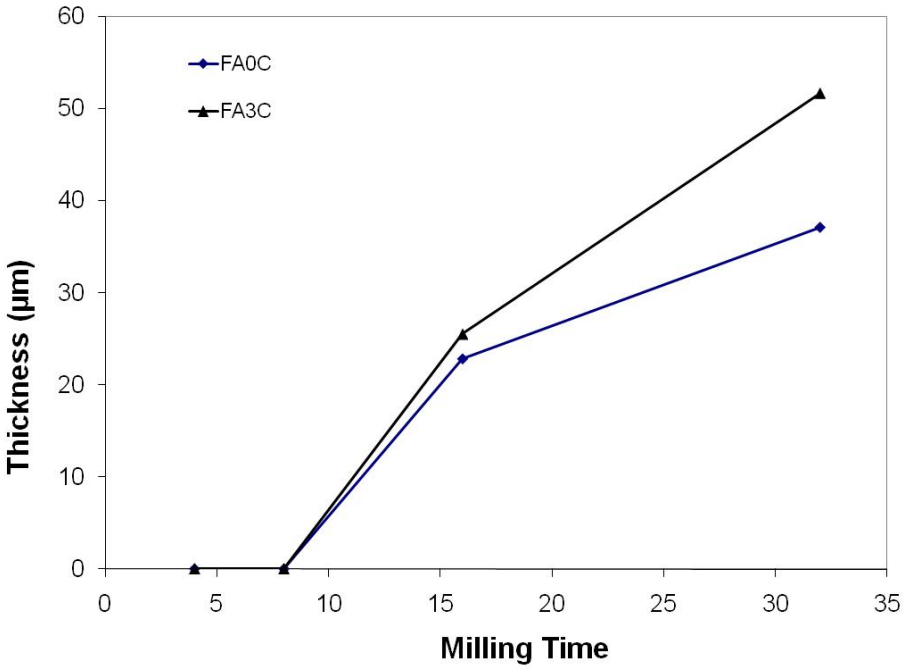

Figure 4. Coating Layer Thickness

4. CONCLUSION

1. The coating layer was formed after milling time 8 hours.
2. Influence of Cr addition was observed on pulverized of Al and thickness of coating layer.

ABSTRACT

Bio-polymer from vegetable cooking oils was synthesis to substitute petrochemical derivatives polymer in a specific treatment in order to ease the degradation pathways. Treatment with titanium dioxide (TiO_2) was found to affect the physical properties of this solid polymer in a systematic way. As the loadings of TiO_2 were increased (up to 10% of monomer weight), large strain responses were obtained; thus the stress vs. strain curves plotted by the Instron tensile test showed an increase from 5% to 31%. This study also revealed a remarkable characteristic in the pigmented polymer exhibiting soft – but – tough behaviour at high TiO_2 loading. The DMTA test also showed that the properties of the sample loaded with 10 % TiO_2 increased its tan delta peak (damping factor) from 0.43 to 0.7. The tan delta peak showed that the damping properties of the material were improved markedly upon loading with TiO_2. This is useful since noise is radiated by vibration, and the application of damping materials to the vibrating surface converts the energy into heat, which is dissipated within the damping materials rather than being radiated as airborne noise.

1. INTRODUCTION

In recent years, the use of polymers made from renewable materials has been developed in diverse areas especially in furniture, mattresses, automotive or building components. Polyurethanes (PU′s) made from renewable materials are one of the most important groups of polymers because of their versatility and they can be manufactured in a wide range of grades, densities and stiffness. In this project, polymers based on renewable materials such as rapeseed (RS) and sunflower oil (SF) were synthesized and cross-linked with methylene di-*p*-phenyl diisocyanate (MDI) to form highly crosslink polymer name as polyurethanes.

Currently, fossil or petroleum-based is used as raw materials needed to make industrial chemicals and nearly all types of plastics. However, nowadays plants could provide a renewable, biodegradable source of high value speciality product such as nylon, glue, paints, cosmetics, lubricants, components of detergents or plastics. These could all be produced from plants rather than fossil or petroleum-based materials. The sustainability of this industrial sector is dependent in the long term on a fundamental shift in the way in which resources are used, from non-renewables to renewables, from high levels of waste to high levels of reuse and recycling, and from products based on lowest first cost to those based on life cycle costs and full cost accounting, especially as applied to waste and emissions from the industrial processes that support construction activity [1].

1.1 Modification of Polymers using fillers

Fillers, either particulate or of fibrous nature, as glass, metal oxides, natural fibres and metals, have been added to thermoplastics and thermosets for decades to form polymer composites. Fillers are used in polymers for a variety of reasons: cost reduction, improved processing, for example in curing with a cross-linking agent such as in sulphur vulcanization, density control, optical effects, thermal conductivity, control of thermal expansion, electrical properties, magnetic

ISSN 114-1284

properties, flame retardancy and improved mechanical properties, such as hardness and tear resistance and many more reasons.

The term 'functional filler' is often used to describe materials that do more than provide cost reduction. Examples of functional fillers include carbon black and precipitated silica reinforcements in tyre treads, the role of stabilisers to reduce in-process degradative effects, and many more miscellaneous additives for polymers such as blowing agents, impact modifiers, lubricants or antimicrobials. Increased polymer consumption over the past twenty years has not only stimulated developments in manufacturing plant, but has also led to a parallel growth in the usage of a large variety of liquid and solid modifiers, including fillers and reinforcements [2]. Fillers may be classified broadly as organic or inorganic substances, and further subdivided according to chemical family.

2. METHODOLOGY

2.1 Preparation of Novelty Hydroxylated Monomer

The development of novel feedstocks for polyurethane monomer derived from renewable materials has become important because the use of polyurethane polymers is increasing at a rate of 1 million tonnes a year [3]. This level is unsustainable in the long term without the development of alternative sources. Oils from vegetable crops can be manipulated chemically to produce a variety of polymeric materials, including polyurethane products.

The reaction of organic isocyanate with compounds containing OH (hydroxyl) groups is capable of wide application in polymer formation [2]. Thus the urethane linkage, –(NHCOO)- can be produced by reacting compounds containing active hydrogen atoms with isocyanate, where polymer formation can take place if the reagents are di- or polyfunctional. The preparation of the hydroxylated monomer was divided into two stages, beginning with the preparation of catalyst (hydrogen peroxide / tungsten powder / phosphoric acid) to generate the epoxides from the unsaturated fatty compounds, while the second stage comprised the acid-catalysed ring-opening of the epoxides to form polyols

2.2 Preparation of Novelty Polyurethanes Polymer

Viscous polyurethanes find application in their liquid state as adhesives or sealants. The polyol monomers can be further polymerised or 'cured' to higher molecular weight solid materials. The curing process involves the addition of a cross-linking agent such as MDI, which allows the polyol group to form a urethane bridge.

The test specimens were prepared according to the standard dumb-bell shape of the tensile test. The dimensions of the samples are as type 1A and 1B (BS EN ISO 527-2:1996). The method is appropriate for use with rigid and semirigid thermosetting moulding and cast materials, including filled and reinforced compounds. The samples for the dumb-bell tensile test were prepared by mixing 15 g (3 g equivalent) of polyol and an appropriate amount of 4,4′-methylene-bis- phenylisocyanate (MDI), different percentages of titanium dioxide (such as 2.5, 5.0, 7.5 and 10.0 % equivalent weight of polyol) and pouring the mixture into the dumb-bell shaped mould.

2.3 Testing of Novelty Polyurethanes Polymer

Polymers can be characterised by a variety of means such as tensile test (disclosing the stress-strain relationships), Dynamic Mechanical Thermal Analysis (DMTA) and many more. The tensile testing of dumb-bell shaped samples was carried out according to ISO 527-2:1996 using an Instron tensile testing machine Model 4303 with installed computer programme. The machine was run at a crosshead speed of 5 mm/min.

A Tritec 200 DMTA (Triton Technology) instrument was employed for dynamic evaluation of the novelty polyurethane. Rectangular test pieces of polyurethane (~15 mm long, 10 mm wide, 2.3 to 2.4 mm thick) were tested in a standard air oven with a single cantilever mode using test frame L and clamp type C at a frequency of 0.5 Hz with a heating rate 5°C/min. In this system, a sinusoidal stress is applied to a vibrator unit using a sinusoidal current. The stress imposed upon the specimen is therefore directly related to the amount of current delivered to the vibrator. All the specimens were studied between 25° C and 150° C.

3. RESULTS AND DISCUSSION

3.1 Effect of addition of TiO_2 on DMTA for Novelty Polyurethanes Polymer

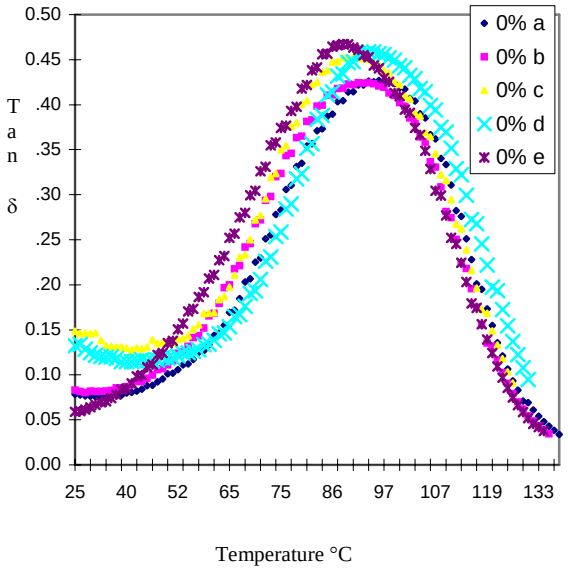

Figure 3.1. Value of tan δ determined by DMTA for 5 samples of neat novelty Polyurethane

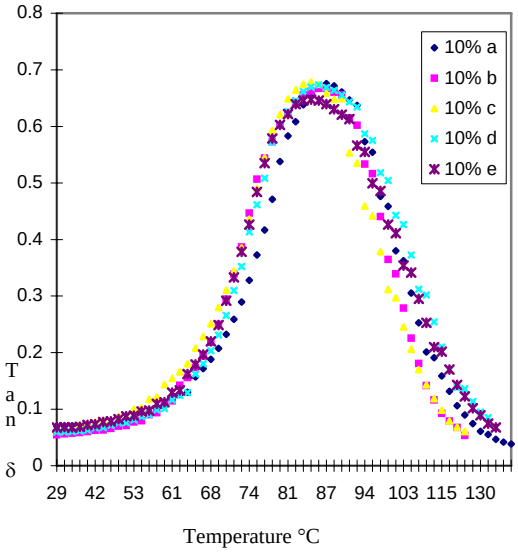

Figure 3.2 Value of tan δ determined by DMTA for 5 samples of novelty Polyurethane loaded with 10% of TiO_2

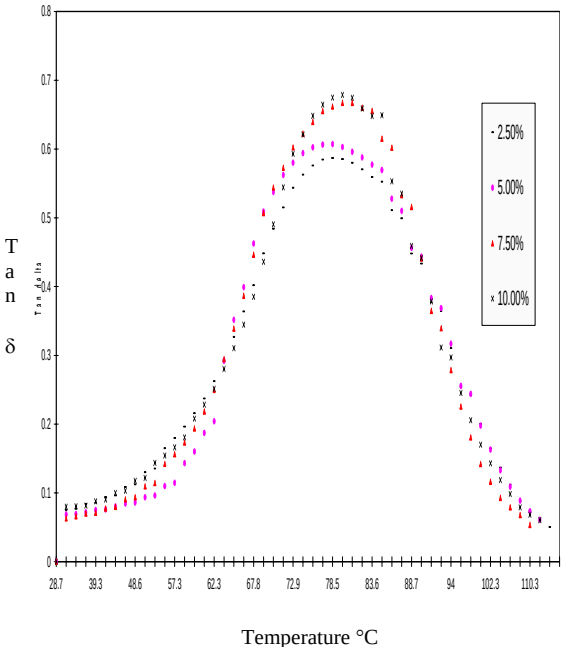

Figure 3.3 Value of tan δ determined by DMTA for novelty Polyurethane loaded with different percentages of TiO_2

The temperature at the maximum value of tan δ corresponds to T_g at which the tan δ value indicates the damping response of the resins. The temperature range for efficient damping (tan δ >0.3) for most of the common homopolymers is around 20 to 30°C [4]. A high tan delta (δ) value is essential for good damping properties. Damping refers to the capacity of a material to dissipate energy during vibration, and is often linked to the mobility of microstructural defects. Polymeric materials with a high damping factor play an important role as insulating or automotive interior components [5]. Commercially, polymers may be applied to the surface of a vibrating substrate to increase damping [6].

The glass transition temperature (T_g) of a composite is important to analyse because the interaction modes between the polymer and the added components can be determined. The glass transition region is the region of maximum damping, at which stage the polymer changes from the glassy to the rubbery state. The broadening of the glass-to-rubber transition is partly due to a broad distribution in the chain length distribution between crosslinks (7-8).

Referring to Figure 3.1 and Figure 3.2 for neat and loaded with TiO_2 (10% of monomer weight) respectively, the results shows the composite of novelty Polyurethane increased its average tan δ peak from 0.45 to 0.7. The sharply increasing the value of tan δ peak showed that the damping properties of the material were improved marked upon progressive loading with TiO_2 but narrowing the glass-to-rubber transition curve. This interesting result may be attributed to both the inherent characteristics of TiO_2 and the development of chemical interactions between the polymer and TiO_2. The T_g value of a polymer is related to the movement of segments of polymer chains in free spaces [9-11].

3.2 Effect of addition of TiO_2 on Tensile Strength for Novelty Polyurethanes Polymer

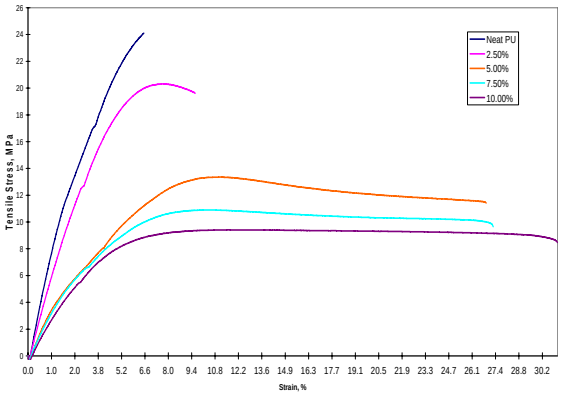

Figure 3.4 Influence of TiO_2 loading for tensile strength of Novelty Polyurethanes samples

Figure 3.4 shows the tensile strength of Novelty Polyurethanes upon loading with TiO_2. The tensile strength decreases, and the elongation to break (%) increases, with increasing levels of TiO_2 composites. Treatment with TiO_2 was found to affect the physical properties of the polyurethane in a systematic way. As the loadings of TiO_2 increased (up to 10% of monomer weight), large strain results were obtained; thus the stress vs. strain curves plotted by the Instron tensile test showed an increase from 5% to 31%. Increase in elongation to break showed a remarkable characteristic exhibiting soft – but – tough behaviour [12], where the toughness of the material is the area under the stress-strain curve.

4. CONCLUSION

Polyurethanes (PUs) have been synthesised successfully from renewable resources namely vegetable oils (rapeseed, sunflower), using MDI as the cross-linking agent. The triglycerides in these vegetable oils provide the alkene functionality as the basis for ultimate conversion to reactive hydroxyl groups. Epoxides can be readily prepared by treatment of the alkenes with a peroxide (for example, hydrogen peroxide, H_2O_2). The ring-opening of the epoxides to yield hydroxylated triglycerides was achieved using hydrochloric acid. The mechanism of urethane formation in the final step is via a nucleophilic attack of the hydroxyl group on the isocyanate groups of MDI.

The tensile test was conducted with different PU samples composites from different batch preparations. As the loading of TiO_2 was increased (up to 10 % of monomer weight), the elongation to break was improved as the TiO_2 loading was increased from 5 % to 31 % (for polyurethanes loaded with 10 % TiO_2). Therefore by increasing the level of TiO_2, one can alter the mechanical properties of the polymer as desired.

A single loss tangent peak was observed in the DMTA test. A high tan delta peak is essential for a good damping material. The loss tan δ peaks for the polymer loaded with 2.5, 5, 7.5, 10 % of TiO_2 were 0.58, 0.6, 0.68, and 0.71 respectively as compared with neat novelty polymer at only 0.43. These data shows that the damping ability is enhanced through the introduction of TiO_2 into the polymer.

ACKNOWLEDGMENT

The author would like to thank Universiti Tun Hussein Onn Malaysia (UTHM), Johor, Malaysia for supporting this research under Short Term Research Grant.

ABSTRACT

This research introduces a study about reactive distillation column system to produce diethyl carbonate by using ASPEN PLUS ™. Further study about reactive distillation system is required to be developed in order to gain industrial process improvement, especially in diethyl carbonate (DEC) production. Suitable thermodynamic and kinetic model parameters from ASPEN PLUS ™ regressions are used to describe this process. The purpose of method is to obtain the optimum process design and operating condition. The optimum process design and flowsheet is shown by minimal total annual cost (TAC). For a steady state condition, optimal condition is reached by 8:1 feed ratio of EtOH:DMC, 38 total trays of distillation column, feed location of dimethyl carbonate (DMC) at 29th stage and feed location of ethanol (EtOH) at 3th stage. From previous system we create one more system to recycle EtOH in order to complete overall system.

Keywords : *ASPEN PLUS™, diethyl carbonate, dimethyl carbonate, process design, reactive distillation*

1. INTRODUCTION

Reactive distillation (RD) is a combination of separation and reaction in a single vessel. Reactive distillation is important in industries because of its benefits that represent in improvements of process efficiency and economic. Advantages of the using of reactive distillation are : increase process efficiency and reduction of investment and operational costs, chemical equilibirium limitations can be overcome, higher selectivities can be achieved, auxiliary solvents can be avoided, azeotropic or boiling mixtures can be more easily separated. This research focusing on diethyl carbonate (DEC) production. DEC is one of the promising candidates for oxygen-containing fuel additive, which has been reported by many researchers. It has more oxygen content than methyl tert-butyl ether (MTBE) (40.6 versus 18.2) and hence not so much needed to have same effect. Engine texts show that DEC reduces particulate emissions almost 50% when the engine is under load. Without load, particulate emissions are reduced by approximately 30% **.** The gasoline/water distribution coefficient of DEC is more favorable than that of dimethyl carbonate and ethanol. So DEC is readily miscible with fuel and does not phase separate. It is also more readily biodegradable. All the properties make DEC an attractive alternative oxygen-containing fuel additive (Wang et al., 2007).

2. THERMODYNAMIC MODEL

Chemical reactions, phase equilibrium characteristic, and transport phenomenon are required to be concerned to obtain a perfect reactive distillation system design. In order to have best operation condition, that is providing production efficiency and reducing energy cost, it is needed to carefully selecting the thermodynamic models in a reactive distillation column system. In this research, UNIQ–RK model is chosen for the description of the thermodynamics of mixture. Experimental data from literatures are used to enhance the thermodynamic predictability of ASPEN properties by using regression.

This systems includes five components: dimethyl carbonate (DMC), ethanol (EtOH), ethyl methyl carbonate (EMC), methanol (MeOH), dimethyl carbonate (DMC). They does not have miscibility gaps, however three binary azeotropes appear in this system, that are : MeOH-DMC, EtOH-MEC, and EtOH-DMC.

This research provides regression for vapor-liquid equilibrium data by using UNIQ-RK model parameter. The UNIQ-RK model can describe strongly nonideal liquid solutions and liquid-liquid equilibrium. Several literatures have conducted the experimental data for components in this system. Regression is required to have a high accuracy prediction model compared to experimental data.

Experimental data for components is obtained from papers. Methanol-DEC vapor liquid equilibrium experimental data is provided from Rodriquez (Rodriguez et al., 2003); EtOH-DMC and MeOH-DMC vapor liquid equilibrium experimental data are also provided by Rodriguez (Rodriguez et al., 2002) in different paper; EtOH-EMC, EtOH-DEC, and DMC-DEC vapor liquid equilibrium experimental data are obtained from Luo (Luo et al., 2000). The other vapor-equilibrium plots for MeOH-EMC, EMC-DEC, and DMC-EMC that have no experimental data in any literatures are based on UNIFAC model parameter from ASPEN built in system. ASPEN offers many built in model parameters; UNIFAC model parameter that used to predict vapor liquid equilibrium for remained components is one of features that support by ASPEN. Thus, all the vapor equilibrium plots can be accomplished.

3 KINETIC MODEL AND PARAMETERS

Transesterification of dimethyl carbonate (DMC) with ethanol to produce diethyl carbonate (DEC) occurs in this reactive distillation system. This system consists of two consecutive reactions with the intermediate product of ethyl methyl carbonate (EMC). The main product is DEC that known as an important reactant and solvents for many chemical processes. Hu-Ping Luo and Wan-De Xiao in 2001 have determined some expressions to represent the kinetic of this reactions and in the year of 2004, another kinetic parameters of this reactions that has been used by Mueller and Kenig (Mueller and Kenig, 2007). This research uses Richter kinetic parameter (Mueller and Kenig, 2007) in ASPEN simulation.

DMC + EtOH ⇔ EMC + MeOH (a)

EMC + EtOH ⇔ DEC +MeOH (b)

Homogeneous catalyst that applied to reactive distillation system complicates in product purification. Heterogeneous catalyst provides significant conversion, selectivity, and solve purification problems. Potassium carbonate (K_2CO_3) is used in this system as suggested as an appropriate catalyst by Angeletti (Mueller and Kenig, 2007). This reaction is a reversible reaction, the reaction rate type is as follows:

$$r_1 = k_{+1} x_{DMC} - k_{-1} x_{EMC} x_{MeOH} \quad (3.1)$$

$$r_2 = k_{+2} x_{DMC} - k_{-2} x_{EMC} x_{MeOH} \quad (3.2)$$

$$k_{+m} = k_{0,m} \exp\left(\frac{-E_{A,m}}{RT}\right) \quad (\text{for } m = 1, 2) \quad (3.3)$$

$$k_{-m} = \frac{k_{+m}}{K_{reac,m}^{eq}} \quad (\text{for } m = 1, 2) \quad (3.4)$$

Where :

K_{reac}^{eq} = reaction equilibrium constant

K = reaction velocity constant [mol.kgcat^{-1} .s^{-1}]

R = gas constant [J .mol^{-1} .K^{-1}]

T = temperature [K]

r = reaction rate related to catalyst mass [mol .kgcat^{-1} s^{-1}]

x = liquid-phase mole fraction [mol/mol]

Table 4 : *Kinetic parameters*

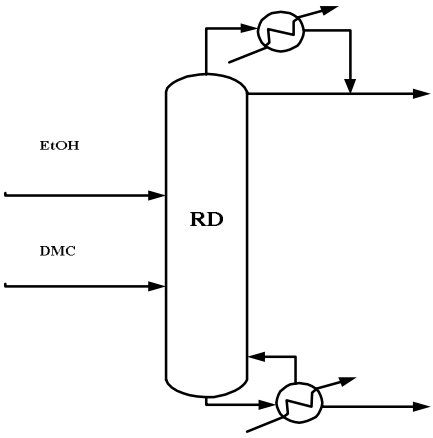
a	39971	2.54×10^5
b	37258	2.02×10^4

6. DISCUSSION

Figure 1: Design system of reactive distillation column process



This is system of reactive distillation system to produce DEC. We set design specs and varies for this system by fix mole purity of DEC at bottom is 0.995 and conversion od DMC is 0.995 %. This system is run by using ASPEN PLUS ™ to design proper distillation system and achieve design specs and varies. Optimum design is determined by calculation of TAC. By changing feed ratio of EtOH and DMC, minimum TAC can be reached.

This figure shows total annual cost (TAC) for several feed ratio. From that figure, it is known that total annual cost minimum for this process is obtained in 8:1 feed ratio of EtOH:DMC with reactive section from 3rd tray until 29th tray. From this feed ratio, it observed later to get a specific feed location that provides optimum design of DEC production in reactive distillation column system.

Figure 2: TAC minimum by varying the feed ratio of EtOH/ DMC

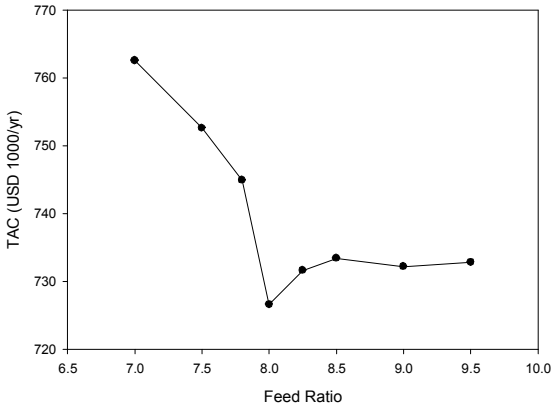


Figure 3: TAC minimum by varying the feed location of EtOH and DMC

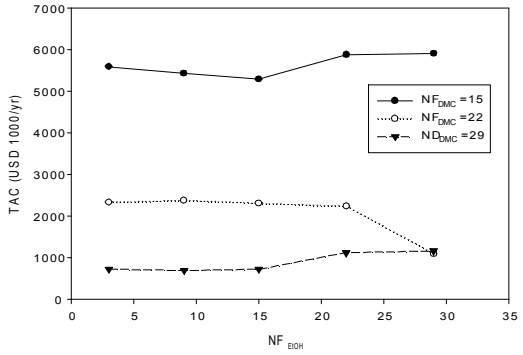

From that figure, total annual cost minimum is obtained by 8:1 ratio of EtOH : DMC and feed location of DMC is at 29th tray and feed location of EtOH 9th tray. Total annual cost minimum is 692.33 (USD 1000/yr).

7. CONCLUSION

Reactive distillation is becoming an important part of industrial improvement. It provides efficiency production and several advantages that develop conventional distillation system. This research is one case of reactive distillation column system in producing diethyl carbonate (DEC) that has been known as important product in industry. By using ASPEN PLUS ™, we design a system to obtain minimum total annual cost. Thermodynamic model and kinetic parameters are chosen accurately to fit the simulation and experimental data. From simulation, total annual cost minimum for optimum design are determined by set feed ratio of EtOH/DMC to 8:1 and feed location of DMC is at 29th t tray and feed location of EtOH 9th tray.

ABSTRACT

Composite membranes were synthesized by photo-grafting polymerization of polysaccaharide celulosic palmitat with a functional monomer methyl methacrylate (MMA) and a photoinitiator (darocure 1173) using UV irradiation. As result, polysaccharide-polymethylmethacrylate compo-site membranes with several weight ratio composition were obtained. The membranes' surface texture, mechanical performance and capacity to adsorb 2-(4-isobutyl-phenyl)-propionic acid (ibuprofen) from methanol solution was evaluated yielding information regarding the effect of the concentration of functional monomer on the resulting membranes' properties.

The composited membranes showed significantly higher mechanical and sorption capability to ibuprofen than that of uncomposited polysaccharide membrane. With the composite insitu polymerization technology, high mechanical properties of the hydrophilized membrane could successfully be combined with the synthetic polymer, yielding substance-specific polymer composite membranes. By the inexpensive preparation provides a good basis for the development of applications of composite membrane polymers in separation processes such as solid-phase selective permeation.

Composite membrane; Photo-initiated graft copolymerization; Solid-phase selective permeation

1. INTRODUCTION

A membrane is a layer of material which serves as a selective barrier between two phases and remains impermeable to specific particles, molecules, or substances when exposed to the action of a driving force. Some components are allowed passage by the membrane into a permeate stream, whereas others are retained by it and accumulate in the retentate stream. In the chiral separation technology, membrane is also attractively developed especially for mass production application due to low consumption of chemical agent, good reliability, and high effectiveness for the separation process [1]. The membrane for the chiral separation process is necessary to have a good chiral recognition, mechanical property and high productivity.

As an approach to obtain a good reliability and mechanical property of chiral membrane, polysaccharide which is known as a high chirality of natural resource polymer attempted to be functionalized with monomer methyl methaacrylate. The reaction of monomer methylmethaacrylate may lead us to obtain polymerization product, as well as poly methyl metha acrylate by using a radical polymerization. However the condition is tend to produce a bulk of homopolymer. In order to develop the physical properties of polysaccharide membrane derived from palmitoyl cellulose, a photo grafting polymerization using UV irradiation will be used as an in situ polymerization method. However, many reaction variables may influence the properties of the polysaccharide-polymethyl-methaacrylate membrane. Here, the effect of weight ratio composition and irradiation time on the producing membrane properties as well as surface texture, mechanical performance and capacity to permeate 2-(4-isobutyl-phenyl)-propionic acid (known as ibuprofen) from methanol solution will be evaluated and discussed.

2. EXPERIMENTAL SECTION

Membrane development has been carried out covering synthesis, mechanical as well as tensile strength and elongation characterization, and permeation performance. The synthesis and permeation experiment processed in BPPT laboratorium, and the mechanical testing was done in BATAN laboratorium.

2.1 Synthesis

Methyl metha acrylate (0,5 g) was poured into palmitoyl cellulose (0,5 gram) solution in dichloromethane (10 ml) in Petridis (diameter 7 cm). After darocure 1173 (0,2 ml) dropped into the mixture, the solvent was evaporated in situ at ambient temperature for 1 hour. The pre-casted membrane

was irradiated under UV lamp (Phillips 20W x 3) for 1, 3 and 5 hours, respectively.

2.2 Mechanical testing

Mechanical testing was carried out following with ASTM-D-1822-L using cutting machine of Dumb Bell Ltd., SAITAMA JAPAN. The cutted samples were then measured by Strograph-R1 (Toyoseiki) to provide the data of tensile strength and elongation ratio.

2.3 Permeation experiment

As feeding sample, 0,1M solution of ibuprofen in methanol (200 ml) was poured into the feeding chamber equipped with the composite membrane at the bottom of the chamber. The concentration of the permeated solution was calculated from obtained specific weight-concentration correlation graph after 1 to 4 hours of permeation.

Table 1. Equipment of chamber for permeation

No.	Equipment's item	Scale
1	Membrane's active area	4,9 mm
2	Diameter	2,5 inch
3	Chamber length	200 mm

3. RESULT AND DISCUSSION

3.1 Synthesis

Synthesized two types of solid flat sheet membranes, those are palmitoyl cellulose and palmitoyl cellulose-g-PMMA membranes were considered to be evaluated to understand the relationship between the membranes's consisted material and their physical properties. Obtained membranes were visually transparent as well as showed in figure 1 below.

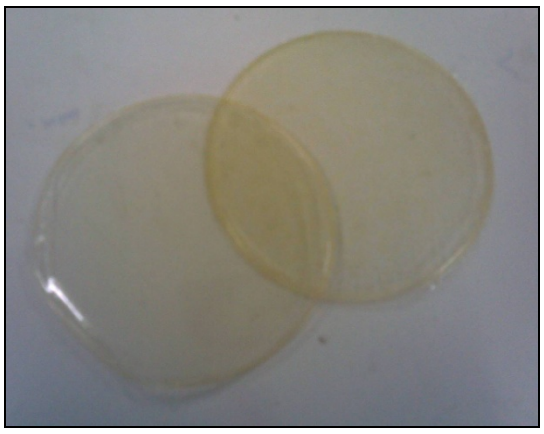

Figure 1. Palmitoyl cellulose base membranes

The preparation of membranes by UV photo grafting might provided a covalently and three-dimensionally cross linked macromolecular substances [2]. By cross linking of methyl methacrylate monomer in bulk within palmitoyl cellulose, it is possible to obtain either compact networks or swellable and/or, respectively, porous, networks with a defined interstitial structure. The effectiveness of this preparation method should be considered with their provided physical properties as well as mechanical strength and elongation ratio.

3.2 Physical properties

3.2.1 Mechanical characterization

Mechanical characterization was carried out to know the strength and the elongation ratio of the prepared membranes. The results of the mechanical test were summarized in graph (Figure 2) below.

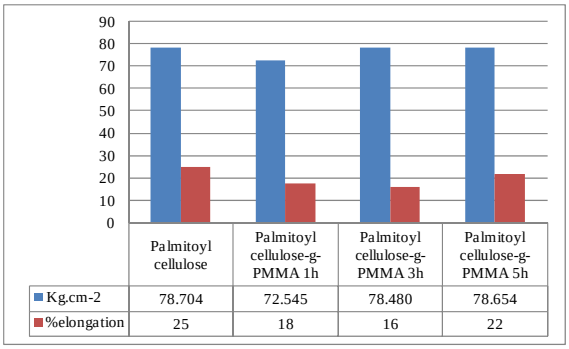

Figure 2. Mechanical properties of membranes

The graph showed a little different value between the mechanical strength of the membrane prepared purely from palmitoyl cellulose and those from grafting with poly methyl methacrylate. However, the grafting process by 1 hour UV irradiation provided the membrane with the lowest strength's value. It indicates that a longer time of irradiation was necessary to complete the polymerization process of MMA monomer. By elongation of the irradiation time for 3 and 5 hours, the mechanical strengths tend to increase up to 8.4%.

As shown in figure 2, the membrane purely prepared from palmitoyl cellulose showed the highest elongation ratio. It indicates that the palmitoyl cellulose membrane has a good plasticity. Due to the polymerization of monomer might occur completely, the closest elongation ratio to that of the palmitoyl cellulose membrane showed by the product of grafting with 5 hour irradiation. It suggests that the bulk polymerization of methyl methacrylate has worked properly in palmitoyl cellulose by enough time of UV irradiation and provided a networked macromolecular substance.

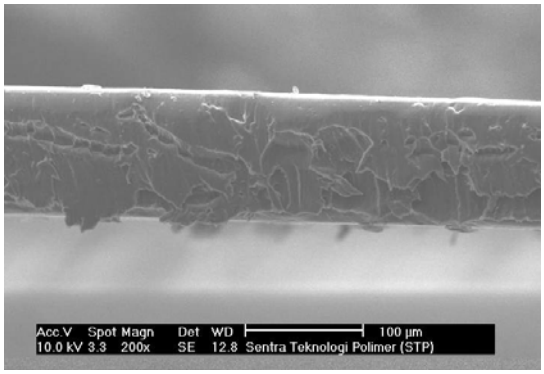
3.2.2 Surface characterization

The membranes synthesized either from palmitoyl cellulose or palmitoyl cellulose-g-PMMA showed a good full-dense membrane as seen in SEM's figure below, with have relatively a lower porosity. From the SEM's characterization, it is known that palmitoyl cellulose and PMMA were miscible each others, and no delaminating effect were observed.

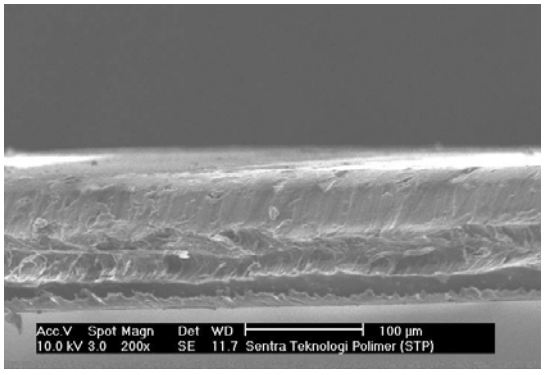
The character is necessary to develop the membranes as permeation medias that distinguish each isomers of ibuprofen which have same structure and size of molecule. By inter-molecular recognition mechanism, those isomers would be separated to passage only one of the isomers.

3.3 Permeation evaluation

As the research purpose that is to develop membranes for separation, permeation of subject has been done using 2-(4-isobutyl-phenyl)-propionic acid (known as ibuprofen) from methanol solution. However, in this paper, only the permeation rate of rasemat (mix of the isomers) would be evaluated without any consideration about the enantiospecific separation.



(a). Palmitoyl cellulose



(b). Palmitoyl cellulose-g-PMMA (1 h)

Figure 3. Cross-section of membranes by SEM

With the equipment as described in table 1 and showed in figure 4 below, the permeation process has worked following to the vertical mechanism. By this mechanism, the reverse flow of the passage permeate from receiver solution might be prevented. As the result, the permeation experiment has provided a better yield of the passage permeate than that of the permeation by horizontal mechanism [3].

Figure 4. Permeation chamber

***Table 2**. Permeation result of membranes*

Membrane name	**Palmitoyl cellulose**	**Palmitoyl cellulose-g-PMMA**		
Preparation	**pure**	**1 hour**	**3 hours**	**5 hours**
Average of membrane thickness (mm)	**0.15**			
Object of permeate	**Ibuprofen**			
Solvent	**Methanol**			
Concentration of feeding (M)	**0.1**			
Volume of feeding (mL)	**200**			
Permeation rate (10^{-5} x $g \cdot m \cdot m^{-2} \cdot h^{-1}$)	**9.8**	**28.2**	**7.0**	**15.3**
Yield of passage ibuprofen (%) (first 1 hour permeation)	**1.95**	**7.56**	**0.47**	**2.74**

As shown in table 2, by the membranes which have average thickness around 150 micrometer, ibuprofen as permeate have allowed to passage away to the receiver with different permeation rate. Although, all of the membranes seem to play

as full dense as they were observed by cross-sectional SEM's character, their permeation rates depended on their preparation condition. The membrane consisted with only palmitoyl cellulose showed a moderate level than others. Around 2 % of ibuprofen passages the membrane after 1 hour permeation. By inserting methyl methacrylate and polymerized bulkily within the base material, the obtained composite membrane showed an enhancement of permeation behavior. This might be considered that the phenomenon could occur due to the polymerization process forming of some nodular inside the base material [4].

4. CONCLUSION

A series of composite membranes has been prepared from palmitoyl cellulose and methyl methacrylate by irradiation under UV lamp using conventional photoinisiator. The performances of the composite membranes were evaluated and compared with base membrane prepared purely from palmitoyl cellulose. The composite membranes have good mechanical properties, however respect to their strength and elongation ratio compared with base material, no enhanced properties were observed. On the other hand, the composite membrane showed a better performance on their permeation rate than that of the base membrane. In the future, further development on their composite preparation method is necessary to obtain the composite membrane with a higher strength but remain their good permeation performance.

ACKNOWLEDGMENT

We would like to thanks to Indonesian Ministry of science and technology for funding our research.

Abstract

A laboratory investigation was carried out to study the reduction behavior of the lateritic iron ore with anthracite coal under isothermal condition in the temperature range 800 ^{0}C to 1100 ^{0}C.

The main mineral content of investigated lateritic iron ore was found as the following: Goethite : 62.8%, Hematite : 18.3% and Magnetite (Fe_3O_4) : 6.2% and other oxide minerals like Alumina : 6.6%, Silica : 4.5% , Chromate : 3.3% and others. The ores and anthracite coal as the reducing agent were co-milled to -60 mesh. The milled mixture material was then heated isothermally att temperatures 800, 900, 1000 and 1100^{0}C for reduction time varied from15 to 90 minutes of each reduction temperature It was found that both temperature and reduction time determine the metallization kinetic in which the maximum value were obtained at higher temperatures and a longer reduction time. The kinetics of metallization at an isothermal temperature showed two stages relation with reduction times, two constant rates (K) were derived. This suggests that two different reduction mechanisms occur during the lateritic iron ore reduction.

Keywords: *iron ore; coal; kinetics; metalization; mixed grinding; reduction*

1. Introduction

Laterites are the products of intensive and long lasting tropical rock weathering which is intensified by high rainfall and elevated temperatures. One of the lateritic ore species is lateritic iron ore, which has significant amount in the world. But so far lateritic iron ore contribution on iron and steel industry is very small or even can be neglected, due to its low Fe content (less than normal requirement 60% Fe). Recently, due to shortage of iron ore raw material, the lateritic iron ore is starting to be utilized as raw material for iron and steel making industry by reducing with suitable technology for example rotary kiln.

Indonesia has much enough lateritic iron ore deposits but so far this lateritic iron ore deposits is not utilize yet as main raw material for Indonesian iron and steel industry. In order to utilize the lateritic iron ore, the research in laboratory and pilot plant scale should be started.

The investigated lateritic iron ore consist mainly of Goethite, a hydrated iron oxide FeO(OH), 62.8%.

If the Goethite is heated, the dehydroxilation will be occurs at about 200 – 350^{0}C

$$FeO(OH) = Fe_2O_3 + H_2O \quad (R1)$$

This is a step which naturally occurs in the reduction precess as a result of heating.

The milled mixture material was then heated isothermally at four different temperatures 800, 900, 1000 and 1100^{0}C for reduction time varied from15 to 90 minutes of each reduction temperature. All reduced materials were analyzed quantitatively with X-ray diffractometer (XRD) in

order to analyze the minerals content in order to study their reduction kinetics characteristic.

The reduction parameter used is metallization (M).

Metallization (M) = $(Fe_R/Fe_T) \times 100\%$. (1)

Where Fe_R = reduced or metallic iron in the reduced material sample

Fe_T = total iron in the ore sample

It was found that both temperature and reduction time determine the metallization kinetic in which the maximum value were obtained at higher temperatures and a longer reduction time. The kinetics of metallization at an isothermal temperature showed two stages relation with reduction times, expressed by two kinds of kinetic curve from which two constant rates (K) were derived. This suggests that two different reduction mechanisms or models occur during the lateritic iron ore reduction.

2. Lateritic Iron Ore Reduction And Kinetic Model

Reaction kinetics in iron ore reduction deal with the rate which iron oxides are converted by the removal of oxygen. The reaction mechanism in lateritic iron ore and coal mixtures is very complex with respect to simultaneous reaction steps due to the following reasons:

1. a system of many particles and many phases, i.e. iron, iron oxide, coal, carbon etc;
2. a system of many gases i.e. CO, CO_2, H_2, H_2O, etc;
3. a system of many chemical reactions, i.e
   a. dehydroxylation of Goethite
      $2FeO(OH) = Fe_2O_3 + H_2O$
   b. reduction of hematite to magnetite:
      $3Fe_2O_3 + CO = 2Fe_3O_4 + CO_2$ (R2)
   c. reduction of magnetit to wustite :
      $Fe_3O_4 + CO = 3FeO + CO_2$ (R3)
   d. reduction of wustite to iron :
      $FeO + CO = Fe + CO_2$ (R4)
   e. Carbon gasification, Boudouard reaction :
      $C + CO_2 = 2CO$ (R5)
   f. Coal devolatilization, coal to carbon;
      Coal = C + voaltile matter (R6)

The reduction of hematite to wustite (R2, R3) is condidered as a complex gas-solid reaction influenced by complex structural changes in the intermediate oxides.

2.1 Reduction Mechanism

The reacting mixture under study is a multiple phase heterogenous system. Heterogeneous chemical reactions take place at interface which move spatially and change their character with reaction time. Heat and mass transfer are not only active within each phase, but also between phases.

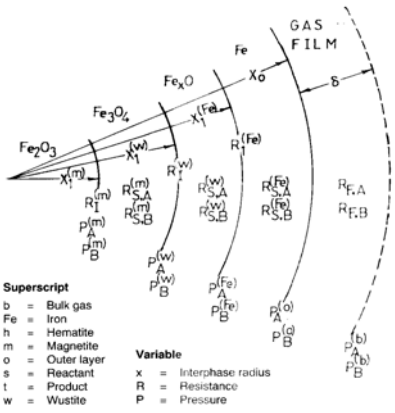

Figure1- Reprsentation of model with three concentric shells [14]

The fundamental steps involved in the reduction of iron oxide are as follows:

1. diffusion of the reducing gas across the boundary layer;
2. intraparticle diffusion of the reducing gas to the reaction interface;
3. phase-boundary reaction, migration of Fe^{++} and electrons to the iron nucleus;
4. intraparticle diffusion of oxidized gas from reaction interface;
5. diffusion of oxidized gas across the boundary layer;

These steps are shown in **Figure 1**.

Dutta et.al [3] shows that reduction of iron ore fines with carbonaceous material consist of two stages reduction as shown in **Figure 2**, the **first** is conversion of hematite to wustite (reaction R2 – R3) and the **second stage** is the reduction of wustite to Fe (reaction R4).

2.2 Iron Ore Kinetic Reduction Model

The complexity of reactions involved in the carbothermic reduction of iron oxide has led to difficulty in the selection of an appropriate reduction model.

There are several methods generally used to describe the kinetics of carbothermic reduction of iron oxide, such as:

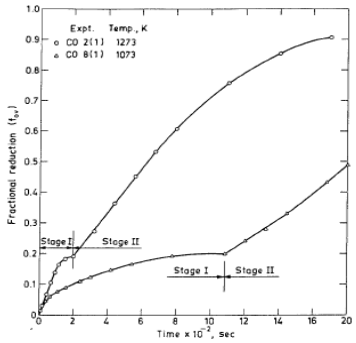

Figure2, Overall fractional reduction vs time [1]

1. Nucleation and growth model. This model consist of several varian models :
   a. The first order reaction,
      $Ln (1-M) = -kt$ (2)
   b. Prout and Tompkin model [Prakash 1996]
      $Ln (M/[1-M]) = kt$ (3)
   c. Avrami-Erofe'ev equation for phase change model
      $[-ln(1-M)]^{1/2} = kt$ (4)

   Where M = metallization
   k = rate constant
   t = reduction time

   The equation (2) – (4) is based on general equation, Avrami equation
   $R = 1 - e^{-Kt\wedge n}$ (5)

   $Ln (1-R) = -Kt^n$ (6)

   Where R = reduced fraction
   K, n = rate constant
   t = reduction time
2. Equation for phase boundary-controlled reaction model
   $1 - (1-M)^{1/3} = kt$ (7)

   Where M = reduced fraction
   k = rate constant
   t = reduction time

Nucleation and growth model typically shows four stages as shown in **Figure 3**:

1. induction period at the beginning of reaction, during which stable nuclei are formed;
2. acceleratory period, which extends up to fractional extents of reaction between 0.1and 0.5, during which some of the nuclei become active and grow;
3. linier period, where the extent of reaction proceed linierly with time;
4. decay period, which appears at high degrees of decomposition.

In order to compare the result of each model and to determine the suit model for the reduction of lateritic iron ore, the root-mean square deviation (RMSD) were applied.

$$RMSD = [(\sum(R_{Fitt} - R_{exp})^2/m]^{1/2} \quad (8)$$

Where
R_{Fitt} = calculation result of reduced fraction
R_{exp} = experimental data of reduced fraction
m = number of experimental data

The model with the lowest RMSD value is the suit model for the lateritic iron ore reduction.

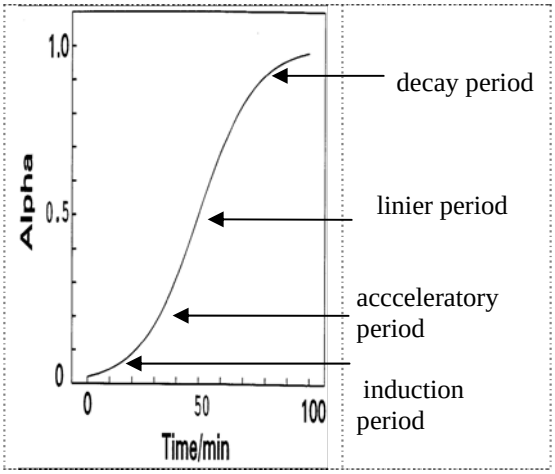

Figure 3, Kinetics steps of nucleation process

3. Experimental Procedure

The experimental procedure is the following:

1. The ore and antrachite coal as reducing agent were milled to -60 mesh by a ball mill. The ore and antrachite coal was mixed with mol ratio between ore and carbon in the antrachite is 1:2, asumption all of the ore is hematite (Fe_2O_3);
2. The milled mixture material was then heated isothermally at four different temperatures 800, 900, 1000 and 1100^0 C for reduction time varied from 15 to 90 minutes of each reduction temperature. The heating curve is shown in **Figure 4**;
3. The ore was heated up to 250^0C for 30 minutes seperately from the milled mixture material in order to analyze the goethite and hematite content changing due to ore heating.

isothermal temperature was increase if the

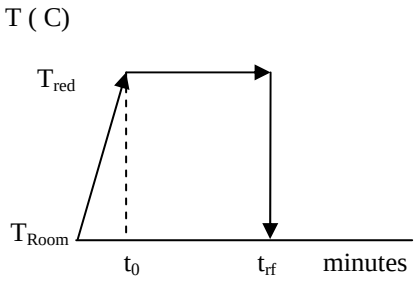

Figure 4, Experimental heating curve. T_{red} = isothermal reduction temperature, T_{room} = room temperature, t_0 = isothermal reduction time start, t_{rf} = isothermal reduction time finish**.**

4. The fresh ore, heated ore and all of the reduced materials were analyzed with XRD and the result was analyzed quantitatively with GSAS (General Structure Analysis Sytem) software.

The antrachite composition is Fixed Carbon : 85.57%; Ash : 10.88%; Lost of ignition (LoI) : 89.12%; Volatile matter : 5.5%; Water content : 1.84%.

4. Result And Discussion

The fresh lateritic ore XRD data was analyzed quantitatively, it was found that the lateritic iron ore consist mainly of Goethite, a hydrated iron oxide FeO(OH), 62.8%. The other iron minerals are Hematit (Fe_2O_3) : 18.3%, Magnetit (Fe_3O_4) : 6.2% and other oxide minerals like Alumina (Al_2O_3) :6.6%, Silika (SiO_2) : 4.5%, Chromite (Cr_2O_3) : 3.3% and others also found in small amount (less than 1%) with Fe total : 54.34%.

If the ore was heated at 250^0C for 30 minutes, the goethite and hematite content would be change, goethite content was reduced very significantly while hematite and Fe content were increased very significantly due to dehydroxylation of goethite (R1), as shown in **Table 1**.

The XRD data of reduced material in this case metallic Fe and total Fe were then coverted into metallization by using **equation (1)**.

During heating from room temperature to the reduction temperature, reduction occurs which was expressed by metallization as shown in **Table 2.**

Figures 5A and **5B** plots the correlation of metallization and time under isothermal condition (800, 900, 1000 and 1100^0C). It was obsereved in these figures that reduction time and temperature determine the metalization, metalization at an reduction temperature and time were increased.

Table 1. The fresh lateritic iron ore and 30 minutes 250^0 C heated ore.

Mineral	Content (%)	
	Fresh ore	Heated ore
Goethite, FeO(OH)	62.8	9.15
Hematite, (Fe_2O_3)	18.3	81.70
Magnetit , (Fe_3O_4)	6.2	9.15
Fe	54.34	69.57

Table 2, Metalization at reduction time = t_0 or M_0.

Temperature (C)	M_0 (%)
800	0.0
900	1.7
1000	12.5
1100	41.2

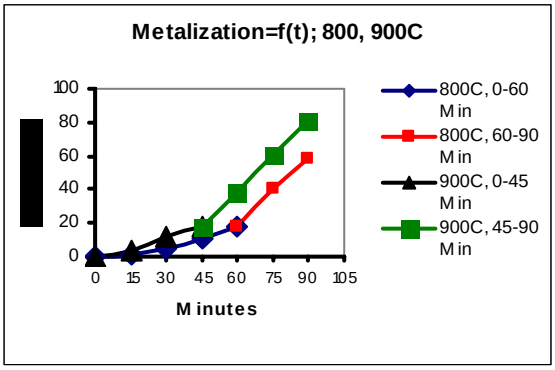
Metalization at an isothermal temperature showed two stages relation with reduction times, means that the reduction of lateritic iron ore consist of two stages, similar to reduction stage of iron ore fines reduction in **Figure 2**, in this case first stage is conversion of goethite, FeO(OH), to wustite, FeO, and the second stage is conversion of wustite to Fe. This suggest that two different constant rates (K) and two reduction mechanism or models occur during the lateritic iron ore reduction.

From **Figure 5A, 5B** also obtained that the conversion time of goethite, FeO(OH), to wustite, FeO, was shorter if the reduction temperature was increase, the conversion at 1100^0C occurs before the isothermal period was achieved (before t_0). The conversion time is shown in **Table 3.**

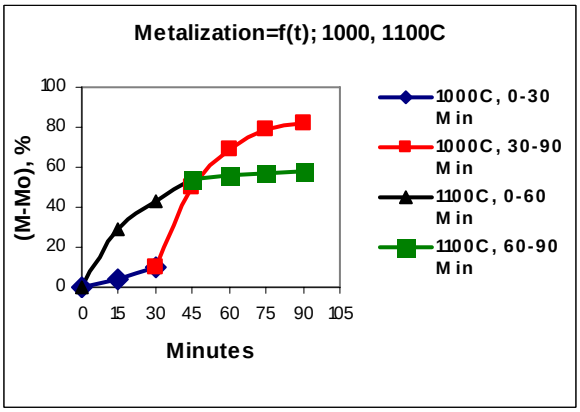
Table 3, Convertion time of goethite to wustite

Temperature (C)	Convertion time of goethite to wustite (min)
800	60
900	45
1000	30
1100	Before t_0

It was also observed in **Figure 5A, 5B** that the reduction pattern follow the nucleation and growth pattern shown in **Figure 3**. For the reduction temprature 800^0, 900^0 and 1000^0C induction, acceleratory and linier period, no decay period were observed, means the conversion of goethite , FeO(OH), to wustite or first stage reduction and conversion of wustite, FeO, to Fe occurs in these temperature and reduction time range. The two



5A



5B

Figure 5A, 5B; Reduction result. M= metalization at reduction time = t minutes, M_0 = metalization at reduction time = t_0. (M-M_0) = metallization at isothermal reduction period.

constant rates (K) were for first stage and second stage reduction.

At the reduction temperature 1100^{0}C no induction and acceleratory period were obsereved, just linier period and decay period were observed means that no conversion of goethite to wustite or first stage reduction was observed, just conversion of wustite to Fe was obsereved in this reduction time range. The two constant rates were for linier and decay periods.

The isothermal reduction metallization (M-M_0) data was correlated with nucleation and growth model, equation (2), (3), (4) and phase boundary-controlled reaction model, equation (7) in order to determine the suit model for lateritic iron ore reduction root mean square deviation (RMSD) parameter (**equation 9**) was applied. The correlation plot of metalization, reduction time and reduction temperature for each model is shown in **Figure 6A – 9B.** Root mean square deviation (RMSD) for each model is shown in and **Table 4** for temperature 800^{0}C, 900^{0}C and

Table 4, Root mean square deviation (RMSD) data for reduction temperature 800^0, 900^0 and 1000^{0}C for First Order Reaction Model (FO), Prout & Tompkins model (PT), Avarmi Erofe'ev model (AE) and Phase Boundary model (PB).

T (C)	RMSD			
	FO	PT	AE	PB
First Stage				
800	1.373	4.092	2.912	1.819
900	1.347	2.421	1.644	1.301
1000	0.800	0.718	0.500	0.777
$\sum$ First stage	3.521	7.231	5.052	3.898
Second Stage				
800	1.37	4.092	4.546	2.117
900	5.072	0.592	1.291	3.473
1000	5.383	9.550	7.880	6.889
$\sum$ Second stage	11.829	14.234	13.717	12.479

Table 5, Root mean square deviation (RMSD) data for reduction temperature 1100^{0}C for First Order Reaction Model (FO), Prout & Tompkins model (PT), Avarmi Erofe'ev model (AE) and Phase Boundary model (PB).

T (C)	RMSD			
	FO	PT	AE	PB
1st stage				
1100	2.482	9.800	7.882	3.225
2nd stage				
1100	0.363	0.373	0.408	0.758

Figures 6A – 9B shows that the reduction models mentioned above were fitt to the experimental result, means the lateritic iron reduction fitt to those models.

Table 4 shows that at the temperature range 800^0 – 1000^{0}C among the reduction models mentioned above, for first stage or conversion of goethite to wustite and second stage or conversion of wustite to Fe, First Order Reaction model had a smallest RMSD compare to the others, 3.521for the first stage and 11.829 for the second stage. Means that the suit reduction model for lateritic iron ore reduction model at temperature 800^0 - 1000^0 is Nucleation and Growth - First Order Reaction Model.

Table 5 shows that at the temperature 1100^{0}C among the reduction models mentioned above, for the conversion of wustite to Fe during linier period

and decay period, First Order Reaction model has a smallest RMSD value compare to the others, 2.482 for the linier period and 0.363 for the decay period. Means that the suit reduction model for lateritic iron ore reduction model at temperature 800^0 - 1000^0 is Nucleation and Growth - First Order Reaction Model.

The constant rate (K) acording to First Order Reaction Model is shown in **Table 6** and **Figure 10.**

Figure 10, The constant rate according to First Order Reaction Model, Ln (1-M) = -kt. K_1 = constant rate for conversion of goethite to wustite, K_2 = constant rate for conversion of wustite to Fe.

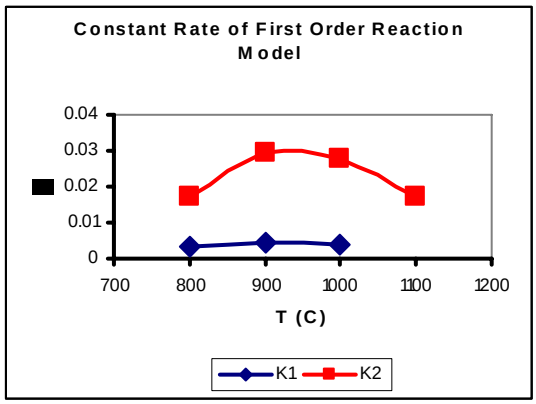

Table 6, The constant rate according to First Order Reaction Model, Ln (1-M) = -kt. K_1 = constant rate for conversion of goethite to wustite, K_2 = constant rate for conversion of wustite to Fe.

T (C)	K_1 (%/min)	K_2 (%/min)
800	0.0032	0.0174
900	0.0047	0.0295
1000	0.0037	0.0276
1100	--	0.0173

Figure 10 and **Table 6** shows that the contant rate conversion of of goethite to wustite was less compare to conversion of wustite to Fe due to less complexity of conversion of wustite to Fe (R4) compare to conversion of goethite to wustite (R1-R3). Constant conversion rate of both conversion goethite to wustite and wustite to Fe, K_1 and K_2 increased if the reduction temperature was increase from 800^0 to 900^0C then decreased from 900^0 to 1100^0C due to decreasing of Fe oxide in the ore.

Conclusion

The reduction kinetics of lateritic iron consist of two conversion stages. Conversion of goethite to wustite and conversion of wustite to Fe, each stage has its own constanta rate (K)

The reduction kinetics of lateritic iron ore fulfill several kinetics model i.e., first order reaction model, Prout & Tompkins model, Avrami-Erofe'ev modeland phase boundary model. By applying the root means square (RMSD) parameter the first order reaction model was determine as the suit model of the reduction kinetics of lateritic iron ore.

Constant conversion rate of wustite to Fe (K_2) was higher compare to constant conversion rate of goethite to wustite (K_1).

Constant conversion rate, (K_1, K_2), was increased if the reduction temperature increased from 800^0 to 900^0 and then decreased if the temperature increasedfrom 900^0 to 1100^0.

Acknowledgement

This reduction research was carried out at chemical laboratory of PT KRAKATAU STEEL, Cilegon and the XRD analysis was carried out at Postgraduate Program of Materials Science laboratory, Jl. Salemba Raya 4, Jakarta.

Thank you to PT KRAKATAU STEEL management where the first author is being employed as Process And Product Research And Development Manager for providing facilities for experimental work. Also thank you to Postgraduate Program of Materials Sciencewhere the first author is being studied for providing facilities for analysis work.

ABSTRACT

AC4B alloy (Al-8Si-2.4Cu) is one of the most desirable cast aluminium to be processed through low pressure die casting (LPDC). However, there are many problems, particularly shrinkage and porosity, that need to be resolved. One way to solve this problem is by using grain refiner. Another constraint is the duration of one cycle LPDC process of ~ 450 kg capacity may take up 4 hours, that causes fading. This research is aimed to understand the fading mechanism of Al-5Ti-1B grain refiner of 0.081 and 0.115 wt. % Ti during LPDC. Fading was observed through the changes of hardness, tensile strength and microstructure.

The results show that the longer the holding time, the lower hardness and the tensile strength of AC4B alloy. On the other hand, the longer the holding time, the higher the ductility and the secondary dendrite arm spacing (SDAS). This indicates that fading occurred before 1 hour. In addition, microstructure observation by using Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Analysis (EDAX) showed the presence of titanium in the alloy which indicates that titanium may act as the nucleant for solidification process.

Keywords
Grain refiner, fading, AC4B, LPDC, Al-5Ti-1B

1. INTRODUCTION

One way to improve the quality of aluminium casting products is by using grain refiner [1-3]. Grain refiner reduces grain size of aluminium casting by resisting the growth of columnar grains and promoting equiaxed grains [4-6]. The grain in aluminium casting can be refined by forming as much dendrites as possible during initial solidification, and maintain that they all grow at the same rate. This only can be achieved if the nucleation starts near to liquidus temperature, or minimum undercooling, by providing particles on which dendrites can readily nucleate and grow [3, 7-8].

There are several types of grain refiner available for aluminium alloys, such as aluminium-titanium, aluminium-titanium-boron master alloys, and titanium or titanium-boron containing salt tablets [7]. The aluminium-titanium and aluminium-titanium-boron master alloys are the most popular to use, such as Al-10Ti, Al-6Ti, Al-3Ti-1B, Al-5Ti-1B, Al-5Ti-0.6B, Al-10B, Al-5B, and Al-3B [9].

The mechanism of grain refinement is related to the nucleant particles which is contained in the grain refiner, i.e. TiB_2 or $TiAl_3$ particles. If titanium is present in the alloy at the levels greater than ~0.15 %, then on cooling, nucleation of $TiAl_3$ occurs before aluminium. Aluminium then nucleates on $TiAl_3$ reducing the undercooling and thus producing a smaller grain size [7,10]. When using aluminium-titanium-boron master alloy as the grain refiner, $TiAl_3$ particles will dissolve and introduce solute titanium in to the melt, while TiB_2 remains as a solid dispersion in the melt [6-7,11]. TiB_2 particles have the order of 0.5 to 5 μm. Although there is still a debate about precise nucleation mechanism, however, for wrought alloys it is generally thought that the mechanism involves nucleation of aluminium on layers of $TiAl_3$ which are formed and stabilised on specific facets of TiB_2 particles [7, 11-12].

The weakness of grain refiner is the fading that occurs within a period of time. Fading may be caused by settling, agglomeration and poisoning of nucleant particles [6-7]. The density of TiB_2 (4.5 g/cm^3) is larger than molten aluminium (2.3 g/cm^3), that makes the particles settle down the furnace [7,13-14]. Presence of borid particles may lead to agglomeration that speeds up the settling

process. During the fast settling the large agglomerate also collides with the smaller one and becomes larger [6-7,13]. Agglomeration also occurs when TiB_2 combines with oxide film and make fast settling [15]. While poisoning of Al-5Ti-1B grain refiner is commonly caused by other elements such as silicon, zirconium, chromium, iron and tantalum [7-8,11-12,16]. When the melt has silicon content exceed 2 %, the coarsening effect will start and extend with the higher silicon content [17-18]. It is also known that addition of AlTiB grain refiner to zirconium containing melt would result quick poisoning. $TiAl_3$ layer can be displaced in the presence of zirconium and tantalum. The poisoning can happen by subtitution of element in $TiAl_3$ layer [7,12]. This research was purposed to study the fading mechanism of Al-5Ti-1B grain refiner in AC4B alloys produced by low pressure die casting (LPDC) process.

2. EXPERIMENTAL METHOD

The melting of AC4B was conducted in reverberatory furnace with the capacity of 500 kg at 810 ± 5 °C. Then aluminium was poured in to the preheated ladle and trapped hydrogen was eliminated by using Gas Bubble Floatation (GBF) for 8 minutes. Rod Al-5Ti-1B grain refiner was added at the begining of the GBF process, with the amount of 0.081 and 0.115 wt. % Ti. Molten metal was then injected through LPDC machine at 700 – 710 ^oC. Fading was observed through the changes of hardness, tensile strength and microstructure for a period of 0 – 2 hour. Samples were taken from thick and thin area of the component to see effect of heat transfer on grain refinement and fading.

3. RESULTS AND DISCUSSION

The microstructure of Al-5Ti-1B grain refiner is presented in Figure 1. The microanalysis of each position is tabulated in Table 1. There are white and grey phases as the matrix. Small white phase is found evenly distributed in the matrix. The white phase has 20.47 wt. % Ti and 53.91 wt. % B. By converting this value to atomic percentage, the white phase can be assume as TiB_2 particle. The similar method was also used to point 2 and 3, point 2 is AlB_2 and point 3 is AlB_2 combined with TiB_2. According to solute paradigm, boride and the other particles can act as nucleating subtrate[19].

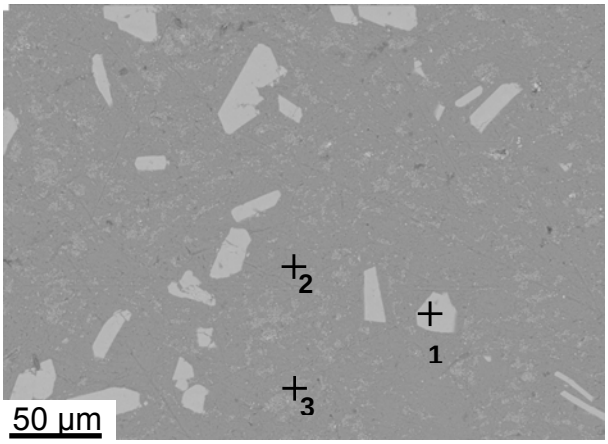

Figure 1. Microstructure of Al-5Ti-1B grain refiner.

Table 1. Microanalysis of Al-5Ti-1B grain refiner at positions shown in Figure 1.

Posi-tion	Content (wt. %)			Color	Phase
	Al	Ti	B		
1	25.62	20.47	53.91	white	TiB_2
2	36.43	0.34	63.23	grey	AlB_2
3	33.24	9.66	57.10	white	$Al\ B_2$ and TiB_2

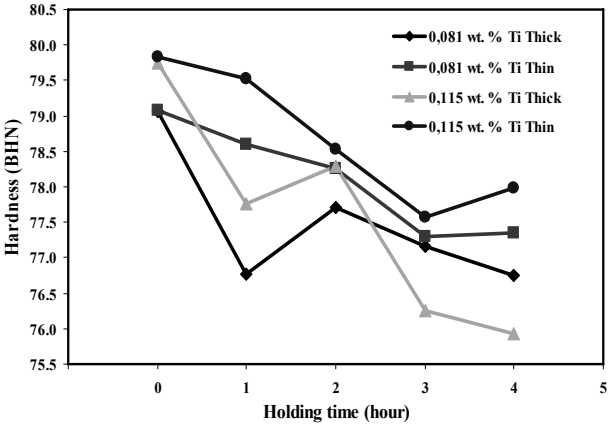

Figure 2. The effect of Ti addition and the sample position on the hardness of AC4B alloys produced by LPDC process for 4-hour period.

The change of hardness with the increase in holding time is provided in Figure 2. The hardness of thin section is generally higher than thick section due to higher solidification rate.

Samples with addition of 0.081 wt. % Ti at thick section shows that the longer the holding time, the lower the hardness of LPDC products. After 4 hours, the hardness dramatically decreased to 78 BHN. Similar trend was found for thin section, as well as for addition of 0.115 wt. % Ti.

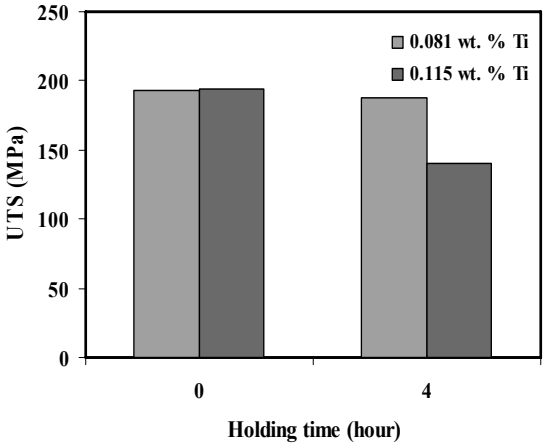

Figure 3. The change of ultimate tensile strength (UTS) of AC4B alloy produced by LPDC after 0 and 4 hours, with addition of 0.081 and 0.115 wt. % Ti.

The change of tensile strength of AC4B alloy produced by LPDC after 0 and 4 hours can be seen in Figure 3. This shows the declining of ultimate tensile strength for both 0.081 and 0.115 wt. % Ti after 4 hours. After 4 hours of LPDC process, the alloy with addition of 0.081 and 0.015 wt. % Ti underwent a decline in tensile strength for 5.6 and 54.1 MPa, respectively. The tendency in tensile strength is similar with that in hardness. Both hardness and tensile strength are parameters of resistance of materials to plastic deformation, so the values are generally proportional [20].

Microstructures of AC4B alloy processed by LPDC with 0.081 and 0.115 wt. % Ti addition are provided in Figures 4 and 5, respectively. It is clear that the dendrites are smaller in the thin section than those in the thick section. Both sections show that the longer the holding time, the larger the dendrites, confirming the results of hardness and tensile tests.

The secondary dendrite arm spacing (SDAS) was quantitatively measured and the results are presented in Figure 6. After 4 hours of LPDC, the size of dendrites in alloy with 0.081 wt. % Ti addition rises by 5.4 μm and 12.7 μm at thick and thin sections, respectively. Alloys with addition of 0.115 wt. % Ti also showed similar results, in which the size of SDAS increases by 14 μm and 7.7 μm at thick and thin sections, respectively.

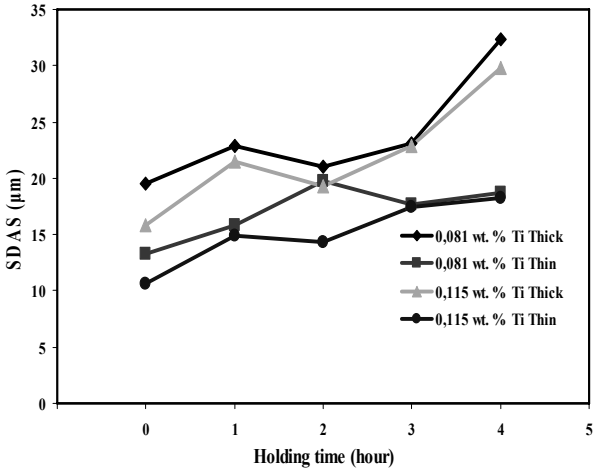

Figure 6. Change in secondary dendrite arm spacing (SDAS) in 4 hours in AC4B alloys added with 0.081 and 0.115 wt. 5 Ti in thick and thin areas.

The change of microstructure of AC4B alloy with addition of 0.081 wt. % using SEM and EDAX for 4 hours period is shown in Figure 7. The results of microanalysis of each point are tabulated in Table 2. The results show that the longer the holding time, the more sparsely distributed the Al_2Cu phase. This tendency is shown both in thick and thin samples. While the Al-Si eutectic phase tends to be coarser by the increase in holding time. The larger size of Al_2Cu, Al-Si eutectic phases and dendrites is correlated with the decrease in hardness and tensile strength of the alloys. Trace of titanium was observed for 0.64 % at point 5 of thick sample of 0 hour (Figure 7 (a)). This may indicate the presence of $TiAl_3$ particle at this point. Therefore, it confirms the mechanism of grain refinement by the presence of nucleant particles in the microstructures that seed the growth of dendrites in the molten metal.

4. CONCLUSIONS

1. The longer the holding time, the lower hardness and the tensile strength of AC4B alloy. On the other hand, the longer the holding time, the higher the secondary dendrite arm spacing (SDAS).
2. The examination using SEM and EDAX shows the presence of titanium that indicates the presence of nucleant particles, particularly $TiAl_3$.
3. The result shows that there is a fading phenomenon in AC4B alloys produced by LPDC process which occurred after 0 hour.

Abstract

The purpose of this research is to find a suitable aluminum alloy for two-piece carbonated soft drink can body material in order to reduce the material thickness from 0.280 to 0.270 mm and thus a production cost. Aluminum alloy AA3104 has been used for many years as a carbonated soft drink can material through deep drawing process followed by wall ironing process until a specific desired can height is obtained. Due to inside pressure on the filled can, the can need to have enough strength to prevent deformation, especially on the bottom area of the can (dome). By reducing material thickness, the strength of the can will also reduce dramatically. For this reason, the material needs to be developed to get a suitable strength, while at the same time retains its good formability. In this research, aluminum alloy AA3104 containing 3 variations of titanium composition were prepared, i.e. Ti 0.00%, Ti 0.010% and Ti 0.013%. The analysis including chemical composition, surface roughness, microstructure, and precipitate resulted from the addition of titanium were carried out. Mechanical properties including tensile, LDR, and formability also have been done. Analyses on the final cans including dome reversal pressure, axial load, and can dimension were also included. The can body measuring data to find the average chart, range chart and Cpk index were done by using a commercial software. As a production process simulation, the strength test also has been done after heating the material at 210°C for 10 minutes. Surface roughness analysis shows that the addition of titanium results in better sheet surface of aluminum alloy AA3104. Microstructure analysis shows that the addition of titanium promotes precipitation on aluminum alloy AA3104. XRD analysis shows that the addition of titanium forms Ti_3Al precipitate while the sample containing 0.013% of titanium has better distribution of Ti_3Al precipitate. Mechanical properties test results show that the addition of titanium increases yield strength, tensile strength and elongation of aluminum alloy AA3104. By increasing the yield strength and tensile strength will also increase the strength while increasing of elongation will increase formability of aluminum alloy AA3104. On the deep drawing and wall ironing processes simulation by using aluminum alloy AA3104 containing 0.013% titanium with 0.270 mm thickness, the results show that the tear off rate reduces from 60 ppm to 23 ppm, dome reversal pressure increases 4.3% and axial load increases 6.74%. Heating the material at 210°C for 10 minutes reduces the yield strength, tensile strength, increases the elongation, and reduces the dome reversal pressure and axial load. Stability and capability study case with 0.270 mm thickness indicates that the material confirms customer requirements. It then can be concluded that the aluminum alloy AA3104 containing 0.013% of titanium with the thickness of 0.270 mm can be used in commercial production for two-piece carbonated soft drink cans.

Keywords : *Two-piece can, deep drawing, drawn wall ironing, aluminum alloy AA3104, formability, yield strength, tensile strength, dome reversal pressure, elongation, axial load strength, tear off rate.*

Introduction

Aluminum alloy AA3104 is commonly used for carbonated soft drink can body with drawn wall ironing (DWI) process, this alloy is called $Al_{12}(Fe,Mn)_3Si$. The reason of using aluminum alloy

is because easy to form and non toxic[1]. The weakness of aluminum is low strength, so that will effect to the low strength of the dome of can when the thickness is reduced for production cost saving purpose. In the DWI can industry, 70% of production cost is from aluminum material. In order to reduce the thickness from 0.280 mm to 0.270 mm, small amount of titanium is added to the alloy to catch the can strength within the desired specifcation.

Experimental.

Three types of aluminum alloy AA3104 with variation titanium content are prepared for this research, i.e. Ti 0.00%, Ti 0.010%, Ti 0.013%, and the following composition is measured using Spark OES.

Table 1 Chemical Composition of Sample

Element	Alloy 1	Alloy 2	Alloy 3
	Content (weight %)	Content (weight %)	Content (weight %)
Si	0.130	0.130	0.130
FE	0.420	0.420	0.420
Cu	0.220	0.210	0.210
Mn	1.000	1.000	1.000
Mg	1.120	1.120	1.120
Zn	<0.0001	<0.0001	<0.0001
Ti	**<0.0001**	**0.010**	**0.013**
Cr	0.030	0.031	0.034
Ni	0.016	0.016	0.016
Pb	0.003	0.002	0.003
Sn	0.002	0.001	0.002
V	0.011	0.011	0.012
Cd	0.002	0.001	0.002
Al	97.040	97.050	97.040

Results and Discussion

Figure 1, 2 and 3 showed that the precipitation area of aluminum sheet alloy AA3104 on the top and longitudinal surface increase by adding of titanium up to 0.013%. This precipitation influence of the material strength.

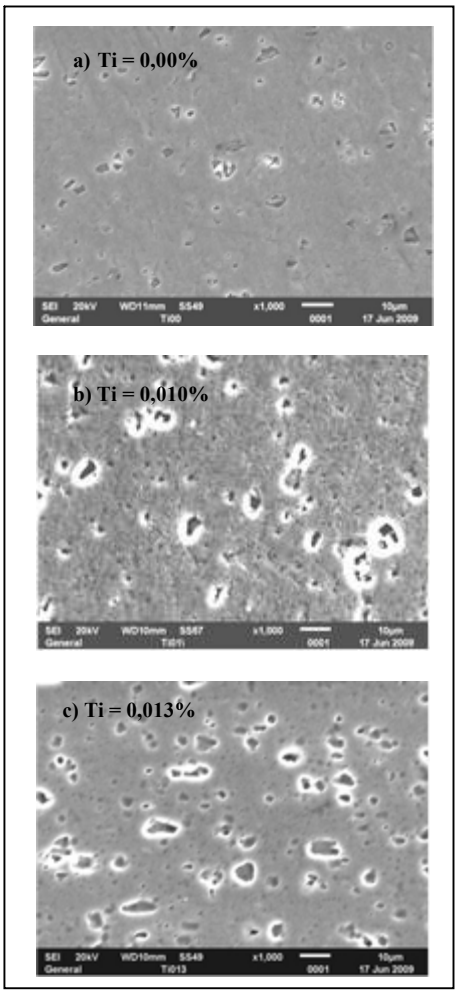

Figure 1. Micro Structure of Top Surface Aluminum Alloy Sheet AA3104 a) Ti = 0,00%, b) Ti = 0,010% and c) Ti = 0,013%

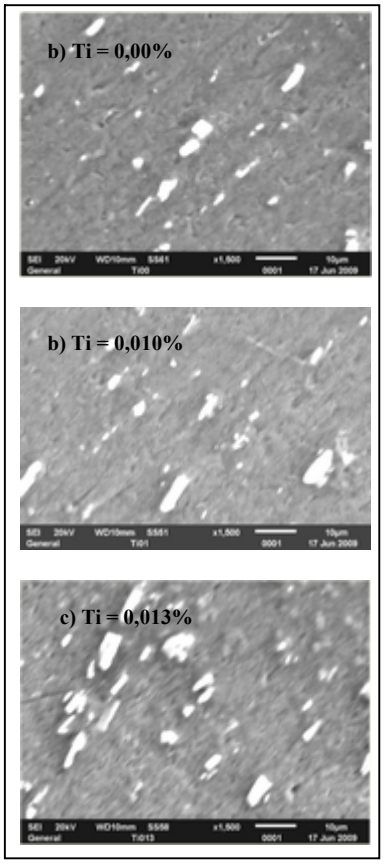

Figure 2. Micro Structure of Longitudinal Surface Aluminum Sheet Alloy AA3104 a) Ti = 0,00%, b) Ti = 0,010% and c) Ti = 0,013%

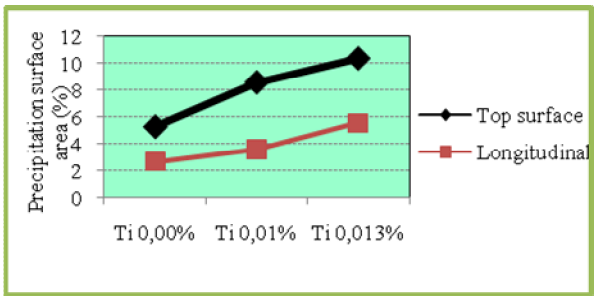

Figure 3. Precipitation Area of Top and Longitudinal Surface Aluminum Sheet Alloy AA3104 with Ti content 0,00%, 0,010% and 0,013%

Figure 4, showed that the sheet surface of Aluminum Alloy AA3104 with Ti content up to 0.013% has uniform particles and less roughness for both Ra and Rz scale, in this case titanium influences the grain size of aluminum alloy or titanium as the grain refiner of aluminum alloy[2]. The fine grain on sheet has an effect to increase of elongation and make a better formability during drawn wall ironing process (DWI).

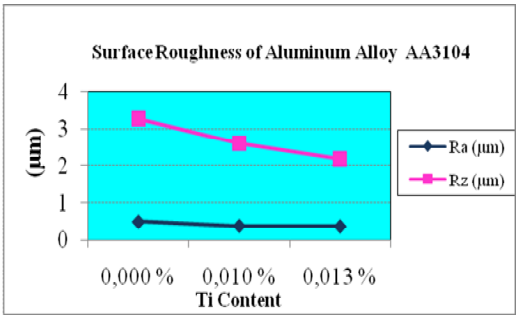

Figure 4 Surface Roughness Aluminum Alloy AA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013%

Figure 5 and 6, showed the tensile and yield strength test result for aluminum alloy AA3104 with the content of Ti = 0.00%, Ti = 0.010% and Ti = 0.013%. For this analysis, the sample was prepared according to the standard JIS 2201 (13B). The sample with titanium content up to 0.013% has tensile strength 3.02% and yield strength 3.52% above the sample without titanium. This is because the titanium formed intermetallic phase $AlTi_3$ and changed the rectangular grain to globular [3]. Tensile and yield sterngth are needed in relation to the can strength, as far as in good formability during DWI process.

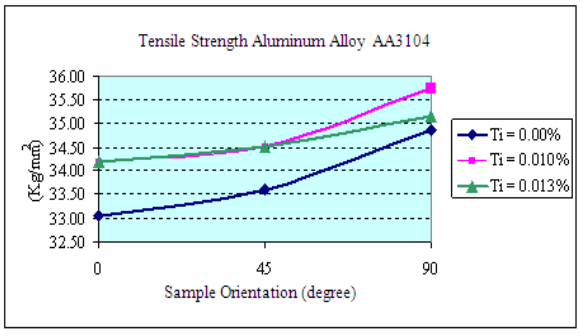

Figure 5 Tensile Strength Aluminum Alloy AA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013%

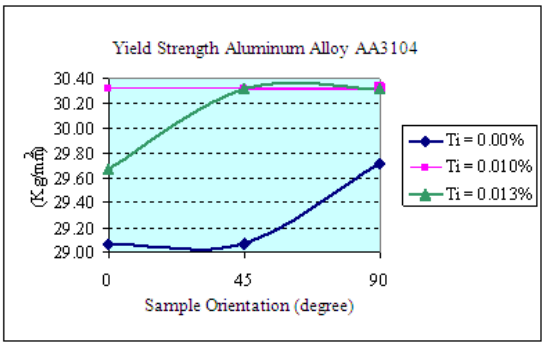

Figure 6 Yield Strength Aluminum AlloyAA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013%

The elongation test result as shown on figure 7 also increase about 46.32% compared to the sample without titanium, this phenomena is related to the finer grain size for sample with titanium content. The material with higher elongation should have better formability for deep drwing process.

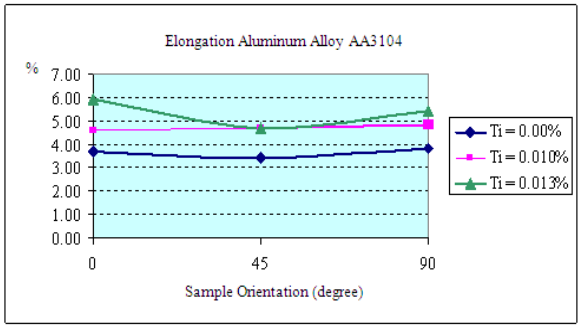

Figure 7 Elongation Aluminum AlloyAA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013%

Figure 8 is the analysis result of Limiting Drawing Ratio for the aluminum alloy AA3104 versus tear off rate during DWI process using Minster Cupper DAC-150-84 and Ragsdale Body maker machine. This analysis is conducted to find out the best LDR ratio in order to have the best tear off rate during DWI process. The best LDR ratio is 1.50.

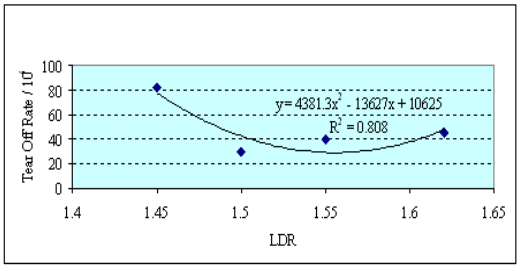

Figure 8 Limiting Drawing Ratio VS Tear Off Rate for DWI Process

Dome reversal pressure (DRP) is the plastic deformation on the dome area after the can is pressured from inside. Since the can will has inside pressure after filling, DRP is the important parameter on carbonated soft drink can. International standard for DRP is minimum 90 PSI.

Figure 9, showed the dome reversal pressure (DRP) for the two-piece aluminum DWI cans are made using aluminum alloy AA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013% before and after baking 210°C for up to 10 minutes. The result shown that the titanium content on the aluminum alloy AA3104 effected to increase the DRP. This is related to the above explanation regarding to the tensile and yield strength.

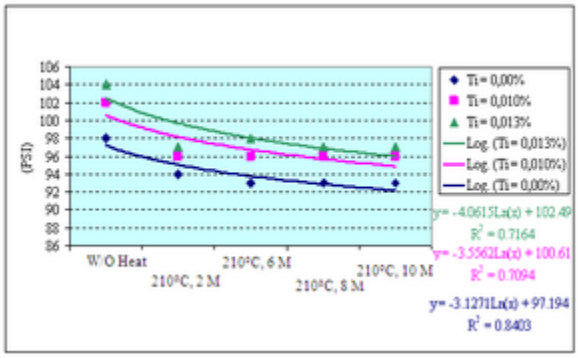

Figure 9 Dome Reversal Pressure (DRP) Without and With Heating Process of Finished Can

Axial load is the can body strength against the verical load. The weak point is in the middle of can body area. This simulation test is related to the closing process with double seaming system. Figure 10 showed that the axial load resistand of can body using aluminum alloy AA3104 with titanium content up to 0.013% have higher axial load resistance compared to the 0.00% titanium content , and reduced after baking for all of them.

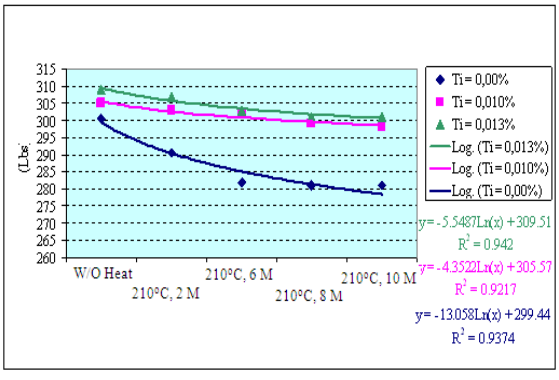

Figure 10 Axial Load Resitance Without and With Heating Process of Finished Can

Tear off rate is the total failure of the cans per million (ppm) during DWI process. Figure 11 showed that the tear off rate for the aluminum alloy AA3104 with titanium content up to 0.013% is better compared to the 0.00% titanium content. This is related to the elongation of material as already explained earlier.

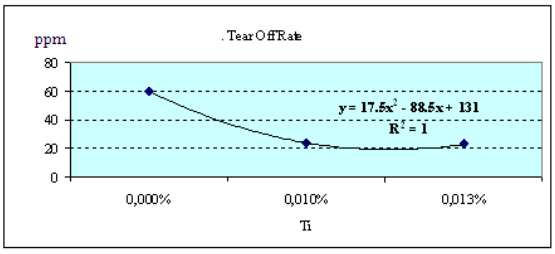

Figure 11 Tear Off Rate of DWI Process Using Aluminum AlloyAA3104 with Ti = 0.00%, Ti = 0.010% and Ti = 0.013%

The stability and capability process also was investigated on this research using SPC software – (NWA Quality Analyst 5.1) for aluminum alloy AA3104 with 0.013% Ti content, 0.270 mm thickness. Using the specific formula, the result was stable and capable, that is mean the material able to use for commercial production [4].

Conclusion

Based on the above investigation, by adding titanium up to 0.013% on the aluminum alloy AA3104 effected to the increasing of precipitation, finer grain size, more uniform particle, formed the intermetallic phase $AlTi_3$ and changed the rectangular grain to globular. These phenomena influence to the mechanical properties of material, i.e. increase tensile strength, yield strength, and elongation.

ABSTRACT

A study of the effect of TiO_2 addition on electrical characteristics of Fe_2O_3 ceramic for NTC thermistor has been performed. The aim was to know whether or not the TiO_2 addition can be made as a method for controlling electrical characteristics of the Fe_2O_3 ceramic for NTC thermistor. Powder of Fe_2O_3 derived from mineral containing Fe_2O_3 and TiO_2 with concentration of 0, 10 mole % and 20 mole % were mixed homogeneously. The mixed powder was pressed with pressure of 4 ton/cm^2 to form pellets. The green pellets were sintered at 1200^{o}C for 2 hours in air. After sintering, some pellets were analyzed by using an x-ray diffractometer (XRD) and a scanning electron microscope (SEM). Electrical resistivity of the pellets was measured at different temperatures. The XRD data showed that the pellets crystallized in Fe_2O_3 hematite. A second phase of Fe_2TiO_5 was found in the ceramics added with TiO_2. The SEM data showed that the grain size of the ceramics decreased with increasing TiO_2 concentration. It was known from the electrical data that the thermistor constant (B) and room temperature resistivity (ρ_{RT}) of the ceramics increased following the increase of the concentration of TiO_2. The value of (ρ_{RT}) and (B) of the Fe_2O_3 ceramics made in this work fits the market requirement.

Keywords: *Thermistor, NTC, Fe_2O_3, TiO_2, ceramic.*

1. INTRODUCTION

NTC thermistors are widely used for many kinds of instruments due to its special characteristic [1]. An NTC thermistor works based on the fact that the resistance of the thermistor decreases/increases when the surrounding temperature increases/decreases. Generally the NTC thermistors are made of spinel ceramics consist of transition oxide such as MnO, NiO, CuO, ZnO and CoO [2-12]. However, the thermistor can also be made from Fe_2O_3 ceramics due to its semiconductive characteristic[13-15].

In order to get capability in thermistor production and to step up the added value of mineral abundant in Indonesia, some researches have been carried out [13-15]. In our previous works [13], Fe_2O_3-based thermistor ceramics from yarosite mineral (containing Fe_2O_3) had been well produced and characterized. It was found that those Fe_2O_3 ceramics had relatively low resistivity. The resistivity of intrinsic Fe_2O_3 ceramic should be large due to its large band gap. So, the low resistivity may be due to the presence of TiO_2. It was found in our previous study that TiO_2 can lower the resistivity of the Fe_2O_3 ceramics [15].

In order to get Fe_2O_3 based-NTC thermistor having variable resistivity some efforts can be done. One of them is by adding additive. The addition of additive such as TiO_2 can be used as a method for controlling resistivity. Theoretically the capability of TiO_2 in lowering the resistivity will be limited by the solubility of TiO_2 in Fe_2O_3. Therefore the addition of TiO_2 with concentration larger than the solubility may increase the resistivity of the Fe_2O_3 ceramics. In this study the effect of TiO_2 addition with concentration of 10 mole % and 20 mole % on the electrical characteristics of the Fe_2O_3 was studied.

2. METHODOLOGY

Powder of Fe_2O_3 derived from yarosite mineral was mixed with TiO_2 powder with concentration of 0, 10 and 20 mole % TiO_2. The processing method for deriving Fe_2O_3

from mineral can be found elsewhere [13]. The mixture was mixed in an electrical blending machine. The homogeneous mixture was pressed with pressure of 4 ton/cm^2 to form pellets. The green pellets were sintered at 1200^{o}C for 2 hours in air. A structural characterization was done by using x-ray diffraction (XRD). Microstructure of the pellet was examined using a scanning electron microscope (SEM). Electrical characteristics were evaluated by measuring the resistivity of the pellets at various temperature from room temperature to 100^{o}C. Thermistor constant (B) and room temperature resistivity (r_{RT}) were determined from ln Resistivity versus 1/T curve based on equation (1) while sensitivity (a) was calculated using equation (2).

$$\rho = r_o \exp (B/T) \quad \ldots\ldots (1)$$

where, ρ = resistivity (ohm.cm), ρ_o = a constant (ohm.cm), B = Thermistor constant and T = temperature in Kelvin (K).

$$\alpha = B/T^2 \quad \ldots\ldots (2)$$

where, α = sensitivity (%/K), B = Thermistor constant in Kelvin (K) and T = temperature in Kelvin (K).

3. RESULTS AND DISCUSSION

3.1 XRD analyses

Figure 1-3 shows that all ceramics crystalized in Fe_2O_3 hematite (JCPDS 33-0664). The major peaks are from the Fe_2O_3 hematite, however, some additional peaks are clearly seen in Figure 2 and 3. These figures are belong to the samples containing 10 % mole and 20 mole % TiO_2. These additional peaks are from second phase. The second phase may be additive of TiO_2 or a reaction product of TiO_2 and Fe_2O_3. The result of analyses shows that the second phase is Fe_2TiO_5 (JCPDS 41-1432). During sintering a part of Fe_2O_3 reacted with TiO_2 additive following a reaction of equation (3).

$$Fe_2O_3 + TiO_2 \rightarrow Fe_2TiO_5 \quad \ldots\ldots (3)$$

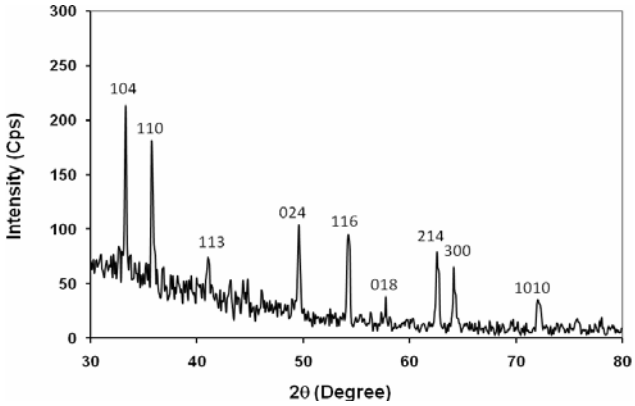

Figure 1: XRD profile of Fe_2O_3 ceramic without TiO_2.

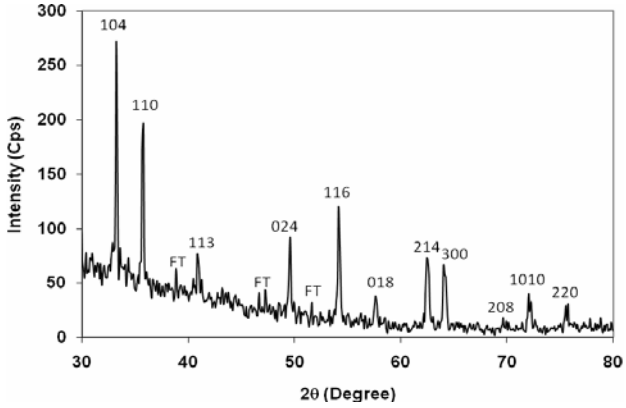

Figure 2: XRD profile of Fe_2O_3 ceramic with 10 mole % TiO_2 addition. FT is peak from the second phase of Fe_2TiO_5.

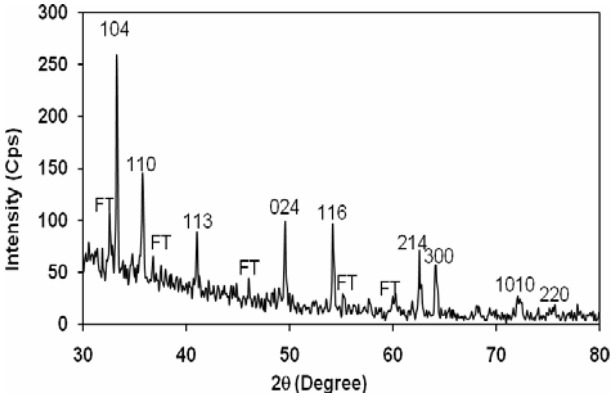

Figure 3: XRD profile of Fe_2O_3 ceramic with 20 mole % TiO_2 addition. FT is peak from the second phase of Fe_2TiO_5.

ISSN 114-1284

a. SEM analyses

It can be seen from Figure 4 that grain of the Fe_2O_3 ceramic containing TiO_2 is smaller than that of the ceramic without TiO_2. The grain becomes smaller following the increase of the concentration of the TiO_2 added. Quantitatively the decrease of grain size of the ceramic as function of the TiO_2 concentration is shown in Table 1. The decrease of the grain size is caused by the presence of the second phase of Fe_2TiO_5 which are segregated at grain boundaries. The second phase inhibited the grain growth during sintering.

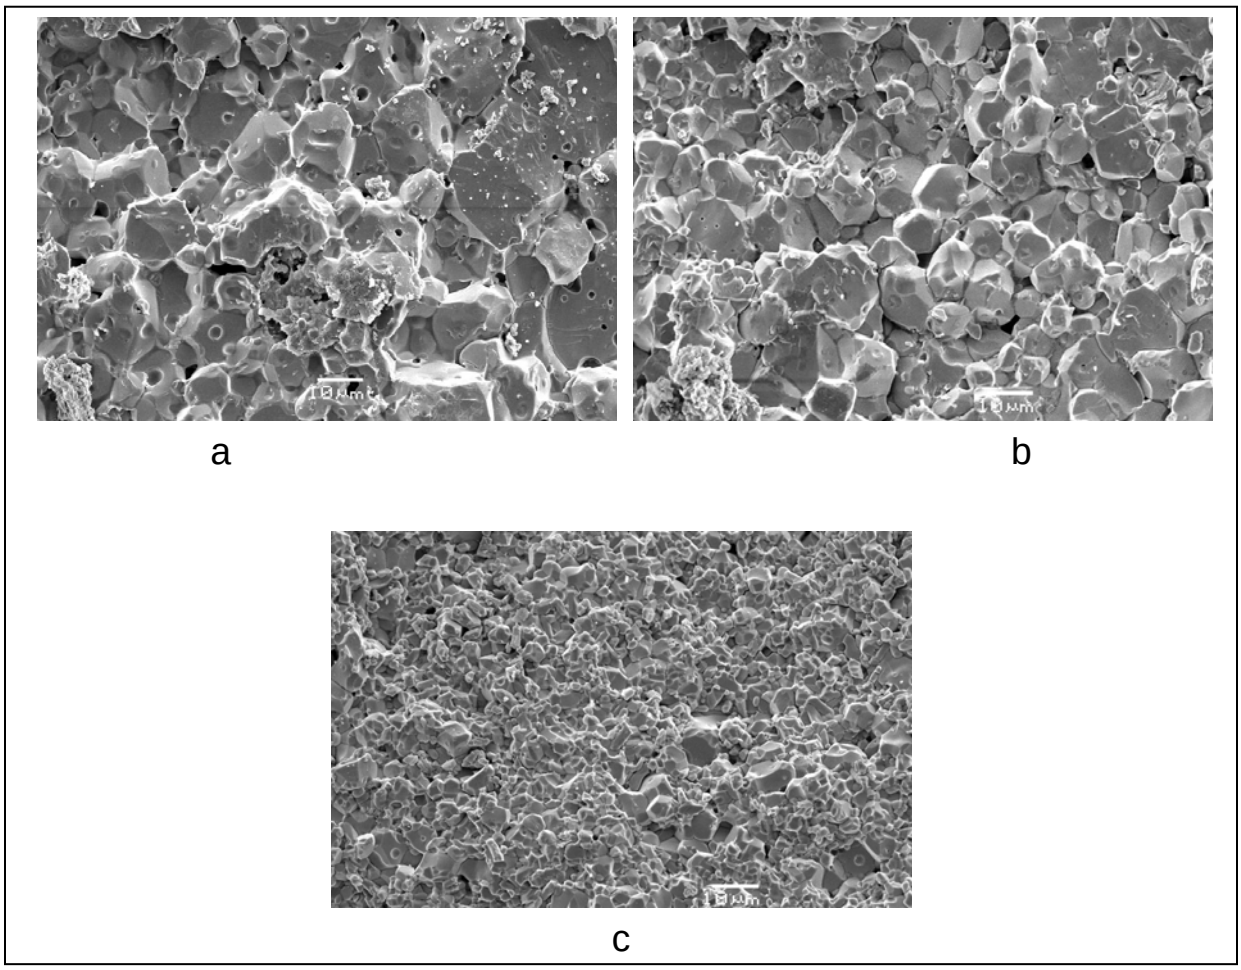

Figure 4: Microstructure of Fe_2O_3 ceramics with and without TiO_2 addition.

a. Without TiO_2, b. With 10 mole % TiO_2 and c. With 20 mole % TiO_2.

Tabel 1. Grain size of Fe_2O_3 ceramics as a function of TiO_2 concentration.

No.	Concentration of TiO_2 (Mole %)	Grain size (μm)
1.	0	19.6
2.	10	14.4
3.	20	9.3

b. Electrical Characteristics

Electrical data of the TiO_2 added-Fe_2O_3 ceramics is shown in Figure 5 and Table 2. The electrical data of Fig. 5 shows that the electrical characteristic of the ceramics follows the NTC tendency expressed by an Arrhenius equation of eq. 1 [2,3,7-15]. As shown in Table 2 and Fig. 5, the room temperature, thermistor constant and sensitivity of the ceramics increases with the increase of TiO_2 concentration. The responsible factor for increasing the resistivity, thermistor constant and sensitivity is the presence of second phases Fe_2TiO_5 which is segregated at grain boundaries. The presence of the second phase resulted in ceramics with small grain. The grain boundaries are scattering center for charge carrier, so the many the grain boundaries are, the large the resistivity is. This situation also causes the thermistor constant and sensitivity become large. Comparing to the value of room temperature resistivity, B and α for the industry (where the room temperature resistivity is not larger than 1 Mohm, B and α are equal or larger than 2000K and 2.2%/K, respectively)[6], the room temperature resistivity, B and α of all ceramics fit the requirement.

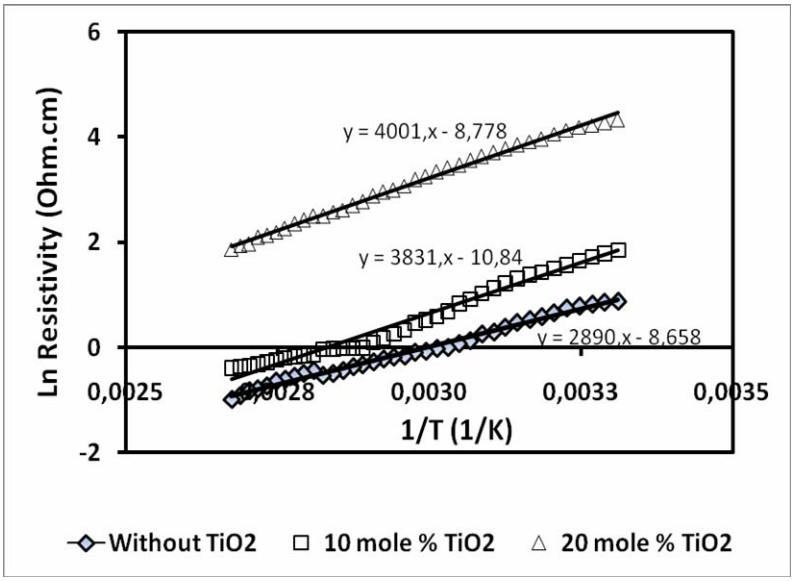

Figure 5: Ln Resistivity vs 1/T for Fe_2O_3 ceramics with and without TiO_2.

Tabel 2. Electrical characteristics of Fe_2O_3 with and without TiO_2 addition.

No.	Composition	B (K)	α (%/K)	ρ_{RT} (Kohm)
1.	Without TiO_2	2890	3,21	0,98
2.	10 mole % TiO_2	3831	4,26	1,93
3.	20 mole % TiO_2	4001	4,45	4,56

4. CONCLUSION

The grain size of the Fe_2O_3 ceramics decreases by addition of TiO_2 because the added TiO_2 reacted with a part of Fe_2O_3 forming Fe_2TiO_5, segregated at grain boundaries and inhibited grain growth during sintering. The addition of TiO_2 increased the room temperature resistivity (ρ_{RT}), the thermistor constant (B) and sensitivity (α) of the Fe_2O_3 ceramics through changing the microstructure. The value of (ρ_{RT}), (B) and (α) of the Fe_2O_3 ceramics made in this work fits the market requirement.

AKCNOWLEDMENT

The authors wish to acknowledge their deep gratitude to Mr. M. Yamin for his help in preparation of Fe_2O_3 from yarosite mineral.

ABSTRACT

This research is aimed to investigate the detail process of Vacuum Assisted Resin Infusion (VARI), which the most important method in composite manufacturing. The Kenaf fiber is used as reinforce, whereas as matrix is used Unsaturated Polyester Resin (UPR). There are two preform used here, they are woven and uni-directional (UD). VARI method is performed to get high quality impregnation composite. Parameter to be identified are the inlet-outlet position and type of preform. Several tests and characterization have done to revealed the properties of composite and its mixture elements. SEM analysis is done to identified the fiber's morphology and degree of impregnation. Viscosity of resin is measured by brokfield test to found out time needed during VARI process. Front flow pattern of resin is observed by camera image incrementally. For woven preform, wetting process done easier than uni-directional (UD). And Diagonal inlet-outlet position let the most efficient of wetting process.

Keywords : *Composite, vacuum, preform, resin flow*

1. INTRODUCTION

The vacuum assisted resin infusion (VARI) offers many advantages over the traditional resin transfer molding such as lower tooling cost and room temperature processing [1]. VARI has chiefly been used to produce large component in short series, such as boats, offshore structures, vehicle body panel, front end for high speed train engines [5]. VARI process simply can be divided into 3 (three) steps: First, pre-molding, fiber preform is put inside the flexible vacuum bag. In this step, inlet and outlet is adjusted to avoid cavity that could make the leakage. Next, vacuum process, by adequate vacuum pressure the resin will pull-in and get into vacuum so the resin will flow and impreg into fiber preform. Finally, at certain time, the curing process will occurred and resin will get solidified. So composite is taken out of the mold. Schematically, steps are described by fig.1 [1].

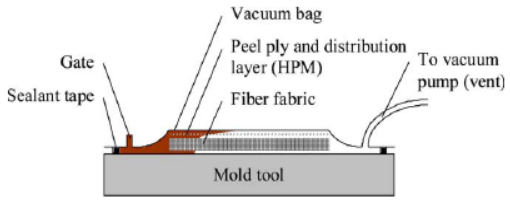

Figure 1 : VARI method

This study focuses on flow pattern of fiber preform and composite properties. Wetting process is the critical point in Vacuum Assisted Resin Infusion (VARI). Incomplete impregnation will lead to defective parts containing dry spots. So processing parameters such as the number and location of inlet and outlet parameter need to be properly set [1]. Preform role as a significant parameter wheather difficult or ease to be flowed by resin. There are two methods in approaching VARI process. They are experimental observation and modeling/simulation. Experimental describe more detail the process and without any simplification at circumstance condition. But, it is very costly due to many experiments that must be done. In other hand, simulation approach give more sophisticated analysis of process. Of course, need to be implemented complex mathematical model, in spite of simplification maybe applied to make it possibly countable.

2. METHOD

Morphological properties of fiber and preform were carried out by using Scanning Electron Microscope - SEM (type JEOL 330). In term of resin curing, the reaction is exotermic. As resin flow, time elapsed before solidification is critical point at pre-cure analysis. Time vs viscosity of resin is plotted by measuring viscosity of the catalized-resin by Brokfield Inst (manufactured Brookfield Engineering Analysis, Inc). In making composite, it was prepared two type of preforms, they are woven and uni-directional (UD) of kenaf fibers. Numbers of fibers stacking here are single layer and 2 (two) plies. During resin flowing, wetting process is recorded incrementally. So by marking the sign, each step/front flow of

resin flowing will be recorded. Degree of impregnation of resin through the fibers is a analyzed by scanning electron microscope. VARI process is powered by vacuum pump with the capacity of vacuum 4 cfm, 5x10-1 Pa.

3. RESULT

3.1. VARI system

VARI system that was designed consist of single vacuum pump, as schematically seen at fig.2. On between port outlet and the pump is placed resin-trap to avoid unintended suck of resin through the pump. On the figure, resin inlet is dummy, whereas the actual experiment will be described later. Vacuum bag with fiber preform inside is placed on the glass table as half molding. As we know another half molding is roled by the vacuum bag.

.

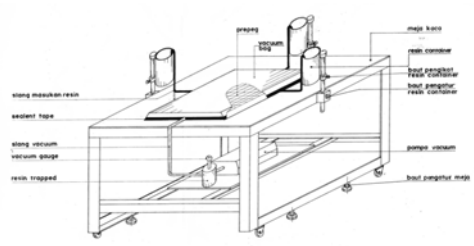

Fig 2 : VARI designed

3.2 Resin curing properties

As mentioned before, to identified the curing properties of resin , we measure the viscosity of resin by Brookfield method. And the result as fig.3 showed that resin curing time is about 15 minutes, which is occurred at 0.1 % hardener. This mean, to process the composite, resin should be completely distributed on whole preform shorter than 15 minutes. Otherwise, the resin will get stuck before complete wet process.

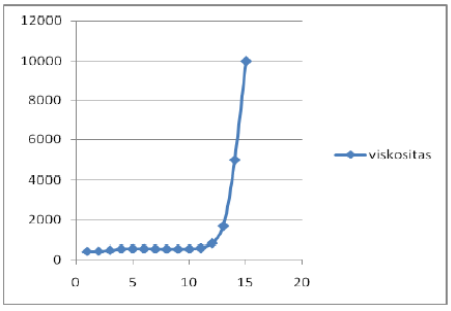

Figure 3: Time vs viscosity of resin

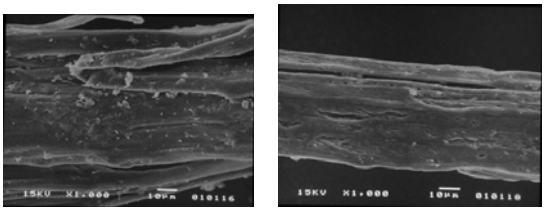
3.3 Fiber - Preform geometry

As received , the fiber is identified regarding the geometry and surface morphology. Figure 4 & 5 describe below more detail. Geometry of preform is given by camera image, whereas surface morphology of fiber is resulted from SEM characterization.

(a) (b)

Fig 4 : camera image of preform : (a) woven ; (b) unidirectional-UD



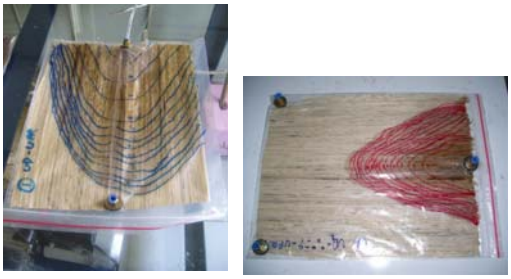
(a) (b)

Fig 5 : SEM image of fiber from prefom : (a). woven ; (b). unidirectional-UD

3.4 Resin front flow patterns

Incrementally observation of resin flow is aimed to understand how does the resin geometrically flowing. This is beneficial to predicting resin wet flow pattern for the specific shape composite.. Here, the result for several type resin front flow profile

3.4.1 Unidirectional (UD) ; I-port vs Y-port ; 1 (one) layer ; time process ± 13 minutes



(a) (b)

Fig 6 : Camera image of wetting process : (a) I- port ; (b). Y-port

3.4.2 Woven ; I-port vs Diagonal-por ; 2 (two) layer ; time process 8 minutes

Fig 7 : Camera image of wetting process : (a) I- port ; (b). Diagonal-port

3.4.3 Woven : Diagonal-port vs Y-port, 2 (two) layer, time process > 5 minutes

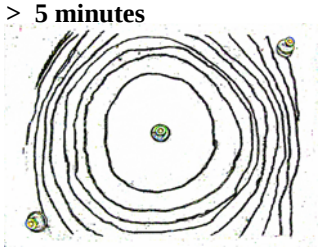


Fig 8 : Image view resin flow of Diagonal port . (the curve line refer to front flow for each minute, dimension 29x34 cm)

by measuring wetting area incrementally we could tabulate the data as given in Table 1 and fig 8.

Table 1 : Resin flow of diagonal port, woven

Time (minute)	Wetting Area (cm2)	Percent area (%)
1	178	27
2	336	51
3	442	68
4	529	81
5	653	100

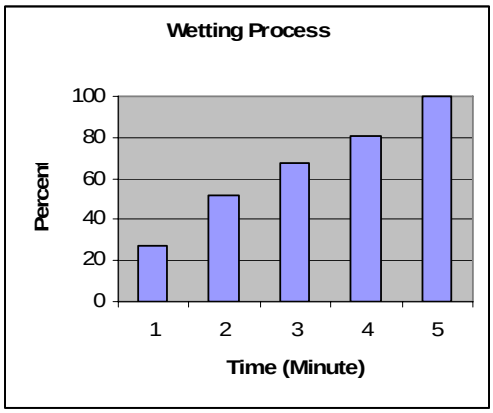

Fig 9 : Chart of resin flow of Diagonal-port, woven .

Whereas, by different condition, for Y-port, image view of resin flow is given by fig 10.

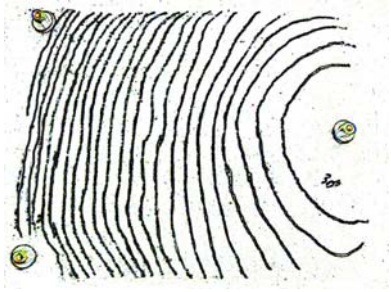

Fig 10 : Image view resin flow of Y-port . (the curve line refer to front flow, where for each line gaps mean 1/2 minutes; dimension 29x34 cm)

So did before, we can measure the area incrementally as given in Table 2 and Fig 11.

Table 2 : Resin flow of Y- port , woven

Time (minute)	Wetting Area (cm2)	Percent Area (%)
1	129	23
2	223	40
3	283	51
4	342	62
5	396	71
6	443	80
7	485	88
8	521	94
9	554	100

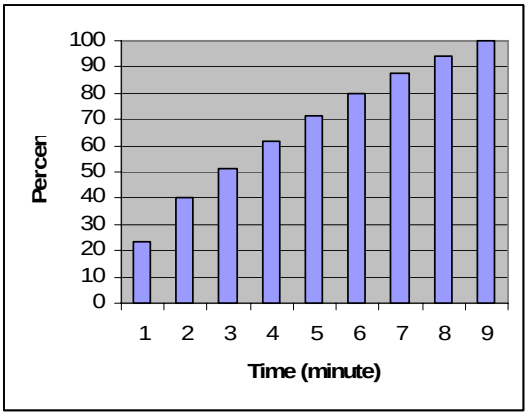

Fig 11 : Chart of resin flow of Y port ,woven

3.5 Resin Impregnation

After resin cured, a better way to identified degree of resin impregnation is observeing cross section of composite. For this purpose, SEM analysis was performed to reveal microstructure of composite as seen the result at fig. 12

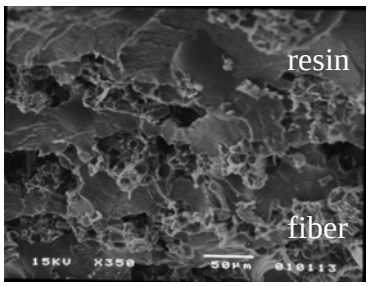

Fig 12 : SEM image of composite's cross section

4. DISCUSSION

As mentioned on previous section, here we can analyze several matter through the research. At first, by fig.3, it is simply said that for hardener content 1%, the resin will solidify by less than 15 minutes. Dramatical rise-up of viscosity after 15 minute (mixing resin + hardener) as evidence for it. Theoritically, short after this glassy state, resin change its phase from liquid into solid. This phenomena occurred due to crosslink mechanism of the resin. [4]

Fig 4 and 5 tell about fiber condition of both preform, they were woven and unidirectional (UD). Although raw material of both preform are the same, kenaf fiber, there were slightly difference between them. As a woven preform, the fiber are perpendicular to each other. Naked eye observation revealed that big portion area of vacancies inside the preform. Those big vacancies role as resin pathway. This is lead to efficient process during resin flow. Resin will flow rapidly even without resin flow media. On the other hand, for UD preform, the fibers lay on paralell manner as it's very dense condition. Through these preform, composite may has a good fiber volume fraction due to rather big portion. But as a drawback, upon manufacturing process, resin will get difficult to wet the preform due to less vacancies. And when observing fiber diameter by SEM, the image exhibit both are have the same diameter $\pm$ 50µm, fit to the previous research about kenaf fiber [3].

Fig 6 describe front flow of resin flow on UD preform. The image explain how the position inlet-outlet lead to different sucking mechanism. With the elapsed time 13 minutes (just before curing), outermost front flow of I- port reach longer distance than Y-port. It mean, I-port give more efficient wetting process than Y-port on uni-directional (UD) preform. Fig 7 show different thing. By these figure, it can be compared wetting process on woven preform according to inlet-outlet position. It was resulted that Diagonal-port has better wetting process than I-port. Where, to accomplishment of total layer, diagonal-port need sorter time than I-port, within $\pm$ 3 minutes.

Fig 8-11 describe wetting mechanism on woven preform. By those, It is clearly explained that for flowing process, resin are linearly flowing. It is proven by chart on fig. 9 and 11 : time vs percent wetting area relation. Mechanically meaning that, gradient of pressure inside the vacuum merely constant during flowing. As we know, source power that make resin to flow into the preform is gradient of pressure from inlet to otlet port due to vacuum pump. Fig 8 and 10 show that on the same preform (woven) resin flow at Diagonal – port resulted in higher efficiency. The time process cut almost 50%, so make it is highly distinct. One reason as hypothesis to explain about that is, condition of pressure gradient Diagonal-port is distributed more homogenously than I-port.

Fig 12 is SEM image of cross section of UD kenaf fiber/ UPR composite. Clean (black) area refer to resin formation after curing. Whereas white rough area represent the fiber inside resin. These observing reveal information that resin successfully impreg to the vacancies between fibers. They role as a binder among fiber. where each bundle fiber enclosed perfectly. Furthermore, at given magnification, no void observed after curing. This is as respectly achievement by VARI, to get high-fiber fraction volume for enlarging the role of fiber on composite [2].

5 . CONCLUSION

Keneaf/UPR composite has successfully manufactured by VARI method. Several parameters were performed and observed. It is reveal some conclusion. First, by comparing woven and uni directional fiber, we got that VARI process for woven preform run easier than unidirectional (UD). Second, Diagonal-port for woven reach more efficient wetting than Y-port. And third, through VARI, resin good impreg onto the fiber as seen by SEM image.

6. ACKNOWLEDGMENT

We appreciate to Research Center for Physics, Indonesian Institute of Science (LIPI) who kindly fund all matter for this research. And special thank to Herlan Abbas, who dedicated support all technical problem we have.

ABSTRACT

The characterization of ceramic pore membrane prepared by dry casting was investigated. The ceramics were made with zeolite and rice husk ash at various compositions: 100:0, 90:10, 80:20, and 70:30 %wt. The average particle size of raw material is about 70 µm. The porous ceramics were produced in several stages: zeolite and rice husk ash powder are mixed using ball mill for 0.5 h; then porous compact are formed by packing suspensions into "green" compact with a certain shape at 20 MPa using hydraulic press, and the green compact is consolidated by sintering at 900°C and 1000°C for 1 h. The porous ceramics were characterized using various parameters, such as: firing shrinkage, porosity, density, compressive strength, bending strength, Vickers hardness, as well as XRD and SEM for microscopic analysis. Experimental results indicate that the method and compositions have strong effects on the crystallinity type, physical, and mechanical properties of the synthesis products. Firing shrinkage and density test result are tend to decrease with increasing of RHA content addition and sintering temperature, but for the others test result such as porosity, compressive strength, bending strength, and hardness Vickers are linear with increasing of RHA content addition and sintering temperature.

Keywords

Porous ceramics, zeolite, rice husk ash, porosity, density

1. INTRODUCTION

Zeolites are hydrated crystalline aluminosilicates with open three-dimensional framework structures, made up of SiO_4 and AlO_4 tetrahedral linked by sharing their oxygen atom to form regular intracrystalline cavities and channels of atomic dimensions. The framework structure encloses cavities occupied by large ions and water molecules, both of which have considerable freedom of movement, permitting ion exchange and reversible dehydration. Zeolit can be represented by the formula $M_{2/n}.O.Al_2O_3.a.SiO_2.b.H_2O$ or $M_{c/n}.\{(AlO_2)_c(SiO_2)_d\}.b.H_2O$ where M is the compensating cations with valence n, a and b is silicate dan water molecule, c and d is the amount of tetrahedra of alumina and silica. Rasio d/c or SiO_2/Al_2O vary from 1 to 5.

Natural zeolites have been widely used because of their unique physical-chemical characteristics such as ion-exchange property and selectivity in sorption [4, 5]. Zeolites are the aluminosilicate minerals that have a porous structure. Zeolite pores consists of 8, 10, 12 and 14 membered of oxygen ring systems to form tube-like structure and pores that interconnected to each other. Tube-like structure can exists as one, two or three direction with different sizes. Zeolites can be classified based on their pore size; small pore within 5Å; medium pore, within 4.5 Å to 6.4 Å; and large pore within 6.5 Å - 7 Å [1] Zeolites are widely used as ion-exchange beds in domestic and commercial water purification, softening, and other applications. In chemistry, zeolites are used to separate molecules (only molecules of certain sizes and shapes can pass through), as traps for molecules so they can be analyzed. Nowadays, zeolites are also employed as alternative heterogeneous catalysts to substitute homogenous catalysts in many organic processes such as in Friedel-Crafts reaction because of its more efficient and environmentally-friendly which can eventually reduce plant corrosion and eliminate environmental problems.

It is well known that many plants have an ability to accumulate silicon compounds. One example is rice (Oryza sativa), one of the major cultivated plants in the world including in Indonesia. It is a fibrous material containing cellulose as the major constituent, lignin, and ash [2]. As the main component in the rice husk ash is the silica, it can be used as a source or added component in preparing advanced materials like SiC, Si_3N_4, elemental Si and Mg_2Si. During production of rice, huge amounts of rice husk are left as waste product. Husk is usually disposed of by combustion, thus giving rice husk ash (RHA). This by-product is produced in many places world-wide and constitutes an environmental problem due to air and water pollution. On the other side, chemical analysis shows that a white variety of RHA can contain up to 90–99% silica. It is, therefore, not unusual that this cheap source of silica may be of interest for numerous industrial uses, including the large-scale

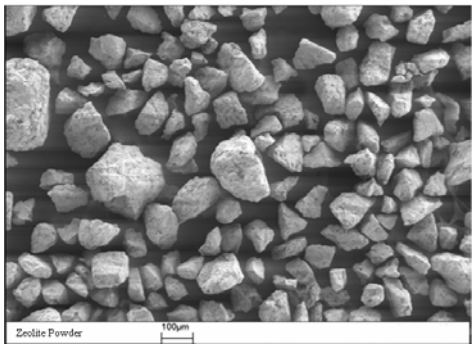
synthesis of porous ceramics. Previously, the content of rice husk ash at different combustion temperatures has been studied. The white ash that was obtained from combustion is generally 10 -15 % of the total dry weight of rice husk. The abundant rice husk ash in Indonesia is giving alternative economical sources for synthesizing zeolite pore ceramics.

Porous ceramic have potential for applications as critical components in many industries because of their inert, strong, reusable, and temperature resistant capabilities. These properties may open various field for applications, such as in thermal insulation purposes, building materials, gas separation, water treatment, and etc. A great deal of research work has been devoted to porous ceramics in the past few decades, including various fabrication techniques with different starting materials [3]. At present, porous ceramic membranes used as separation media are usually made from high purity powders such as Al_2O_3, ZrO_2, SiC, and mullite. However, high cost resulted from the expensive starting materials and high sintering temperature, which limit their applications, especially in water treatment application. Therefore, searching for cheaper starting materials with lower sintering temperature is meaningful. Porous ceramics are produced within a wide range of porosities and pore sizes depending on the application intended. The manufacture of porous ceramic is concerned with macro pores (above 0.1 μm in diameter) for microfiltration, micro pores (ranging from 0.1 μm to 2-3 nm) for ultrafiltration, and nano pores (less than 3 nm) for nanofiltration [4]. Porous ceramic are especially suitable for processes with high temperatures and harsh chemical environments or for processes were sterilizability of the membrane is important [5, 6].

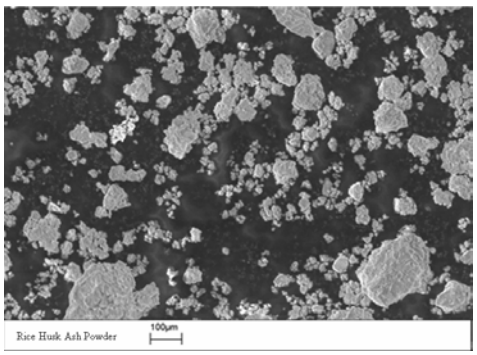
In this paper, our objective was focused on preparation of the wide-pore zeolite, a potentially interesting aluminosilicate for many catalytic applications. The objective of this paper is to explore the synthesis of zeolite using white rice husk ash as the silica source. In this study the synthesis of zeolite pore ceramics using amorphous rice husk ash which was obtained by controlled burning of rice husk, as silica sources. The brief discussion on manufacture and modification of porous ceramic with special attention to zeolite and rice husk ash are presented. The effect of each composition on performance of the ceramics not only in porosity but also in others properties, such as: firing shrinkage, density, compressive strength, bending strength, Vickers hardness, XRD, and SEM are discussed.

2. METHOD

Natural zeolite powder was obtained from Pahae, Simangumban, North Sumatera, Indonesia (figure 1.a). The main chemical compositions of the natural zeolite pahae was 60.18% SiO_2, 14.25% Al_2O_3, 11.61% CaO, 3.96% MgO, 4.41% Fe_2O_3, 3.47% K_2O, 1.64% Na_2O, 0.48% TiO_2 by weight. Meanwhile, the rice husk (figure 1.b) was obtained from Gunung Sindur, Bogor, West Java, Indonesia. Rice husk was cleaned with water and boiled with 1 N HCl for 3 h to remove impurities. Then it was burned at 900 ^oC for 2 h under oxygen atmosphere. The obtained ash was found to be an amorphous phase having the following chemical compositions: 94.18% SiO_2, 0.20% Al_2O_3; 1.50% CaO, 1.58% K_2O, and 2.54% Fe_2O_3 by weight. The average particle size of the zeolite and rice husk ash is about 70 μm (as shown in figure 1.a and 1.b). The synthesis of zeolite ceramic pore membrane was prepared by dry casting method. The mixture of zeolite and rice husk ash at various compositions: 100:0, 90:10, 80:20, and 70:30 in %wt ratio with sodium silicate (Na_2SiO_3 5 %wt) as binder agent was ball milled for 0.5 hour. After mixing process, zeolite and rice husk ash powder was then placed in cylindrical steel to obtained porous compact (green body) with a certain shape at 20 MPa using hydraulic press. Final process of synthesis, the green compact was consolidated by sintering in electrical furnace at 900 ^oC and 1000 ^oC for 1 h. After soaking the samples were furnace cooled and the specimens are ready for tested.



(a)



(b)

Figure 1. Photomicrograph of (a) natural zeolite and (b) rice husk ash as raw material

In the casting (shaping) process of ceramics, it usually used the additive (binder agent) to simplify casting process and also to control the microstructure of the material that will be produced. The main function of binder is to increase the strength before heat treatment process applied as green body. Sintering is densification process of particle in high temperature below the melting point, to increase the density and strength of material. In drying process, microstructure changes occur. The green

body obtained from dry casting process is sintered to decrease water content and eliminate the binder which is still remaining in specimen.

The density and porosity of the sintered specimens was determined by Archimedes' method. Analysis of the crystalline phases present in the sintered specimens was based on their X-ray diffraction (XRD) patterns with CuK radiation. Types of zeolite were identified by comparing the peak positions (2 and their intensities from the obtained XRD-pattern with that of pure phase). The microstructure photographs were observed on Scanning Electron Microscopy (SEM). The measurement of compressive, bending strength, hardness, and firing shrinkage were performed to confirm the mechanical properties of specimens.

3. DISCUSSION

The density and porosity of the sintered specimens were measured using Archimedes water displacement method at room temperature. The porosity and density as a function of RHA content at different sintering temperature is shown in figure 2.

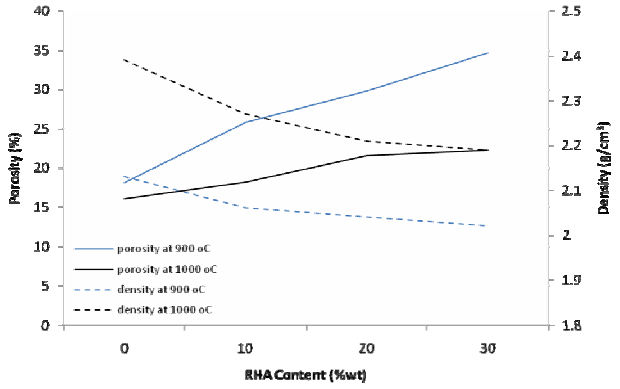


Figure 2. Effect of RHA content to the density and porosity behavior at sintering temperature 900 °C and 1000 °C

The RHA concentration addition strongly affected the porosity and density. This indicates that the porosity and density result can be widely controlled by the RHA concentration addition to the specimen. On the other hand, the density and porosity of the sample is determined almost entirely by the intrinsic Si addition of RHA itself. Porosity test results of specimen for sintering 900 °C were 18.08, 25.78, 29.69, and 34.59 %; and for sintering 1000 °C were 16.07, 18.19, 21.51, and 22.22 % measured by Archimedes method, for RHA content 0, 10, 20, and 30 wt% respectively. Density test results of "green" compact specimen were 1.45, 1.42, 1.35, and 1.34 g/cm^3 measured by Archimedes method, for RHA content 0, 10, 20, and 30 wt% respectively. After sintering process, density test results of specimen for sintering 900 °C were 2.13, 2.06, 2.04, and 2.02 g/cm^3; and for sintering 1000 °C were 2.39, 2.27, 2.21, and 2.19 g/cm^3, for RHA content 0, 10, 20, and 30 wt% respectively.

This observation is based on considering not only the porosities and pore sizes but also other mechanical properties testing. The mechanical properties of porous ceramics are shown in figure 3, 4, and 5 in sequence. The compressive and bending strength as a function of RHA addition at different sintering temperature is shown in figure 3. The influence of RHA addition and especially sintering temperature changed the distribution of compressive and bending strength significantly. The higher sintering temperature, the higher compressive and bending strength is at the same given weight fraction of the RHA increase. Compressive strength test results of specimen for sintering 900 °C were 8.48, 15.82, 17.50, and 27.59 MPa; and for sintering 1000 °C were 35.25, 49.34, 70.87, and 74.08 MPa, for RHA content 0, 10, 20, and 30 wt% respectively. Bending strength test results of specimen for sintering 900 °C were 4.03, 5.77, 6.38, and 7.25 MPa; and for sintering 1000 °C were 17.87, 18.09, 18.58, and 20.46 MPa, for RHA content 0, 10, 20, and 30 wt% respectively.

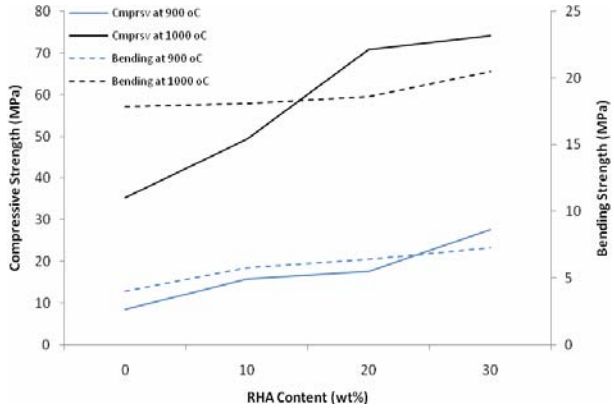

Figure 3. Effect of RHA content to the compressive and bending strength behavior at sintering temperature 900 °C and 1000 °C

The hardness Vickers and firing shrinkage as a function of RHA addition at different sintering temperature is shown in figure 4. Hardness is an indicator of a materials resistance to permanent deformation. Hardness is increase with increasing of RHA content and sintering temperature. For specimen at sintering temperature 900 °C, the influence of RHA addition and especially sintering temperature changed the distribution of hardness Vickers slightly (liable flat). However, at temperature 900 °C, the hardness Vickers was increased slightly. This may be due to the pore structure of the specimens (as evidenced in SEM photomicrograph at figure 7) that have good distribution of porosity. This investigation also indicated that substantial improvements were apparent in sintering temperature process. Meanwhile, the shrinkage is an unwanted phenomenon, because it causes deformation of material. Hence, ceramics pore should be design in a way that doesn't allow the local shrinkage or deformation when it applied in industry. The participation hard phase Si from RHA to hardness and

shrinkage phenomenon has a significant influence. The higher is percentage participation of RHA the lower shrinkage percent of specimen. Firing shrinkage test results of specimen for sintering 900 ^oC were 27.22, 18.01, 11.84, and 9.65 %; and for sintering 1000 ^oC were 40.64, 31.09, 27.89, and 11.95 %, for RHA content 0, 10, 20, and 30 wt% respectively. Meanwhile, hardness test results of specimens for sintering 900 ^oC were 339.14, 340.48, 344.08, and 346.22 HVN; and for sintering 1000 ^oC were 354.34, 355.62, 375.18, and 452.32 HVN measured by micro hardness tester with pyramidal diamond 1 kgf load, for RHA content 0, 10, 20, and 30 wt% respectively.

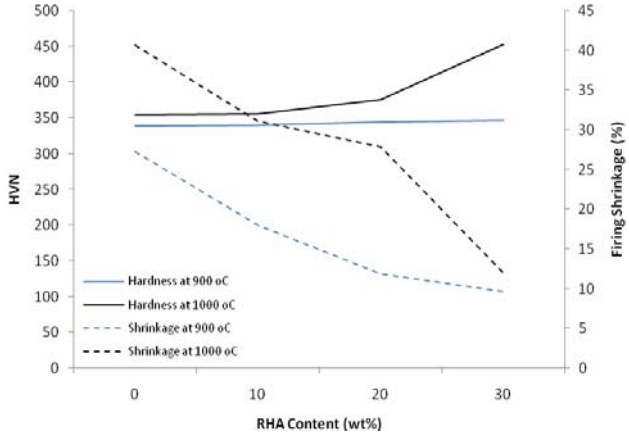

Figure 4. Effect of RHA content to the hardness vickers and firing shrinkage behaviour at sintering temperature 900 ^oC and 1000 ^oC

The last step of researches for produced material was microstructure evaluation. This was carried out in scanning electron microscope (SEM) and X-ray diffraction (XRD). The X - ray diffraction (XRD) pattern analysis of the specimen at 30 %wt RHA addition and sintering temperature 900 ^oC investigated in this work is shown in figure 5. The specimen which has showed maximum porosity was chosen for X-ray analysis as well.

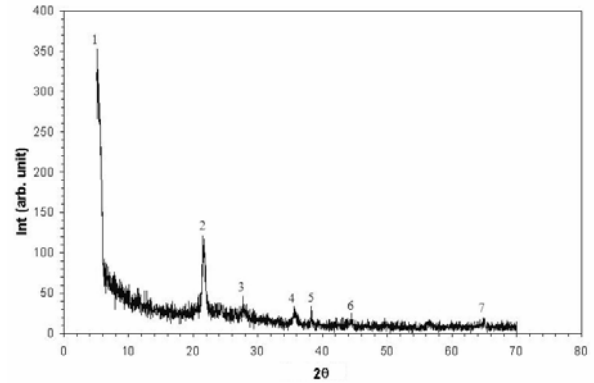

Figure 5. X-ray diffraction of 30 %wt RHA specimen fired at sintering temperature 900^oC

As seen, the phases in the diffractograms presenting mainly on the presence, in sequence: Sodium Silicate ($NaSi_7O_{13}$), Aluminium Silicate ($Si_{7276}Al_{2772}O_2$), Silimanit (Al_2SiO_5), Andalusit ($Al_2(SiO_4)O$), Zeolite ($Si_{11,96}Al_{0,04}O_{24}$), Silikon Dioksida ($SiO_2$), and Mulite ($Al_2(Al_{2,5}Si_{1,5})O_{9,75}$) peaks. The main characteristic signals of specimen are at 5.7588^o, 21.598^o, 27.9006^o, 35.6551^o, 38.3257^o, 44.3925^o, and 64.6558^o, respectively. The possible phases were also searched and confirmed by x-ray diffractogram database (JCPDS).

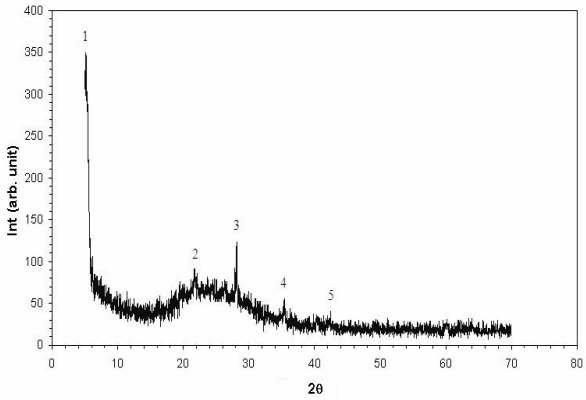

Figure 6. X-ray diffraction of 0 %wt RHA specimen fired at sintering temperature 1000^oC

Meanwhile, the X - ray diffraction (XRD) pattern analysis of the specimen at 0 %wt RHA addition (100 %wt natural zeolite) at sintering temperature 1000 ^oC investigated in this work is shown in figure 6. The specimen, which has showed minimum porosity as the extreme comparison, was chosen for X-ray analysis as well. The phases in the diffractograms presenting mainly on the presence, in sequence: Aluminium silicate ($Al_2Si_{24}O_{51}$), Zeolite ($Si_{11,96}Al_{0,04}O_{24}$), Zeolite ($Si_{11,96}Al_{0,04}O_{24}$), Zeolite ($Si_{11,96}Al_{0,04}O_{24}$), and Zeolite ($Si_{11,96}Al_{0,04}O_{24}$) peaks. The main characteristic signals of specimen are at 5.4161^o, 21.6651^o, 28.0789^o, 35.7085^o, and 38.2659^o, respectively. The possible phases were also searched and confirmed by x-ray diffractogram database (JCPDS). These are typical of the main phases found in the natural zeolite and confirmed further in experiments now.

In order to examine the morphology of obtained specimen in XRD patterns were viewed under scanning electron microscope. Figure 7 shows the scanning electron microscope (SEM) images of the specimen with 30 %wt RHA which is fired at sintering temperature 900 ^oC. It shows the best distribution of porosities and pore size of the specimens. The sintering temperature and RHA addition changed the distribution of porosities and the pore size significantly (as also shown in figure 1); the higher RHA addition (30 %wt) and sintering temperature at 900 ^oC increased the porosities from 18.08 percent to 34.59 percent but it decreased the diameter pore size of about below 1 □m. In one of their earlier studies [6], the author observed the influence of sintering temperature on porosity and pore size with particle shaped by uniaxial pressing; at temperature of about 960 ^oC was found good enough for filter fabrication. In the present study, all fabricated materials (sintered at 900 and 1000 ^oC) are found useful for

filtration applications which have the pore size above 0.1 μm in diameter, its mean the classification of porous ceramics is concerned with macro pores which is suitable for microfiltration application. Sintering also is a crucial parameter for successful fabrication. It needs reliable characterization technique to provide information on the formation of porosity at the sintering temperature applied.

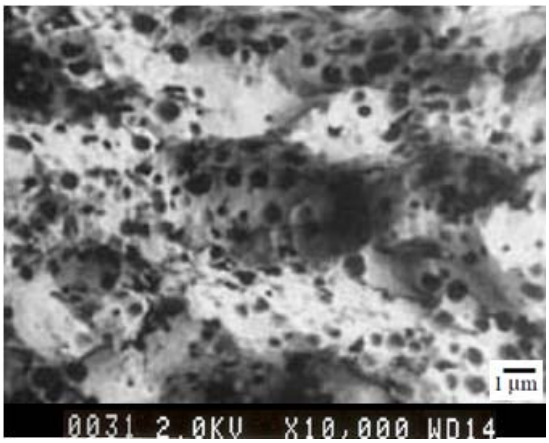

Figure 7. SEM photographs of 30 %wt RHA specimen fired at sintering temperature 900 ^{o}C

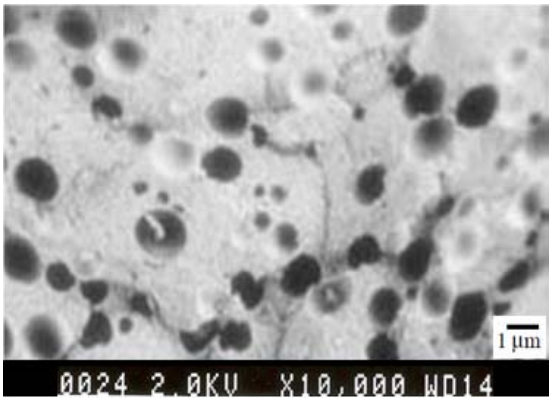

Figure 8. SEM photographs of 0 %wt RHA specimen fired at sintering temperature 1000 ^{o}C

Meanwhile, for the specimen with 0 %wt RHA (100 %wt natural zeolite) at sintering temperature 1000 ^{o}C, as shown in figure 8, it shows less distribution of porosities. The sintering temperature and specimen compositions changed the porosities only slightly, but it has significant increasing the median pore size of about above 1 □m. The explanation was supported by the ratio of Si/Al in natural zeolite in which has the influences to the new seed porosity

4. CONCLUSIONS

In this study, macroporous zeolite materials were successfully prepared from natural zeoilte and rice husk ash. Rice husk ash is a cheaper and environmental friendly alternative silica source in mass production of versatile macroporous materials. Thus, further studies on the synthesis of other types of porous microporous materials from RHA and their application will be investigated.

ABSTRACT

Magnetic nanoparticles have been of great interest because of their extensive applications. For many of their applications, the synthesis of controlled sized particles is of key importance. This work prepares magnetite particles through relatively simple method of coprecipitation. To control particle size in coprecipitation method, this work tried to use polymer stabilizer to obtain more uniform magnetite particle size. Polymer used in this study was poly(ethylene glycol methacrylate-*co*-methacrylic acid) (poly(EGMA-*co*-MAA). The methacrylic acid unit in the polymer was expected to interact with the surfaces of the iron oxide particles. The ratio of iron salt:polymer was varied between 1:0.85, 1:0.7, and 1:0.42. The smallest average particle size is 182.3 ± 72.3 nm (Fe:poly = 1:0.85) and the largest average particle size is 907.8 ± 222.1 nm. Since the polymer synthesized was insoluble in water, it is less effective in controlling magnetite particle size prepared by coprecipitation method.

Keywords
Magnetite, coprecipitation method, polymer,

1. INTRODUCTION

Magnetite is common ferrite that has a cubic inverse spinal structure with the formula of Fe_3O_4. The compound exhibited unique electric and magnetic properties based on the transfer of electrons between Fe^{2+} and Fe^{3+} in the octahedral sites [1]. Magnetic nanoparticles have been of great interest because of their extensive applications in high density data storage, biochemistry, hyperthermia, in vivo drug delivery and MR contrast reagent [2-7]. For many of these applications, the synthesis of controlled sized particles is of key importance, because the electrical, optical, and magnetism properties of these particles depend strongly on their dimensions. The magnetic structure of the surface layer usually is greatly different from that in the body of nanoparticle, and the magnetic interactions in the surface layer could have a notable effect on the magnetic properties of nanoparticles.

Various synthetic procedures have been used to synthesize magnetic nanoparticles. Magnetite (Fe_3O_4) nanoparticles dispersed in solvents are frequently used as ferrofluids [8]. Magnetic nanoparticles have often been synthesized by the coprecipitation of ferrous (Fe^{2+}) and ferric (Fe^{3+}) ions under basic conditions [9]. This coprecipitation method could also be done with ultrasonic irradiation [10]. Other synthetic methods include the thermal decomposition of an alkaline solution of an Fe^{3+} chelate in the presence of hydrazine, and the sonochemical decomposition of an Fe^{2+} salt followed by thermal treatment [11]. Recently, the synthesis of monodisperse and sized-controlled magnetic ferrite nanoparticles has been reported by several groups. Hyeon and co-workers reported the synthesis of monodisperse and highly crystalline γ-Fe_2O_3 and cobalt ferrite nanoparticles without the need for a size selection process [12]. Alivisatos and co-workers synthesized γ-Fe_2O_3 nanoparticles from direct decomposition of $FeCup_3$ [13]. Uniformly sized magnetic nanoparticles were synthesized by the high temperature reaction of iron (III) acetylacetonate [14].

This work prepares magnetite particles through coprecipitation method. It is extensively used method for preparing magnetite. To control particle size with coprecipitation method, this work tried to use polymer stabilizer to obtain more uniform magnetite particle size.

2. MATERIAL AND METHOD

2.1 Material

tert-Butyl methacrylate (Aldrich, 98%), ethylene glycol methyl ether methacrylate (EGMA)

ISSN 114-1284

(Aldrich, 99%), methyl 2-bromopropionate (MBP) (Aldrich, 98%), 2,2'-bypyridyl (Bipy) (Aldrich, 99%), iron(III) chloride hexahydrate ($FeCl_3.6H_2O$, Aldrich), iron(II) chloride tetrahydrate ($FeCl_2.4H_2O$, Aldrich), ammonium hydroxide solution (25%, Fluka), copper(I) chloride (Merck), and fuming hydrochloric acid (Merck).

2.2 Synthesis of poly(EGMA-*co*-*t*BMA)

Copper chloride (70 mg) and 2,2'bipyridyl (218 mg) were added in three-necked flask. The flask was purged with nitrogen gas for a few minutes. Then a mixture of *tert*-butyl methacrylate (3.96 g), ethylene glycol methyl ether methacrylate (20 g), and 2.4 mL of ethanol were added to the flask. Last, methyl 20bromopropionate (117.5 mg) was added. The mixture was heated at 60°C in an oil bath for 3 h. The experiment was stopped by opening the flask and exposing the catalyst to air. The final mixture was diluted in ethanol and passed through a silica column (70-230 mesh) to remove copper catalyst. The filtered solution was dried in low-pressure oven. The polymer obtained appeared as a yellowish rubbery material.

2.3 Hydrolysis of poly(EGMA-*co*-*t*BMA)

Twenty grams of poly(EGMA-*co*-*t*BMA) and 180 mL of 1,4-dioxane were added in a round bottom flask. The mixture was stirred to dissolve the polymer. Then 10 mL of concentrated HCl (37%) was added and the flask was capped with a condenser. The mixture was refluxed for 6 h and subsequently cooled to room temperature. Then the filtered solution was diluted with water. Water was removed by rotary evaporation. The polymer obtained appeared as a brownish rubbery material.

2.4 Preparation of Fe_3O_4 particles

The magnetic nanoparticles were tried to synthesized via conventional precipitation methode in the presence of the copolymer poly(EGMA-*co*-MAA), used as a particle stabilizer. Iron(II) chloride and iron(III) chloride ($[Fe^{3+}]/[Fe^{2+}] = 2$) were added in a round bottom flask under nitrogen atmosphere and were subsequently diluted in water (overall iron concentration in water approximately 6 g/L). The polymer was added in the reaction mixture under nitrogen atmosphere. The ammonium hydroxide solution was slowly added under strong stirring conditions, resulting in the formation of a dark precipitate. This mixture was purified by dialysis in water.

2.5 Particle characterization

Prepared particles were dried in a vacuum oven for Fourier transform infrared spectroscopy (FT-IR) analysis. The present of Fe_3O_4 were analysed with x-ray diffraction (XRD). Particles morphology was characterized with scanning electron microscopy (SEM). Particles sizes were analyzed with particle size analyzer (PSA).

3. RESULT AND DISCUSSION

In this work, magnetite particles were prepared by coprecipitation method. Mixed solution of Fe^{3+} and Fe^{2+} were reacted with ammonium hydroxide solution to form Fe_3O_4, as swhon in eq. 1.

$$2FeCl_3 + FeCl_2 + 8NH_3 + 4H_2O \rightarrow Fe_3O_4 + 8NH_4Cl \quad (1)$$

Coprecipitation method is a common method of producing magnetite particles, because its relatively simple procedure. However, with this method, a suitable particle surface treatment is needed to form stable magnetite particles. To obtain controlled particle size, this work attempted to use polymer stabilizer. The polymer studied was random copolymer of poly(ethylene glycol methacrylate-*co*-methacrylic acid) (poly(EGMA-*co*-MAA). The methacrylic acid unit in the polymer was expected to interact with the surfaces of the iron oxide particles [15]. The ratio between polymer particles and total iron concentration (Fe:polymer) was varied by 1:0.85, 1:0.7, and 1:0.42.

The infrared spectra showed at Fig. 1. The three FT-IR spectra showed key absorption of Fe_3O_4 particles at around 500-575 cm^{-1} [16]. Specific band at 590 cm^{-1} assigned to Fe-O vibration was also noticed [17]. The XRD pattern of magnetite particles obtained is shown in Fig. 2.

From the SEM images of obtained magnetite particles (Fig. 3), it was difficult to determine the single particle size. The SEM images showed what might be the occurrence of magnetite particle agglomeration.

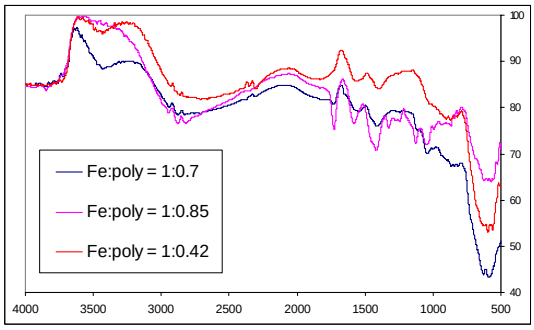

Figure 1. FT-IR spectra of prepared magnetite particles.

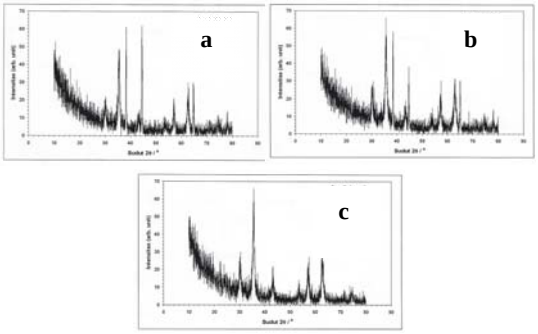

Figure 2. XRD pattern of prepared magnetite with Fe:poly ratio of: a) 1:0.85, b) 1:0.7, and c) 1:0.42

Table 1 shows PSA measurement of three batches of magnetite particles prepared in this work. Obtained particle sizes are relatively large and did not belong to the scale of nanoparticles. The smallest average particle size is 182.3 ± 72.3 nm (Fe:poly = 1:0.85) and the largest average particle size is 907.8 ± 222.1 nm.

The polymer we tried to use was random copolymer of poly(EGMA-*co*-MAA). It appears that this copolymer is not soluble in water. Water solubility of the polymer stabilizer is important in order to polymer to be dispersed among magnetite particles and to make sure that the methacrylic acid unit interacts with the surface of iron oxide particles. This work use ethylene glycol methacrylate as one of monomer in the random copolymer. Reference [18] shows that in the case of poly(EGMA-*co*-MAA), the copolymer is not soluble in water since the single ethyleneglycol unit is insufficient to solubilize the hydrophobic polymer backbone. Thus, poly(oligo(ethylene glycol) methacrylate-*co*-methacrylic acid) (poly(OEGMA-*co*-MAA) is more soluble in water than poly(EGMA-*co*-MAA). The large particle size measured from PSA and SEM suggest that the copolymer used in this work can not act as a particle stabilizer because of its insolubility in water. It was shown by the tendency of prepared magnetite particles from coprecipitation method to precipitate when kept at shorter time. Thus, nanoscaled magnetite particles did not occur. Correlation between obtained magnetite particle size and Fe:polymer ratio can not be taken as the polymer rarely involve in stabilizing the magnetite particles.

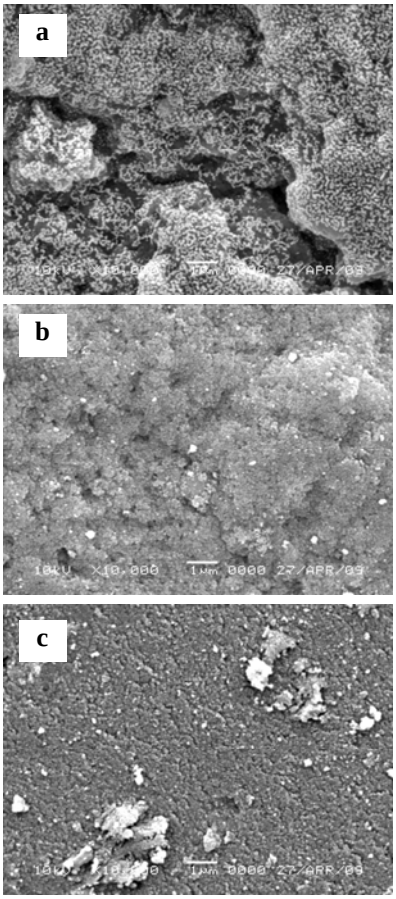

Figure 3. SEM image of magnetite with Fe:poly ratio of: a) 1:0.85, b) 1:0.7, and c) 1:0.42

Table 1. Particle size of the magnetite particles prepared in the present of polymer stabilizer

	Iron salts/polymer Fe:poly (w/w)	Mean diameter (nm)
1	1:0.85	182.3 ± 72.3
2	1:0.7	907.8 ± 222.1
3	1:0.42	797.3 ± 196.2

4. CONCLUSION

The random copolymer used in this study of preparing magnetite particle is insoluble in water. This happen because the single ethyleneglycol unit is insufficient to solubilize the hydrophobic polymer backbone. Thus, this random copolymer is less effective in stabilizing magnetite particles and can not be used to control magnetite particle size.

ABSTRACT

Chitosan is a chitin derivate matter that called multifunction groups because it has three groups, i.e. amine-acid, primary hydroxyl, and secondary hydroxyl groups. Chitosan has ability to kill bacteria. Its polycation is able to restrain the growth of molds and bacteria. On the other hand, the using of chitosan as material for biodegradable packaging film has already proven and even already been applied commercially for food. The two functions of the material as packaging and as antimicrobial agent can be called antimicrobial packaging. However, so far, the scientific research of the efficacy of chitosan base film as antimicrobial packaging is very rare. In this research, a film was developed from chitosan and tested to its efficacy of selected microorganism.

The purposes of this research was to investigate the efficacy of chitosan-based antimicrobial film against Staphylococcus aureus (S. aureus)s, Escherichia coli(E. coli) and Salmonella typhimurium (S. typhimurium). The methodology used in this research were (i) producing antimicrobial film and (ii) antimicrobial assay of the film for selected microorganism.

The efficacy of chitosan antimicrobial film for E. coli and S. thyphimurium were greater than S. aureus. Efficacy of antimicrobial film was also influenced by storage temperature. Results from efficacy test conducted for those selected microorganism was storage at 5°C had greatest effect whereas storage at 37°C had the smallest effect.

Keywords
Chitosan, antimicrobial film, Staphylococcus aureus, Escherichia coli, Salmonella typhimurium,

1. INTRODUCTION

As a result of consumer demand on packaging, it has encouraged the creation of innovative packaging to maximize benefits and minimize the negative impact of packaging. The function of packaging to protect food products to be the main guarantee for consumers. Antimicrobial (AM) packaging is a concept that combines innovative materials and packaging materials in an anti-microbe system. In principle, the AM agent can be added to any polymer material. The AM agent will released slowly from the packaging to product to prevent the damage of food packaged causing by microbe growth such as fungi, bacteria and others. Antimicrobial packaging materials are increasing of interest as a potential technique for safely preserving food products. On the other hand, AM packaging is also a simplify of the producing packaging by manufacturing packaging materials and AM agent in one stage.

AM packaging has been developed trough research in the last few years. However the implementation of packaging in commercial scale is very rare. Hence, more research should be done to trigger to speed up its application. The present work will concentrate on fabrication of the AM film-chitosan base. The film then it assayed under different temperature of storage against , *E. col,i S. typhimurium* and *S. aureus.*

2. MATERIAL AND METHODS

2.1. Material and Apparatus

The material used in the research were chitosan, acetate acid, glycerol and aquadest. Other chemicals was ethanol. The apparatus needed for analysis were test plate, test tube, drops pipette, mixer, spatula, magnifying glass, glass beaker, erlenmeyer and incubator.

2.2. Methods

The chitosan AM film was produced by the modification of Vodjani and Torres method [1]. Chitosan of 3 g was diluted on 1% (v/v) of acetic acid and heated on the temperature of 50^{o}C for 60 min. When the solution was homogen, immediately 0.5% (v/v) of glycerol was added. After the solution has been prepared, the solution is poured to the top of the film frame. The sheet of chitosan AM film and then is dried in the oven of 40°C for 24 h. The flow process of producing AM film is shown in Figure 1.

The films were tested for their inhibition against the selected microorganisms: *E. Coli*, *S. Typhimurium* and *S. aureus* by using an agar disc diffusion method [2]. Each film sample was cut into a circle of 5 mm in diameter and sterilized with UV light for 2 min prior to being placed on an agar plate surface seeded with 1 mL of test culture. The plates were incubated for 7 days at the temperature of 5, 15, 27 and 30^{o}C. The clear zone formed around the film disc in the media was recorded as an indication (Figure 2) and inhibition index was calculated by the equation (1) [3].

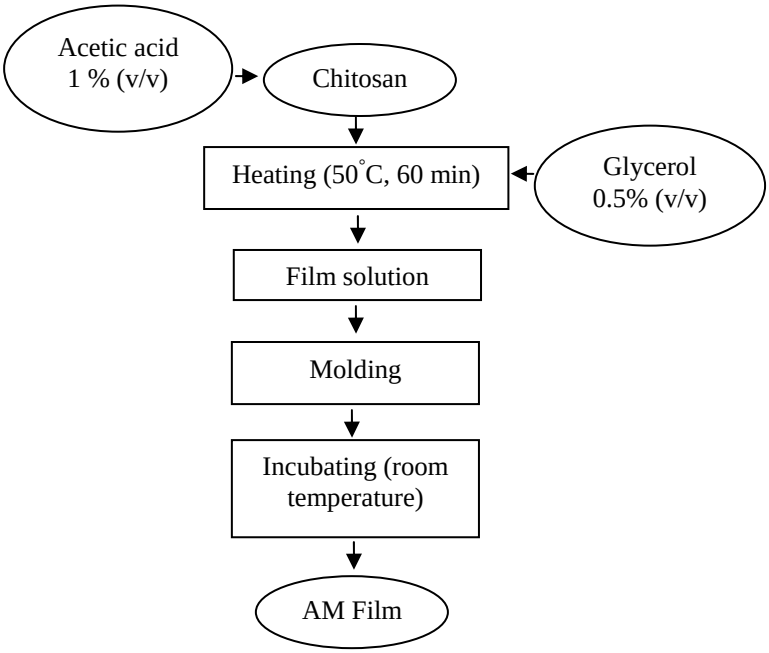

Figure 1. Flow process for chitosan AM fim producing

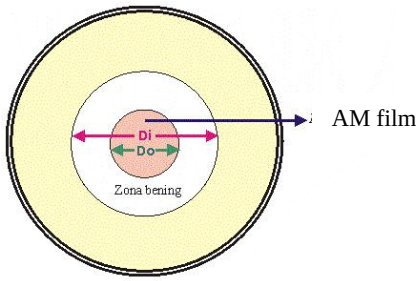

Figure 2. Clear zone

$$\text{Inhibition index (\%)} = \frac{(Di - Do)}{Do} \times 100\ \% \text{.....(1)}$$

Where :
Di = internal diameter
Do = ekstenal diameter

3. RESULT AND DISCUSSION

AM against bacteria is shown by perform the clear zone on the agar plate. Clear zone is a zone where bacteria can not grow and proliferate as a result of active material in the film, while the zone indicated microbe growing was shown by colours colony. Figure 3 presents the graph index of inhibition of the AM film against E. coli. It is shown that a decreasing in the index of retardation during the storage for all temperature of 5, 15, 27 and 37°C tested in this study. It means that the longer storage of the film, the active substance from chitosan used to prevent the *E. coli* bacteria is also reducing. The higher temperature of storage the film, the lower the effect of retardation obtained, indicated by the low index retardation. A similar results was also obtained in literature [4].

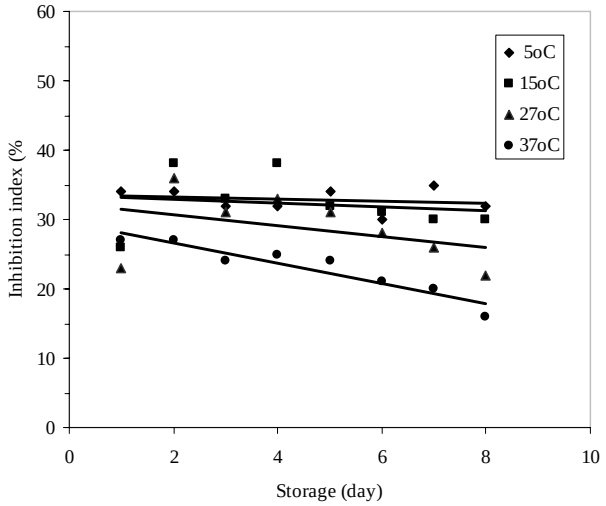

Figure 3. Inhibition index of AM film against *E. coli*

In the graphs presented in Figure 4, it appears that the film activity against *S. typhimurium* also decreased during storage, however, at low temperatures, namely 5 and 15°C, the decreasing in the index is not too significant. The declining might occurred more rapidly in line with the increasing temperature of storage. It means that the ability of chitosan AM film to kill banteria is low in high temperature.

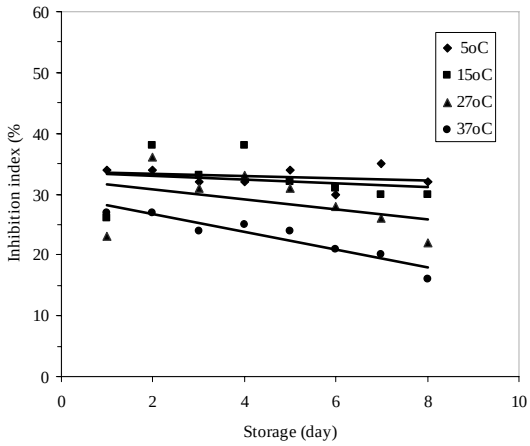

Figure 4. Inhibition index of AM film against *S.. typhimurium a*

Figure 5 shows that the longer the film storage, the lower activity of the AM film against *S. Aureus*. The higher temperature storage of AM film is also resulted on the lower the effect of retardation obtained as indicated by the low index of inhibition.

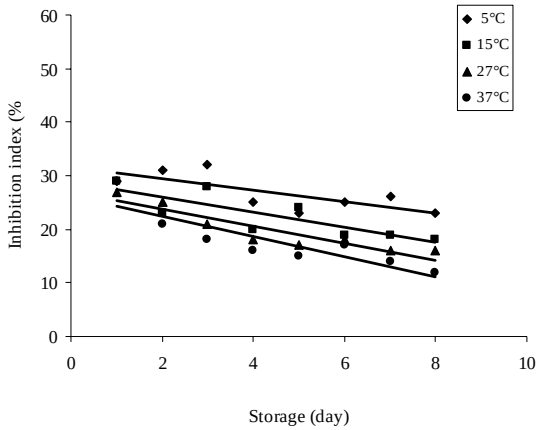

Figure 4. Inhibition index of AM film against *S. aureus*

However, from the Figure 3, 4 and 5 above shows that the retardation film of the *E. coli* and *S. typhimurium* was greater compare to *S. aureus*. According to literature [5], the gram-negative bacteria (*E. coli* and *S. typhimurium*), has more negative ion in its cell and thinner peptidoglican thus it makes more sensitive to chitosan.

As it is shown that the reducing of inhibition index are linear along the storation. Hence, it can calculate the slopes as indicates a decreasing rate of active substances containing in AM film material and estimate the shelf life of the AM agent in days as displayed in Table 1.

Tabel 1. Shelf life of chitosan AM film

Temterature of storage (^{0}C)	Shelf life (days)		
	E. coli	*S. typhimurium*	*S. aureus*
5	24,10	90,72	29,77
1	19,66	78,29	20,50
25	18,99	38,73	17,18
37	16,92	20,13	13,86

4. CONCLUSION

The results of the present study highlighted the promising potential and feasibility of chitosan base films for use as AM packaging materials. Chitosan film is evidently able to prevent microorganisms. The level of inhibition index of the bacteria growth are depending on the temperature and the period of storage. The AM film could inhibit *E. coli* and *S. typhimurium* greater than *S. aureus*.

ABSTRACT

A model for comminution processes in ball mills is presented. The model provides an empirical approach using the physically realistic modelization of the ball mill system, but also deployes the statistical method to extract relevant thermodynamics observables. Those physical observables are investigated by treating the whole system as a statistical macroscopic ensemble.

Keywords
nano process, ball-mill, canonical ensemble, modelling

1. INTRODUCTION

The comminution processes in recent years attract the attention among scientists and engineers due to the increasing demand of ultrafine powders for nanotechnology applications in many areas. The demand then requires the improvement of comminution equipments like ball mills, roller mills and so on. Unfortunately, the development of such comminution equipments always contains a lot of uncertainties due to a wide range of unknown parameters. These, in fact, lead to significant statistical errors. In order to overcome such problems, several models have been developed to quantitatively describe comminution process in various types of mills [1,2,3,4,5].

On the other hand, mathematical modeling and simulation may provide prior information and constraint to the unknown parameter ranges which should be useful to develop more optimized experimental strategy in comminution processes. However, in most cases of mathematical models, the physical observables like grain-size etc are extracted from a set of equation of motions (EOM). Such EOM's are considered to govern as complete as possible the dynamics of the system, from the mechanical motions to the evolution of grain-size distribution. This approach is obviously suffered from the nonlinearities of the equations under consideration, and then the requirement of high computational power to solve them numerically. This fact often discourages a quantitative and deterministic approach for the simulation of such system. These nonlinear effects like chaotic behavior of the sphere motions within the mill encourages some works modeling the system using semi-empirical approaches [6]. However most of semi-empirical models require a large number of experimental data based on prior observations [7], or measured variables obtained from simulation results by other authors [8,9].

In this paper we deploy a novel model and approach developed recently which is combining the deterministic approach for milling bodies motion, and the statistical approach to relate them with considerable macroscopic physical observables [10].

2. THE UNDERLYING MODEL

The whole system is modeled empirically using hamiltonian method. It is represented by a total hamiltonian describing all aspects of dynamics in the ball mills. It is further used to calculate the partition function and extracting the relevant thermodynamics observables.

The dynamics of each 'matter' in the system, i.e. balls and powders inside the vial, is described by a hamiltonian $H_m(r,t)$. The index m denotes the powder (p) or ball (b) and $r = (x,y,z)$. The hamiltonian contains some terms representing all

relevant interactions working on the matters inside the system [10],

$H = H_0 + V_{int} + V_{ext}$ (1)

with v denotes the vial, while H_0 is the free matter hamiltonian and V's are the internal and external potentials.

The internal potential contains all considerable interactions among matters, i.e. among powder-powderm, powder-ball, ball-ball, powder-vial and ball-vial. The details of all potentials can be found in [10].

Using statistical mechanis, the hamiltonian is related to the partition function,

$Z \propto \exp [- \beta H]$, (2)

with $\beta = 1/k_B T$ for temperature T independent H. Further, the partition function is used to extract some statistical observables, for instance Helmholz free energy,

$F_H = -1/\beta \ln Z$, (3)

and pressure,

$P = -F_H/V$. (4)

Please note that the above equations hold for classical and general system. For a canonical system like our case, it is represented in a continue form in term of space displacement x and momentum p respectively [10].

Considering the normalized partition function, finally we found the pressure to be,

$P = 1 - F \beta \ln^{-1} (2m\pi\beta)$, (5)

where the auxiliary function F represents all geometrical contribution of vial and its motions.

3. RESULT AND DISCUSSION

Making use of Eq. (5) we can draw general behavior of pressure in term of system temperature. Note that this result is independent from the geometrical form and motions of vial. The behavios is depicted in Fig. 1 as a function of system temperature T.

From the figure, it is clear that the pressure depends highly on the system temperture. Its rough behavior is same for any ball mills, but the shapes are determined completely by the function F characterizing the geometrical structures and motions in the inertial system. Therefore Eq. (5) provides a general behavior for temperature-dependent pressure in the model, while the geometrical structure and motion of vial is absorbed in the function F. Its physically meaningfull region is depicted in Fig. 1 for any temperature along the horizontal axis.

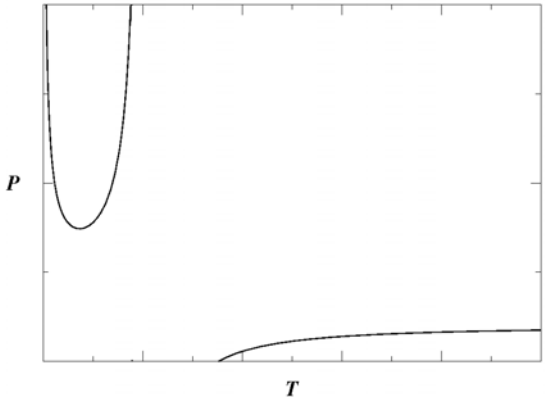

Fig. 1 The normalized temperature-dependent pressure in the system of any ball mills.

From the figure, the physically meaningful region is between $0 < T < 1/(2m\pi k_B)$, and $T > T_{th}$ where the threshold temperature is always greater than $1/(2m\pi k_B)$ respectively.

7. CONCLUSION

We have considered a model for communution processes in ball mills using hamiltonian approach. This approach has a great advantage on extracting the physical observables directly from the hamiltonian without a need to solve a set of equation of motions of the whole system which always leads to unsolvable non-linear problems.

More complete numerical calculation is required to take into account the contribution of geometrical shapes and motions of vial represented by the function F.

ABSTRACT

It is found that under mechanical loading, Transformation Induced Plasticity (TRIP) steel shows a time-dependent strain under a constant applied stress, the strain keeps increasing during the holding process. This phenomenon was previously assumed due to temperature decrease during the holding process, thus the temperature decrease should take place at the same time scale as the strain variation. However, no experimental evidence confirming this relation was observed. To investigate this, a thermocouple was attached to the tensile specimens and recorded the temperature variation while the specimen was being tensiled with different loading schedule at the fixed stress rate, 5 MPa/s. The loading modes used for the tests were stepwise loading, loading-unloading and loading-holding for 72 hours. The retained austenite volume fraction of each specimen after tensile tests was measured using Vibrating Sample Magnetometer (VSM). From the present study, the temperature effect on strain development during the holding process only plays a role in the beginning of the holding process and it will end when the temperature reaches room temperature, afterwards isothermal martensitic transformation (IMT) mechanism is observed to take place.

Keywords
Tensile loading, martensitic transformation, TRIP steels, plastic deformation, time-dependent effect.

1. INTRODUCTION

TRIP Steel is well-known for its properties combination between strength and ductility, it becomes a favorite material for automotive application due to its ability to absorb energy during crashing and the low cost. The existence of TRIP effect in the material is due to the transformation of retained austenite phase to martensite when a certain amount of external stress is applied to the material. The easiness of retained austenite phase to transform to martensite becomes an important factor to produce TRIP effect in a material and it will depend on the retained-austenite stability. It will be affected by its chemical composition, size and orientation [1, 2]. A certain amount of heat will be generated in the material, when it is tensiled to a certain stress level. It can be determined by assuming that all the energy absorbed during straining was converted to heat [3]. It was assumed previously [4], in a stepwise tensile test during the holding process, that the subsequent decrease in the temperature delivers the driving force of austenite transformation. The adiabatic heat evolved was calculated and the temperature decrease during holding process was simulated to have similar time constants to the strain increase. The present work is to observe the factors influencing the strain development during the holding process when a certain amount of external stress applied to the material in a stepwise tensile loading.

2. EXPERIMENTAL

2.1 Experimental Material

The material used in this work was galvanized TRIP steel with chemical composition shown in Table 1. The yield stress, ultimate tensile stress and uniform elongation of the material are 468 MPa, 738 MPa and 22% respectively.

Table 1: Chemical composition of TRIP Steel

Elements	C	Mn	Si	Al	P	Fe
%wt	0.185	1.610	0.352	1.100	0.089	Bal.

The M_s temperature of the material was calculated and the result is 439 K. The material was machined to get tensile test specimens as stated in ASTM E8 standard.

2.2 Tensile Loading and Temperature Measurement

Three different tensile loading were carried out, stepwise loading, loading-unloading and loading-holding for 72 hours. The schematic illustration of stepwise and loading-unloading test can be seen in Figure 1. It was performed in a Zwick Z100 100 kN at the same stress rate, 5 MPa/s. It was chosen due to its load cell capability considering the strength of the TRIP steel. The specimen was gripped using a serrated-wedge grip with screw-like fastener. It was chosen considering the smoothness of the specimen surface. This kind of grip can tightly hold the specimen and eliminate slip during the test.

For the stepwise loading test (Fig. 1(a)), the specimens were tensiled starting from 100 MPa until 700 MPa, held for 20 minutes for every 100 MPa higher. During this holding process the temperature and strain variation were observed.

In the loading-unloading test (Fig. 1(b)), the specimens were tensiled until the tensile load reached 400 MPa, 500 MPa, 600 MPa or 700 MPa. After the specimen reached the target stress level, it was held for 10 minutes, and then unloaded to 0.6 MPa (10 N). After the specimen reached this stress level it was loaded again to the previous target level and held for another 10 minutes. The temperature and strain variation during holding were also observed. This loading-holding-unloading cycle was carried out three times for each specimen at each target stress level.

The third tensile test was loading to 700 MPa and held for 72 hours.

In order to observe the temperature variation during tensile loading, a type-K thermocouple was attached to the tensile specimens and the temperature variation was recorded using Yokogawa DL750 ScopeCorder. The Cu-wire was spot-welded only in the middle of the specimens since other locations show the same behaviour of temperature evolution during the tensile test. The wire was attached between the extensometer needles, the thinnest part of the specimen when it was loaded. The ScopeCorder was set to record temperature in the range of 273 K to 373 K, the frequency chosen was 10 Hz and the duration was varied between 15 min/div and 30 min/div.

2.3 Magnetic Test

The retained austenite volume fraction of each specimen after tensile tests was measured using Lake Shore 7307 Vibrating Sample Magnetometer (VSM). The 2 x 2 x 1.25 mm^3 sample weight was measured and afterwards it was put in the sample holder. During the measurement, the specimen inside the holder vibrated vertically, with an amplitude 0.7 mm and frequency 82 Hz, due to a sinusoidal signal from the transducer. This signal made the specimen to undergo a sinusoidal motion. The pick-up coils on both sides of the sample holder recorded the signal from the sample motion. Method used for data acquisition was point by point, with a maximum field of 2 T. The average time per point was 10 seconds and the number point was 41. From this measurement, the relation between field and magnetic moment per mass was obtained. The values of saturation magnetization (M_{sat}) can be used as indication of retained austenite phase fraction in the specimen by using equation [5]:

$$f_\gamma = 1 - \beta \frac{M_{sat}(c)}{M_{sat}(f)} \quad (1)$$

where f_γ is the volume fraction of retained austenite, β is a constant equal to 0.989 [5] to consider the contribution of cementite on magnetization at room temperature, $M_{sat}(f)$ is the saturation magnetization of austenite-free sample and $M_{sat}(c)$ is the saturation magnetization of austenite-containing sample.

3. RESULTS

The plot of stress vs. time, strain vs. time and temperature vs. time can be seen in Figure 2.

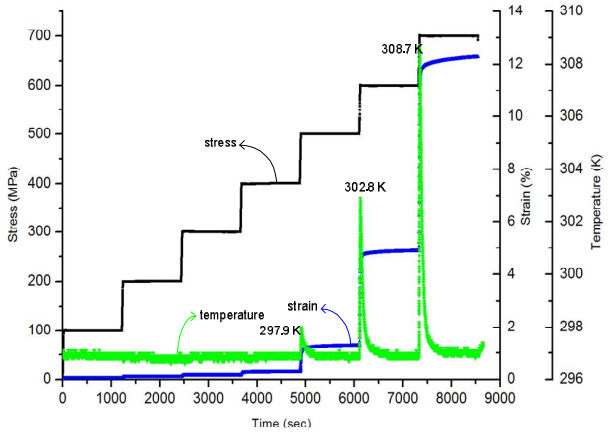

Figure 2: Plot of stress-time, strain-time and temperature-time of stepwise tensile tests.

The plots between strain – time and temperature – time for each stress level, 400, 500, 600 and 700 MPa, can be seen in Figure 3. The $\Delta\varepsilon$ in the figure represent the strain increase during holding process, it was calculated by subtracting the end strain (ε_{end}), where the holding process finished, with the initial strain ($\varepsilon_{initial}$), where the holding process started. Similarly ΔT represent the temperature difference between room temperature when the experiment were carried out and the highest temperature reached when the specimen was tensiled.

The plot of strain vs. time during the third tensile test is depicted in Figure 4. The strain increase during the 72 hours holding process is summarized in table 2 for the first 30 minutes of holding and the rest of the holding process. The data for the first 30 minutes of the holding process are divided into three parts, the first consecutive 10 minutes.

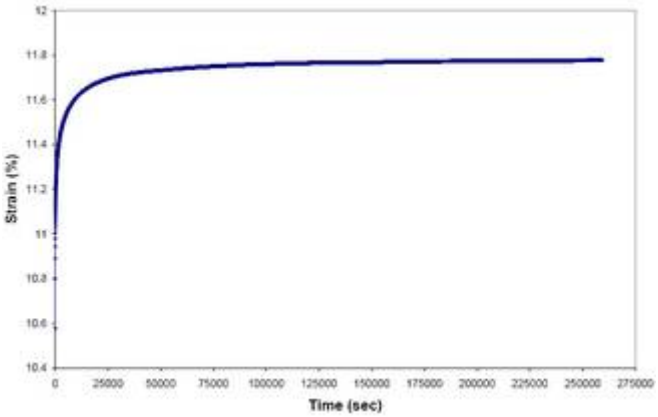

Figure 4: Plot of strain – time in loading – holding tensile test. The material was hold for 25900 sec (72 hours)

Table 2: Delta strain and average strain rate values during 72 hours holding in loading-holding tensile test.

Test duration (sec)	$\Delta\varepsilon$ (%)	Average strain rate (s^{-1})
0 – 600 sec (first 10 minutes)	0.712	1.2×10^{-5}
601 – 1200 sec (second 10 minutes)	0.077	1.3×10^{-6}
1201 – 1800 sec (third 10 minutes)	0.047	7.8×10^{-7}
1801 – 259.200 (71 hours and 30 minutes)	0.363	1.4×10^{-8}

The retained austenite calculation results from magnetic test can be seen in Figure 5.

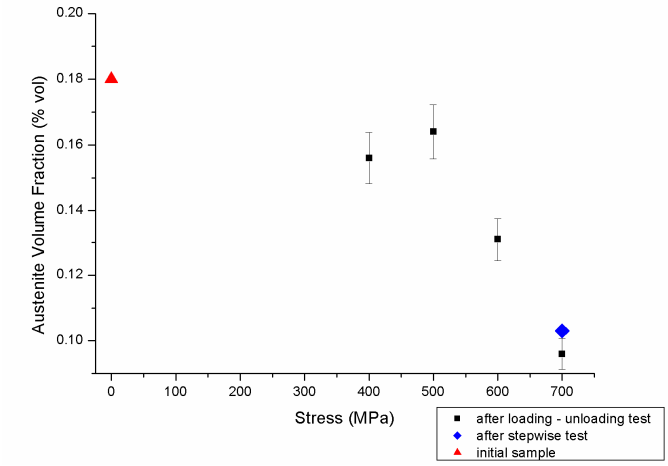

Figure 5: Plots between austenite volume fractions remained in the specimen after loading – unloading and stepwise tests vs. stress level used during the tensile test. The austenite volume fraction in the initial specimen was also measured and plotted in the graph.

4. DISCUSSION

4.1 Temperature Effect on Strain Development during Holding Process

The evolution of temperature during tensile will decrease as the holding process started. The plots between strain – time and temperature – time during the holding process can be seen in Figure 6. For the loading – unloading test, the heat only evolved during the tensile process before the first holding process but not before the second and third holding processes. From Figure 6, the relation between strain increase and temperature decrease is not linier, as one can see in Figure 7. The strain value used in this graph is normalized to the initial strain. It shows that the time scale for both processes is not the same, and that the strain continues to increase when the temperature has become equal to room temperature.

The increase in strain can be correlated to martensite formation. Martensite grains will form a larger volume compared to austenite, thus, martensite formation will have a contribution to the change of the specimen dimension by increasing the strain. The austenite transformed can be correlated to the austenite volume fraction reduction from its initial amount in the initial specimen. It can be seen from the magnetic test result (Figure 5), the loading-unloading specimens and stepwise specimens show smaller amounts of retained austenite than the initial one, thus, there was an austenite transformation in the specimen during the test.

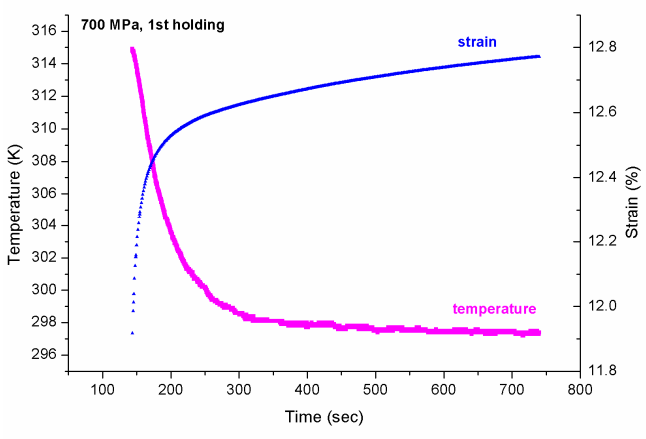

Figure 6: Plots between temperature – time and strain – time during the first holding process in loading – unloading tensile test, tensiled to 700 MPa.

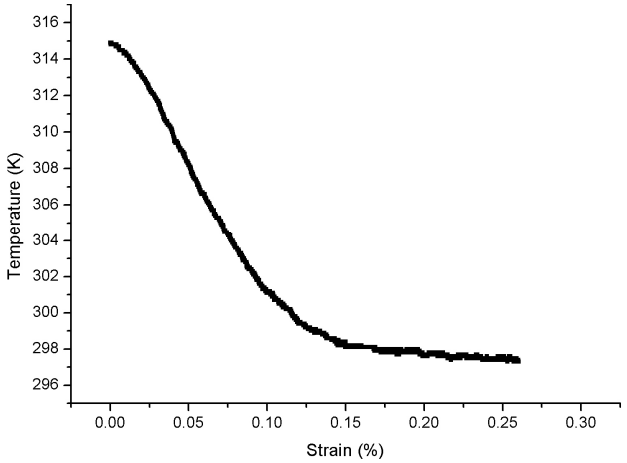

Figure 7: Plots of temperature vs. strain in loading – unloading tensile test, tensiled to 700 MPa, at the first holding process.

The decrease in temperature will increase the chemical driving force for martensite formation and increase the formation of shear bands [6]. The decrease in temperature can affect both the ΔG^{ch}, the free-energy difference providing the chemical driving force, and the rate of shear band formation both will increase. The increase in shear band formation will lead to an increased number of shear band intersections which become the nucleation site of martensite. Thus, it will tend to promote the martensite formation during the temperature decrease.

After approximately 100 seconds of holding, the rate of increasing strain becomes lower as well as the rate of temperature decrease. It is observed [7] from micrographs of TRIP steel deformed in tension to a strain of 0.02, partially transformed grains can easily be found which is evidence that autocatalytic effect is very weak or absent in TRIP Steel. In the absence of autocatalytic effect during the martensite formation, the transformation rate to achieve full martensite formation over austenite grains in the material becomes lower.

A prior tensile loading applied to the material is likely to have an effect on the strain development and heat evolvement in the material during tensile process. For a specimen tensiled to 700 MPa, the stepwise test shows ΔT-value as much as 11.8 K, whereas in the loading – unloading test the value of ΔT is 17.6 K. The difference in the highest temperature reached at the moment in which the holding process started has correlation with its initial strain. The stepwise has lower initial strain value than the loading – unloading test, which is 10.9% for stepwise and 11.3% for loading-unloading test (Figure 8). If the condition was assumed to be adiabatic, the area formed under stress – strain line in the stress – strain plot show all amount of energy absorbed during straining which was converted to heat.

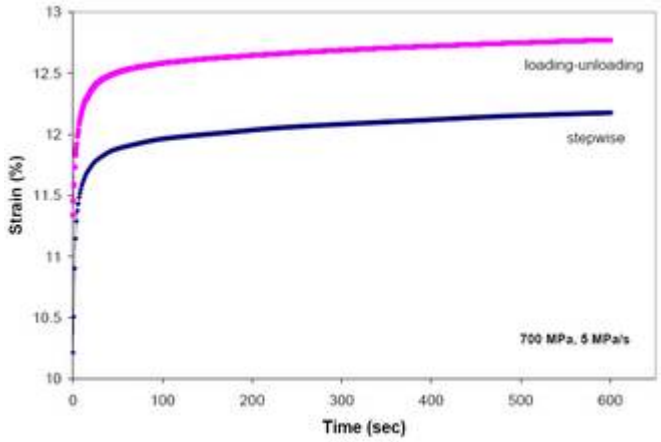

Figure 8: A strain – time plot of a stepwise tensile test when it reaches 700 MPa and loading-unloading tensile test to 700 MPa.

In the stepwise test, the previous deformation will have a work-hardening contribution to the austenite which will possibly make it less stable, and hence lower the initial strain value when the holding process starts. The rate of transformation in stepwise test tends to lower as the stress value increases (Figure 9). It might be due the least stabile fraction of austenite already being transformed at a lower stress level, the austenite becomes more stable and less amount of austenite can be transformed under certain level of deformation.

4.2 Isothermal Effect on Strain Development during Holding Process

In loading-unloading tensile test, at the second and the third loading process, the temperature increase due to tensile process in average was close to zero. It was only observed in the first 50 seconds of the holding process, the increase of temperature is approximately 0.3 K and afterwards the temperature value remains constant. This condition is observed for both second and third holding process. The time – strain and time – temperature plots for the second and the third loading process can be seen in Figure 10 and Figure 11. During this holding process, the relation between strain and time is logarithmic rather than linear, especially in the first several seconds of the holding process. The transformation process is faster in the beginning of holding than in the end of it. The strain still continued to increase whereas the temperature stays at constant value. This process can also be identified as isothermal martensitic transformation (IMT). The IMT process has its own critical temperature, denoted as M_{si}. Below this temperature the IMT process can proceed at a constant temperature

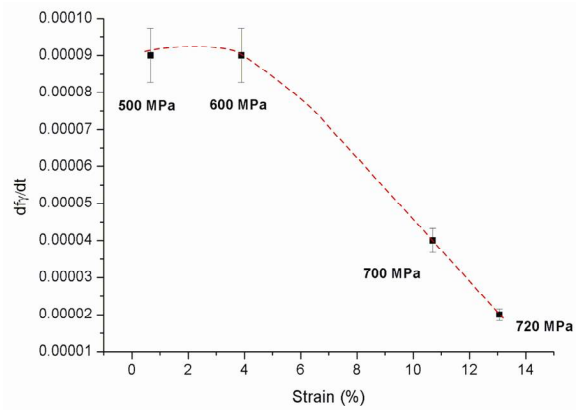

Figure 9: A plot between austenite transformation rate during holding at 500, 600, 700 and 720 MPa with strain, which corresponds to the holding stress level.

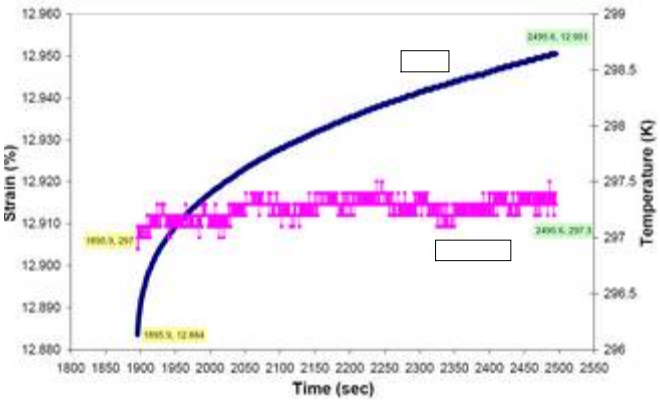

Figure 11: Strain development in the third loading process, holding for 10 minutes. The temperature value stays constant during the holding. The data was obtained from tensile test to 700 MPa.

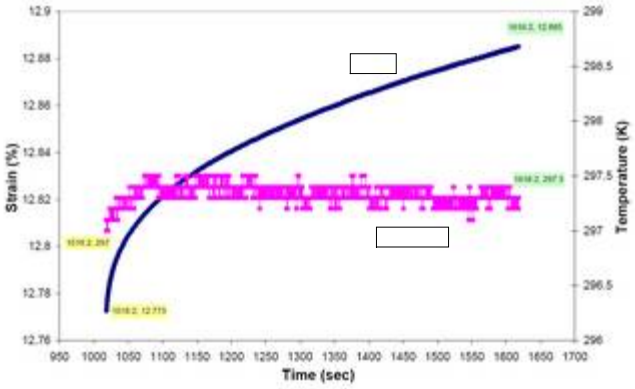

Figure 10: Strain development in the second loading process, holding for 10 minutes. The temperature value stays constant during the holding. The data was obtained from tensile test to 700 MPa.

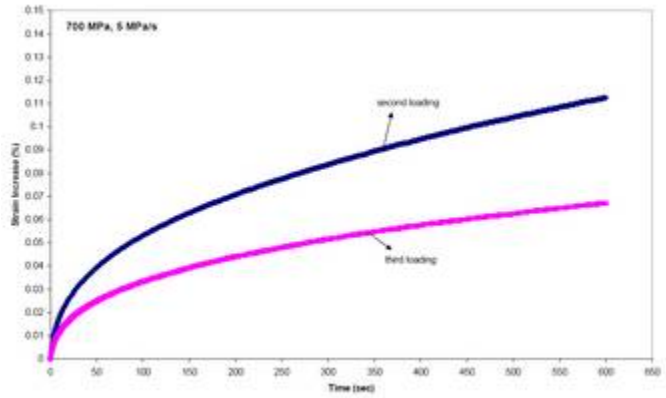

Figure 12: Strain development in the second and third loading process for tensile test to 700 MPa. The third loading process shows a slower development rate than the second one.

Even though the shape of the time-strain plot looks the same, the rate of strain development between the second holding and the third one is different. From Figure 12, it is seen that the third one has lower rate than the second one. This plot is obtained by normalizing the time to zero and normalizing the strain to the strain value at the beginning of the holding process (initial strain). The transformation rate can be very low but also very fast, depending on the M_s temperature of the material and the difference between M_s temperature and the temperature at which the IMT process is carried out [7].

In the third, when the material was held for 72 hours, the strain kept increasing even though at very low rate (Table 2). It shows that holding the material under mechanical loading at room temperature for TRIP Steel counted as a low rate IMT process. The rate can be altered due to some external factors, one of it is pre-strain. The more pre-deformation applied to the material, the lower the IMT rate will be [7]. This effect is already seen in Figure 12. The third loading has lower development rate than the second loading since the material has already suffered more deformation than the second one. Compared to the M_s temperature of this material, room temperature where the tensile test was carried out has a difference of 142 K and the test can be counted as low temperature situation, where the IMT process is likely to occurred.

The effect of prior deformation on the transformation can also be seen from stepwise and loading-unloading test results. For instance at 700 MPa, even though the initial strain value is higher in the first holding process of loading – unloading test than in stepwise test, when the IMT starts, the rate to form martensite becomes higher in the stepwise than in one step

tensile test (Figure 13). This behavior can be explained using martensite nucleation rate equation proposed by Raghavan-Entwisle-Pati-Cohen [8,9] and IMT activation energy equation [7] :

$$\dot{N} = \left\{ n_i + f\left(p - \frac{1}{\bar{V}} \right) \right\} \upsilon \exp\left(-\frac{\Delta W_a}{RT} \right) \quad (2)$$

$$\Delta W_a = W_0 - k\Delta G \quad (3)$$

where $\dot{N}$ is martensite nucleation rate, n_i is the initial density of nucleation sites, f is martensite volume fraction, p is the parameter of autocatalytic effect, $\bar{V}$ is the mean volume of the martensite plates after the test, υ is lattice vibration frequency, ΔW_a is activation energy for nucleation, R is gas constant and T is test temperature. a and k are constants, W_0 is extrapolated value for ΔG to zero at linear relation of ΔG vs. ΔW_a .

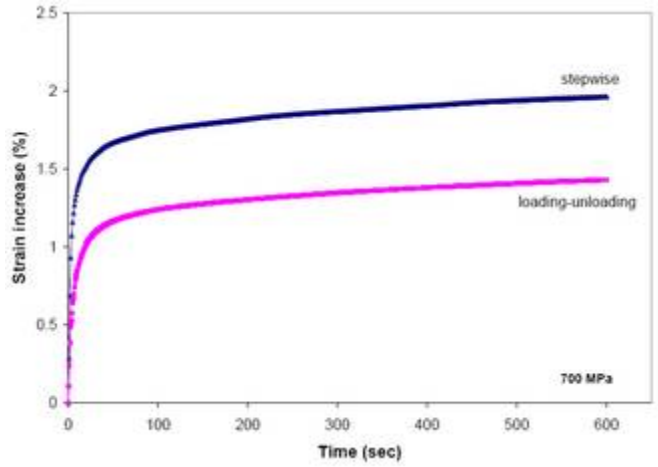

Figure 13: The strain development rate in stepwise and loading-unloading tensile test, loading to 700 MPa.

By assuming that k , a and T_a have the same value in both conditions, lower temperature will result in higher temperature difference with the M_s temperature, thus the thermodynamic driving force becomes higher and according to equation (3), the activation energy will be lower. From equation (2), since the value of testing temperature is the same at both situations, the exponential factor in the equation will be lower when the activation energy is higher. It is assumed that both conditions will have the same density of initial nucleation sites, lattice vibration frequency and autocatalytic parameter. It is being calculated previously [10] that this parameter will have the same value if the testing temperature and the stress level used are the same. The contribution of volume fraction of martensite and martensite plate mean volume will increase the nucleation rate as its values are increasing. In stepwise test, these two parameters are lower than in loading-unloading tensile test, however it is observed in Figure 13 that the strain rate development is higher than the loading-unloading tensile test. Hence, the activation energy has higher effect in the nucleation rate of martensite. IMT process under mechanical loading at room temperature, besides being affected by the test temperature, will also be affected by the heat generation and the consequent temperature increase during the loading process.

At lower stress level, 400 MPa, in stepwise test and loading – unloading test, the activation energy for IMT process is the same, since there is no heat generation in the material. According to equation (2), the nucleation rate will be only affected by martensite volume fraction and martensite plate mean volume, while the rest of the parameters are assumed to be the same in both conditions. Since the stepwise test possessed higher initial strain value than the loading-unloading tensile test, thus the strain development rate of stepwise test will also be higher than the loading-unloading tensile test, as shown in Figure 14. In the stepwise test, loading and afterwards holding at 100, 200 and 300 MPa is assumed to have a contribution to the formation of martensite in the material before the loading reaches 400 MPa. Some austenite might be work-hardened but more austenite is transformed to martensite. The fraction of martensite becomes higher than the loading-unloading tensile test to 400 MPa

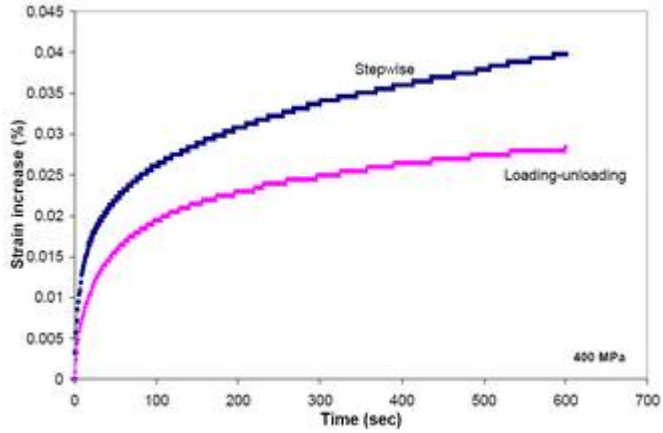

Figure 14: The strain development rate in stepwise and one step tensile test, loading to 400 MPa at 5 MPa/s

5. CONCLUSIONS

The conclusions that can be drawn from the present work are:

- The temperature effect on strain development during the holding process only plays a role in the beginning of the holding process.
- Driving force of martensite formation and rate of shear band formation, are temperature-dependent parameters, they will increase as the temperature decreases. Their contribution during the holding process is to promote the martensite formation.
- The IMT mechanism takes place after the temperature reaches constant value at room temperature.

- Martensite formed from the previous mechanism will have an effect on the IMT activation energy. At the same temperature, the martensite nucleation rate under IMT mechanism will tend to increase when the prior-martensite in the material is higher.
- The activation energy of IMT has a strong relation with thermodynamic driving force of martensite formation.
- The effect of stress rate on the strain will differ depending on the amount of heat generated in the material.
- The effect of previous deformation in the material, e.g. the effect of lower loading step to the higher loading step strain value in stepwise test, tends to lower the strain value and heat generation in the material.

ABSTRACT

In GIST (Gwangju Institute of Science and Technology) area, data on particulate matter concentrations ($PM_{2.5}$ and PM_{10}), and chemical compositions concentrations are important and useful to know air quality, particularly for urban areas, Gwangju city, South Korea, under stagnant atmospheric conditions, especially on the daytime and on the nighttime. The objective of this study was to investigate the chemical composition concentration of the air ion species (Na^+, NH_4^+, K^+, Mg^{2+}, Ca^{2+}, Cl^-, NO_3^-, and SO_4^{2-}) in fine particles ($PM_{2.5}$) and to study concentrations of PM_{10} in the GIST area on September 24 to October 7, 2007. Measurement of $PM_{2.5}$ concentration was carried out by using an Medium Volume $PM_{2.5}$ Particulate was collected with a $PM_{2.5}$ cyclone inlet in twice every day during 12-hour, every 9.00 am and 9.00 pm. Concentrations measurement of PM_{10} were obtained real time by using the Beta Gauge monitor. The Teflon filters from the $PM_{2.5}$ cyclone sampler were used for the analysis of ionic species (anion (Cl^-, NO_3^-, and SO_4^{2-}) and cation (Na^+, NH_4^+, K^+, Mg^{2+}, Ca^{2+})) by ion chromatography. The average concentrations of $PM_{2.5}$ and PM_{10} were on the night (from 9.00 pm to 9.00 am) higher than the concentrations on the day (from 9.00 am to 9.00 pm). The highest concentration of $PM_{2.5}$ and PM_{10} were on the nighttime of October 4, 2007, and the contents were SO_4^{2-}, Ca^{2+}, NH_4^+, Cl^-, and K^+. While the contents of $PM_{2.5}$ and PM_{10} on the daytime of October 4, 2007 were Na^+, Ca^{2+}, K^+, NH_4^+, and SO_4^{2-}. The average concentrations of NO_3^-, Cl^-, K^+, Mg^{2+} on the nighttime were higher than the ones of NO_3^-, Cl^-, K^+, Mg^{2+} on the daytime. The average concentrations of NH_4^+, SO_4^{2-}, and Ca^{2+} on the daytime were almost closed to the concentrations on the nighttime.

1. INTRODUCTION

Particulate matter, also known as particle pollution or PM, is a complex mixture of extremely small particles and liquid droplets found in the air. Some particles, such as dust, dirt, soot, or smoke, are large or dark enough to be seen with the naked eye. Particles can only be detected using an electron microscope. Particle pollution is made up of a number of components, including acids (such as nitrates and sulfates), organic chemicals, metals, and soil or dust particles [1].

The size of particles is directly linked to their potential for causing health problems. Environmental Protection Agency **(**EPA) is concerned about particles that are 10 μm in diameter or smaller, because those are the particles that generally pass through the throat and nose, and enter to the lungs [1]. Once inhaled, these particles can affect the heart and lungs, and cause serious health effects. EPA groups particle pollution into two categories:

1. Inhalable coarse particles, such as those found near roadways and dusty industries, are larger than 2.5 μm and smaller than 10 μm in diameter.
2. Fine particles, such as those found in smoke and haze, are 2.5 μm in diameter and smaller. These particles can be directly emitted from a source, such as forest fires, or the particles can form, when gases emitted from power plants, industries and automobiles react in the air.

The average diameter of single human hair is about 70 μm, around 30 times larger than the largest fine particle (2.5 μm). These particles come in many sizes and shapes, and can be made up of hundreds of different chemicals. Some particles, known as primary particles are emitted directly from a source, such as construction sites, unpaved roads, fields, smokestacks or fires. Others form in complicated reactions in the atmosphere of chemicals such as sulfur oxides (SOx) and nitrogen oxides (NOx) that are emitted from power plants, industries and automobiles. These particles, known as secondary particles, make up most of the fine particle pollution in the country.

Small particles less than 2.5 μm in diameter pose the greatest problems, because they can get deep into lungs, and some may even get into bloodstream and cause serious health problems (Fig. 1). Fine particles ($PM_{2.5}$) also are the major cause of reduced visibility (haze). Numerous scientific studies have linked particle pollution exposure to a variety of problems, including increased respiratory symptoms, such as irritation of the airways, coughing, or difficulty breathing, for example; decreased lung function; aggravated asthma; development of chronic bronchitis; irregular heartbeat; nonfatal heart attacks; and premature death in people with heart or lung disease. People with heart or lung diseases, children and older adults are the most likely to be affected by particle pollution exposure.

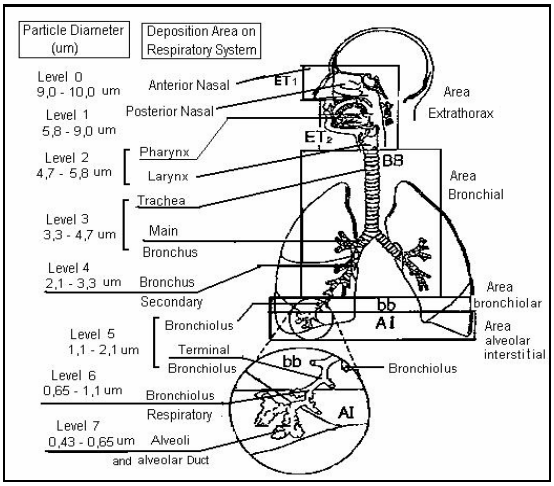

Figure 1. Deposition of the aerosol particles in respiratory system.

The Clean Air Act, which was last amended in 1990, requires EPA to set National Ambient Air Quality Standards (NAAQS) for widespread pollutants from numerous and diverse sources considered harmful to public health and the environment. The Clean Air Act established two types of national air quality standards. Primary standards set limits to protect public health, including the health of "sensitive" populations such as asthmatics, children, and the elderly. Secondary standards set limits to protect public welfare, including protection against visibility impairment, damage to animals, crops, vegetation, and buildings. EPA revised the air quality standards for particle pollution in 2006. The NAAQS standards in 2006 tighten the 24-hour fine particle ($PM_{2.5}$) standard from the current level of 65 $\mu g/m^3$ to 35 $\mu g/m^3$, and retain the current annual fine particle standard at 15 $\mu g/m^3$. The Agency decided to retain the existing 24-hour PM_{10} standard of 150 $\mu g/m^3$ and the Agency revoked the annual PM_{10} standard, because available evidence does not suggest a link between long-term exposure to PM_{10} and health problems [1].

Airborne particulate matter is one of the important markers of air quality and is of important health concern in urban areas, especially with respect to a number of chronic respiratory diseases. There is an abundance of epidemiological evidences associating increased air particulate pollution with the incidence of adverse human health effects [2, 3]. Fine particles ($PM_{2.5}$) as well as particle components such as sulfate ion (SO_4^{2-}) and strong acidity (H^+) also are strongly associated with increased mortality and other adverse health effects [4]. Ion-ion sulfate (SO_4^-), nitrate (NO_3) and ammonium (NH_4^-) are the most common component of secondary particles in the atmosphere. These particles are formed in the atmosphere from direct emissions of sulfur dioxides (SO_2), nitrogen oxide (NO_x) and ammonia (NH_3) gases. Ion-ion SO_4^{2-}, NO_3^- , and NH_4^+, dominate the identifiable components within the fine fraction ($PM_{2.5}$) [5]. In large urban areas, nearly half of NO_x emissions are caused by automobile exhaust. HCl is mainly produced by coal combustion and refuse incineration, and industrial waste incinerations primary pollutant, and by the reaction of HNO_3 with NaCl in sea-salt particles as a secondary pollutant [6].

In GIST (Gwangju Institute of Science and Technology) area, data on particulate matter concentrations ($PM_{2.5}$ and PM_{10}), chemical compositions and gaseous concentrations are important and useful to know air quality, particularly for urban areas as Gwangju city under stagnant atmospheric conditions, especially on the daytime and on the nighttime. The objective of this study was to investigate the chemical composition concentration of the air ion species (Na^+, NH_4^+, K^+, Mg^{2+}, Ca^{2+}, Cl^-, NO_3^-, and SO_4^{2-}) in fine particles ($PM_{2.5}$) and to study concentrations of PM_{10} in the GIST area, Gwangju, South Korea.

2. METHODS

Aerosol sampling was collected on September 24 to October 7, 2007 in Samsung Building, the GIST area, Gwangju, South Korea (35.10 N, 126.53 E). As shown in Fig. 2, the sampling site is located in the city of Gwangju, which is the fifth largest city in Republic of Korea and located 330 km south of Seoul. Its population of approximately 1.4 million people occupies an area of 501.4 km^2 in which there are 0.3 million motor vehicles [7]. Aerosol sampling was conducted in a mobile laboratory trailer at the Gwangju Institute of Science and Technology (GIST), which is located in a northern suburb of Gwangju and surrounded by rural areas from north to east of the sampling site. The Hanam industrial complex is located several kilometers southwest from the sampling site.

Measurement of $PM_{2.5}$ concentration was carried out by using an Medium Volume $PM_{2.5}$ Particulate was collected with a $PM_{2.5}$ cyclone inlet in twice every day during 12-hour, every 9.00 am and 9.00 pm. Cyclones system are airborne system of diameter size selective inlets that create a circular air motion. This circular motion separates fine and coarse particles. Cyclones are Teflon coated to minimize the loss of reactive gases (e.g. HNO_3, NH_3) to the internal surfaces of the cyclone [8]. A $PM_{2.5}$ cyclone inlet is integrated with gooseneck adapter, coupler, and 47 mm Teflon filter pack with quick release at outlet. The Teflon filter with 47 mm diameter and 2.0 µm pore size was placed in filter pack. Aerosol samplers were operated with flow rate 16.7 lpm. The flow rate was calibrated with dry test gas meter, and to know aerosol volume. The filter was put in Petridis, then wrapped with Teflon tape and aluminum foil, and stored in a refrigerator after sampling.

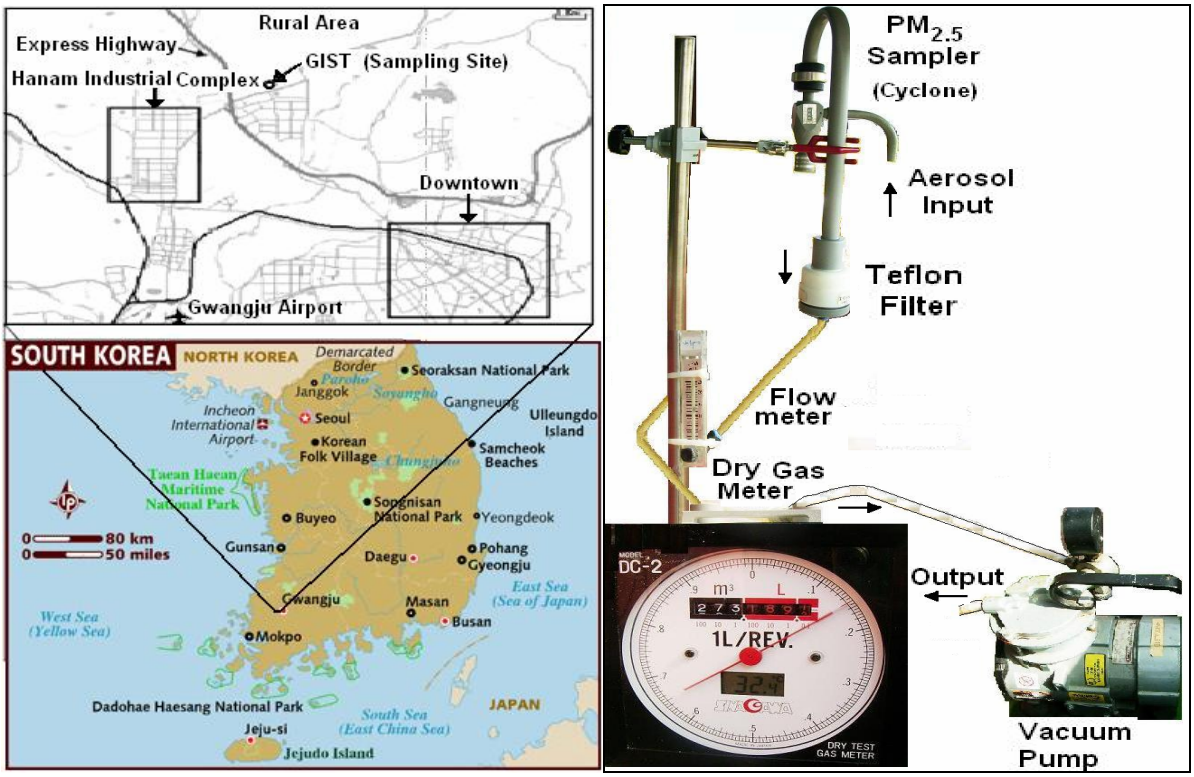

Figure 2. Location of the sampling site and the sampling instruments of $PM_{2.5}$.

All samples were refrigerated between collection and analysis after sampling to minimize losses due to volatilization and evaporation during transportation. Aerosol mass of fine particle fraction were measured by the gravimetric method using an electronic microbalance with a sensitivity of one µg. $PM_{2.5}$ concentration (C) was calculated with divide between difference of particle mass after and before sampling with sampling volume. m_t is filter mass after sampling (µg), m_0 is filter mass before sampling (µg), t is sampling time (minute), and F is the flow rate of sampling (m^3/minute).

$$C = \frac{m_t - m_0}{t \cdot F} \quad \mu g/m^3 \qquad (1)$$

The teflon filters from the $PM_{2.5}$ cyclone sampler were used for the analysis of ionic species by ion chromatography (IC), made in Dionex, DX-120 type (Figure 6). Each sampled filter that collected in Petridis was put into a 20 ml vial, wetted with 15 ml distilled deionizer water (DDW) and shaken with shaker machine during 1 hour with speed 200 rpm. Then each solution of sample was taken 4 ml for anion (Cl^-, NO_3^-, and SO_4^{2-}) analysis and 4 ml for cation (Na^+, NH_4^+, K^+, Mg^{2+}, Ca^{2+}) analysis. All solution was entered into special vial for the analysis of IC. At the same time standard eluent solution, 4 ml was made also to calibrate anion and cation with the concentration of 1, 5, 10 and 20 ppm respectively. The eluent solution for anion measurement is sodium carbonate (Na_2CO_3) 600 mM (15.90 g / 250 ml) and sodium bicarbonate ($NaHCO_3$) 680 mM (14.28 g / 250 ml) with flow rate 1.2 ml/min. The eluent solution for cation measurement is Methane Sulfonic Acid (CH_3SO_2OH) 1 M (96.10 g/l) with flow rate 1 ml/min. Total conductivity for anion is between 16 and 20 µS (µSiemens) and for cation 3 µS. Blank solution of distilled deionizer water is made also as control solution. All solution was analyzed by IC average 20 minutes for ionic concentration.

Concentrations measurement of PM_{10} were obtained real time by using the Beta Gauge monitor at the distance of about one kilometer from the $PM_{2.5}$ sampling site in the GIST eastside. Some meteorological data in the Gwangju area, such as temperature, pressure, wind speed, wind direction, and relative humidity, were obtained from website (www.kma.go.kr) of the Korean Meteorological Administration (KMA) [9].

3. DISCUSSION

The measurement results of $PM_{2.5}$ and PM_{10} concentration in the GIST area were shown in Figure 3. The average concentration and its standard deviation of $PM_{2.5}$ were 39.838 ± 17.265 µg/m^3 on the night (from 9.00 pm to 9.00 am) higher than 35.557 ± 8.920 µg/m^3 on the day (from 9.00 am to 9.00 pm). The maximum and minimum concentrations of $PM_{2.5}$ were 85.173 and 18.796 µg/m^3 on the night respectively, and on the day 47.747 and 21.002 µg/m^3 respectively. This case is similar with the study of Haobo Wang and David Shooter, which found that nighttime of particle matter concentrations were higher than their daytime
concentrations in Christchurch, New Zealand [10]. The highest concentration of $PM_{2.5}$ was 85.173 µg/m^3 on the night (Oct. 4, 21.00 to Oct. 5, 9.00 am (Night 11)). This was possibly, because underway building making at southeast

side of the sampling site and the wasteland at east side of the sampling site releases fine particles, so that the fine particles of dust can be collected by the filter. The occurrence of these fine particles was proved by the low visibility on October 5, at 3.00 am to 7.00 am which is only 2.5 to 4 km. In Korea, it is commonly defined that the haze occurs, if the visibility range is less than about 5 km by the eye [9]. The increase of fine particles ($PM_{2.5}$) and acidic gas pollutants were associated with the rate of incidence of adverse human health effects as well as visibility impairment. The average weather condition on October 4, 21.00 to October 5, 9.00 am (Night 11) is brune (haze), temperature (18.18 ^oC), relative humidity (90.75 %), wind speed (0.9 m/s = 3.24 km/h), wind direction (45^o / North-East). In addition, the mean $PM_{2.5}$ concentrations of the haze episodes was lower than those of other cities such as Athens, Greece (80.7 μg/m^3 (1990)), Mexico city, Mexico (94.4 μg/m^3 (1992)), Beijing, China (127 μg/m^3 (2001)), Seoul, South Korea (131 μg/m^3 (2001), 50.3 μg/m^3 (1996), 75 μg/m^3 (spring), 95 μg/m^3 (summer), 90 μg/m^3 (fall), 85 μg/m^3 (winter, 2003-2004) [9, 11].

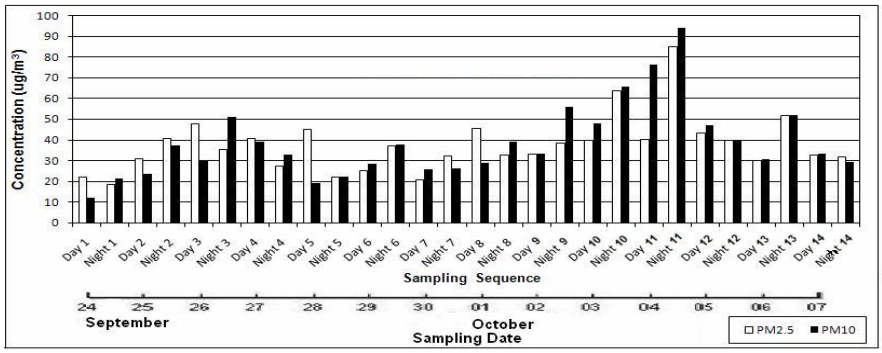

Figure 3. The measurement results of $PM_{2.5}$ and PM_{10} concentration.

The highest concentration of $PM_{2.5}$ on October 4, 21.00 to October 5, 9.00 am (Night 11) can be caused by Asian Dust. According to KMA, Korea, the Asian dust measurement results of PM_{10} concentration on Night 11 were also in fact the highest, even the concentration were high on the daytime and the nighttime. The air mass trajectory on September 24 to 30, 2007 was originated from the desert areas of Mongolia and China (northen) passed through the northeastern part of China, where highly polluted areas and agricultural areas are located. Agricultural burning occurs especially at these areas during the fall season [9]. The air mass trajectory on September 24 to 30, 2007 also was originated from southern China, which includes the major industrial areas [11]. The air mass trajectory on October 1 to 7, 2007 was originated from the China (northeastern) where highly polluted areas and agricultural areas are located. Therefore PM_{10} concentrations on Night 11 were reality the highest, because the air mass concentration from China was the highest on that time. The measurement results of PM_{10} concentration by Beta Gauge monitor in the GIST eastside was similar with the Asian dust measurement results of PM_{10} concentration by KMA. The average PM_{10} concentrations and its standard deviation on the day and the night were 34.018 ± 15.676 μg/m^3 and 43.274 ± 19.581 μg/m^3 respectively.

The highest contributors to the $PM_{2.5}$ mass are major ionic species such as NO_3^-, SO_4^{2-}, and NH_4^+ [9]. The measurement results of nitrate (NO_3^-) anion concentration can be shown Figure 4. The average NO_3^- concentration on the daytime was lower than the one on the nighttime. The average NO_3^- concentrations and its standard deviation on the daytime and the nighttime were 0.636 ± 0.327 μg/m^3 and 1.144 ± 0.791 μg/m^3 respectively. The highest concentration of NO_3^- was 2.825 μg/m^3 on nighttime of Oct. 3, 2007 and 1.136 μg/m^3 on daytime of Sept. 27, 2007. The NO_3^- ions are related with visibility impairment [9]. If the NO_3^- concentration is increase, so the visibility is decrease. This case was proven the low visibility on October 3, 2007 the nighttime until 3 km and the daytime until 11 km. Nitrates are used by plants as nutrients, exploited in agriculture as a fertilizer and chemical manufacturing. Based on the wind direction (average South-West and on Sept. 27, and Oct. 3, 2007), that cases were probably caused by the existance of NO_3^- from chemical process of Hanam Industrial.

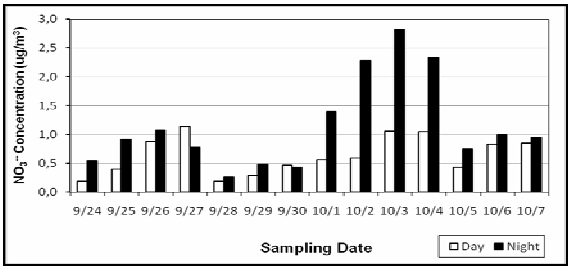

Figure 4. The measurement results of NO_3^- anion concentration.

The measurement results of anion concentration and calibrate of sulfate (SO_4^{2-}) can be shown Figure 5. The average SO_4^{2-} concentration on the daytime was almost closed to the one on the nighttime. The average SO_4^{2-} concentrations and its standard deviation on the daytime and the nighttime were 2.605 ± 2.377 μg/m^3 and 2.734 ± 2.671 μg/m^3 respectively. The highest concentration of SO_4^{2-} was 11.151 μg/m^3 on the night and 9.561 μg/m^3 on the day of Oct. 4, 2007. The SO_4^{2-} ions are related with visibility impairment also [9]. If the SO_4^{2-} concentration is increase, so the visibility is decrease. This case was proven the low visibility on October 4, 2007 the nighttime until 2.5 km and the daytime until 7 km.

Sulfates are important in both the chemical industry and biological systems. Based on the wind direction (South-West on the daytime and North-East on the nighttime of Oct. 4, 2007), that cases were probably caused by the existance of chemical process in Hanam Industrial on the daytime and of biological systems (a agricultural area) on the nighttime.

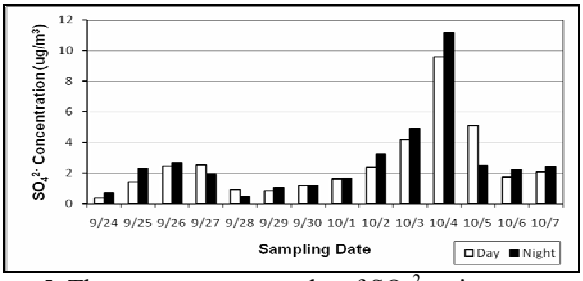

Figure 5. The measurement results of SO_4^{2-} anion concentration.

The concentration measurement results and calibrated of ammonium cation (NH_4^+) can be seen Figure 6. The average NH_4^+ concentration on the daytime was almost closed to that on the nighttime. The average NH_4^+ concentrations and its standard deviation on the daytime and the nighttime were 1.105 ± 1.027 μg/m^3 and 1.362 ± 1.359 μg/m^3 respectively. The highest concentration of NH_4^+ was 5.292 μg/m^3 on the night and 4.038 μg/m^3 on the day of Oct. 4, 2007. The distribution of ammonium ion is from a localized source into the soil. Based on the wind direction (South-West on the daytime and North-East on the nighttime of Oct. 4, 2007), the highest NH_4^+ concentration was probably originated from in the automobile exhaust of Highway and from in the combustion processes of Hanam industrial on daytime and from agricultural biomass burning of a rural area on nighttime.

The average Na^+ concentration on the daytime was higher than that on the nighttime (Fig. 7). The average Na^+ concentrations and its standard deviation on the daytime and the nighttime were 0.660 ± 0.316 μg/m^3 and 0.535 ± 0.213 μg/m^3 respectively. The highest concentration of Na^+ was 0.836 μg/m^3 on the night of Oct. 7, 2007 and 1.064 μg/m^3 on the day of Oct. 1, 2007. Sodium ions are the principal cation in sea salt vapor and chemical process. Based on the wind direction (North on the daytime of Oct. 1, and on the nighttime of Oct. 7, 2007), the highest Na^+ concentration was probably originated from the Japan Sea.

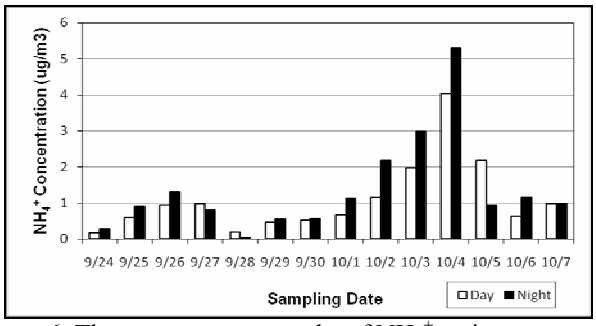

Figure 6. The measurement results of NH_4^+ cation concentration.

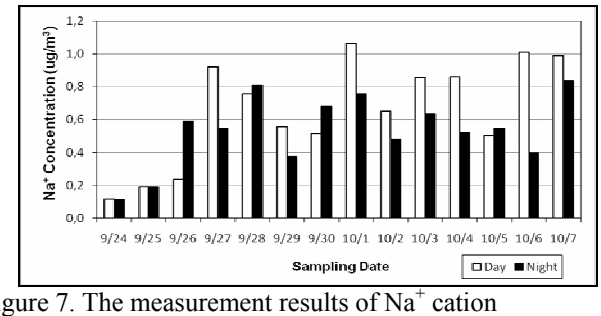

Figure 7. The measurement results of Na^+ cation concentration.

The average Cl^- concentration on the nighttime was higher than that on the daytime (Fig. 8). The average Cl^- concentrations and its standard deviation on the daytime and the nighttime were 0.306 ± 0.067 μg/m^3 and 0.389 ± 0.099 μg/m^3 respectively. The highest concentration of Cl^- was 0.591 μg/m^3 on the night of Oct. 4, 2007 and 0.507 μg/m^3 on the day of Sept. 27, 2007. Cl^- (chloride) ions are the principal anion in sea salt vapor and chemical process. Based on the wind direction (South-West on the daytime of Sept. 27, and North-East on the nighttime of Oct. 4, 2007), the highest Cl^- concentration was probably originated from chemical process in Hanam Industrial on the daytime and from the Japan Sea on the nighttime.

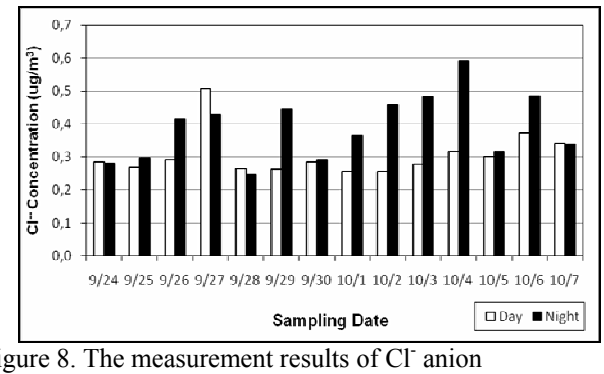

Figure 8. The measurement results of Cl^- anion concentration.

The average K^+ concentration on the nighttime was higher than that on the daytime (Fig. 9). The average K^+ concentrations and its standard deviation on the daytime and the nighttime were 0.365 ± 0.074 μg/m^3 and 0.416 ± 0.082 μg/m^3 respectively. The highest concentration of K^+ was 0.629 μg/m^3 on the night and 0.564 μg/m^3 on the day of Oct. 4, 2007. Potassium ion is primarily used in fertilizers and the chemical industries. Based on the wind direction on Oct. 4, 2007, the highest K^+ concentration was probably originated from chemical processes of Hanam industrial on daytime and from agricultural biomass burning of rural area on nighttime.

The average Mg^{2+} concentration on the nighttime was higher than that on the daytime (Fig. 10). The average Mg^{2+} concentrations and its standard deviation on the daytime and the nighttime were 0.484 ± 0.030 μg/m^3 and 0.522 ± 0.151 μg/m^3 respectively. The highest concentration of Mg^{2+} was 1.041 μg/m^3 on the night of Sept. 29, 2007 and 0.560 μg/m^3 on the day of Sept. 27, 2007. Based on the wind direction

(North-East on Sept. 29, and South-West on Sept. 27, 2007), that cases were probably caused by the existence of Mg^{2+} ion from Hanam industries on Sept. 27, 2007 and the dust existence of agricultural biomass burning on Sept. 29, 2007.

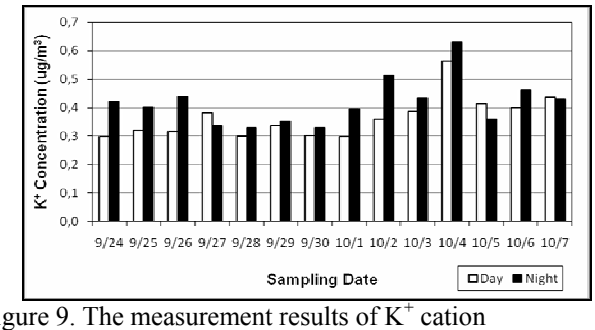

Figure 9. The measurement results of K^+ cation concentration.

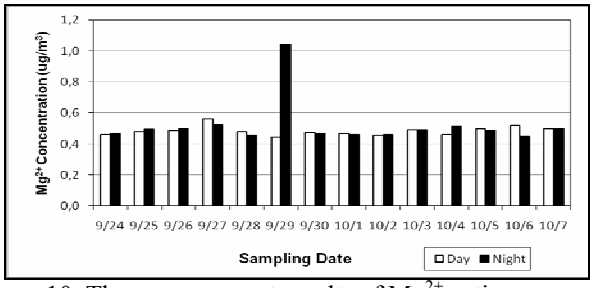

Figure 10. The measurement results of Mg^{2+} cation concentration.

The average Ca^{2+} concentration on the nighttime was closed to that on the daytime (Fig. 11). The average Ca^{2+} concentrations and its standard deviation on the daytime and the nighttime were 0.548 ± 0.073 μg/m^3 and 0.550 ± 0.080 μg/m^3 respectively. The highest concentration of Ca^{2+} was 0.711 μg/m^3 on the night and 0.675 μg/m^3 on the day of Oct. 6, 2007. Calcium ion is as an alloying agent used in the metal production, and cement factory. Based on the wind direction (North-East on the daytime, and South-East on the nighttime of Oct. 6, 2007, that cases were probably caused by the existence of Mg^{2+} ion from building materials on the nighttime and the dust existence of agricultural biomass burning on the daytime.

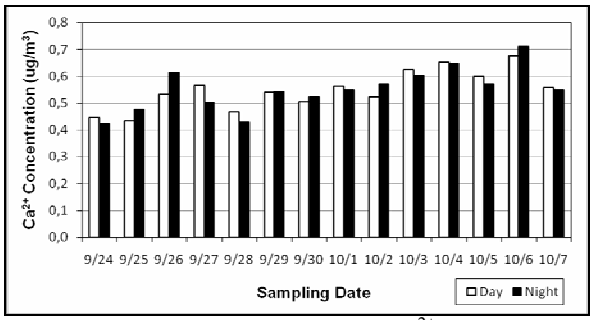

Figure 11. The measurement results of Ca^{2+} cation concentration.

4. CONCLUSION

The average concentrations of $PM_{2.5}$ and PM_{10} were on the night (from 9.00 pm to 9.00 am) higher than those on the day (from 9.00 am to 9.00 pm). The highest concentration of $PM_{2.5}$ and PM_{10} were on the nighttime of October 4, 2007, and the contents were SO_4^{2-}, NO_3^-, Ca^{2+}, NH_4^+, Cl^-, and K^+. While the contents of $PM_{2.5}$ and PM_{10} on the daytime of October 4, 2007 were Na^+, Ca^{2+}, K^+, NH_4^+, and SO_4^{2-}. The average concentrations Na^+ on the daytime were higher than those on the nighttime. The average concentrations of NO_3^-, Cl^-, K^+, and Mg^{2+} on the nighttime were higher than the ones on the daytime. The average concentrations of NH_4^+, SO_4^{2-}, and Ca^{2+} on the daytime were almost closed to those on the nighttime. The average concentrations of PM_{10}, were lower and the average $PM_{2.5}$ concentrations were a little higher than the ones of the US NAAQS standard respectively.

ACKNOWLEDGMENT

Many thanks to Prof. Young Joon Kim, Dr. Suil Kang, Dr. Suthipong Sthiannopkao, all administrative staffs of IERC (International Environmental Research Center) and GIST, and all members of Air Quality Monitoring Laboratory, GIST as well as all of internship students for their kindly help and support.

ABSTRACT

Geothermal energy is an alternative energy to replace oil and gas energy. In its development, geothermal fluid contains compounds that corrosive to carbon steel pipe. This corrosive compounds are carbon dioxide (CO_2), chloride compounds, and hydrogen sulfide as the most corrodent. API 5LX65 carbon steel was used as a test specimen. This specimen was put in 3.5 %b/v NaCl with H_2S gas to get corrosion process. The pH value was varied by addition of acetic acid. Corrosion rate was calculated based on weight loss. Result of corrosion rate calculation at pH 3.2 demonstrated an increasing of corrosion rate with an increasing temperature at 25°C – 75°C and decreasing at 97°C. This decreasing in corrosion rate may be attributed to the fact that sulfide iron film was composed as corrosion product. Meanwhile, at 75°C with variation of pH value, the calculation result demonstrated that corrosion rate was decrease with an increasing of pH value from 3.2 to 6.1, and then increase at pH 6.6. The increasing of H_2S gas concentration causes the increasing of corrosion rate. Corrosion layer as corrosion product was known from SEM and EDS. Results of SEM and EDS showed that the surface morphology demonstrate a pitting corrosion.

Keywords: *Corrosion rate, Carbon steel, Temperature, pH, Hydrogen Sulfide.*

1. INTRODUCTION

Geothermal energy is an alternative energy to replace oil and gas energy. In its development, geothermal fluid contains compounds that corrosive to carbon steel pipe. This corrosive compounds are carbon dioxide (CO_2), chloride compounds, and hydrogen sulfide as the most corrode [1]. Existence of H_2S in aqueous can cause corrosion at carbon steel pipe and yield solid sediment in the form of sulfide iron or dissolve ion and cause thinning corrosion or pitting corrosion.

Internal corrosion of oil-producing equipment by carbon dioxide has been thoroughly investigated by many workers [2-3]. Materials selection for installations handling well fluids with CO_2 and H_2S is often dictated by the H_2S concentration alone, according to accepted standards. For short-life wells, this may lead to over-specification and unnecessarily high construction costs. Normal carbon steel could be a candidate for pipelines carrying an H_2S containing water phase. Lyle and Schutt explain corrosion at carbon steel that effect of dissolve H_2S gas is localize corrosion and at the surface of carbon steel formed sulfide iron coated. The character of iron sulfide coat is porous so that can be corroded [2]. Sridhar, N., et all, supporting that sulfide iron represent less sulfide corrosion product that can improve corrosion rate. Result of research above can be concluding that H_2S gas can cause corrode at surface of material [3].
Some experiment study has been conducted and publication in many literature such as Ikeda al et., 1984, Videm. Et al, 1994, Valdes, Et al, 1998 is limited to attempt of laboratory experiment from size to condition of experiment which adapted by the condition in field. The addition a few of H_2S gas at CO2 environment can cause local corrosion and thinning corrosion improvement radically [4]. Russell D.Kane, explain that stress corrosion cracking is happened in API 5CTN-80 steel at geothermal environment because of hydrogen embrittlement. These hydrogen atoms produce by sulfidation process at metal surface [5]. Basuki, E.A. dan Martojo,W., tells that the tendency of gas and oil produce which progressively mount requiring carbon steel pipe with high strength to detain oil fluid pressure. Carbon steel with higher C content will improve strength of steel, but it can cause degradation of toughness fracture. So it can be decrease of sulfide stress cracking [1].

The aim of this research was to study the variation of temperature and pH in carbon steel corrosion rate at hydrogen sulfide environment. The corrosion rate was calculated using weight loss method.

2. EXPERIMENTAL

API 5LX56 Carbon steel were use as spesiment. The dimenstion of speciment is 29.48 mm x 11.29 mm x 2.94 mm. The test solution was distilled water with 3.5% NaC1 saturated with H_2S gas mixture. The corrosion processes were done for 24 h. Acetic acid use to arranged pH value and temperature process between 25-100°C. The corrosion rate was calculated using weight loss of specimen. After exposure, the steel specimen was removed from the test section, dried and stored in a desiccators. The corroded steel surfaces were examined by scanning electron microscopy (SEM), and energy

dispersive spectroscopy (EDS) was used to determine the composition of the corrosion film.

3. RESULT

Figure 1 shows the temperature dependence of steady-state corrosion rates on carbon steel at pH 3.5. The corrosion rate increase with increasing of temperature from 25°C to 75°C and at higher temperature the corrosion rate value decreased. This is because of sulfide iron coated in the surface of the specimen. At figure 1 also shows the higher corrosion rate is 0.694 mpy at 75°C.

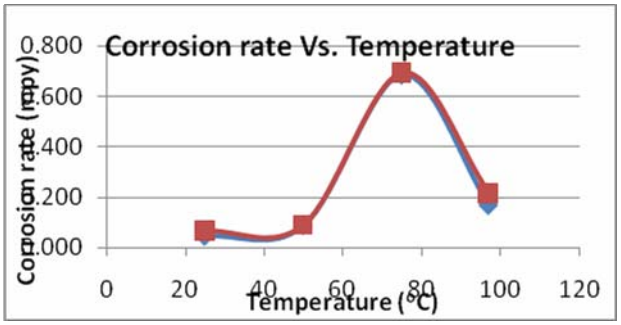

Figure 1. Corrosion rate vs. temperature, at pH 3.5 and 24h.

The temperature at highest corrosion rate from figure 1 was used to fine correlation of corrosion rate at various pH. Figure 2 shows the pH dependence of steady-state corrosion rates on carbon steel at 75°C. However, only the highest value is cited in figure 2. Corrosion rates in H_2S environments were significant decrease from pH 3.2 to 6.1 and increase at pH 6.6. The corrosion rate was increase because effect of amount H_2S in environments.

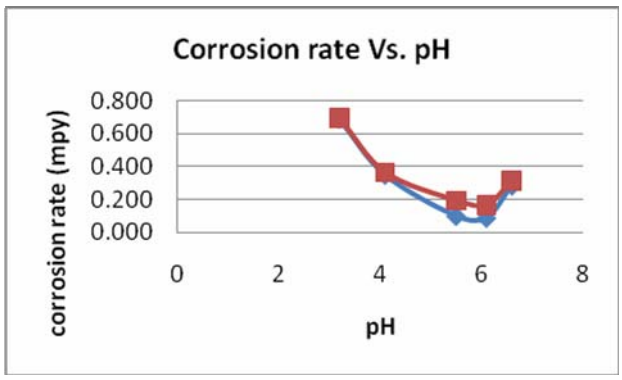

Figure 2. Corrosion rate vs. pH, at temperature 75°C and 24 h.

This result is strengthened with surface morphology result from SEM analysis (Figure 3). Figure 3.a shows surface morphology of carbon steel before corrosion test. The dark black from that figure is morphology of carbon steel from the specimen. On the other hand, Figure 3.b and 3.c reveal the morphology of the layer formed on carbon steel after corrosion test for pH 6.1 and pH 3.2 at temperature 75°C during 24 h. it can be noticed that the layer in not uniform. SEM observations at high resolution have revealed numerous cracks and porosities as shown in Fig. 3.c. These indicate that thinning and localize pitting corrosion product. The chemical composition of specimen determined by SEM/EDS is given in Table 1. The chemical composition of the matrix and the nodular graphite was determined in carbon steel, as shown in Fig. 3.a. regarding the matrix, iron, manganese, nickel, vanadium, chrome and titanium were detected whereas the nodular graphite contains carbon (4.88 at.%). The surface layer formed after corrosion test (Figure 3.b and 3.c) includes mainly iron, sulphur and oxygen.

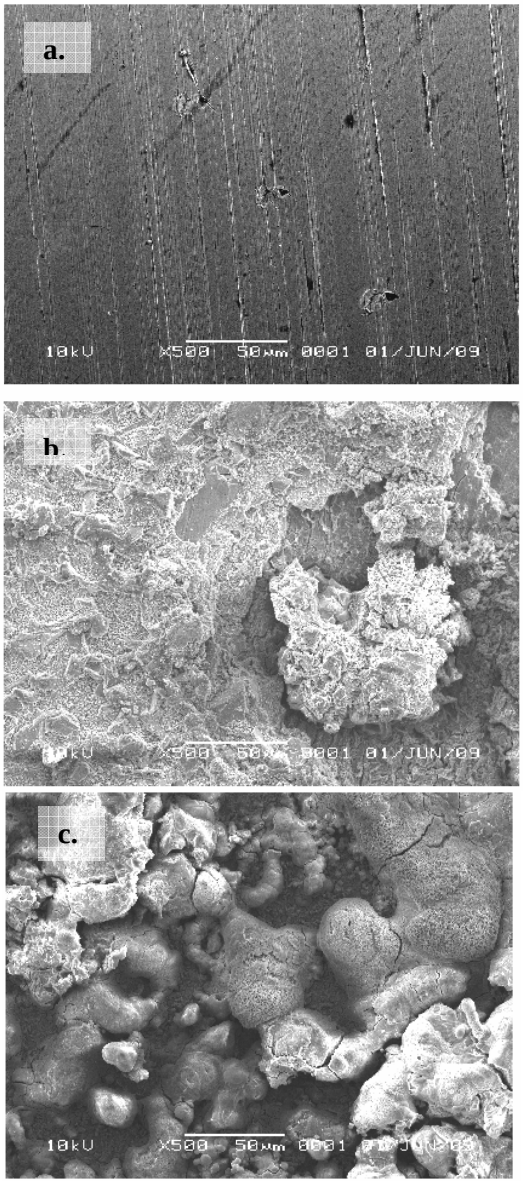

Figure 3. Surface morphology of Carbon Steel API 5LX65: (a) Before corrosion test (b) After corrosion test at temperature 75°C, and pH 6.1, 24 h, (c) After corrosion test at temperature 75°C, and pH 3.2, 24 h,

Table 1. Chemical composition of the sites reported in Fig. 3 obtained from SEM/EDS examinations (in at.%)

Speciment	Fe	C	Ti	V	Cr	Mn	Ni	O	S
Carbon steel	91.98	4.88	0.10	0.40	0.28	1.04	1.32	-	-
After corrosion test, at pH 6., 75°C, 24 h	42.27	-	-	-	-	-	-	28.09	29.64
After corrosion test, at pH 6., 75°C, 24 h	40.63	-	-	-	-	-	-	58.95	0.42

Compared to the content of elements in the layer formed on carbon steel after corrosion test at pH 6.1 and pH 3.2 is characterized by significant enrichment in sulfur (between 29.64 and 0.42 at.%) and oxygen (between 28.09 and 58.95 at.%), as determined on Fig. 3.b and 3.c and reported in Table 1. This result can be notice that corrosion test with pH 6.1 formed sulfide and oxide compound which seen from SEM/EDS analysis (Table 1). Meanwhile, SEM/EDS for specimen after corrosion test with pH 3.2 notice that iron oxide was formed in the surface of specimen.

4. DISCUSSION

4.1. Corrosion mechanism effect of H_2S

The H_2S-promoted increase in corrosion rate is almost one order of magnitude. Similar results have been reported by others. Reaction that happened in system when there are H_2S in system shall be as follows:

$$H_2S_{(g)} = H_2S_{(l)} \quad (1)$$

The dissociation reaction in H_2S aqueous shall be as follows:

$$H_2S_{(aq)} + 4e^- \rightarrow H_2S^-_{(aq)} \quad (2)$$

$$H_2S^-_{(aq)} + H^+_{(aq)} \rightarrow H_2S...H_{(aq)} \quad (3)$$

$$H_2S...H_{(aq)} \rightarrow H_2S_{(aq)} + H_{(aq)} \quad (4)$$

Molecules of H_2S adsorb on the metal surface and react with free electrons from the metal (eqn.2). These intermediates act as bridge-forming ligands with adsorbed protons (eqn. 3). Finally, hydrogen is liberated on disintegration of the complexes (eqn. 4) [6-8]

Consequently, H_2S can increase the hydrogen evolution rate without taking part in the net reaction. Since corrosion behavior deteriorated after H_2S addition on carbon steel, it appears to be unaffected by the presence of nonferrous compounds in the corrosion products. Thus, the catalytic mechanism given by eqns (1-4) seems to be a more probable cause of the increased corrosion rates.

4.2. pH Effect

At low pH value (< 2.0), dissolved iron and iron sulfide do not precipitated at metal surface. These should be dissolved and precipitated at high solubility of iron sulfide phase at lower pH than 2.0. In this case, H_2S play a role as accelerator at solubility of iron. At pH value 3.0 to 5.0, H_2S can inhibit iron to $FeSH^+$ as mackinawite.

At pH value 3.0 to 5.0, H_2S is become $FeSH^+$ as mackinawite that can be as an inhibition effects of corrosion. This metastable mackinawite could change into another sulfide compound which more protective such as troilite. Protectiveness or inhibition effect of H_2S depends on stability and protectiveness of formed sulfide [7]. H_2S concentration has a great effect to the protectiveness of sulfide layer. The higher concentration of H_2S, the more the amount of mackinawite in the layer [8]. This formation of mackinawite cause defect structure that cannot prevent iron corrosion effectively. At high concentration of H_2S, there will be more mackinawite precipitated on metal surface.

According to mechanism of corrosion in CO_2/H_2S environment, corrosion can be anticipated with some environmental factor such as chemical solution, rate of flow, temperature, pressure, H_2S concentration and any other factor that influence metal corrosion rate. The formation of corrosion product layer depends on environment condition as diffusion barrier for corrosive specimen which has significant effect to metal corrosion rate.

Commonly, structure and composition of FeS protective layer depend on concentration of H_2S in environment system. $FeSH^+$ at electrode surface can be directly mixed into mackinawite layer [8], or hydrolyzed to become Fe^{2+} that depends on solution pH value [7, 9]. At a range pH value 3.0 to 5.0 with low concentration of H_2S, FeS protective layer inhibit corrosion rate at metal sample [7]. Mackinawite formed through solid phase reaction at pH value 7.0 to 7.4 and room temperature. But, at pH value 5.5 – 7.0 precipitation of FeS was produced imperfectly [10](Harmandas dan Koutsoukos, 1996).

4.3. Temperature Effect

Temperature increases the rate of almost all chemical reactions. Figure 1 illustrates common observations on the effect of temperature on the corrosion rates of carbon steel metals. That is, an almost negligible temperature effect is followed by a very rapid rise in corrosion rate at higher temperatures [11].

Perhaps the most important single factor in corrosion is the effect of temperature. Accordingly, if is very important that the temperature of the surface of the specimen (which is the corroding temperature) be identified and known. Figure 1, shows corrosion increases from low rate to several mils per years as a result of increasing the temperature.

5. CONLUSION

Corrosion measurements of carbon steel and pure iron in the presence of H_2S were performed in a flow loop. Result of corrosion rate calculation at pH 3.2 demonstrated an increasing of corrosion rate with an increasing temperature at 25°C – 75°C and decreasing at 97°C. This decreasing in corrosion rate may be attributed to the fact that sulfide iron film was composed as corrosion product. Meanwhile, at 75°C with variation of pH value, the calculation result demonstrated that corrosion rate was decrease with an increasing of pH value from 3.2 to 6.1, and then increase at pH 6.6. The increasing of H_2S gas concentration causes the increasing of corrosion rate. Corrosion layer as corrosion product was known from SEM and EDS. Results of SEM and EDS showed that the surface morphology demonstrate a pitting corrosion.

ABSTRACT

The application of dual phase steel is growing due to the increasing demand of light weight structure. Dual phase steel has an excellent property combination of high strength, ductility and formability which is favourable for metal forming processes. As dual phase steel consists of ferrite matrix and martensite islands as strengthening particles, it is important to understand the interaction between the two phases with very dissimilar mechanical properties. This paper reported the results from finite element simulation and experimental studies which were carried out to investigate the behaviour of dual phase steel under plastic deformation. Metallographic and SEM observation were done for specimens under 10% to30 % engineering strain. After measuring the ferrite grain size and the martensite particle size, finite element method was applied to represent the microstructure into two dimensional micro mechanical model. Experimental study confirmed that the grain of ferrite underwent elongation meanwhile the distance amongst martensite particles became shorter. Micro voids then occurred in the area of martensite concentration. Finite element analysis results demonstrated that ferrite phase experienced higher strain than martensite particles and stress concentration took place in the boundary interface between phases.

Keywords
Dual phase, finite element, micromechanical.

1. INTRODUCTION

In the last decade the application of the sheet forming technology in industries has changed rapidly due to the increasing demand of geometrical complexity and high performance of the metal parts required by design. To fulfill these needs, the advanced high strength steel - dual phase steel - has been developed. The excellent features of this material are its high tensile strength and its good formability. Therefore, the use of dual phase (DP) steel is increasing, especially in automotive industry [1, 2, 3].

Dual phase (DP) steels consist of a ferritic matrix containing a hard martensitic second phase in the form of islands or particles obtained by heat treatment processes. The volume fraction of hard second phases determines its strength and the soft ferrite phase gives this steel excellent ductility. In some instances, hot-rolled DP steels can have a microstructure also containing significant quantities of bainite which is required to enhance its stretching capability.

Although many studies [4, 5, 6, 7] has been carried out to investigate the metallurgical aspects and to optimise the mechanical properties and formability of dual phase steel, unfortunately the material behavior under plastic deformation have not been studied sufficiently. This paper will discuss the interaction of ferritic matrix and martensite particles subjected to uniaxial stress. To understand the interaction, experimental studies as well as simulation using finite element method (FEM) were carried out which was focused on elastic plastic behaviors of the two phases in micro scale. The results from micro mechanical modeling could be then used to optimize the grain size, particle distribution and to predict failure.

2. TENSILE TEST AND MICROSTRUCTURE OBSERVATION

2.1 Material

DP steel used for this study was from commercial brand Docol 800DP supplied by Swedish Steel Manufacturer SSAB. Docol 800DP is classed into advanced high strength steel since its ultimate strength is about 800 MPa. The material was delivered in from of cold rolled sheet with nominal thickness 0.75mm. Table 1 shows its chemical composition.

Table 1: Chemical composition of Docol 800DP.

Chemical Components	composition in w%
Carbon, C	0.12
Silicon, Si	0.20
Manganese, Mn	1.50
Phosphorus, P	0.015
Sulfur, S	0.002
Niobium, Nb	0.015
Aluminium, Al	0.04

2.2 Uniaxial tensile testing

Uniaxial tensile tests were carried out following the ASTM E8 standard. Tensile specimens of dog bone shape

were cut from the sheet and oriented 0^o, 45^o and 90^o of the rolling directions in order to assess the anisotropy factor.

Figure 1 shows the true stress-strain curve obtained from tensile test with strain rate 0.05 s^{-1}. From the graph, the material could be assumed isotropy as the true stress strain curves from rolling directions 0^o, 45^o and 90^o demonstrated no significant variation. The ultimate engineering strength was slightly below 700 MPa and total elongation was about 30%. The engineering stress-strain was converted into true stress-strain and the ultimate true stress was 870 MPa and total elongation was 27%.

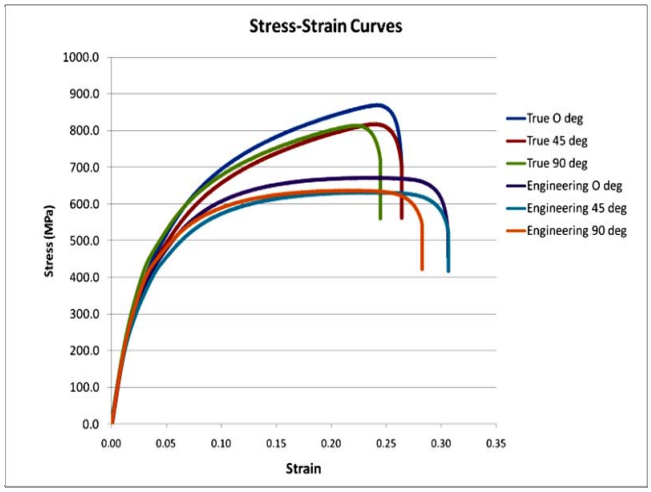

Figure 1: Stress strain curve of DP steel

2.3 Microstructure observation

Optical metallographic as well as scanning electron microscope (SEM) examinations were carried out whereby the microstructure was to reveal. Figure 2(a) shows the as-delivered microstructure in which the martensite particles were not so well distributed. However, the mechanical properties were satisfactory according to tensile test results.

Figure 2(b), 2(c) and 2(d) show microstructures after specimens were 9.5%, 18% and 26% plastically deformed (equivalent to 10%, 20% and 30% engineering strain). From micrographs, it can be seen that ferrite grains elongated meanwhile martensite particles shifted only. The higher the deformation the more martensite particles assembled in certain areas. Micrograph from the area near the failure zone in Figure 2(e) shows that voids grew in the interface between ferrite and martensite.

Grain and particle size measurement were conducted according to ASTM standard E 112. The mean size of ferrite grain was 9 μm and the mean size of martensite particle was 2 μm.

3. FEM MICRO MECHANICAL MODELING

Dual phase steel can be categorized as multiphase steel for it has two separate phases. For multiphase material, it is important to understanding the local mechanics and mechanisms governing the elastic–plastic deformation as heterogeneous solids. By using micro-modeling approach, phase combinations of different size, morphology, phase distribution and volume fraction can be analyzed by only having the properties of each existing phase.

3.1 Wilson-Theta method for time integration

In this study, material was subjected to tensile stress. Because the force in the uniaxial tensile testing was gradually increased, tensile testing could be considered as dynamic problem, or time function problem. The general representation of dynamic problems in FEM is as follow:

$$F = [K]\,u + [C]\,\dot{u} + [M]\,\ddot{u} \tag{1}$$

Where F is the external force, K is the stiffness matrix, C is the damping matrix, M is the mass matrix, u, $\dot{u}$ and $\ddot{u}$ are the displacement, velocity and acceleration respectively.

FE implicit time integration using Wilson-Theta method was applied in this study. Wilson's method is a linear acceleration method in which the acceleration is assumed to vary linearly within each time interval from t to $t + \Theta\Delta t$, where $\Theta \geq 1.0$. If $\Theta = 1.0$, the linear acceleration will be reduced. In practice, $\Theta = 1.4$ is often selected [8]. Displacement, velocity and acceleration at the time $t + \Theta\Delta t$ are then written as follow:

$$\dot{u}_{i+1} = \dot{u}_i + \frac{\Theta\Delta t}{2}(\ddot{u}_{i+1} + \ddot{u}_i) \tag{2}$$

$$u_{i+1} = u_i + \Theta\Delta t\,\dot{u}_i + \frac{\Theta^2(\Delta t)^2}{6}(\ddot{u}_{i+1} + 2\ddot{u}_i) \tag{3}$$

FE method seeks u_{i+1} to solve the equilibrium equation (1) which becomes:

$$F_{i+1} = Ku_{i+1} + M\ddot{u}_{i+1} \tag{4}$$

Substituting acceleration $\ddot{u}_{i+1}$ from (2) and (3) gives:

$$F'_{i+1} = F_{i+1} + \frac{M}{(\Theta\Delta t)^2}\left(6u_i + \Theta\Delta t\,\dot{u}_{i+1} + 2(\Theta\Delta t)^2\ddot{u}_i\right) \tag{5}$$

By combining the similar terms and rewriting (5) into load vector expression, the general equation becomes:

$$F_{i+1} = F_i + \Theta(F_{i+1} - F_i) \tag{6}$$

3.2 Geometrical representation and discretization

Determination of geometrical representation is a decisive step in micro-mechanical modeling to guarantee an effective transition from a solid with a repetitive microstructure to an equivalent homogeneous continuum which represents the two phase microstructure. A representative volume element; could be a cylinder, a sphere etc, is assumed to compose the solid in a repetitive way and each small volume matches its neighboring cells in all aspects. This is indeed a simplifying assumption, but has proved to be satisfactory and is widely accepted.

Modeling the microstructure as a plane element or axisymmetric cell reduced the complexity of 3D modeling and minimizes the computational cost. Representative elements in form of a cylinder for the matrix and sphere for the particle have been reported very effective to model DP steel with variation in phase composition [9, 10]. A single cell was decomposed from a homogenous stacked hexagonal array which represented grain structure. Figure 3 shows the simplified geometrical representation.

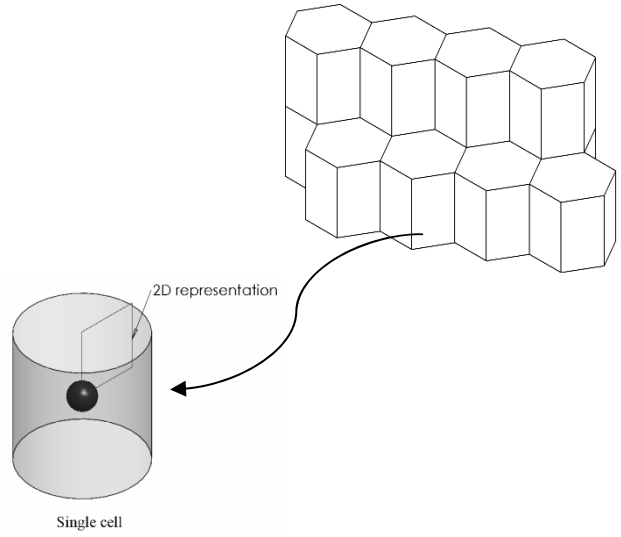

Figure 3: Stacked hexagonal array and a single cell of representative volume element

In this study, multi cell model was introduced instead of single cell although the stacked hexagonal array approach was still used. The configuration of the representative elements in multi cell as well as FE discretisation can be seen in *Figure 5* and Figure *6*. The multi cell model was thought to be capable to model not only the grain elongation but also the movement of the islands and the occurrence of voids. Multi cell mechanical model managed to effectively simulate fracture in multiphase steel, as reported in [11].

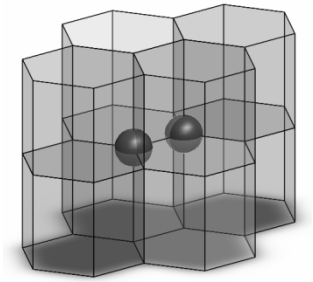

Figure 4: Configuration of multi cell volume representation

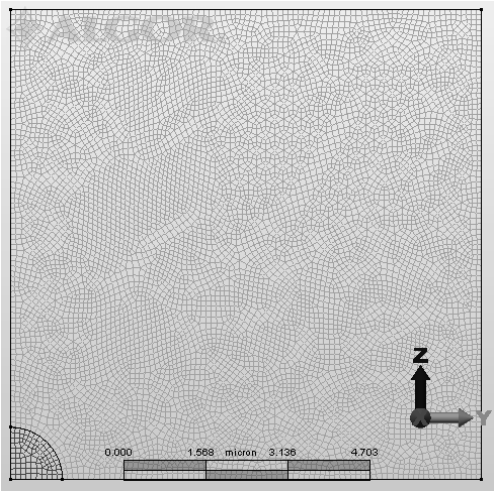
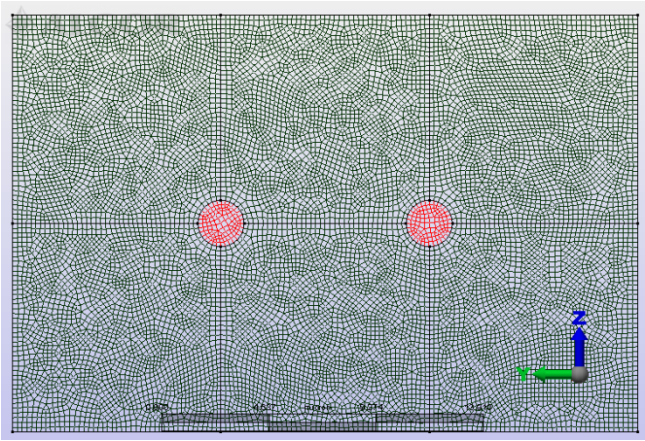


(a) 2D discretization single cell



(b) 2D discretization of multi cell

Figure 5: Single and Multi cell configuration and its 2D representation.

3.3 Elastic plastic hardening model

Stress-strain curve from tensile testing (Figure 1) indicates that dual phase steel deformed not only elastic-plastically but also hardened isotropically. Therefore the constitutive model for isotropic elastic plastic hardening can be used to represent the material behavior.

In the elastic plastic approach, total strain 'rate' tensor is decomposed into elastic and plastic components:

$$\dot{\varepsilon}_{ij} = \dot{\varepsilon}_{ij}{}^{e} + \dot{\varepsilon}_{ij}{}^{p} \tag{7}$$

The elastic strain $\dot{\varepsilon}_{ij}{}^{e}$ is described by Hooke's law. On the other hand the plastic strain $\dot{\varepsilon}_{ij}{}^{p}$ may occur only if the flow criterion below is fulfilled.

$$\text{If} \begin{cases} f < 0, & \dot{\varepsilon}_{ij}{}^{p} = 0 \\ f = 0, & \dot{\varepsilon}_{ij}{}^{p} = \dfrac{3}{2}\dfrac{\dot{\varepsilon}^{p}}{\sigma}\sigma'_{ij} \end{cases} \tag{8}$$

The Von Misses yield function f can be written as:

$$f = \sigma - \bar{\sigma} \tag{9}$$

where $\bar{\sigma}$ is the flow stress and the equivalent stress σ is defined by Von Misses is as follow:

$$\sigma = \sqrt{\frac{3}{2}\sigma'_{ij}\,\sigma'_{ij}} \tag{10}$$

Where σ'_{ij} is the deviatoric stress. The equivalent plastic strain $\dot{\varepsilon}^{p}$ can be found from expression:

$$\dot{\varepsilon}^{p} = \sqrt{\frac{2}{3}\varepsilon_{ij}{}^{p}\,\varepsilon_{ij}{}^{p}} \tag{11}$$

The hardening factor is described by the increase of flow stress $\bar{\sigma}$ as function of plastic strain according to the material model:

$$\bar{\sigma} = K\left(\varepsilon_0 + \dot{\varepsilon}^{p}\right)^{n} \tag{12}$$

The values of material parameters for ferrite matrix and martensite particle used for FE model are presented in Table 2.

Table 2: Material parameters for ferrite and martensite [12]

Parameters	Ferrite	Martensite
Stress constant K	597 MPa	2409 MPa
Elastic limit ε_0	0.002	0.002
Strain hardening coefficient n	0.07	0.31
Poisson's ratio r	0.28	0.28

True stress-strain curves for ferrite and martensite were created by using material model equation (10) and parameters in Table 2. The comparison of the stress-strain curves of the two phases can be seen in *Figure 6*. From the curves, the mechanical properties dissimilarities can be clearly depicted.

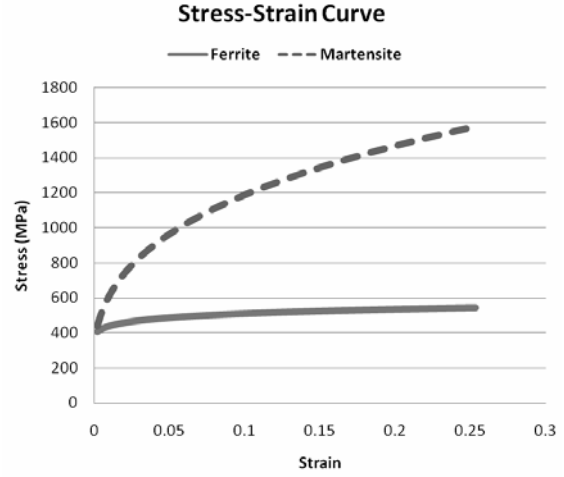


Figure 6: Stress strain curves of ferrite and martensite plottet from material model in equation (10)

3.5 Simulation results

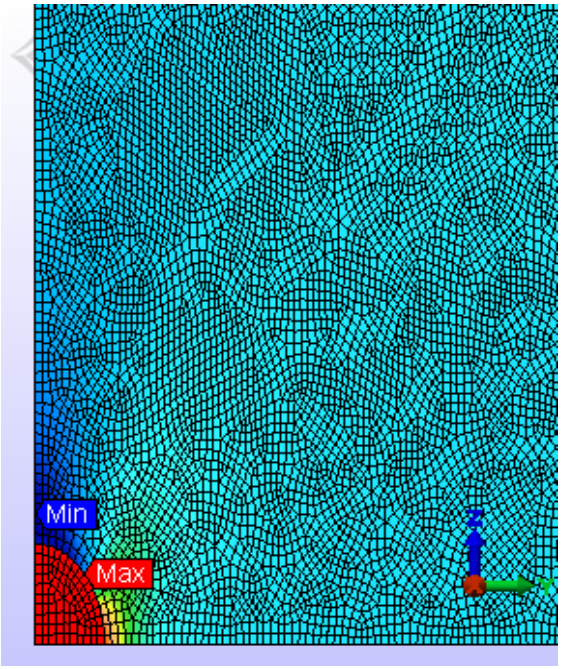
Contour plots of the equivalent stress and strain for both single cell and multi cell models can be seen in *Figure 7* and *Figure 8*. The red areas correspond to the highest stress or strain and blue areas correspond to the lowest.

In the single cell model as well as in the multi cell model, martensite phase had higher stress than ferrite, but lower strain. When an external force was applied into the ferrite-martensite structure, the stress conveyed from ferrite matrix to martensite second phase. Because the ferrite had higher formability than the martensite, ferrite matrix had higher strain or deformation. However due to the higher strength, the martensite bore stress more.

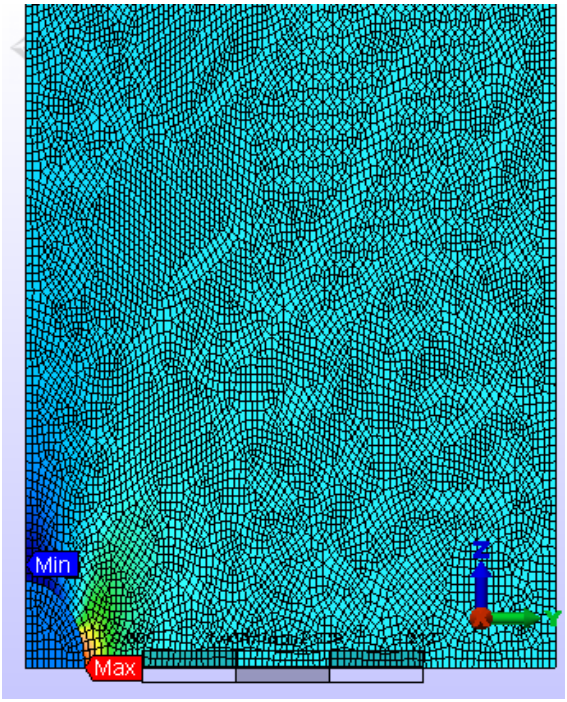
Grain boundary or transition area was the area with the highest strain concentration or the most critical zone. In this model, the surface contact between martensite and ferrite was defined as bounded interface. In this contact definition, the nodes in the interface were matched. If stress was conveyed from ferrite to martensite and cause deformation or strain, strain was accumulated in the transition areas and could initiate failure. Table 3 presented the values of the stress and strain at different areas.

Table 3: Stress and strain values at 26 % deformation

Area	Stress	Strain
Ferrite	0.130 N/μ^2	0.51
Martensite	0.205 N/μ	0.48
Grain boundary	0.135 N/μ^2	0.69

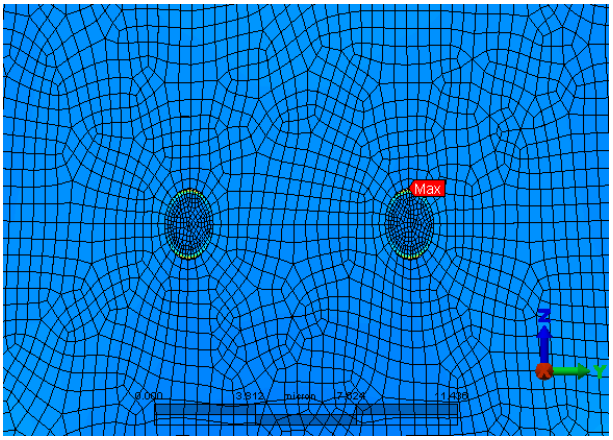


(a) Stress distribution from single cell model

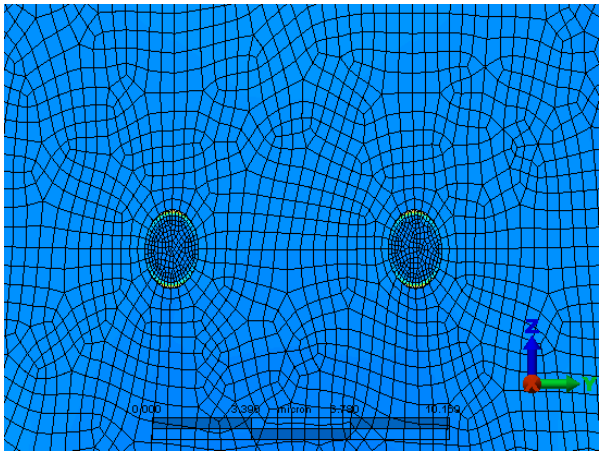


(b) Strain distribution from single cell model

Figure 7: FE simulation results from single cell



(a) Stress distribution from multi cell model

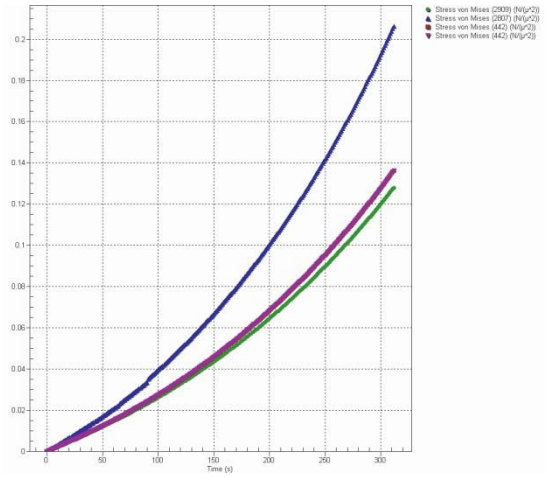


(b) Strain distribution from multi cell model

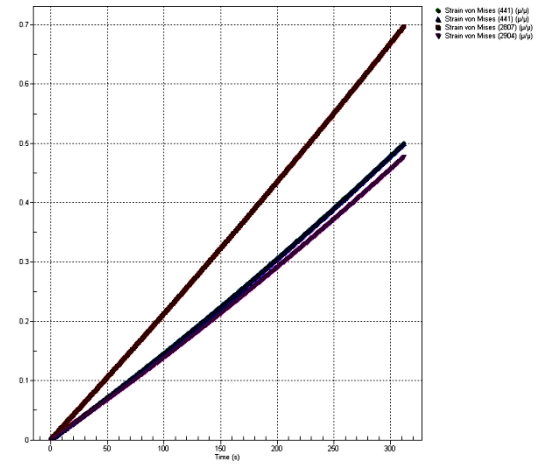
Figure 8: FE simulation results for multi cell

The FE results from multi cell model in *Figure 8* show that the large elongation of the ferrite caused the martensite particles moved closer. The same phenomena could also be clearly observed in the photographs of microstructures in *Figure 2*. If the martensite particles concentrated in a certain area, the strengthening function of the particles in the steel declined. Multi cell model came out with different area of stress and strain concentration although still on the grain boundary.

Figure 9 show the stress and strain profile graph of the two phases and a node in the boundary. The graph depicted that the differences of stress and strain grew with the increase of deformation



(a) Stress profile



(b) Strain profile

Figure 9: Stress and strain profile at ferrite and martensite

7. CONCLUSION

Experimental observation as well as FE simulation of micro mechanical model were conducted to study the behavior of the dual phase steel under deformation. Conclusions drawn from the study are:

1. Boundary interface between ferrite matrix and martensite second phase was the most critical area due to the strain accumulation. This was recognized in the FE simulation and supported by SEM micrograph.
2. The multi cell micromechanical model was considered better regarding the representation of the behaviour of the dual phase steel under plastic deformation.
3. The difference of stress and strain in the martensite, ferrite and phase interface grew with the increase of deformation.

Study of Aggregation and Orientation of Photo-Responsive Molecule of Disperse Red 19 Film Deposited On Silane Substrate Surface

Heindrich Taunaumang [1], Donny Royke Wenas [1]

[1]*Physics Department, Mathematics and Sciences Faculty, Manado State University*,

ABSTRACT

Study of aggregation and orientation of photo-responsive molecules such as Disperse Orange 44, Disperse Red 1 have been carried out for optimizing optical properties for application photonics devices such as optical switching and optical data storage. Usually the photo-responsive molecules are available in form of powder, however, for photonics devices application this material must be prepared in form of film with good quality i.e., smooth surfaces, homogenous thickness, good optical stability, transparency and good optical properties. In this research the photo-responsive material of Disperse Red 19 film was deposited on silane substrate surface by using physical vapor deposition (PVD). The relationship between the property and structure of the Disperse Red 19 film is mainly focused of this study. The result of vacuum deposited Disperse Red 19 film shows a smooth surface with homogeneous thickness. Furthermore, the results of FTIR and UV-VIS measurements and also XRD measurement are performed. These results indicated that the Disperse Red 19 film show a specific aggregation and orientation which is promising for developing photonics devices application.

Keywords *: Disperse Red 19, vacuum deposition , silane, aggregation, orientation*.

1. INTRODUCTION

Photo-responsive molecule with its structure consists of donor, acceptor and azobenzene bridging groups have been subjected to the optical material research for optimizing optical properties in order to be suited for photonics technology application. When this molecule is exposed to light (photon), this molecule undergoes trans-cis isomerization phenomenon that caused a changing in index refraction. This phenomenon is utilized as a basis of photonics devices such as optical switching, optical data storage [1,2].

The photo-responsive materials such as Disperse Orange 44, Disperse red 1 and Disperse Red 19 have been known as a nonlinear optical chromophore in the developing of nonlinear optical and photorefractive polymer [3,4,5], because of its high nonlinear optical properties (hyperpolarizability) due to -electron clouds delocalization.

For photonics devices application, the photo-responsive molecule should be performed in film with good quality that possesses smooth surfaces, homogenous thickness, and good optical stability.

This research is to study the relationship between the molecular structure and the

property of Disperse Red 19 photo-responsive film. This film was deposited on silane substrate surface produced by using Physical Vapor Deposition (PVD) method.

The film was characterized by means of UV-VIS , FTIR and XRD measurements.

2. EXPERIMENT

a. Sample preparation

Photo-responsive material used in this research is Disperse Red 19 (DR19). This material purchased from Aldrich supplier in form of powder. This molecules has molecular weight of 330,35 and melting point of about 300^{o}C [6]. The structure of this molecule is shown in figure 1.

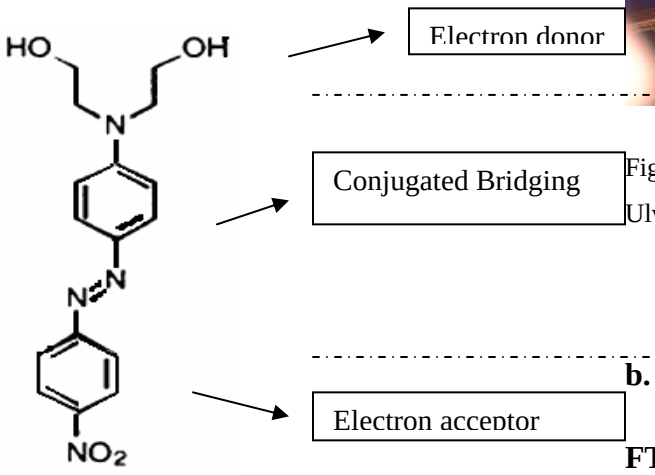

Figure 1. The molecular structure of Disperse Red 19

This molecules is available in form of powder and then prepared in form of solution and film. The solution of DR19 sample was prepared by dissolving DR19 powder into N-methyl pyrollidinone (NMP) solvent. The homogeneous solution of DR19 was obtained by stiring the solution for about one hour by using a magnetic stirer. The film sample was prepared by using the Physical Vapor Deposition (PVD) method. The crucible temperature was used 173^{o}C. The DR19 film was deposited on silene substrate surface. The substrate surface temperature was chosen to be 26^{o}C. The evaporator equipment used in this experiment was VPC-type from Ulvac Sinku Kiko as shown in figure 2.

Figure 2. Evaporater of VPC-410 type from Ulvac Sinku Kiko.

b. Sample Characterization

FTIR measurement

In this research the FTIR spectra was obtained by using FT-IR 801 Single Beam Spectrophotometer. The FTIR characterization was measured in range of 4600-400 cm^{-1}. For this measurement, the sample preparation of

ISSN 114-1284

DR19 powder was prepared in KBR matrix and for sample of film was deposited on silicon wafer. Before the measurement was carried out, the background of the sample was first measured, in order to avoid any moda which appear from the KBr matrix or substrate. The experimental results are shown in Figure 3 and 4.

UV-VIS measurement

The optical characteristics of DR19 molecules in form of solution and film were obtained from UV-VIS spectra. This measurement was carried out using an instrument of Beckmen DU-7000 Single Beam Spectrophotometer. This measurement obtained UV-VIS spectra in range of 250-800 nm. The background of the sample was first measured. The solvent used for DR19 solution sample was N-methyl pirrolidinone (NMP). For the DR19 film sample was deposited on silicon substrate. The experimental results are shown in Fifure 5 and 6.

XRD measuremet

The X-Ray Diffraction (XRD) measurement is intended to investigate the physical structure i.e., crystal structure and crystallinity of DR19 film. The XRD measurement was carried out by using instrument of Philips Diffractometer in the range of measurement : 2 (3.5-75^o). The XRD spectra was recorded by scan 2 at 30 kV, 30 mA with the radiation source CuK (= 1,5406 Angstrom). The sample of DR19 film on silane substrate was prepared for this measurement. The experimental results is shown in Figure 7.

3. RESULTS AND DISCUSSION

The experimental results of FTIR measurement of DR19 powder and DR19 film are shown in Figure 3 and 4. The identification of the FTIR absorption peak are shown in Table 1 and 2.

The FTIR spectra for DR19 film exhibit very weak absorption band of NO_2 stretching (1512 cm^{-1}) and C=C of phenyl ring (1589 cm^{-1}) due to orientation of this group perpendicular to the substrate surface. The very weak of this NO_2 stretching is probably restricted by hydrogen bonding as indicated by a board absorption band in range of 1250-1000 cm^{-1}.

Figure 5 shows UV-VIS spectra for sample of DR19 solution (NMP solvent). This figure shows a maximum absorption (λ_{max}) at 506 nm. The maximum absorption at 506 nm corresponding to electronic energy transition of 2.5 eV. This spectra exhibits a broad absorption band with high intensity which indicates of strong oscillator of DR19 molecule. This absorption band corresponding to π-π* electronic transition from the donor group to the acceptor group in DR19 monomer.

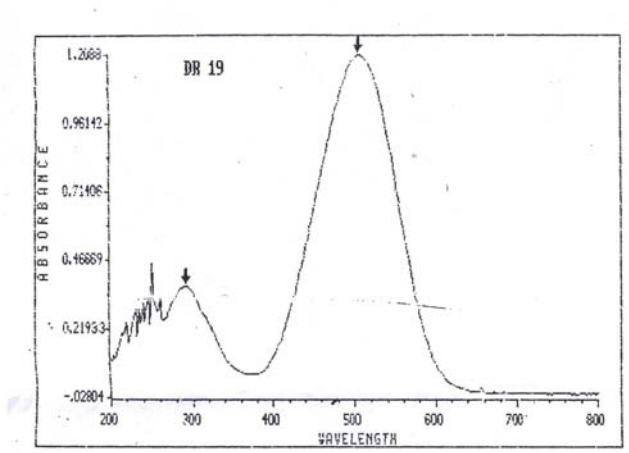

Figure 5. Spectra of UV-VIS measurement of solution of Disperse Red 19 Powder

Figure 6 shows UV-VIS spectra for the 19 film deposited on silane substrate surface. This spectra shows a broad absorption band in the visible region with high intensity which is significantly different compared to absorption band of DR19 solution (Figure 5). This differences due to in DR19 film the inter-molecules distance is more closer then in solution (isolated molecules) its mean that the inter-molecules interaction in the film is more stronger as well.

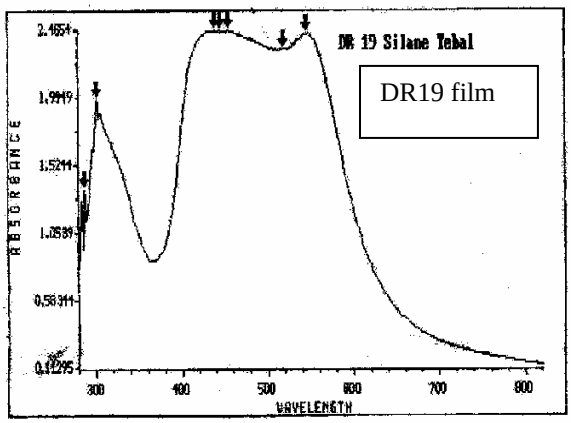

Figure 6. Spectra of UV-VIS measurement of vacuum deposited film of Disperse Red 19 on silane substrate

The UV-VIS spectra shows two absorption peaks in visible region i.e., at λ_1 = 444 nm and λ_2 = 544 nm which corresponding to electronic energy transition of E_1 = 2.8 eV and E_2 = 2.3 eV respectively. Figure 6 also clearly shows a shifting in absorption peak to the longer wavelength (red-shift) of about 38 nm and shifting to the shorter wavelength (blue-shift) of about 62 nm compared to the absorption peak in solution (506 nm). This is as indication of molecules aggregation in the DR19 film. As reported that the blue shift and a red shift in absorption peak are correlated to dipolar aggregation H-type and J-type respectively [9]. According to the point-dipole model that the shifting of absorption peak strongly depends on a magnitude of angle between dipole moment transition and aggregate stacking direction. If the angle between moment dipole transition and stacking direction equal or smaller then 54^o, so the maximum absorbance aggregates is called red-shift (J-aggregation). And if the angle between dipole moment transition and aggregates stacking direction is bigger then 54^o so this maximum absorbance aggregates is called blue-shift (H-aggregation). Based on this results indicate that some of molecules in the film are oriented in parallel and others oriented in perpendicular to the substrate surface.

Figure 7 shows XRD spectra of the DR19 film on silane substrate. This spectra indicates that the physical structure of the DR19 film is amorphous. This is as indication of the order of molecular orientation on the substrate surface which are randomly. This result is supported by the UV-VIS measurement.

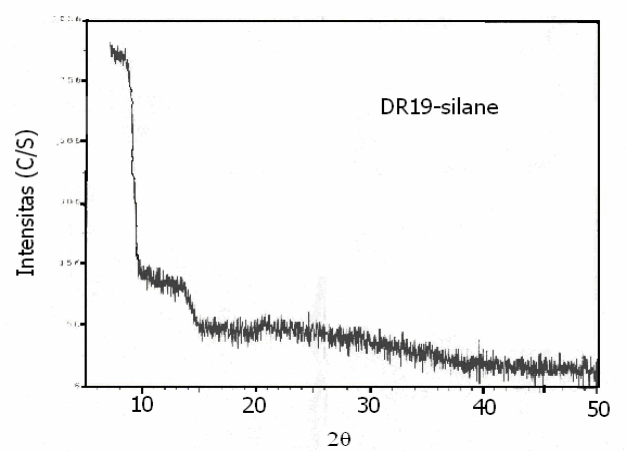

Figure 7. The XRD spectra of DR19 on silane substrate.

4. CONCLUSION

The DR19 film on silane substrate surface was obtained by physical vapor deposition method possesses a smooth surface and homogeneous thicknesses. A broad absorption of the FTIR spectra of the DR19 film in range of 1250-1000 cm^{-1} as indication of strong intermolecular interaction due to hydrogen bonding.

This UV-VIS measurement indicates that the DR19 film consist of combination of H-type and J-type molecular aggregation. This phenomenon is supported by the XRD measurement results for DR19 film on silane substrate which are amorphous.

Abstract

Dimethyl Ether as an alternative energy which is synthesized from syngas has been improved in some countries. The need of energy fulfillment becomes the significant attention considering the fact that energy supply in form of fuel has become less and less in quantity so that the technology innovation is required to solve this problem. To help better understanding on thermodynamic characteristic of direct synthesis reaction of Dimethyl Ether, we have to analyze the thermodynamic effect on operation variable namely temperature, pressure, and equation of state H2/CO toward the reaction activity, such as conversion, selectivity and yield. The thermodynamic analysis can be accomplished by using simulator that use Gibbs Reactor module on Chemcad Software. On Gibbs module, we find that the possible reactions do not have to be specified. However, we are justified to classify the components which are possible getting involved in the reaction activity. The products of potential reactions, then, are based on the altering of the minimum Gibbs free energy from those reactions. Therefore, Gibbs module is more effective and appropriate to be applied on the simulation of balanced chemical equation.

Key word:
Dimethyl Ether Synthesis, Thermodynamics analysis, Gibbs reactor

1. Background of the study

The energy crisis has become an interesting topic to debate since the past century over many countries around the world. The requirement of energy completion for the sake of human life could absolutely not be granted only by available natural resources. This problem has won the awareness of so many researchers to create and seek for substitution energy. Many inventions on technological aspects have been formed to help solving this problem. The newest energy substitution of the natural energy is not only expected to discharge the human needs effectively but also have to be more efficient in cost. One of the energy substitutions is Dimethyl Ether which is made of the synthesis process of syngas (synthetic gas).
Dimethyl Ether (DME) is considered as the twenty-first century energy, which can be applied on diesel truck, generator, and is also tempted to substitute LPG (liquefied Petroleum Gas) or gas for cooking [1]. It can also be used to operate diesel machine because it has simple molecular formula so it is not less productive to form emission of such components on burning process. The components are exactly named NO_x, CO, and SO_x. They are produced in the lowest level so it supports the realization of the environmental standard in some countries including Europe (EURO5), U.S. (U.S. 2010) and Japan (2009 Japan), and is also supposed to be applied because it has higher cetane number than that of oil for burning process. It numbered about 55-60 higher than oil which has only 40-50 [2]. By using this kind of alternative energy, we expect to have cleaner environment due to the less-contaminated of pollutant it produced which is also smaller that that of oil [3]. In addition, the DME can be applied to substitute LPG. It is becoming the most important alternative energy in develop countries especially China, India, and Brazil because they require portable fuel (tank packed fuel). They need it to supply for the suburban society which is living in distant from city and facilities. Another important thing is that DME which is regarded as environmentally-friendly fuel contains no toxin and burn without producing particulate emission.
DME can be synthesized from natural gas, coal, and also natural residue (biomass). There are two kinds of synthesis process that has so far been performed to produce DME. The first is called traditional process that is done through the synthesis process of methanol and continued by dehydration system [4]. The second method is by using catalyst which can produce methanol and ether from synthetic gas in the same reactor [5]. To get the optimum condition of operation we have to observe the thermodynamic of DME synthesis reaction first.

2. Basic of the Theory

Dimethyl Ether, or is best known as methoximethane, oxybismethane, methyl ether, wood ether, and DME, is colorless and odor of smell. Dimethyl Ether can also be soluble with water [6]. Its formula is patterned below CH3OCH3. The empirical formula of DME is patterned below C2H6O (the same with that of ethanol). Dimethyl Ether is also used as aerosol fuel and consumed together with propane to give thermal expansion within low temperature of -60ºC. This character is useful for cryogenic freeze. It is a valuable alternative energy for perfect burning process of petrol liquefaction, natural gas

liquefaction, diesel and gasoline. Again, Dimethyl Ether can be made of natural gas, coal and biomass.

Conventional DME is produced by using methanol dehydration method. Nowadays, many researchers are still busy seeking and developing new method in order to be able to produce DME in immense scale. However, they put their main concern on making DME by synthesizing hydrogen and CO which are commonly called by syngas. It is produced from methanol by combining two molecules of methane to create two new molecules, DME and water. This reaction is identified as reversible reaction (see equation of the 4th reaction).

DME can be used as fuel to diesel machine, petrol (30 % DME and 70 % LPG) and turbine. DME works better on diesel machine because it has high cetane number, which is higher than that of oil for diesel which has only 38-53. However to make a diesel machine which needs DME as its fuel, we have to change and modify some part of it. And as a synthetic fuel, the result of burning activity produced by DME is relatively cleaner than that of oil (without black carbon) which can also replace conventional diesel, LPG or is able to be changed into hydrogen for fuel cell. Beside that, DME can be decomposed for some hours at troposphere and surprisingly has no cause of greenhouse effect and the eroding of ozone stratum. Moreover, it is not characterized as corrosive at some metals. Consequently, DME is considered as an environmentally-friendly fuel and is promisingly safety for our surroundings.

The Reaction of DME Synthesis

DME product which is common to use involves the methanol dehydration reaction (see equation 4 below), however recently in five years the researchers have established the technology of direct synthesis of DME from syngas (hydrogen and monoxide carbon) with the aim of producing DME in huge scale with little money in order to use it as fuel.

Direct synthesis of DME needs temperature of 210-290ºC and pressure about 3-10MPa; intervention catalyst is also used to get synthesis and dehydration of methanol. The chemical reactions and heat reaction for synthesis of DME are listed below:

$$3CO + 3H_2 \Leftrightarrow CH_3OCH_3 + CO_2 + 246.0 \ kJ/DME \quad \cdots (1)$$

$$2CO + 4H_2 \Leftrightarrow CH_3OCH_3 + H_2O + 205.0 \ kJ/DME \quad \cdots (2)$$

$$2CO + 4H_2 \Leftrightarrow 2CH_3OH + 182.6 \ kJ/DME \quad \cdots (3)$$

$$2CH_3OH \Leftrightarrow CH_3OCH_3 + H_2O + 23.4 \ kJ/DME \quad \cdots (4)$$

$$CO + H_2O \Leftrightarrow CO_2 + H_2 + 41.0 \ kJ/DME \quad \cdots (5)$$

The synthesis of DME from syngas at equation (1) has three main steps: reaction of methanol synthesis at equation (3), dehydration reaction at equation (4) and changing reaction at equation (5). If the rate of changing reaction is slow, combination of reaction (3) and (4) produce the reaction of (2). Entirely, the reaction is exothermic reaction, and to the core, the increasing of temperature reaction is caused by the formation process of methanol. Due to the characteristics of exothermic reaction, the problem of minimizing heat that are created from synthesis of DME is becoming a major problem to be seek for the best technology as a solution to overcome with. The JFE Corporation (Japan) has improved the synthesis of DME by using Slurry Reactor since 1989. Slurry consists of inert solvent and catalyst particle. Reactant gas formed bubbles and is diffused to solvent liquid. In here, the chemical reaction happens in catalyst. The heat of the reaction will quickly be absorbed by solvent liquid which has high capacity and conductivity of heat, consequently the distribution of temperature in reactor become homogeny. Another technology which has advanced using DME as its alternative fuel, is Haldor Topsoe [7] (U.S.) by applying fixed bed reactor.

3. Methodology

Thermodynamic analysis of Dimethyl Ether reaction directly from syngas is focused on using the Chemcad software Batch Version 5.2 (Chemstation Inc. 2901 Wildress Drive, Suite 305 Houston, Texas 77042 U.S.A.). The analysis is aimed to determine the condition of optimum operation that will be applied to fixed bed reactor. From all of the available reactor module on Chemcad module, Gibbs module reactor is chosen based on fully consideration of effectivity from Gibbs reactor module in thermodynamics analysis by reducing the Gibbs free energy in each possible reaction [8].

In the Gibbs reactor the number of product that are produced, the composition and condition of heat reaction are calculated based on free Gibbs energy minimally, appropriate with all complementary mass. All of the components which are used on the flow sheet must be written on the component list which subsequently is required to count the minimum free Gibbs energy, except which are specifically not joined along with (identify as inert).

The flow diagram of thermodynamic analysis is shown in figure 1. On that diagram, firstly we have to do the step of making model (flow diagram) then accomplish the input data standard component database, pressure, and temperature of feed input. Whereas, the minimum information which is needed by Gibbs reactor is bait input and rate input. If we want such a different state with the feed input, we can arrange the temperature and pressure. The reactor can also be utilized to liquid fuse or vapor or the mixture of both things. This reactor can also be used for isothermal state at particular temperature or is adjusted with feed temperature. For adiabatic reactor, the amount of stagnant heat can be attached or even eliminated, so that the temperature border can be set. The analysis of thermodynamics which has been done in this article is by arranging isothermal reactor mode.

The simulation is done to know exactly the influence of variable operation state, such as temperature, pressure, and feed ratio (H_2/CO). The result of simulation which vary from data of composition product, yield and conversion, are analyzed to get the data of optimum operation state for Dimethyl Ether synthesis.

ISSN 114-1284

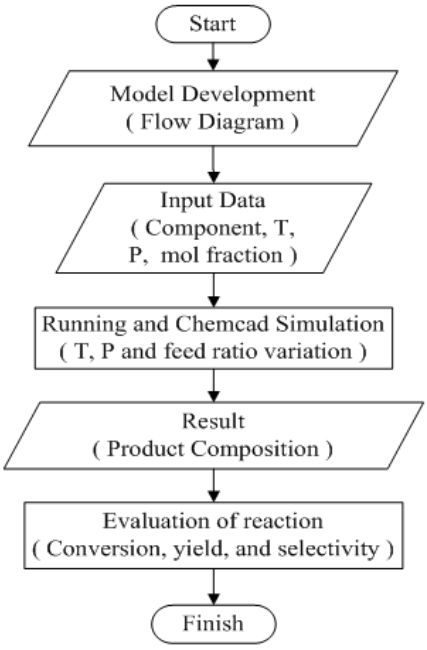

Figure 1. *Flow diagram of thermodynamic simulation*

4. Result and Discussion

4.1 The Influence of Pressure

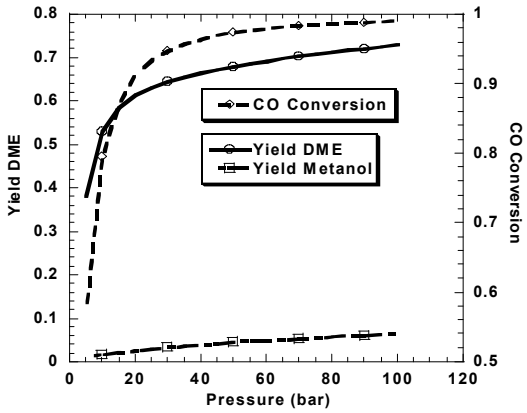

Figure 2. *Effect of pressure to performance of reaction at temperature 250℃ and feed ratio (H_2/CO) 2:1*

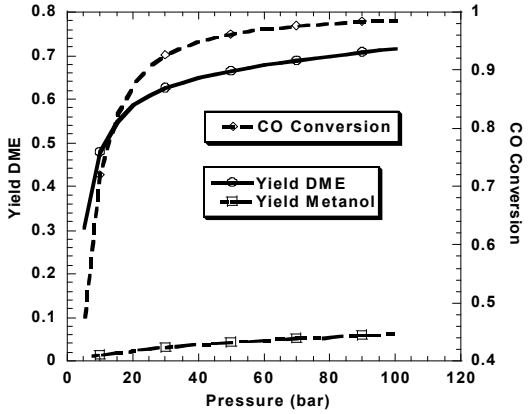

Figure 3. *Effect of pressure to performance of reaction at temperature 260℃ and feed ratio (H_2/CO) 2:1*

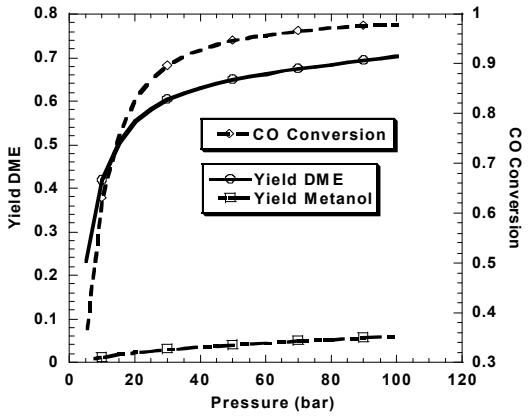

Figure 4. *Effect of pressure to performance of reaction at temperature 270℃ and feed ratio (H_2/CO) 2:1*

The simulation is executed in any stable temperature that is because it is really shown reaction activity influenced only by parameter of pressure from simulation result (picture 2-4) we can see that until the pressure of 60 bar CO conversion, DME yield occur an acutely raise, after 60 bar pressure, the rising will still be happened but in relatively lower number rather that that of the previous pressure. From the simulation result, we can also see that in whatever pressure exert, the prominent produced is DME in which the yield is higher that methanol.

Appropriately with the balance reaction principal, that pressure is set to be higher as a result the balance reaction incline to move to the part which has smaller molecule. On the direct synthesis of DME (Equation on reaction 1 and 2), the reactant component has greater number of molecule than that on product molecule. So it can be proved that DME position in the product can easily increase when the pressure is up.

The result of the simulation above, can also illustrate that the conversion is moving up significantly at the interval of pressure 60 bar, this case happens because the synthesis reaction of methanol become the border of all the reactions. This also indicates that the reaction of DME formation can also be done at the same pressure interval in the synthesis reaction of methanol.

ISSN 114-1284

On simulation graphic above, we can also find that the DME is also constructed as the first product adjacent to methanol [9]. This is for the reason that in the direct synthesis reaction of DME, methanol will conversed straightforwardly to DME and water. Thermodynamically, the degree of which a chemical reaction can be estimated from Gibbs energy cost in each reaction. According to journal literature, the data Gibbs energy for reactions which in involved to the DME formation is listed below:

$$CO + 2H_2 \Leftrightarrow CH_3OH, \Delta G_{600\,K} = 45.4\,{}^{kJ}/_{mol} \quad \cdots(6)$$

$$2CH_3OH \Leftrightarrow CH_3OCH_3 + H_2O, \Delta G_{600\,K} = -10.7\,{}^{kJ}/_{mol} \quad \cdots(7)$$

From Gibbs energy data above, we can see that Gibbs energy for synthesis reaction of methanol. So, thermodynamically the DME compound will be easier to be formed (liked) than methanol compound.
From this simulation, we can conclude that operation of DME synthesis is on 30-70 pressure.

4.2 The Influence of Temperature

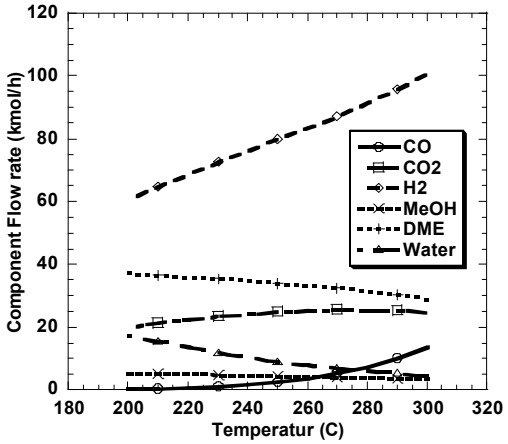

Figure 5. *Product composition as a temperatur function (at pressure 50 bar and feed ratio 2:1)*

The result of simulation above is accomplished with variation of temperature between 200 to 300 ºC with pressure of 50 bar and of bait ratio of H_2/CO in proportion to 2:1. From that result, we can see also that the product of DME occurs in a descending within the increasing of reaction of temperature. This case can be explained by looking up the synthesis reaction of DME as exothermic reaction (see equation of reaction 1 and 2) by which the increasing of temperature will effect on the balance reaction which tempted to move to the reaction which characterized as endothermic, to which the reaction will shift to the reactant. The water gas shifts reaction 9WSGR) [10] in which CO is the real product that experience enlarger amount as the increasing of the temperature reaction or we can say as endothermic (see equation of reaction 5). This simulation is done by pressure state of 50 bar, by which the election of pressure as optimum condition of synthesis reaction of DME is principally based on the reaction activity when CO conversion experience significant increase until 50 bar. And for the next, it will still increase but not as much as before. The pressure effect has undeviating proportion to product DME so in whatever amount of pressure that are produced by DME, the yield is still higher rather than other product such as methanol, CO2, and water. According to simulation result of the temperature influence to the product composition, we determine the optimum temperature in 270ºC, output composition of CO2 become greater than water. It is clear that this case is not necessitated since the character of CO is as pollutant on air.

4.3 The Influence of Feed Ratio H_2/CO

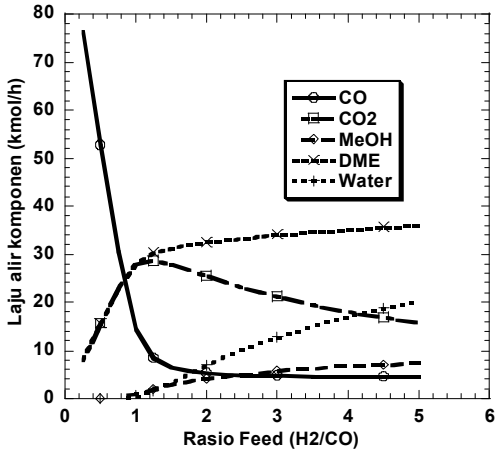

Figure 6. *Product composition as a feed ratio function (at temperatur 250℃ and pressure 50 bar)*

Simulation of feed ratio H_2/CO influence is performed by marking from 0,5 to 5 to see how it effects on the reactor and the product composition. According to simulation, we can see that DME will be increased along with the ratio mark which is increasing too. Whereas, CO conversion is significantly enhancing until reaching 2:1 feed ratio, then conversion experience relatively at constant cost. CO_2 occurs in maximum condition when feed ratio in the reactor is as big as 1:1 proportion. This case can be explained by giving attention on equation of the first reaction that is written before and that of direct synthesis reaction of DME with 1:1 proportion. H_2/CO produces DME and CO_2 as the main product. While for the equation of the second reaction with 2:1 feed ratio will result on DME and water has higher yield than water. From the simulation result we can conclude that the optimum feed ratio state for synthesis reaction of DME is about 2:1. It is regarding to the proportion when feed ratio reach 2:1 or we called it as CO conversion which is determined as nearly constant and that of the last product of DME which will be closely to constant distance.

5. Conclusion

Thermodynamically, direct synthesis reaction is more dominant than synthesis reaction of methanol that

participates along with it. It is proved with the data of Gibbs which is obtained from the literary journal restating that number of Gibbs energy on synthesis of DME reaction is about -10,7 Kj/mol (see equation of reaction 7) much smaller than Gibbs energy from synthesis reaction of methanol which has only 45.4 Kj/mol (see equation of reaction 6). The pressure of operation opted about 50 bar, which is because of security reason and simulation of reaction activity can be concluded that CO conversion is experiencing the significant raising until 50 bar. The temperature of operation is chosen for 270ºC regarding to the catalyst stability that has limitation of operation temperature distance, besides it is also because this temperature produce higher CO rather than water that indicate unwanted pollutant produced in higher number. Bait Ratio (H2/CO) that is chosen for research condition in proportion of 2:1 due to he sthyochiometric condition for direct synthesis reaction of DME has to be fulfilled that effect on distance formation of DME becoming relatively constant if the bait ratio become mere numerous.

ABSTRACT

A natural based nanocomposite film consisting of chitosan, montmorillonite (MMT) and cashew nut shell liquid (CNSL) was synthesized. The nanocomposite was prepared by mixing suspension of clay particles (filler, MMT) with a solution containing chitosan as macroscopic polymer matrix. In this study, it was proposed that non-ionic long chain-alkyl molecules with possible interactions with the amine group of chitosan could be used as plasticizer. As natural source for these compounds, an extract of CNSL was used. A series of chitosan/MMT composite samples containing two different clay contents and sample with an additional CNSL are prepared. FTIR spectroscopy of the nanocomposite films indicated that by addition of CNSL amide groups of the chitosan are probably less attached and have more space for vibration. CNSL seems to provide intermolecular spaces between the chitosan molecules. AFM analysis showed that the composite has particle size of 100 nm and less, which confirmed that nanocomposite has been successfully produced by this method. Addition of CNSL as plasticizer improved the tensile strength by 10% and the elastic modulus by almost 18%. Cell growth was observed on all the nanocomposite samples studied here.

Keywords
montmorillonite (MMT), chitosan, CNSL, nanocomposite

1. INTRODUCTION

The use of biopolymer as component of composite for packaging materials is very much studied recently. Studies regarding to the improvement of composite properties such as brittleness, low heat distortion temperature; gas permeability, etc. for a wide range application are very much interested. Additionally, the development of biobased nanocomposites are carried out with intention to provide physical protection for food, improving food integrity as well as protection from microbes and fungi [1].The use of biobased nanocomposites for packaging material has been reviewed [2,3].

Chitosan as biopolymer is also very much studied for development of new composite material with montmorillonite (MMT) clay. Various experiments including the modification of MMT properties by converting the MMT into organo-montmorillonite (OMMT) prior to the nanocomposite preparation [4], as well as the variation of MMT concentration [5] and different dimension were studied [6] to enhance the properties of chitosan/MMT composite. Studies on interaction of small molecules such as glycerol as plasticizer with chitosan in chitosan film was also thoroughly studied [7,8]. Regarding to the limited water resistant and mechanical properties of original biopolymer, studies on the improvement of those properties by including hydrophobic material into the biopolymer composite [9,10] or by addition of other small molecules to enhance hydrophobicity [11,12,13] or plasticity [14,15] were carried out. Since application of the chitosan composite as packaging material for food is strongly considered, especially regarding to the its antimicrobial activity, most studies of chitosan/clay nanocomposite have also included antimicrobial activity test.

It is known that the properties polymer/clay composite are strongly afftected by addition of surfactant into the composite. On those system, the typical molecules are

long-chain alkyl quaternary ammonium chlorides [16,17,18], which is easily incorporated into the clay structure. Large molecule additions, except the use of long-chain alkyl quartenary amines or pollyglycol [19,20], in order to manipulate the composite properties are seldom studied. In the present study, it was proposed that non-ionic long chain-alkyl molecules with possible interactions with the amine group of chitosan could be used as plasticizer. As natural source for these compounds, an extract of cashew nut shell (cashew nut shell liquid-CNSL) was used. A series of chitosan/MMT composite samples containing two different clay contents and sample with an additional CNSL are prepared. CNSL is known as a source for cardol, cardanol and anacardic acid, phenolic compound with a long-chain alkyl group. A typical solvent-extracted CNSL contains anacardic acid (60-65%), cardol (15-20%), cardanol (10%) and traces of methylcardol [21]. Addition of CNSL as a source of relatively big molecules into the composite was intended also to improve the hydrophobicity as well as the mechanical properties of resulted composites.

2. EXPERIMENTAL

2.1 Materials

Montmorillonite (MMT) employed in this study was K10 montmorillonite from Sigma-Aldrich. This montmorillonite is well known as having a CEC of 70-100 meq/100 g. Chitosan purchased from Sigma-Aldrich (Cat Nr. C3646) had a degree of deacetylation of 85% minimum. Commercial cetyltrimethyl ammonium bromide (CTAB) from E-Merck (Cat. No. 1.02342) was employed for this study. Cashew Nut Shell Liquid (CNSL) was extracted from cashew nut shell originated from Sumba Island, Indonesia. Prior to the use for composite preparation, chitosan was pretreated in basic solution of 10% NaOH. The extraction procedure for CNSL was as follows: Adequate of fresh redistilled n-hexane was added to the cashew nut shell in a round glass flask. Extraction was carried out by refluxing 100 g cashew nut shell in 250 ml of n-hexane for 2 hours and followed by filtration and evaporation of n-hexane.

2.2 Preparation of Na-Montmorillonite and organo-montmorillonite (OMMT)

The OMMT was prepared by cation exchange between Na-MMT galleries and CTAB in an aqueous solution. MMT (2 g) was dispersed using a stirrer in distilled water to obtain clay suspension, and allowed to stand for 24 h after vigorous stirring for 30 min. CTAB (2 g) was dissolved in distilled water, and then dropped slowly into the MMT suspension at 85°C under stirring. After stirring for 4 h, the product was washed several times with distilled water and filtered to ensure the complete removal of bromide ions, which were detected with $AgNO_3$ until no AgBr precipitate was found. The product was dried at 85°C to yield OMMT.

2.3 Preparation of Chitosan/Montmorillonite Composite

The chitosan solution was prepared using a 1% acetic acid solution. 4 g chitosan was dissolved in 100 ml acetic acid solution (1%) and stirred for 4 hours to obtain a homogeneous mixture. A 2% clay suspension in acetic acid solution (1%) was also prepared. The suspension was added into the resulted gel such that a 1% and 3% MMT content in the mixture was obtained. The mixture was stirred at 50°C for 2 days to obtain a homogeneous chitosan/MMT suspension. This procedure was carried out using K10 montmorillonite (Sigma-Aldrich), Na-exchanged K10 and CTAB exchanged K10. For samples containing CNSL, a solution of 25 mg CNSL in 100 ml ethanol was prepared separately. The CNSL solution was added accordingly into the chitosan/MMT mixture after a rigorous 2 days mixing, that a final 1% CNSL content was obtained.

2.4 Characterization

2.4.1 Infrared (IR) Spectroscopy

All IR spectra were obtained using a Nicolet Avatar 370MCT (Thermo Electron Corporation, USA) equipped with a standard transmission accessory. Spectra of the composite films were recorded and analysed using OMNIC version 7.0 software, in the range of 650–4000 cm^{-1} at a resolution of 1 cm^{-1}, the background was taken using an original chitosan powder. IR of the composite film was performed in transmission mode with crushed powders in KBr discs in the range of 650–4000 cm^{-1} at a resolution of 1 cm^{-1}.

2.4.2 Atomic Force Microscopy (AFM)

Tapping mode AFM was performed on a Multimode Nanoscope IV microscope (Veeco Corporation, USA). Commercial Si cantilevers (FESP, Veeco Corporation, USA) were used for all experiments. The images were processed and analysed using the Nanoscope 5.31r1 software (Veeco Corporation, USA).

2.4.3 Differential Scanning Calorimetry (DSC)

In the present work, DSC 2920 (TA Instruments) was used for the measurement. The instrumental cell constant and temperature calibration were performed using indium. Chitosan/MMT samples were analysed under continuous heating conditions (10°C min^{-1}) between room temperature and 200 °C. 8-10 ± 0.1 mg of sample was weighed into a standard aluminium pan and placed onto the DSC cell platform.

2.4.4 Mechanical Properties

The mechanical properties of chitosan/ MMT nanocomposites were tested using an Universal Testing Machine, Orientec Co. Ltd., Model UCT, 5-T. The specimens were prepared according to ISO 527-2. All specimens were tested using a crosshead speed of 1 mm/min.

2.4.5 Cell Growth-Test

1 cm^2 membranes were transferred to wells of a 12 well Iwaki tissue culture plate (cat# 3815-012). Membranes were seeded with HEK 293 cells at density 10^5 cells/cm^2 (3.85 x 10^5 cells per well in a 2 mL volume) in DMEM (Invitrogen) +10% FCS (JRH) + 2 mM L-glutamine + 100 U/ mL penicillin 100ug/mL streptomycin (Invitrogen). HEK 293 cells were grown in the presence of the membranes for 20 hours at 37C 5% CO_2. At 20 hours media was removed and replaced with 2 ng/mL Hoescht 33342 (Sigma) stain in complete media and incubated at 37°C 5% CO_2 for 0.5 hours. Staining was visualized under appropriate fluorescent excitation/emission conditions for Hoescht stain. The photographs were taken with a 20 X objective on a Leica laborluxD fluorescent scope.

3. RESULTS AND DISCUSSION

Table 1 as shown below gives the list of sample used for the studies. . Each sample contains 3% of clay or its modified one. CNSL was added as a solution in ethanol, 1% w/w of the chitosan used for film preparation.

Table 1. List of samples tested for the studies. Each sample contains 3% of clay or its modified one. CNSL was added as a solution in ethanol, 1% w/w of the chitosan used for film preparation.

Clay type		CNSL Addition
K10	Untreated	No
K10-CTAB	Organic clay	No
K10-CN	Untreated	Yes
K10-CTAB-CN	Organic clay	Yes

3.1 Infrared spectroscopy

FTIR analysis of the composite films were performed to study the structural changes causes by modification of clay component prior to the preparation of composite. The IR spectra were taken by transmission as well as DRIFT method. The spectrum of chitosan is characterized by broad and intense band at 3450-3200 cm^{-1} (hydrogen bonded OH stretching overlapped with N-H stretching bands); C-H stretching band at 2783 cm^{-1}, The N-H deformation band of chitosan was found at 1559 cm^{-1} .The strong bands at 1656 cm^{-1} and 1599 cm $^{-1}$ are ascribed to the amide I (C=O stretching) and amide II (N-H bending modes) of the chitosan.

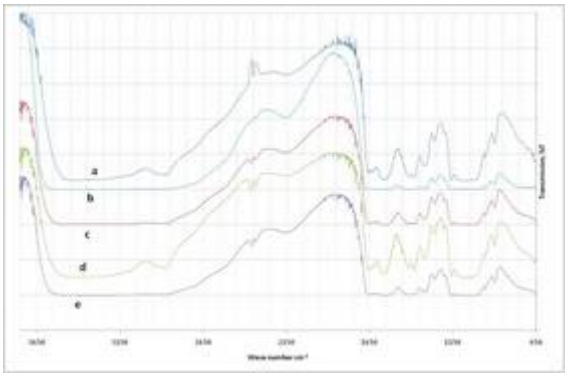

Figure 1. Transmission FTIR spectra of (a) pure chitosan (CS) film; (b) CS/3% K10; (c) CS/3% K10-CN; (d) CS/3% K10-CTAB; and (e) CS/3% K10-CTAB-CN composites

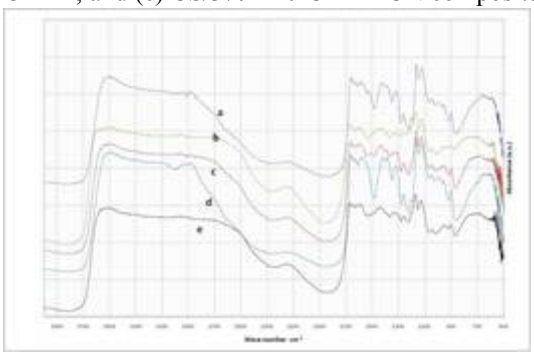

Figure 2. DRIFT spectra of (a) pure chitosan (CS) film; (b) CS/3% K10; (c) CS/3% K10-CN; (d) CS/3% K10-CTAB; and (e) CS/3% K10-CTAB-CN composites

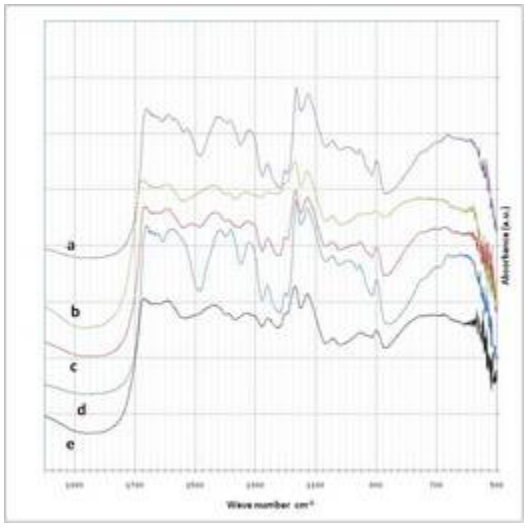

Figure 3. DRIFT spectra of (a) pure chitosan (CS) film; (b) CS/3% K10; (c) CS/3% K10-CN; (d) CS/3% K10-CTAB; and (e) CS/3% K10-CTAB-CN composites.

Generally, the amide bands are shifted to the higher wave number by addition of the CNSL. By addition of CNSL amide groups of the chitosan are probably less attached and have more space for vibration. CNSL seems provide intermolecular spaces between the chitosan molecules. This should be result in a higher plasticity of the resulting material. The C-O stretching band around 1160 cm^{-1} remained undisturbed by the addition of CNSL.

3.2 Atomic Force Microscopy (AFM)

AFM analysis was conducted to determine the nanoscale structure of the composite synthesized.

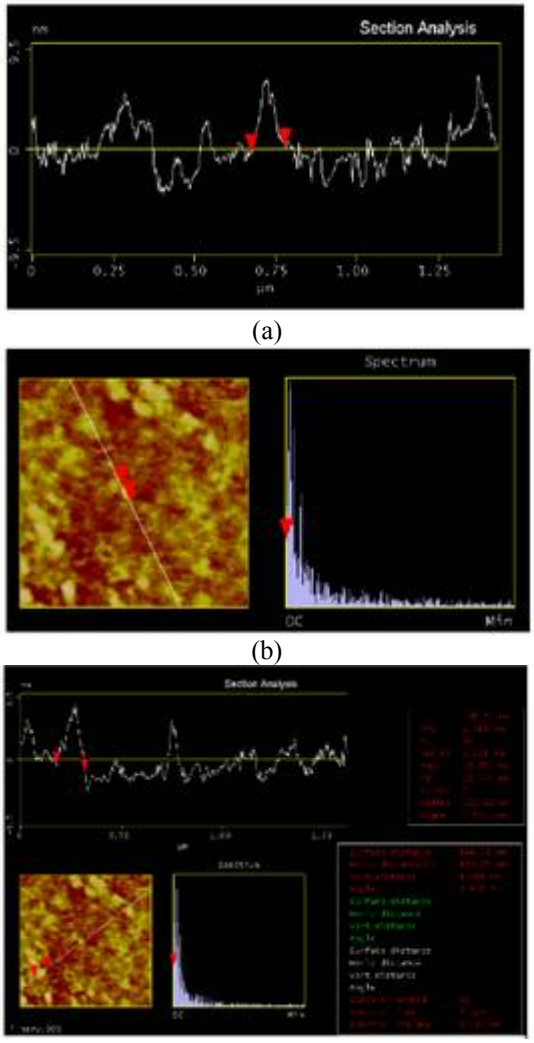

Figure. 4 Morphology analysis of longitudinal section of CS/K10-CTAB using AFM (a) Particle horizontal size of 103 nm (b) Area of analysis (c) Particle horizontal size of 139 nm

As shown in Fig. 4, the MMT particle forming the composite has the length of 103 nm (Fig. 4a) and 139 (Fig. 4c). However, the surface height is less than 9,5 nm. This can be explained as follows. The MMT particles forming the composite only consist of a few layers, resulting the MMT particles thickness of less than 10 nm. Although the length of the particle is more than 100 nm, the formation of particles of less than 10 nm indicates the presence of exfoliation from the MMT particles. Since the MMT are used as fillers, then most likely the composite synthesized was in the form of *ordered intercalated nanocomposite.*

3.3 Differential Scanning Calorimetry

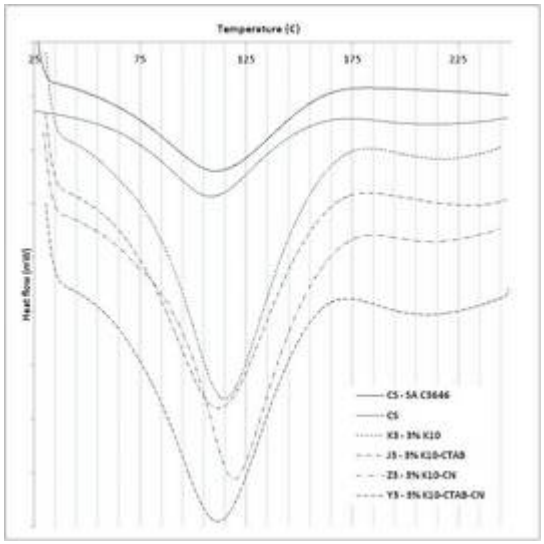

Figure 4. DSC thermogram of samples. From above downwards: (a) chitosan (CS) powder (C3636, Sigma-Aldrich), (b) CS film, (c) CS/3%-K10, (d) CS/3% K10-CTAB, (e) CS/K10-CN and (f) CS/K10-CTAB-CN.

As shown by the thermogram, glass transition in DSC was not observed. That indicates that amorphous structure does not exist. No thermoset cure temperature was observed from 25°C to 250°C. Most probably no crosslinking, formation of new bonds occured in the material at that temperature range. DSC thermograms show only that water released from the film at similar temperature range as on the original chitosan when the formula of composite film was containing CTAB. It could be explained, that the preparation of organo-montmorillonite (OMMT) has removed most of the trapped water molecules from the MMT, such that less water existed in the MMT as well as in the resulting composite film. It was expected that the hydrophobicity would be increased by the addition of CNSL, which means, it was also expected that water molecules would be released at much lower temperature from the film containing CNSL in the formulation. The thermograms shows that there was no effect for OMMT, but on composite containing plain unmodified MMT (c and e) water molecules were released at higher temperature, CNSL addition into the formula seems result in

stronger water retention in the film. The CNSL component molecules has retained the trapped water molecules on montmorillonite.

3.4 Mechanical Properties

Table 2. Tension test result of nanocomposite samples

Sample code		Yield strength [Mpa]	Tensile strength [Mpa]	Rupture [Mpa]	Elastic Modulus [Mpa]
CS/K10-CTAB	avg	59.4	76.9	75.9	2470
	std. dev.	1.5	8.4	9	220
CS/K10-CTAB-CN	avg	66.8	84.6	84.5	2910
	std. dev.	3.9	10.6	10.7	250

From the measurements shown in Table 2, it is shown that the addition of CNSL increases the modulus elasticity, yield strength, tensile strength as well as the rupture of the composite. The tensile strength is improved by 10% and the elastic modulus by almost 18%.

(b)

Figure 5. Tension test graphic result (a) CS/K10-CTAB (b) CS/K10-CTAB-CN

3.5 Cell Growth-Test

It was difficult to differentiate the living cell from the film, since the chitosan film gives a strong background fluorescence using this particular method. Despite of this problem, it could be conclude that cell growth were observed on all the samples studied here.

4. CONCLUSION

A natural based nanocomposite film consisting of montmorillonite, chitosan and cashew nut shell liquid (CNSL) has been successfully synthesized. It has been proven that CNSL seems to provide intermolecular spaces between the chitosan molecules. AFM analysis showed that the composite has particle size of 100 nm and less, which confirmed that nanocomposite has been successfully produced by this method. The preparation of organo-montmorillonite has removed most of the trapped water molecules from the montmorillonite, such that less water existed in the montmorillonite as well as in the resulting composite film, as shown by the DSC analysis. However, the addition of CNSL component molecules has retained the trapped water molecules on montmorillonite. Addition of CNSL as plasticizer improved the tensile strength by 10% and the elastic modulus by almost 18%. Cell growth was observed on all the nanocomposite samples studied here.

ABSTRACT

In the development of highway, the most important thing is subgrade, because the subgrade is the most important factor to determine the density needed for flexible pavement. If the subgrade is soft clay that has low and sensitive bearing capacity toward the change of water concentration, it will cause the instability of the highway. Therefore, chemical stabilization is needed to improve the subgrade. This research concerns with the chemical stabilization of soft clay and coconut fiber. The result shows that the addition of coconut fiber can increase 3.19% CBR (California Bearing Ratio) of the soft clay. The 10% and 20% addition of coconut fiber can increase 220% bearing capacity of the subgrade. The test result indicates that the highest density of subgrade takes place in the 20% addition of coconut fiber with 1.21 gr/cm^3 MDD (Maximum Dry Density) but the real soil increases 20% bearing capacity. Then, the smallest value of Swelling Potential takes place in the 20% addition of coconut fiber with 11.11% regression compared to the real soil.

Keywords

chemical stabilization, bearing capacity, soft clay, coconut fiber

1. INTRODUCTION

Soil is a material consisting of aggregate (grain) solid minerals that are not tied to each other chemicals and organic material from the mold was. Soil as a useful building material in a variety of civil engineering works in addition to the Soil also serves as a foundation of the building. (Braja M. Das, Noor Endah, Indrasurya B. Mochtar, 1988). Soil is the part that is not separated from human life, most human activity associated with the Soil. For example, among other farming activities on the plant and the structure of road.

At the first break even until now in remote areas have been using coconut fiber which is the rest of the coconut harvest crops up to the road that damaged when exposed to rain as they often passed by and the road is not paved. But after a while the road is dry and the coconut fiber to filled earlier integrates with the Soil and the Soil on the road crust, and logged more time on the ground does not damage before to filled with coconut fiber, then Soil on the road to be stable. Soil treatment is to give thought to examine how far coconut fiber can increase the bearing capacity soil stabilization method with the chemical.

A very important factor in determining the thick pavement needed on the road asphalt (flexible pavement) is a subgrade. When Subgrade is a clay soil which has bearing capacityed the low and very sensitive to changes in water level, will cause instability road. Therefore, the required improvements to the Soil. improvements to the soil carried out among the chemical stabilization. Stabilization is a process to improve the nature of Soil in a way to add something on the soil in order to increase resources to bearing capacity. Stabilization method that is widely used mechanical stabilization and chemical stabilization. Stabilization is to add mechanical strength and resources to bearing capacity improvements to the way Soil and improvements to the nature of the structure-mechanical nature of the Soil, while the chemical stabilization is to add strength and strong bearing capacity to the Soil to reduce or eliminate the way the nature of the technical nature of soil-less mix in a way beneficial to the soil material chemicals such as cement, lime or pozzolan. Subgrade layer is 50 cm - 100 cm thicks which is the bottom of surface construction pavement a road or runway aircraft. Subgrade must have the high bearing capacity and able to maintain the volume changes during the service even though there are differences in environmental conditions. Subgrade can be a base soil can compacted native Soil if the original well, the Soil that brought from other places and then or soil material with stabilization.

ISSN 114-1284

Primary function is to receive Soil pressure due to the traffic load on the surface so that the Soil should have the high bearing capacity an optimal fashion so that a result is able to receive the traffic load without changes and damage that means. Bearing capacity of Subgrade can be estimated with the practice or the classification results of the CBR test, plate loading test, and so on (Sukirman, 1995).

In this research tried to make improvements to the Soil with chemical stabilization using coconut fiber. As with the coconut fiber is a waste (waste product) that is very rarely used, easily obtained than the amount of coconut fiber and relatively much cheaper price compared with lime, cement and sand. It tried to take advantage of this coconut fiber as a soil stabilization material. And is expected to use the coconut fiber, the ground water level can be reduced so that it can be used as subbase and subgrade materials. From the background above can be formulated as a problem, Whether stabilization of soft clay with coconut fiber can increase the bearing capacity of Soil? And How many percent of the addition of coconut fiber on the soft clay soil that produces the highest bearing capacity

2. REFERENCES

2.1 Soil

Soil is a material consisting of aggregate (grain) solid minerals that are not tied to each other chemicals and organic material from the mold was. Soil as a useful building material in a variety of civil engineering works in addition to the Soil also serves as a foundation of the building. (Braja M. Das, Noor endah, Mochtar B. Indrasurya).

2.2 Soil Stabilization

Soil stabilization is to make efforts to meet the Soil requirements and the needs of a particular technique. If the Soil has been stable, the Soil will have the strength, kemampumampatan (compressibility), created for ease of building on it (Dr. Ir. Hapsoro Tri Suryo Utomo). Stabilization is a process to improve the nature of Soil in a way to add something on the Soil with the goal to get the changes the physical nature of Soil to the better, for example:
a. Stabilization in the soil volume (volume stability)
b. Increase resources to bearing capacity Soil (strength or bearing capacity
Stabilization method that is widely used:

1) Mechanical stabilization (mechanical stabilization of soil) Stabilization method is used on Soil that has great run-down flower. Stabilization of soil mechanics can be done in a way:
a) basic soil mix with good soil. This can be done with a mix of native soil akan distabilisasi with sand with a certain amount so that the run-down nature of the flower's native Soil to be reduced.
b) the use of opium Subgrade (soil compaction) Use of opium is a process in which material dipadatkan Soil, so that the volume of empty space (void) of Soil in the first place will be off the air so heavy volume of soil will be increased.

2) stabilization Chemicals (chemical stabilization of soil) Chemical soil stabilization in soil stabilization is a way to add or blend with the native Soil of other chemicals. Of chemical soil stabilization include:

a) soil stabilization with lime (lime stabilization)
b) soil stabilization with cement (cement stabilization)
c) soil stabilization with asphalt (bituminous stabilization)
d) and stabilization with other materials such as fly ash.

2.3 Mineral Particles Of Clay

Soil is a clay sized less than 0.002 mm. Particles is the main source of cohesion in a cohesive soil (Bowles, 1991). Loam soil is the Soil that is up to the microscopic size of the sub microscopic corrosion that comes from the chemical elements of rock composer, is very hard clay soil in the dry and the water level in the plastis are. At the higher water content clay is sticky (cohesive) and very soft (Das, 1994)
Nature of the clay soil was as follows (Hardiyatmo, 1999):

a. Fine grain size, less than 0.002 mm,
b. Low permeability,
c. The increase in capillary high water,
d. Are very cohesive,
e. Rate decrease of flowers,
f. Slow process of consolidation.

Fine grain soil, especially clay soil akan much influenced by the water. The nature of the soil clay will compacted greater on the clay in the dry compacted than the optimum compacted the optimum wet. In compacted the clay that is relatively dry optimum water shortages because of the clay has a greater tendency to sink in the water as a result is easy to use nature (Hardiyatmo, 1999).

The influence of water content is very big on the strength of clay soil. The addition of water will cause the distance between long distant grain tensile strength so that the interesting inter-grain will be reduced. Conversely, if the water content in soil is reduced to (dry), then the water will form a thin layer of water (water film) around the cavity between the grain and cause a high voltage capillary. Capillary voltage was formed by the surface tension of water will increase the strength of clay soil slide.

2.4 Coconut fiber

Coconut fiber, coconut skin and consists of fibers embedded in the skin in between the hard (coconut shell), in which approximately - approximately 35% of the total weight of mature coconut, coconut for a different variety of Percentage above will be different too. (Budi Lestariyo).

Composed of coconut fiber on mineral and organic elements, namely; hemisellulose and pectin (which is a component dissolved in water), lignin and sellulose (components that are not soluble in water), potassium, calcium, magnesium, nitrogen and protein. Comparison of the components depending on the age of fiber kelapanya. Lignin in coconut fiber fiber ranged from 40 to 50%.

Fibers are relatively short-fiber, fiber cells throughout approximately - approximately 1mm diameter with 15 micron fiber a strand and consists of 30 to 300 cells or more, viewed from the cross cut. Fiber length of fibers ranging 15 to 35 cm diameter with 0.1 to 1.5 mm. Fiber fiber has a high floating power, resistant to bacteria, salt water and cheap, are the weakness is, can not pelleted with both the fiber and are rigid. (Budi Lestariyo).

2.5 Pavement Road

Pavement road is layers of material are placed on the Subgrade to receive the traffic load so that the burden of these (plus pavementnya own weight) can stand up by Subgrade. The goal of creating a structure pavement way to get a flat surface so that the vehicle can be through in all weather conditions. There are two types of pavement way, namely:

a. Pavement rigid (rigid pavement), in which the concrete material in general, have the strength to withstand the voltage enough so it would keep the traffic load.
b. Pavement flexible (flexible pavement), where only material mainly spread the traffic load to the bottom of the field with a wider base so that the Soil does not receive the load exceeds the bearing capacity..

To see pavement flexible arrangement can be seen in the image on 1 as follows:

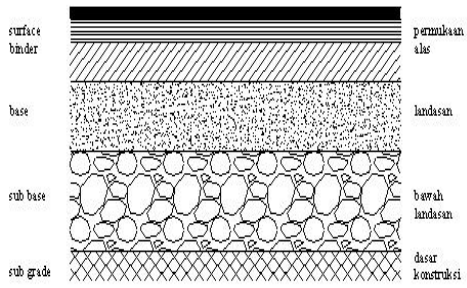

Figure 1. Structure pavement flexible

Flexible Pavement layer stack consists of:

1) surface course
Surface layer is created with the purpose of security and comfort of road users. Surface layer should be resistant to damage due to load and non load (Wear and tear). Asphalt is the material most appropriate for the additional surface layer pavement pelekat is flexible because the aggregate material and water-resistant.

2) base course
This section is located under the surface layer, working to prevent voltage collapse due to the high concentration of wheel load. Besides, the base layer provides for the surface layer.

Given the need to directly receive the wheel of a high voltage, then the quality of the material foundation layer must be high also. CBR is the minimum value of 80%. To get a high CBR value required gradation well.

For the foundation layer of aggregate is used preferably from the broken stone (stone crused). Aggregate of this kind have a high corner of the slide from the rounded aggregate (rounded) because the interlocking between the grains become more powerful.

3) subbase course
Layer beneath the foundation is part pavement that lies between the Soil basis (subgrade) and Lapis foundation (base course). Main function of this layer is part of the structure to spread the burden pavement wheels. Layer beneath the foundation to use this material, which is relatively cheap, so save the cost of construction.

Materials used in the foundation layer is a material non plastis, form there, silt or sand clayey. Layer below the foundation should have a CBR value of 25 when compacted with the water content field. However, if the material is good not much found, then the 10 cm top foundation layer can be replaced with lower-quality materials have provided CBR> 8 on the bad condition.

Layer beneath the foundation is not required if the Soil CBR basically more than 25. When CBR is <25, the necessary foundation layers down to the minimum thickness 10 cm.

4) Subgrade
Subgrade in the pavement is the original Soil surface has been improved with the use of opium or quality with stabilization chemicals. Strength and duration pavement road structure is highly dependent of the nature and resources to bearing capacity the Subgrade. According to requirements, minimum subgrade CBR road is 5%, while for the airport between 6% and 10%.

Improve the quality of the Subgrade (subgrade) will pavement structure provides a more economical. This included use of opium, but not often need to be a chemical stabilization.

2.6 Indek Propertis Soil

Testing Index Propertis Soil consists of testing the water content, weight and content and specific gravity which aims to see the physical attributes of Soil.

2.7 Atterberg Limit

Very important kind of grain on the ground is fine plastisitasnya. This is because the clay minerals in the soil. Plastisitas Soil is the ability to adjust to the changes in the form of a constant volume without fracture or fracture-crash. Depending on the degree of water, Soil can be liquid, plastis, semi-solid, or solid. Physical position on the smooth hard-ground water level is a certain consistency. (Qunik Wiqoyah, 2006).
Atterberg, 1911 (in Hardiyatmo, 1999), providing a way to describe the boundaries of the Soil of consistency with the hard-smooth considering the actual water content. Boundary is the limit of the liquid (liquid limit), limit plastis (plastic limit), and limit decrease (shrinkage limit). index elasticity (plasticity index) (PI) is the difference between liquid limit (LL) and the limit plastis Soil (PL)

2.8 Optimum Density

Aracteristics of soil can be assessed from the standard laboratory test called the Proctor test. This soil density test to determine the relationship between water content and density of Soil so that it can be a maximum density and optimum water content. Density is highly dependent on soil water content, the smaller the water content of the soil will be the greater, as well as reverse it. Its calculation using the equation 2.7 and 2.8 below:

a. content of heavy wet soil;

$$\gamma = \frac{B2 - B1}{V} \quad \text{.....(2.7)}$$

$B1$ = berat mold

$B2$ = berat tanah + mold

V = volume mold

b. content of soil dry weight

$$\gamma d = \frac{\gamma x 100}{(100 + w)} \quad \text{.....(2.8)}$$

w = water content after the use of opium

2.9 CBR (California Bearing Ratio)

CBR is a comparison between the burden of a material against the penetration of the standard depth of penetration and speed of the same. CBR is an empirical way to determine the strength of the Soil, other than the CBR is also useful to have boosted the value of Soil resources in densely maximum. CBR value is the price of the basic quality of the soil compared with the standard form of broken stones that have CBR value of 100% in the shoulder the burden of traffic. CBR can be divided in accordance with an example how to get the Soil that is the field CBR (CBR field inplace or CBR), CBR field rendaman (undisturbed soaked CBR) and CBR laboratory (laboratory CBR). CBR laboratory can be divided into two kinds, namely laboratory rendaman CBR (soaked laboratory CBR) and CBR laboratory without rendaman (unsoaked laboratory CBR) (Soedarmo and Purnomo (1997), Determining the value of CBR soil samples carried out against the use of opium is compacted with the standard. If the CBR value is determined with the soaking rendaman held for 4 days (96 hours). CBR rendaman test method is to asumtion the rain or when bad condition in the field that will provide the influence of the addition of water on the ground water has been reduced, so that it will lead to the development of a (swelling) and a decrease in strong bearing capacity of Soil.

Test results can be obtained by measuring the size of the load on a certain penetration. The amount of penetration as the basis for determining CBR penetration is 0.1 "and 0.2", is calculated with the equation 2.9 and 2:10 the following:

Penetrasi 0,1" (0,254 cm)

$$\text{CBR (\%)} = \frac{P1}{3x\,1000} x\,100 \ \% \text{.....(2.9)}$$

b. Penetration 0,2" (0,508 cm)

$$\text{CBR (\%)} = \frac{P2}{3x\,1500} x\,100 \ \% \text{.....(2.10)}$$

with:
P1: pressure test on the penetration of 0.1 "(g/cm3)
P2: pressure test on the penetration of 0.2 "(g/cm3)
From the second value is used in calculating the value of the largest

2.10 Swelling Potential

Clay minerals, grain size of soil, water content and index plastisitas highly influential on the swelling potential of clay

No	Test Type	Test No			Average
		1	2	3	
1	Water content	53.404	52.741	53.179	53.108
2	Unit Weight	1.623	1.408	1.495	1.509
3	Specific Gravity	2.631	2.525	2.463	2.5398

soil. Increasing the percentage of grain size based on the faction clay (0.002 mm) and index plastisitas on various clay minerals will increase the percentage of swelling potential (Chen, 1975). The addition of water in the ground kind of grain or fine clay will soil volume changes (swelling). Relationship between the swelling of the index plastisitas can be seen in Table1

Table 1 Relationships between the swelling potential of the index plastisitas

Swelling Potential	Indeks plastisitas
Low	0 - 15
Medium	10 - 35
High	20 - 55
Very high	>35

The addition of water in the ground kind of grain or fine clay akan soil volume changes (swelling). More details, the situation can be seen in Figure 2

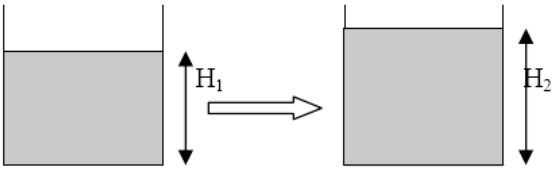

Figure 2. The influence of addition of ground water in hard-smooth

Swelling value can be calculated that occurred with 2:11 of the following:

$$\text{Swelling} = \frac{\Delta H}{H1} x100\ \% \text{.....(= 2.11)}$$

With:
ΔH=H2-H1
ΔH:he swelling due to increased water (cm), H1:high test substances before the addition of water (cm), H2:higher test object after the addition of water (cm).

4. RESULTS AND DISCUSSION

4.1 Data Material Testing Results

Test material consists of Index Propertis (water content, unit weight, specific gravity), soil particle gradation, and atterberg limit. This test aims to see the technical nature of the Soil that will be used in research. The test results index propertis and atterberg limit can be seen in Tabel 2 to 3 as follows:

Table 2 Analysis of Index Propertis Soil

No	Test Type	Test No			Average
		1	2	3	
1	Water content	53.404	52.741	53.179	53.108
2	Unit Weight	1.623	1.408	1.495	1.509
3	Specific Gravity	2.631	2.525	2.463	2.5398

Table 3 Analysis of Atterberg Limit

No	Test Type	Test result		
		LL	PL	PI
1	Atterberg Limit	52,33	44,94	7,39

Results of testing (Table 2) obtained water content from an average of three sample is 53.108% and the Unit Weight of soil on average is 1.509 gr / cm ³ and the average weight of soil types from three sample is 2.5398. With the value of 53.108% water content the soil including soil with high water content. In general, GS loam soil ranged from 2.5 to 2.9, the soil including clay.

Index Plastisitas very influential on the development potential of Soil that is the higher the index plastisitas akan large development potential.

Results of testing (Table 3) LL values obtained 52.33%, 44.94% PL. Based on the equality of 2.4 obtained Plastisitas Index (PI) 7.39%, according to the Atterberg, 1911, (Table 3) including the clay soil silty with plastisitas are.

3.2 Soil Testing

Testing consists of the Soil use of opium (Modified Proctor), and swelling potential CBR (California Bearing Ratio). The test aims to test the making of objects. test results opium den, swelling potential, and the CBR can be seen in sub-section 3.2.1 to 3.2.3 as follows:

3.2.1 Test for use of Modified Proctor

Soil use of opium is very dependent on the value of the volume of dry weight, the greater the value of the volume of dry Soil will be more compact. In data processing for Soil use of opium, to look for relationships between the degree of water (Water Content) and the volume of dry weight (Dry Density). This is useful to know the value of MDD (Maximum Dry Density) and OMC (Optimum moisture Content).
The value of MDD (Maximum Dry Density) and OMC (Optimum moisture Content) for each soil mix - coconut fiber can be seen in table 4 following:

Table 4 Results of each comparison test optimu mix

No	Comparison of Mixed	MDD (gr/cm³)	OMC (%)
1	100 % : 0 % (soil: coconut fiber)	1.11	34
2	90 % : 10 % (soil: coconut fiber)	1.20	30
3	80 % : 20 % (soil: coconut fiber)	1.21	29
4	70 % : 30 % (soil: coconut fiber)	1.19	31
5	60 % : 40 % (soil: coconut fiber)	1.03	44
6	50 % : 50 % (soil: coconut fiber)	1.09	39
7	40 % : 60 % (soil: coconut fiber)	1.08	35

MDD value is used to find the weight of the mixture for CBR (California Bearing Ratio) value by multiplying the volume of the MDD. While the value of OMC, is the number of degree of water required to obtain maximum density. So, when CBR test, the water depends on the value of OMC. To see the value of MDD (Maximum Dry Density) and OMC (Optimum moisture Content) on the comparison of each soil mixture - coconut fiber are presented in picture 4.2 and 4.3 below:

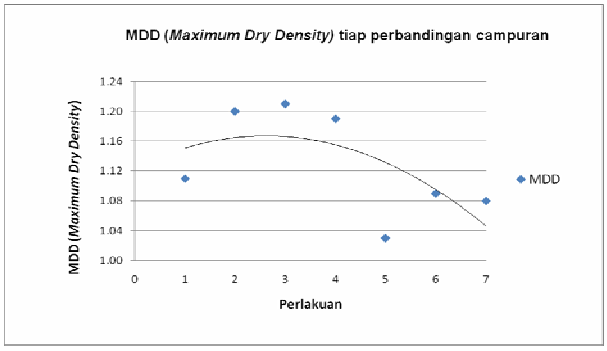

Figure 3. Graph MDD (Maximum Dry Density) for each comparison of a mixture

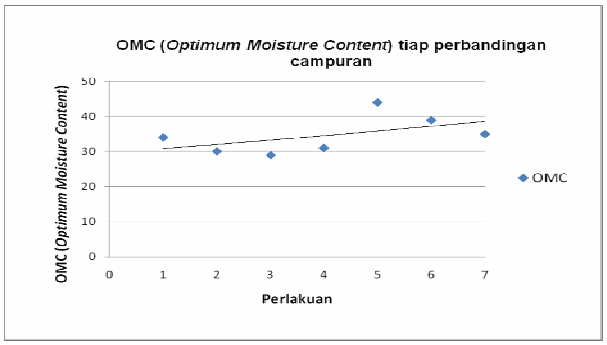

Figure 4. Graph OMC (Optimum moisture Content) for each comparison of a mixture

Graph of MDD (Maximum Dry Density) for each comparison mixture (picture 3) obtained a value MDD (Maximum Dry Density) occurred in a mixture of the highest 80%: 20% (soil: coconut fiber) with a value of MDD 1.21 gr / cm ³. MDD (Maximum Dry Density) compared to the native Soil, Soil with MDD mixture of coconut fiber to increase 10%. However, the addition of coconut fiber greater than 30% does not increase the effective density of Soil, can be seen from the picture MDD to decrease the value of 4.2 after mixing exceeds 30%.

Graph of OMC (Optimum moisture Content) of the comparison showed that the value of a mixture of OMC (Optimum moisture Content) occurred at the highest mix of 60%: 40% (soil: coconut fiber), as shown in Figure 4.

3.2.2 Test swelling Potential

Potential development of Soil resources to the very influential bearing capacity. If the potential to decrease the development of Soil resources to bearing capacity improved Soil. Swelling potential testing, soil testing after the use of opium in the Modified Proctor soaked Soil for 4 days. Then the swelling potential value can be searched with the equation 2.9. The swelling potential value for each comparison of soil mix - coconut fiber can be seen in table 5 below:

Table 5 Results of each comparison swelling potential mix

No	Comparison of Mixed	Swelling Potential (%)
1	100 % : 0 % (soil: coconut fiber)	66.67
2	90 % : 10 % ((soil: coconut fiber)	61.54
3	80 % : 20 % ((soil: coconut fiber)	55.56
4	70 % : 30 % ((soil: coconut fiber)	74.29
5	60 % : 40 % ((soil: coconut fiber)	71.43
6	50 % : 50 % ((soil: coconut fiber)	70
7	40 % : 60 % ((soil: coconut fiber)	75.67

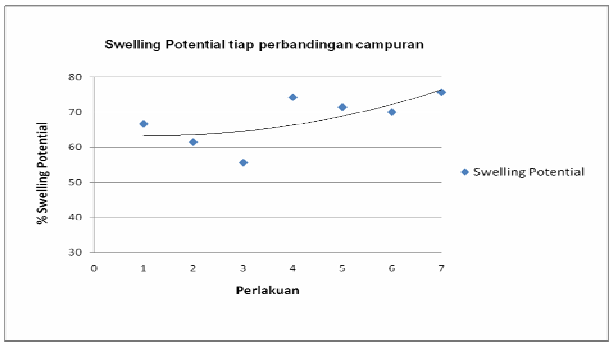

Figure 5. Graph swelling potential for comparison of each mixture

Figure 5 shows the relationship between the size of the development and comparison of Soil in the mixture after rendam for 4 days. Figure also shows that the lowest potential value of swelling occurred in a mixture of 80%: 20% (soil: coconut fiber) with swelling potential value of 55.56%. Large decrease compared to the native Soil that is 11.11%.

3.2.3 Tests for CBR (California Bearing Ratio)

Resources to bearing capacity the Subgrade can be estimated, among others, the practice of CBR checks. CBR value is one of the parameters used to identify resources to bearing capacity Soil planning in the basic layer pavement. When the Subgrade has a high CBR value, will reduce the practical thickness pavement which is located on the Subgrade (subgrade).

The value of CBR (California Bearing Ratio) for each comparison of soil mix - coconut fiber can be seen in table 6 below:

Table 6 Results of each comparison CBR test mixture

No	Comparison Value Mixed	CBR
1	100 % : 0 % (soil: coconut fiber)	0.99
2	90 % : 10 % (soil: coconut fiber)	3.19
3	80 % : 20 % (soil: coconut fiber)	3.19
4	70 % : 30 % (soil: coconut fiber)	2.98
5	60 % : 40 % (soil: coconut fiber)	1.29
6	50 % : 50 % (soil: coconut fiber)	1.10
7	40 % : 60 % (soil: coconut fiber)	2.10

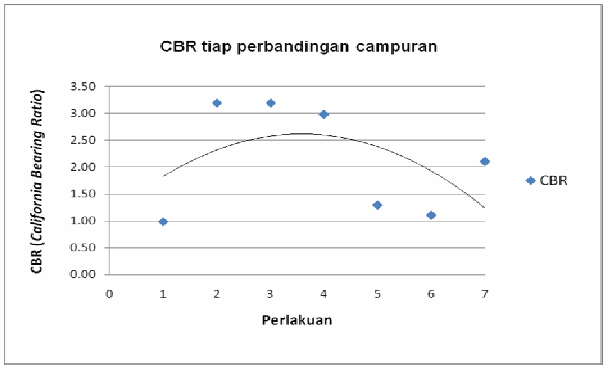

Figure 6. Graph CBR value for each comparison of a mixture

Mixing soil material with coconut fiber stabilizer which can increase the stability of the Soil value of CBR. Figure 6 shows the relationship between the size of the CBR value and the comparison mix. Figure also shows that the addition of coconut fiber is very good to increase the bearing capacity loam soil.

Figure 6 also shows that the highest values occur in the CBR mixture 90%: 10% and 80%: 20% (soil: coconut fiber) with a CBR value of 3.19%. Large increase compared to the native Soil that is 220%.

4. CONCLUSION

From the results of the research and analysis that was done then the conclusion can be drawn as follows:

1. The addition of coconut fiber in the clay soil can increase the bearing capacity of Soil, that is can be seen from the CBR test results obtained at the highest CBR value of the addition of 10% and 20% coconut fiber with the CBR value 3.19%, with large increase of 220%. 10% and 20% coconut fiber is the addition on the ground, because the composition of soil and coconut fiber is balanced.

2. Test results from use of opium obtained the highest density of Soil on the addition of 20% coconut fiber with a value of MDD (Maximum Dry Density) 1.21 gr / cm ^{3}, compared with the original Soil was increasing by 10%. Swelling of the test results obtained Potential Potential smallest value of swelling occurred on the addition of 20% coconut fiber, with a large decrease in 11.11% if compared with the native soil.

ABSTRACT

The behavior of damage parameters in adhesive bonding has been investigated in order to predict the location of the initial crack in the adhesive region. The research was started by investigating the interaction between the adhesive and its substrate in different types of joint configuration. The first natural choice was the simplest adhesive joint configuration known as Single Lap Joint (SLJ). It was found that although simple in loading condition which was tensile loading, stress state that occurred in the adhesive region was relatively complex. From analysis of the adhesive region it was found that damage initiated at a location where the von-Mises stress and Triaxiality have a maximum value. Although SLJ only expanded on axial load, the stress state that occurred can be categorized as multi-axial as indicated by the variation of the Triaxiality value. From this finding, it can be stated that for multi-axial stress states, Triaxiality is an important factors for crack initiation. Several adhesive joint configurations were considered, starting with the Butt-joints (BJ), the Cleavage Joints (CJ) and finally the Scarf Joints (SJ). The SJ was chosen since a simple relationship existed between triaxiality and adhesive bondline angle. Triaxiality can be determined numerically using finite element analysis and experiments. Finally, the damage parameters were constructed as a function of von Mises stress and triaxiality.

Keywords
Triaxiality, Damage Evolution, Finite Element, Experimental

1. INTRODUCTION

The definition of adhesive bonding is a process of joining two parts/structures using a non-metallic material (adhesive). The number of applications for adhesives in bonding structural components is rising rapidly. Interest is high in aerospace, infrastructure, automotive, marine, and biomedical communities.

The advantages of adhesive bonding are: a) microstructure unaffected, b) load distributed uniformly at right angles to loading direction, c) different materials and very thin parts can be joined, d) high strength in combination with riveting, e) metals with different electrochemical properties can be joined (insulating effect of adhesive), f) distortion-free joining and g) weight saving and light constructions.

The disadvantages are: a) limited form stability, process parameters must be held within very narrow range, b) change of properties of joint with time (ageing of adhesive layer etc.), c) complicated strength calculation, repair possibilities limited, d) low peeling strength, e) creep sensitive, f) complicated control of process, g) low adhesive layer strength must be compensated by large joining area, h) influence of time on process properties and i) low tolerance pre-treatment of joining parts surfaces.

1.1 Triaxiality of Adhesive Joints

Structural engineer in general considers that a uniaxial tensile test is suitable to describe the behaviour in structures. But, in a multi-axial loading state, this understanding needs to be updated. Scaffer et al. [1] stated that the void nucleation, void growth, and void coalescence models depend on the triaxiality. If the triaxiality value rised, tendency to failure increased. He also stated that a proper calculation of the triaxiality needs 3D non-linear analysis.

A unique behaviour of triaxiality is that it can be controlled by adjusting the geometry or loading mode. Barsoum [2] had performed research where triaxiality was controlled and was kept constant during the test by maintained the ratio between tension and torsion fixed. Decreasing the torsion will also decrease the triaxiality and vice versa. Seppala et al. [3] explained that void growth occurs because system tries to relax from an applied tension load in order to minimize the elastic energy. Material around the void will deform plastically to accommodate the void growth. Naturally, a plastic deformation emerges because of local shear stress that might occur from an applied load or from a stress field around the void, even if it is a hydrostatic stress.

Dutta and Kushwaha [4] found that a stress state is an important factor in a crack initiation and the strain failure. The stress state generally can be presented by the stress triaxiality, which has a very important role in ductile failure. Higher triaxiality value show how dominate a hydrostatic stress in stress field. On the contrary, a stress deviatoric component has important role compared to the hydrostatic stress at low triaxiality values. Void growth rate related directly to the stress triaxiality value and plastic strain accumulation. Scahfer et al [1] has performed a non-linear finite element analysis of a round bar with a notch, which was subjected to a small-scale tension load. They analysed

the stress levels at failure and found that the failure locations are consistent with the locations where the stress triaxiality are higher in all cases considered.

1.2 Investigation of SJ

Among many types of different adhesive joint configuration, a scarf joint has been investigated extensively and became a theoretical and experimental subject. This is due to a good mechanical property of this joint, regardless the type of loading applied. In fact, because of a substrate bevel shape, the loading due to bending moment caused by bad alignment can be reduced. Objois et al. [5] has researched the behavior of the SJ. The research is based on an analytical theory developed by Wasiama [6]. The theoretical equation is based on the following assumptions: (1) adhesive layer was far enough from ends of specimen where the load was applied so Saint-Venant assumption was still valid, (2) on the cross section of substrate, the normal stress distribution was homogeneus, (3) because thickness was small enough compare to other two dimensions, a plane strain assumption can be applied, (4) material of adhesive and substrate were assumed homogenous and isotropic whilst mechanical behavior was linear elastic and (5) on adhesive-substrate interface, where strain field was continuous, adhesion was assumed perfect.

2. TRIAXIALITY CHARACTERISTIC

Lemaitre proposed that in the field of damage mechanics, the stress triaxiality, not the von Mises equivalent stress, governs the damage process [7]. This is to say, to analyze a mechanical response of a construction with high constraint, such as the solder joints in electronic packaging where a thin ductile layer of solder alloy constrained by the surrounding rigid elastic substrates, the concept of stress triaxiality should be introduced [8,9].

A study about triaxiality is based on the fact that this variable has a very important role to determine a generalized damage solution. Because of its part in the damage evolution formula as one of the independent variable, theoretically, triaxiality can be controlled. In an experimental level, this means that the experiment should be designed and developed to such extent where triaxiality also can be controlled. To choose which adhesive joint is suitable for this purpose, an analysis whether theoretically or numerically should be carried.

Practical choice is of course a Finite Element (FE) analysis. Since calculation of triaxiality need a von-Mises equivalent stress and a hydrostatic stress at any point in adhesive layer, those values can be extracted directly. With the finite element analysis, no matter how complex the structure is, the triaxiality value can be obtained. It is contrary to an analytical solution where only limited solutions available for simple structures.

In the formula to calculate triaxiality, there is a variable T_x, which contains a von-Mises equivalent stress and a hydrostatic stress. The hydrostatic stress is a stress that can make an element shrink or grow without change in shape. Hydrostatic stress itself can be extracted from the principal stresses. Since the principle stresses are three stresses in three-dimensional direction, it raises question whether to use three-dimensional or two-dimensional analysis to extract stresses. Is it enough to model a joint as a two-dimensional element without sacrifying its accuracy? If triaxiality calculation can be performed in two dimensions, for example by using a plane-stress or a plane-strain assumption, the complexity and the computing time can be reduced.

The triaxiality is like a map of stress state of a structure in this case is an adhesive joint. The triaxiality is predicted unique belong to a particular type of the adhesive joint. The main issue presented in this chapter is the selection process of joint that has a good and simple relation between changing the load or geometry correlated with the triaxiality value. The triaxiality from several types of adhesive joints in three-dimensional model is evaluated and compared. Continue with a comparison between the three-dimensional and two-dimensional model.

3. TRIAXIALITY OF SLJ

SLJ geometry is shown in Figure 1. In this model, the adherends were made from 2014-T6 Aluminium with Young Modulus, E = 70000 N/mm, Poisson's Ratio, v = 0.33. The adhesive was made from FM-73™ film-form from Cytec. The material properties of FM-73 are as follow: Young Modulus (E) = 1211.25 N/mm^2, Poisson's Ratio, v = 0.38. The model uses a multilinear kinematic hardening material.

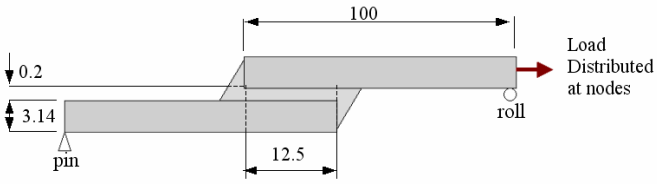

Figure 1: Geometry of single lap joints with boundary conditions

Several assumptions of FE modeling of a SLJ have been made. The SLJ has been modeled using a 2D plain strain element (Plane82 from ANSYS element library). This is a 2D higher order element. With the presence of nodes in the middle of element, this element has advantages: a) more accurate results for mixed (quadrilateral-triangular) automatic meshes and b) irregular shapes can be tolerated without much loss of accuracy [10]. Final meshing is shown in Figure 2.

In ANSYS, a hydrostatic stress is defined as NLHPRE. The following values are calculated from the two stresses results presented above.

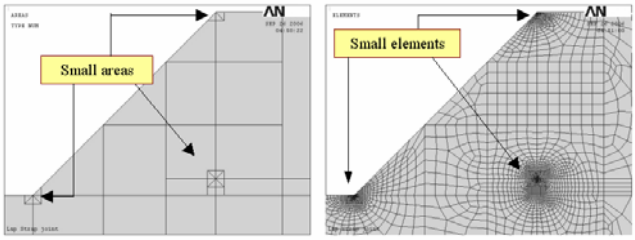

Figure 2: (a). Areas where the finest meshing sizes are located (b). Final Meshing

A triaxiality ratio is defined as:

$$T_x = \frac{\sigma_H}{\sigma_{Eq}} \quad (1)$$

The triaxiality function is defined as follow:

$$R_v = \frac{2}{3}(1+\nu) + 3(1-2\nu)T_x^2 \quad (2)$$

Where ν is *Poisson's Ratio* and T_x is *Triaxiality Ratio*. If the hydrostatic stress and the equivalent stress values are already available, a triaxiality contour of *Tx* (triaxiality ratio) and R_v (triaxiality function) can be calculated. Both stress results should be saved in a table so called the Element Table (ETAB), a facility available in ANSYS. With the Element Table, several mathematical manipulations of the stored data can be performed with its functions. For this purpose, the following functions are used: *Exponentiation*, *Multiply* and *Add* items. Triaxiality function is shown in Figure 3.

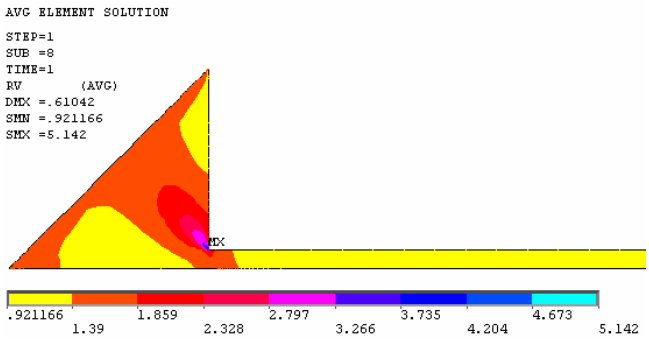

Figure 3: Contour of Triaxiality function (Rv) at load level 60%

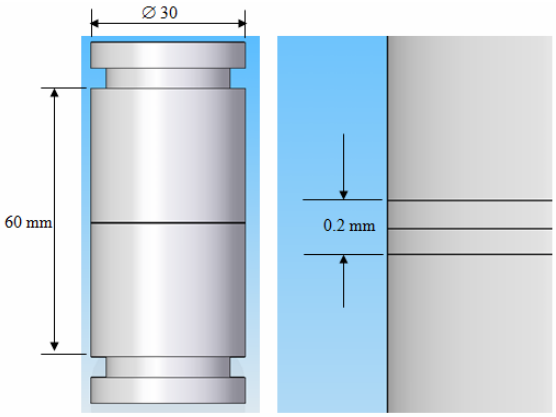
4. TRIAXIALITY OF BJ

4.1 BJ under Tension loading

The first natural choice to analyze was a BJ under tension load. The BJ is modeled based on ASTM STP standard adapted from Prakash [11]. Based on the standard geometry, a three-dimensional model was developed as shown in Figure 4 by using Solidedge™. Model consists of four solid geometries. First two solid geometries represent substrate (upper and lower) and two other represent adhesive layer.

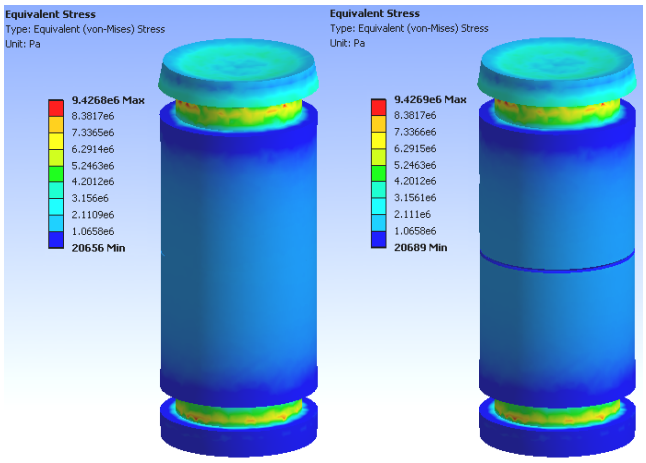
There are two reasons behind this modeling technique: (1) Firstly, an adhesive was modeled using two solids geometries because a finer meshing in the adhesive region was required. Since in ANSYS Workbench the stresses values in three layers of adhesive are needed. First and third layer are layers represent contact interface between the adhesive and the substrate (upper and lower). The second layer represents the adhesive layer in the middle of adhesive. (2) Secondly, it is easier to extract those stresses after the geometry model was imported to the finite element application; in this case is ANSYS Workbench.



(a) (b)

Figure 4: CAD model of BJ (a) Overall model and (b) Zoom at Adhesive region

Next, the CAD model was saved in an IGES format because the ANSYS recognized this model as a solid model. To check that the contact between solids is attached properly, a continuity analysis is done by giving the same material property to all solid model, in this case is mild steel. If the contact regions were properly attached each other, no discontinuity in stress or displacement occurred. Figure 5 shows a comparison between a stress contour (a) before and (b) after real adhesive property (FM 73) was applied to the joint. From those analyses results, we can quite confident that the model is reasonable and the contact between solid models is perfectly match each other.



(a) (b)

Figure 5: Equivalent stress (a) before and (b) after including adhesive layer

After a contact model has been validated, next step was to extract stresses needed for calculating the triaxiality: a von-Mises equivalent and the three principal stresses since hydrostatic stress can be calculated by averaging all of the principal stresses. Using the function *Meshgrid*, a triaxiality result then is plotted as surface function and shown in Figure 6.

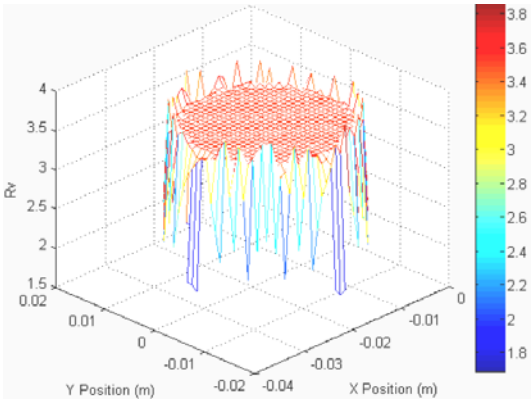


Figure 6: Triaxiality values of mid-layer adhesive BJ under tension load after refinement, F = 1000N

From Figure 6, it is shown how an edge effect contributes to the curve shape. At the edge, singularity problem exists and raised von-Mises equivalent stresses. As a consequence, the triaxiality values drop at the edges. If a finer meshing applied, the amount of dropped triaxility values will decrease. Now, consider values in the middle, the triaxiality values are nearly constant at 3.5. From the result, conclusion can be made that when an adhesive is subjected to a pure tension, the triaxiality will be 3.5. To check whether the triaxiality change when the tension load was changed, another analysis was performed with tension load was raised to 2000 N. No changes in triaxiality were found.

4.2 BJ under Torsion Loading

The analysis continued with a BJ with a torsion loading. The torsion is a common load for a circular shape beam like the shaft. The BJ will suffer a pure shear so it was predicted that a different triaxiality value with the one from tension load would exist. The result of triaxiality after mesh refinement is shown in Figure 7. A peak arise at the center of BJ where there is no torsion in that point. But the triaxiality value at peak is not much different and still at value 0.92. From this analysis, a conclusion has been made that for the case of pure shear, the triaxiality value was fixed at 0.92. From both tension and torsion analysis, general conclusion can be made that the triaxiality values for both cases lies in extreme values. A prediction has been made that the values of triaxiality always lie in between extreme values, 0.92 and 3.5.

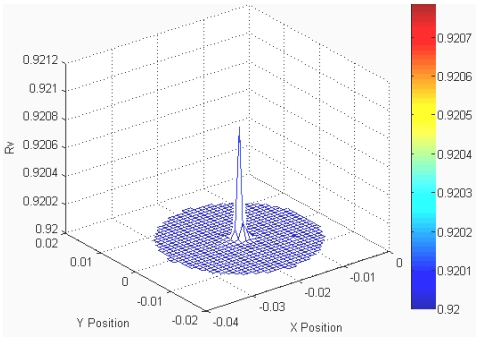

Figure 7: Triaxiality values contour of BJ under torsion T = 150 N.m after refinement

4.3 BJ under Mixed Loading

From the previous analysis, a prediction has been made that in order to control the triaxiality values in a BJ, a mixed loading between tension and torsion should be applied. To prove the prediction, two analyses will be compared. First load combination was torsion 150 N.m and tension 1000 N. The triaxiality result is shown in Figure 8. The result was nearly similar with the one in Figure 7 except the two observations: Firstly, the spike is not as sharp as the previous one which means more points have affected its values; Secondly, the peak had higher value, which is near 1.2. An interesting fact is majority of triaxiality still at value 0.92. It means that triaxiality for this case is still dominated by the torsion load.

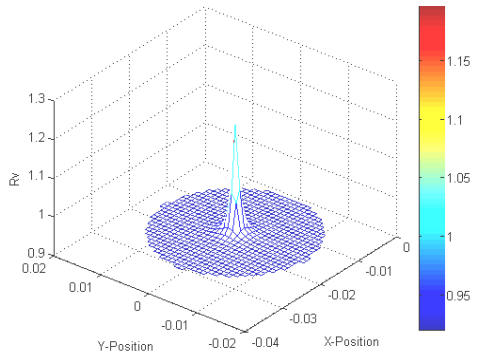

Figure 8: Triaxiality values contour of mid-layer adhesive BJ under mixed load torsion T = 150 Nm and tension L = 1000 N

A second load combination is considered with lowering the torsion became 15 N.m and held the tension at the same value 1000 N. The triaxiality result is shown in Figure 9. It is shown that the peak arises to maximum value nearly 3.5, which is a value at pure tension condition. More points also increase its value around the center and follow the parabolic shape. From this plot we can say that for this case the torsion is less dominant than the first case.

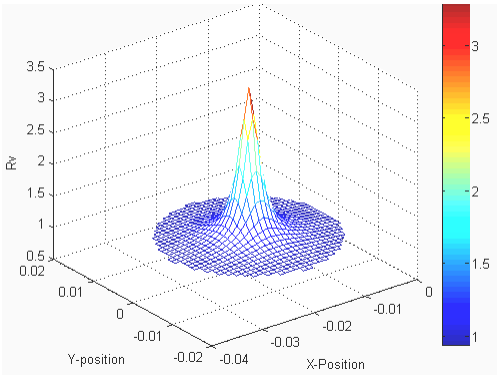

Figure 9: Triaxiality values contour of BJ under mixed load, torsion = 15 Nm and tension = 1000 N

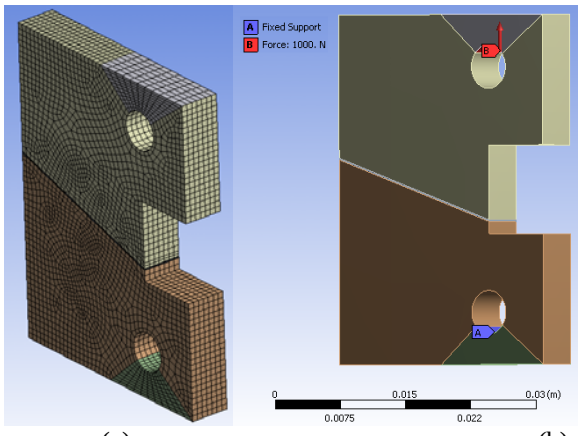
From the two analyses, the effect of mixed loading can be seen and can be controlled by adjusting the combination values of both tension and torsion load. From all of the figures considered, the transition of triaxiality from different loading can be seen and understood.

5. TRIAXIALITY OF CJ

A CJ is a joint that can receive a mixed loading even tough it is only subjected to a tension load. The geometry of joint as shown in Figure 10 that makes one line of the tension load can be transferred into the tension and the bending. From its geometry profile, it is easily to predict that half layer of an adhesive bondline will suffer compression whilst the other half will suffer tension.

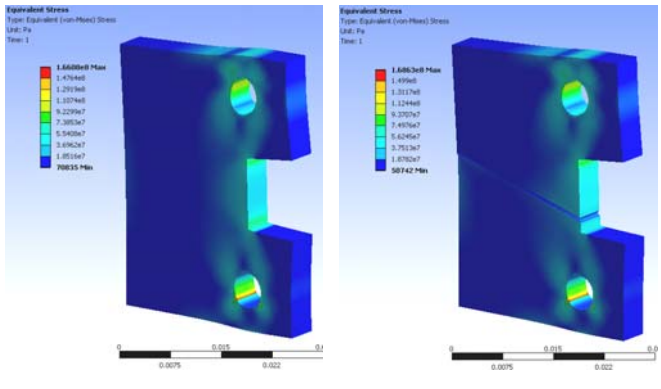
Analysis is performed to the CJ model, which is referring to the standard CJ adapted from ASTM D 1062 [12]. A modification has been made by change the thickness to 5 mm. The purpose of this changing is to lower the tension load needed to make this joint fail. Meshing is shown in Figure 10 (a). Boundary conditions were given with a tension load 1000 N distributed at the upper area of the hole in the upper substrate and fixed support at the lower area of the hole in the lower substrate as shown in Figure 10 (b).



(a) (b)

Figure 10: Model of 3D CJ after modification: (a) Meshing, (b) Boundary conditions

As usual, to verify that the geometries have perfectly match at contact region, an analysis with material mild steel for all solid models, including the adhesive region, has been performed. The result is quite satisfying where no discontinuity values of the von-Mises contour stress across the adhesive region can be observed. The result then is compared with the one after the adhesive material insertion, FM 73. Now the adhesive layer can be seen from the von-Mises contour stress as shwon in Figure 11. Two observations can be noted as follow: (1) the stress concentration occurs near the hole was not affecting the adhesive region and (2) half of the adhesive layer suffer compression (left region of bondline) and half other suffer tension (right region of bondline). Like any structure, which was subjected to bending moment, there was a point along bondline somewhere near the middle that carries no moment.



(a) (b)

Figure 11: Equivalent stress Contour and total deformation: (a) Continuous mild steel and (b) after adhesive material replacement

The result from a finer model is shown in Figure 12. As predicted before, there is a line across the thickness that has zero moment, which now is clear that this related to minimum triaxiality value, which is 0.92. From the legend, it can be seen that the range of triaxiality values is between 0.92 and 3.6, which is still consistent with the result from BJ.

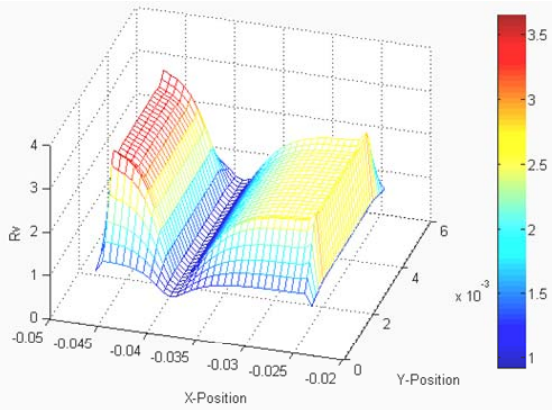


Figure 12: Triaxiality values of CJ in middle layer after refinement, bondline angle 18.5^{O}

A comparison will be made with a two-dimensional model using the plane-strain element. The purpose of this

comparison was to check whether its two-dimensional model can be used instead of the three-dimensional analysis. In region where singularity has no effect, it is likely that the two-dimensional model will be fit with the three-dimensional model. To compare both models, firstly, triaxiality values extracted from line in the middle by averaging triaxiality along two lines L1 and L2 as shown in Figure 13. The three points indicated reference points.

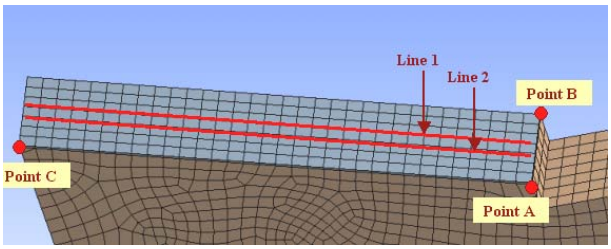

Figure 13: Notations in mid-layer of CJ model.

The result of average triaxiality value compared to the one from plane-strain analysis is shown in Figure 14. It is shown that the triaxiality profile along bondline from both results show good agreement. Discrepancy arises at edge because of the differences in meshing size. Small shifting of low region also occurs because the loading condition does not exactly have the same distribution. A load condition in three-dimensional model was applied on a surface while the load in two-dimensional model was applied at nodes.

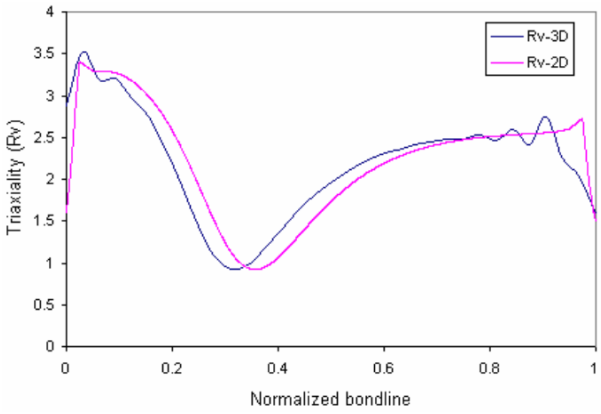

Figure 14: Comparison of triaxiality values of CJ between 3D and plane strain model, bondline angle 18.5^{O}

After a good agreement has been made between the three-dimensional and the two-dimensional analysis, for the next analysis, two-dimensional model will be used. Finally, it is important to check the effect of a changing orientation angle between the bondline and the horizontal line. The triaxiality of four different bondline orientation angles has been computed and displayed in Figure 15.

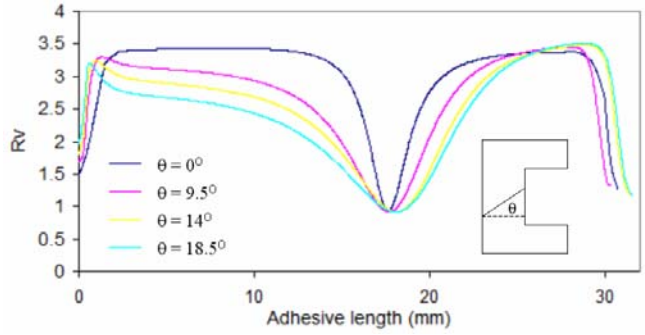

Figure 15: Effect of orientation to triaxiality value along bondline.

Figure 15 shows four triaxiality profiles along the bondline. Note that different end points existed because the bondline line is not the same and is not normalized. It was shown that at the elevation zero hence bondline is along horizontal line, majority of values were at maximum (like pure tension in BJ's case) except the narrow low peak at neutral line where the bending moment is zero. The change of the triaxiality profile can be seen here as the elevation rises.

6. TRIAXIALITY OF SJ

Another type of an adhesive joint, which has a simpler profile compared to the CJ, is the SJ. The load applied to the SJ is tension and co-linear hence no bending moment occurs. But, since the construction similar to the CJ where the orientation angle exists, the load applied transferred into tension and shear stress. The use of the SJ is quite common because larger contact area makes the joint stronger and can split the loading as described before. SJ model has been developed using the same technique as the CJ modeling and has shown in Figure 16.

After meshing is done, boundary conditions are applied in the green region with a fixed support at upper hole surface of upper substrate and force a 1000 N distributed at lower hole surface of lower substrate

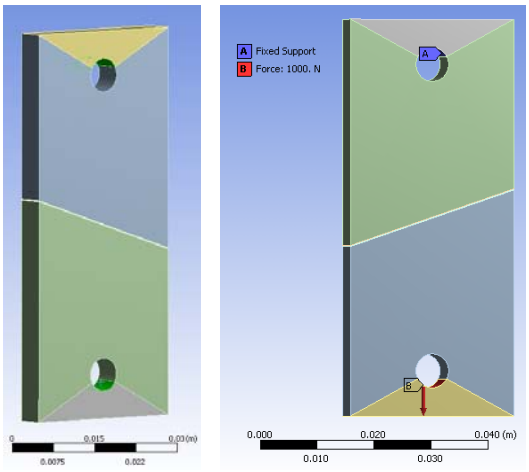

Figure 16: SJ model (a) Loading contact, (b) boundary conditions: Fixed support and distributed load

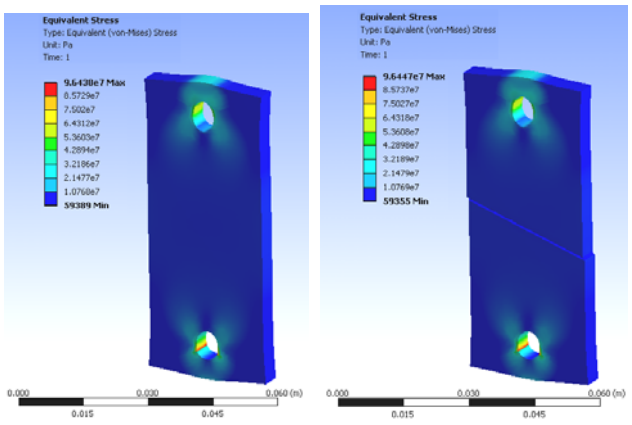
A static analysis of SJ with a mild steel properties applied to all solid models has been performed and are shown in Figure 17 (a). The contour of von-Mises equivalent stress is continues across adhesive geometry, which shows that a solid region adjacent to each other are in contact properly. Second analysis with real adhesive property, FM 73, is then performed and is shown in Figure 17 (b). Now the adhesive region can be seen. From this analysis, also it can be seen that the stress concentration near the hole does not affect adhesive region.



(a) (b)

Figure 17: Von-Mises equivalent stress contour of SJ (a) full mild steel, (b) after FM 73 inserted

The finer mesh have been made and analyzed with the triaxiality result is shown in Figure 18. Now, the triaxiality shape changes with the middle region far from the edge have nearly constant value of 1.67. Near the edge, the triaxiality values drop and a ripple effect also occurs. This ripple effect will be seen clearly in two-dimensional analysis comparison. The legend shows that range of triaxiality lies between 1 to nearly 1.8.

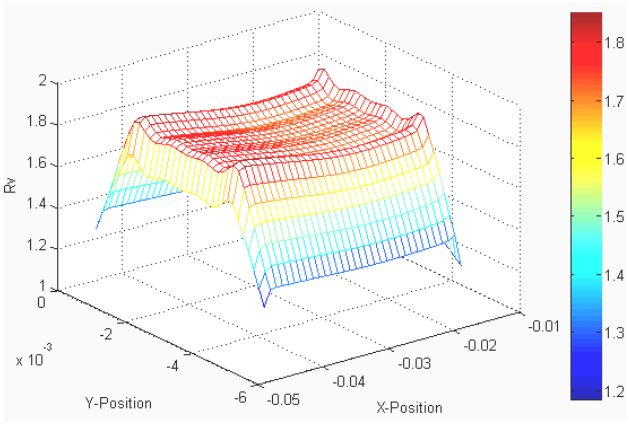


Figure 18: Triaxiality values of SJ in adhesive layer after refinement, bondline angle =18.5^{O}

With the same method as in a CJ, in order to compare a three-dimensional analysis with a two-dimensional analysis, the triaxiality value along the mid line needs to be extracted. Two-dimensional analysis has been performed using a plane-strain element. The comparison is shown in Figure 19. A slightly different result also occurs just like the one from the CJ result. The reasons of the difference are the fact that the boundary conditions are not exactly the same, which is the same reason behind the difference in CJ. From here, it is quite confident to state that the two-dimensional analysis can be used to represent the SJ model.

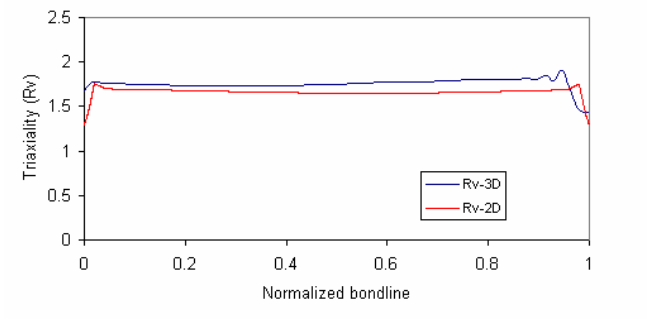

Figure 19: Comparison of triaxiality values of the SJ between 3D and plane strain model

Analysis continued for other orientation of bondline. Five different elevations /orientation angles are considered and the triaxiality results are shown in Figure 20.

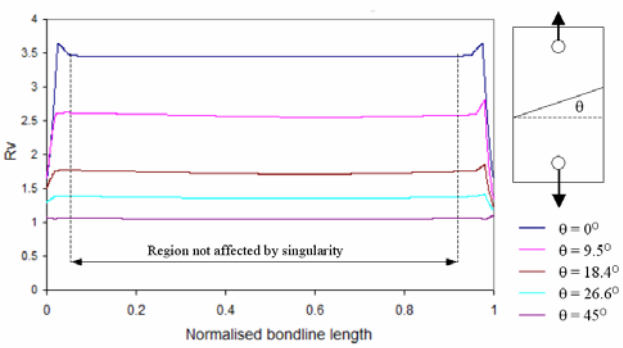

Figure 20: Triaxiality of the SJ as a function of orientation angle

It is clear now how a triaxiality profile change from no elevation specimen, where a maximum the triaxiality value exists, to the highest elevation, where the triaxiality value has minimum value. It is also shown that for every orientation, the triaxiality has constant value along its bondline region where the singularity has no effect.

7. CONCLUSION

After analyzing the three cases of loading in a three differents joint which are BJ, CJ and the SJ, conclusion can be made as follow:

1. The triaxiality (Rv) is not constant along bondline for two cases of joint: BJ and CJ

2. In a practical or a laboratory scale, adjusting and maintaining torsion-tension load combination at fixed value for BJ is a bit hard to implement.
3. Characterize of the triaxiality is influenced by the loading state and not just the geometry.
4. For a laboratory scale, a BJ and CJ are not easily implemented but from the finite element analysis, several important aspects related to the triaxiality behavior are covered and understand.
5. The triaxiality values along its bondline are constant for all orientation considered except a small region at ends, the triaxiality drops as the effect of singularity.
6. The constant value of triaxiality along its bondline is a good feature of this joint. Based on results in Figure 20, the triaxiality value versus angle can be fitted using least square method so the other triaxiality value for particular angle can be extracted.

ABSTRACT

Most of eggshell nutrients contain $CaCO_3$ and, therefore, this calcium rich material could be used as bone implant starting material. The obtained calcium can be reacted with phosphate compound to produce hydroxyapatite (HA), a biomaterial whose composition and structure are almost similar to those of bone minerals. This research reported that hydroxyapatite (HA) derived from eggshell using hydrothermal method had been synthesized. Hydrothermal synthesis was held in a closed autoclave under controlled temperature and pressure. The starting material was chicken eggshell heated at 1000°C for 5 hours to remove their organic components and decompose the calcium carbonate into calcium oxide (CaO). CaO solution resulted from 5 hours calcination was then dropped by $(NH_4)_2HPO_4$ solution of several concentrations which were 0.06 M, 0.3 M and 0.6 M. This mixture remained for 8 hours inside the hydrothermal autoclave under two different pressures, 2 atm and 5 atm. Sample was then sedimentized through an aging process of 12 hours. Characterization using X-ray diffraction showed that the most crystalline HA in this experiment was resulted from 1 M calcined eggshell solution added with 0,6 M diammonium hydrophosphate solution at hydrothermal pressure of 5 atm. XRD analysis also showed that the HA volume fraction of this sample was very high. The same trend was also shown by FTIR spectra. SEM image presented that the particles were homogeneous and non-agglomerated.

Keywords
Eggshell, hydroxyapatite, hydrothermal, calcination, crystallinity

1. INTRODUCTION

About 95% eggshell nutrients contain $CaCO_3$. Therefore, this calcium rich material could be used as bone implant starting material to produce hydroxyapatite (HA), bone substituted biomaterial.

There are several methods for synthesizing HA. Some of them are wet method, dry method, hydrothermal method, and flux method. Hydrothermal method was chosen in this study in order to get well crystallized and non-agglomerated HA with homogeneous in size and shape. This method also has advantages like rapid heating, fast reaction and high yield [1-4].

HA is chemically similar to the mineral component of bones and hard tissues in mammals; its chemical formula is $Ca_{10}(PO_4)_6(OH)_2$. Several methods of characterization, which are X-Ray Diffraction (XRD), Fourier Transform-Infra Red (FT-IR), Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Analysis (EDXA, may be employed to confirm the formation and characterize the material.

HA is a bioactive material. It has the ability to integrate in bone structures and support bone ingrowths without breaking down or dissolving. Therefore, it could be used as bone fillers in the forms of powders, porous blocks or beads to fill bone defects or voids [5-8].

This research was conducted to synthesize HA from chicken eggshells. Bio-based HA crystal is a potential biomaterial to serve as a biocompatible bone implant. Moreover, this implant might have its economical value as it uses chicken eggshells waste as the starting materials.

2. MATERIALS AND METHODS

The materials used in this research were chicken eggshells, diammonium hydrophosphate, $(NH_4)_2HPO_4$, and aquabides.
This research consisted of three experimental steps, which were eggshell calcination, hydrothermal synthesis and HA characterization.

2.1 Eggshell Calcination

Eggshells, firstly, were cleaned and heated at 1000°C to remove their organic components and decompose the calcium carbonate into calcium oxide. The sample color became white after heating. To find out the optimum duration of heating indicated by the largest amount of calcium oxide obtained, the heating was performed during 5, 10 and 15 hours. The optimum time was then chosen for further experiments.

2.2 Hydrothermal Synthesis

The calcined eggshells consisting the largest content of CaO was diluted by aquabides in three different molarities, which were 0.1 M, 0.5 M and 1 M. The CaO solutions were then dropped by $(NH_4)_2HPO_4$ solutions stoichiometrily keeping the ratio of Ca/P being 1.67. The concentrations of $(NH_4)_2HPO_4$ solutions, therefore, were 0.06 M, 0.3 M and 0.6 M. Each of these 3 solutions containing CaO and $(NH_4)_2HPO_4$ remained at pressure of 2 atm (120°C) and 5 atm (150°C) for 8 hours, respectively, in a hydrothermal autoclave.

After heating, sample was sedimentized through an aging process for 12 hours. Then, the sediment was gained by a process of filtering before heating at 110°C for 3 hours to remove water from sample. Finally, HA was obtained as white dried powder.

2.3 Characterization

XRD characterization used PHILIPS model APD 3520 diffractometer. FTIR characterization used BRUKER model TENSOR 37 FTIR Spectroscopy. SEM-EDXA characterization used JEOL JCM-35C scanning electron microscope. The sample was coated by gold-palladium (80% of Au and 20% of Pd) beforehand. Coating processes used an Ion Sputter JFC-1100 machine.

3. RESULTS AND DISCUSSIONS

3.1 Characteristics of Calcined Precursor

FTIR characterization resulted that there were some carbonate contents in all samples indicated by the presence of IR carbonate's group bands around wave number 1450 cm^{-1} and 875 cm^{-1}. Table 1 shows the percentage of transmission of carbonate groups. Samples heated for 5 hours had the least content of carbonate groups indicated by high transmission percentage which were 52% transmission at 875 cm^{-1} and 38% transmission at 1450 cm^{-1}.

Table 1: Percentage of transmission of carbonate groups

Heating time (hrs)	Percent transmission (%)	
	1450 cm^{-1}	875 cm^{-1}
5	38	52
10	38	47
15	23	33

This finding was emphasized by XRD results. Figure 1 shows the XRD patterns of eggshells heated at 1000°C for 5 hours. It was also found from volume fraction calculation that 68.27 % of the samples heated for 5 hours were calcium oxides.

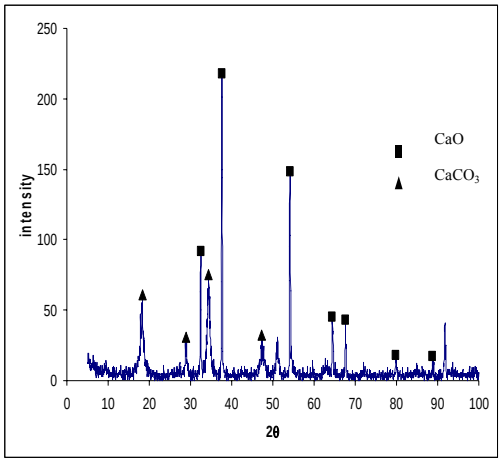

Figure 1: XRD patterns of eggshell heated at 1000 °C for 5 hours

Calcination processes of eggshells, that liberate CO_2 and leave CaO molecules, are reversible. Once the calcium oxide product has cooled, it immediately begins to absorb CO_2 from air. After a certain time, it is reconverted into $CaCO_3$ since Gibbs free energy decreases. Experimentally, therefore, cooling process has to be conducted rapidly.

3.2 Characteristics of HA

3.2.1 X-Ray Diffraction (XRD)

XRD characterization presented that all samples had similar peaks corresponding to hydroxyapatite (JCPDS 9-432), type A-carbonated apatite (JCPDS 35-180), type B-carbonated apatite (JCPDS 19-0272), and octa calcium phosphate (JCPDS 44-778). There were also two low intensity peaks indicating calcium oxides at 2θ > 50 degrees.

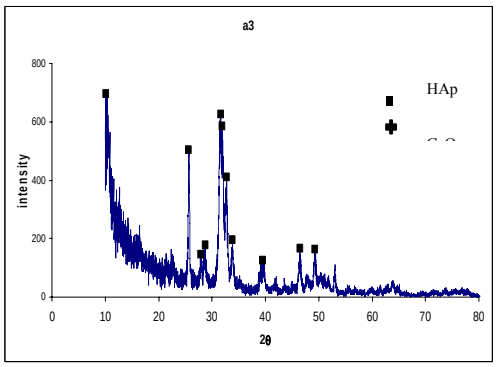

Figure 2: XRD patterns of highest precursor concentration samples pressurized at 2 atm.

Figure 2 shows the XRD patterns of 1 M CaO added with 0.6 M $(NH_4)_2HPO_4$ solutions pressurized at 2 atm.

Lattice parameters for hexagonal structure of HA were determined by using Cohen's method. Table 2 shows lattice parameters of the samples which are very close to reference. This high accuracy lattice parameters supported the conclusion that the samples were composed of HA.

Table 2: Lattice parameters of samples (reference: a =9.418 Å, c = 6.884 Å)

Pressure (atm)	Molarities (M)		Parameters (Å)	
	CaO	$(NH_4)_2HPO_4$	a	c
2	0.1	0.06	9.54	6.94
2	0.5	0.3	9.74	7.13
2	1	0.6	9.23	6.74
5	0.1	0.06	9.42	6.86
5	0.5	0.3	9.49	6.92
5	1	0.6	9.37	6.82

Volume fraction calculation revealed that samples with higher molarity precursor yielded higher mass product. Samples containing 1 M CaO and 0.6 M $(NH_4)_2HPO_4$ solutions pressurized at 2 atm resulted 8.6169 g mass product, while samples containing the same concentrations but pressurized at 5 atm resulted 8.436 g mass product.

Table 3: Mass product and volume fraction of all samples.

Pressure (atm)	Molarities (M)		Mass product (g)	Volume fraction (%)
	CaO	$(NH_4)_2HPO_4$		
2	0.1	0.06	0.6672	93.75
2	0.5	0.3	4.6104	96.13
2	1	0.6	8.6169	94.02
5	0.1	0.06	0.5811	92.05
5	0.5	0.3	5.023	89.00
5	1	0.6	8.436	95.61

Table 3 shows the mass product and the volume fraction. All samples showed volume fraction of more than 92%. Table 4 shows crystal size and crystallinity of all samples. Crystal size was varied and ranged from 28.37 nm to 106.37 nm. High crystallinity was presented by all samples with the degree of crystallinity more than 95%.

Table 4: Crystal size and crystallinity of all samples

Pressure (atm)	Molarities (M)		Crystal size (nm)	Crystallinity (%)
	CaO	$(NH_4)_2HPO_4$		
2	0.1	0.06	85.16	96.99
2	0.5	0.3	32.74	96.95
2	1	0.6	106.37	96.20
5	0.1	0.06	28.37	96.56
5	0.5	0.3	32.75	95.53
5	1	0.6	30.40	96.59

3.2.2 Fourier Transform-Infra Red (FT-IR)

All IR spectra showed the stretching and vibrational modes of OH^- groups at 3570 cm^{-1} and 635 cm^{-1}, whereas the bands derived from 635 cm^{-1} indicated groups of HA [9]. Considering sharp band at 635 cm^{-1}, 2-atm pressurized samples had less HA than 5 atm-pressurized samples. Another parameters corresponding to HA were the presence of PO_4^{3-} groups at 1090 cm^{-1}, 1034 cm^{-1}, 962 cm^{-1}, 603 cm^{-1}, 565 cm^{-1} and 472 cm^{-1}. Vibrational modes at 1090 cm^{-1} and 1034 cm^{-1} were categorized as asymmetry vibrational band indicating crystalline phase calcium phosphate compound. These two bands also explain that all samples performed crystalline phase. Figure 3 shows the FTIR spectra of all samples. The appearance of crack structure of phosphate absorption band at 565 cm^{-1} and 603 cm^{-1} also demonstrated the crystalline phase of the samples. Figure 3 shows that all samples had their cracks.

However, FTIR spectra also shows that there are some impurities, such as CH_3^+, OH^- stretch in H_2O and CO_3^{2-}. All samples indicated the existence of OH stretch, as a broad band at 3400 cm^{-1} and as a split band at 3570 cm^{-1}. The presence of carbonate also indication of type A- and type B-carbonated apatite. As the transmission is high, the presence of type A- or type B-carbonated apatite is minor.

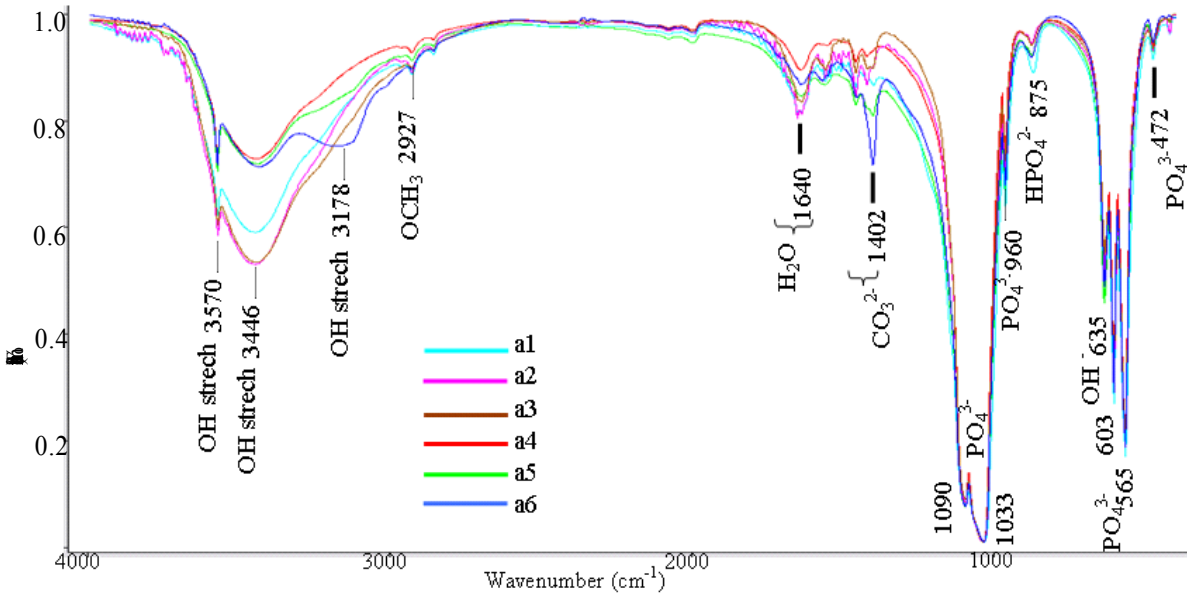

Figure 3: FTIR spectra of all samples (a1, a2, a3 containing low, high, higher precursor concentration, respectively, pressurized at 2 atm; a4, a5, a6 containing low, high, higher precursor concentration, respectively, pressurized at 5 atm).

3.2.3 EDXA and SEM

The results of EDXA are shown at Table 5, all samples had Ca/P value in the range of 1.3 – 1.7. Furthermore, EDXA emphasized XRD result in which samples are dominated by HA. EDXA also showed the compound exist in sample, which are CaO and P_2O_5 indicating precursor materials. Figure 4 shows SEM image with 20000-times magnification. It shows the homogeneous and densely arranged microcrystalline particles.

Table 5: Ca/P ratio of all samples

Pressure (atm)	Molarities (M)		Ca/P
	CaO	$(NH_4)_2HPO_4$	
2	0.1	0.06	1.675
2	0.5	0.3	1.726
2	1	0.6	1.420
5	0.1	0.06	1.354
5	0.5	0.3	1.644
5	1	0.6	1.531

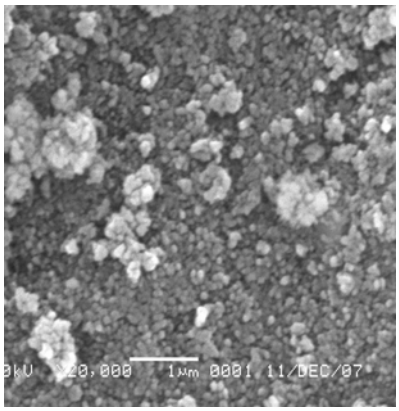

Figure 4: SEM picture of samples pressurized at 5 atm.

4. CONCLUSION

Hydrothermal method pressurized at 2 atm and 5 atm seemed to result highly crystalline HA indicated by XRD peaks and supported by lattice parameters very close to pure HA. However, some calcium oxide as starting materials still existed on samples. FTIR spectra also showed the presence of type A and type B carbonated apatite.

High precursor concentration and hydrothermal pressure resulted high volume fraction and mass product of HA. High crystallinity and small crystal size of HA were also obtained in the experiments. SEM image of this sample showed homogeneous and non-agglomerated particles.

ABSTRACT

Aluminum metal matrix nanocomposites has been produced by powder metallurgy process. The aluminum powder and 10%, 20% and 30% weight of the SiC nanoparticles mixed in a mixing unit. The green body billet was obtained after the mixed particles pressed in a 10 mm diameter cylinder with a unidirectional 1 ton/cm^2 compacting force. The billets were sintered in an innert atmosphere at 620^{0}C that was known as solid state sintering and at 720^{0}C that was known as liquid phase sintering. The sintering was done in 2 hours time. The microstructures of nanocomposites when was sintered in 620^{0}C exhibit alpha grain of pure aluminum surrounded with nanocomposites. The nanocomposites that were obtained after sintering process in 720^{0}C exhibit homogeneous nanocomposites microstructures.

Keywords
Alumunum metal matrix nanocomposite, Powder metallurgy process

INTRODUCTION

Aluminum metal matrix nanocomposite is metal matrix composite that use nanoparticle to act as strengthening element. There are two type of manufacturing metal matrix nanocomposite. Powder process method and liquid process method. The powder process method have several type, such as mechanical alloying or mechanical attrition method, vapor deposition method and mixing method.
Generally, powder processes of metal matrix nanocomposites produced by mechanical attrition. This processes introduced the nanoparticulates into the metal powder by the use of planetary ball mill. The ball to powder weight ratio is at about 40 to 1. After the powder compacted and sintered, the particulates act as strengthening component in the metal matrices and increase the mechanical properties of the composite.
Differs from general powder metallurgy processes, this research use mixing process of SiC nanoparticles and aluminum particles in a mixing unit. Mixing process was done in 2 hours. The mixed powder then pressed in a cylinder and sintered in 620^{0}C and in 720^{0}C at 2 hours time in vacuum condition.
Because of the easy of manufacturing process, the mixing process can be done in larger quantity and can be applied to manufacture several industrial product.

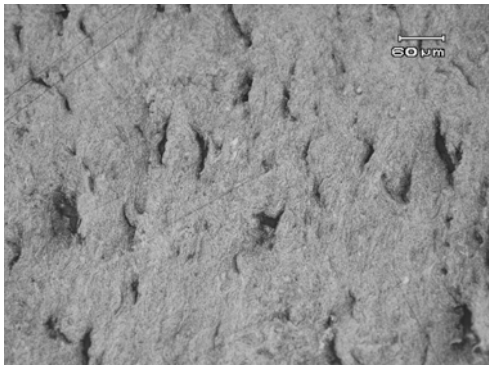
EXPERIMENTAL

Samples consisting of 10 grams of aluminum powder each mixed with different content (10%, 20% and 30%) of nanoparticles SiC in a mixing unit. Mixing processes were done in 2 hours time. The mixer rotate at 3 rpm. The aluminum powder was obtained from Merck and the SiC nanoparticles was obtained from NaBond Technologies, Co, Limited, China. The samples then pressed in a cylinder to obtain 10 mm diameter to 30 mm length green body billet. Pressing force was carried out at unidirectional compacting force of 1 tons/cm^2. Before the mixed powders were poured to the cylinder, the cylinder wall was lubricated with zinc stearate.
The 10 mm diameter green body billets were inserted into a pyrex tube to undergo sinter process. The process was carried out in a vacuum condition. The tube was heated in a muffle furnace. Sinter processes at 620^{0}C and 720^{0}C were done 2 hours time. After sinter process, the billets were cut for metallographic investigation. Also, samples were taken from sintering process have undergone

microhardness testing. The tests were carried out in Vickers methods using 25 grams weight.

RESULTS AND DISCUSSIONS

Metallographic examinations in samples that were taken after sintering process indicated that some porosity occurs. Metallographic examinations used optical method. Figure 1 show that the porosity occurs in all areas of the samples.



Optic, unetch, 200x

Figure 1. Porosity of the sample contain of aluminum and 10% SiC after sintering at 720^0C

Figure 2 shows metallograpic result of sample that was taken after sintering process at 620^0C. There are two types of microstructures, alpha grain of pure aluminum and composite microstructures surrounding alpha grains. The composite microstructures consist of SiC nanoparticles and aluminum matrix. The appearance of composite microstructures means that the outer areas of the aluminum particles liquefy and intrude the SiC nanoparticles and surrounded it with aluminum at the time of sintering process.

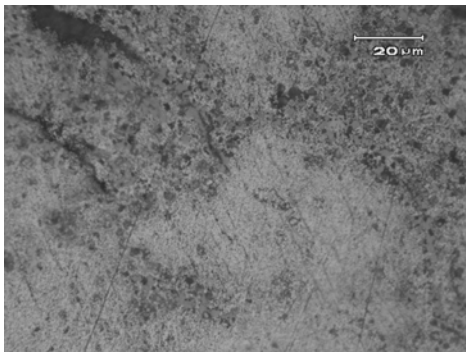
The hardness of the composite microstructures is similar between the samples at 100 to 120 Vickers Hardness Number. The hardness of the aluminum grain is at about 33 VHN

Figure 3 shows metallograpic result of sample that was taken after sintering process at 720^0C. Composite microstructures found over all of the sample area. It is indicating that the aluminum liquefy at the sintering time and intrude to all of SiC nanoparticles cluster and surround it with aluminum. Optical method in metallographic examination to the samples sintered in 720^0C can not differentiate the microstructures of different SiC content. It is because of lower magnification ability of the optic microscope.

The porosity which was still found in the samples sintered at 720^0C as can be seen in figure 1 indicated that the melting of the aluminum particles occurs at limited area. It is caused by the present of nanoparticles which thickens the aluminum liquid when aluminum liquid mixed with nanoparticles at liquid phase sintering time.

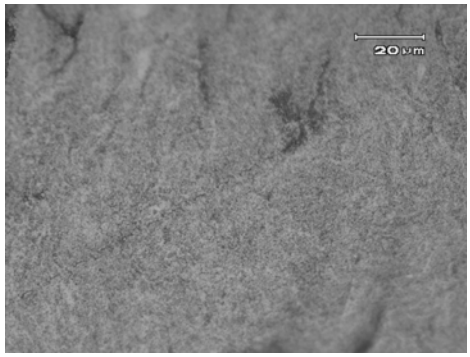
The porosity formerly comes after compaction process. The high ratio between length to diameter of billet at 3:1 causes this porosity. The application of zinc stearate can not resolve the problem if the ratio is too high. The porosity distributed evenly in all of the area of the billet. It indicate that compression force is not sufficient at all of the billet body and as the result of higher ratio of length to diameter. To eliminate the porosity, the ratio between length to diameter of billet must be maximum 1:1.

Also, the porosity was caused by the lack of sintering time. Although the sintering temperature at 720^0C or beyond the liquidus temperature and applied at 2 hours sintering time, it is apparently clear that the full density result is far from being reached. Finally, the porosity is still found after hot rolling process.



Optic, unetch, 1000x

Figure 2. Microstructure of sample contain with aluminum and 10% SiC after sintering at 620^0C. White area indicate alpha grain of pure aluminum surrounded with grey area of composite structure



Optic, unetch, 1000x

Figure 3. Microstructure of sample contain with aluminum and 10% SiC after sintering at 720^0C sintering. Sample indicate homogenous grey area of composite structure

CONCLUSSION

Aluminum metal matrix nanocomposite can be manufactured by powder metallurgy process using mixing method. Sintering at solid state phase produce two types of microstructures, alpha grains of pure aluminum and composite microstructures surrounding the alpha grains. Sintering at liquid phase produces homogeneous nanocomposite microstructures.
Porosity is still found although sintering is done at liquid phase and after hot rolling process. The porosity can be eliminated if the ratio between length and diameter of billet maximum 1:1.

Abstract

*A welding of austenitic stainless steels of different types, AISI 304 and AISI 316 L was carried out using GTAW (Gas Tungsten Arc Welding) method with a straight polarity. A single-*V *groove was chosen and filler metals of E308 and E316 were used with argon shield. Weld metal's microstructure was evaluated using an optical microscope. The Cr_{eq}/Ni_{eq} ratio of the weld metal was found to be about 1.67 with ferrite number (FN) about 10. The microstructure was identified to have a ferritic-austenitic (FA) solidification mode termed type B. The morphology of delta ferrite formed was vermicular (skeletal) type. This type of microstructure has a typically good resistance to hot cracking and corrosion.*

Keywords: stainless steel, welding, microstructure

INTRODUCTION

Welding of austenitic stainless steels or commonly grouped as 300-series, contains 15-32% chromium and 8-37% nickel is one of the most practically carried out in industry. More than 90% of stainless steel welding involves the 300-series, mostly due to the good weldability of austenitic stainless steels. They are readily weldable with common arc processes such as; gas tungsten arc welding (GTAW), shielded metal arc welding (SMAW), gas metal arc welding (GMAW) processes and other techniques. Other important factors are the good corrosion resistance and mechanical properties both at low and high temperature. Weldments of 300-series stainless steels possess high toughness, even at the as-welded condition. Welding of dissimilar metals is usually applied for transitional joints in many equipment and constructions for economic reasons [1].

However, problems may arise in dissimilar metals welding such as improper choice of electrodes and welding parameters will result in welding defects. This work reports the microstructure formation in the weldment of dissimilar stainless steel 300-series using different electrodes/filler metals [2].

EXPERIMENTAL DETAILS

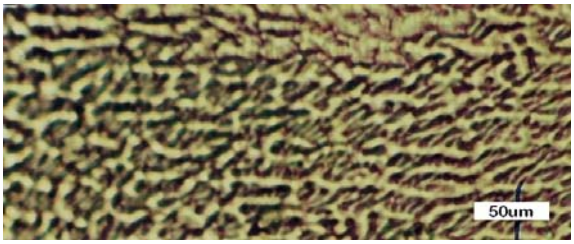
Plates of stainless steels AISI 304 and 316L 6mm in thickness were welded by Gas Tungsten Arc Welding (GTAW) Esab-Aristotig200 Sweden using E308 and E316L filler metals. A single V-type groove was applied in each specimen. The electrode is EWTh-2 2,4mm diameter using straight polarity. Argon was used as the shielding gas at 15 ft3/hour flow rate. The heat input for welding was controlled by varying the electric current and welding speed.

Microstructure characterization of the resulting specimens was carried out by optical microscope. All of the experiment and characterization was done at The Department of Metallurgy and Materials Engineering University of Indonesia - Depok.

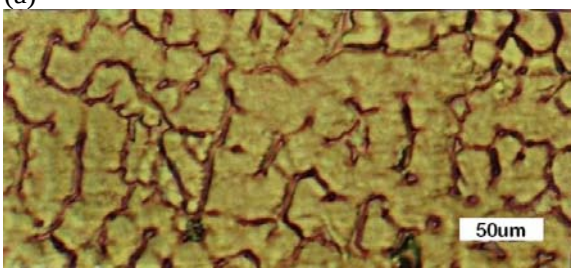
RESULTS AND DISCUSSION

The area for microstructure evaluation in this report includes weld deposit and heat affected zone (HAZ) of both E304 and E316L.

As seen in figure 1 (a) and (b), it was found that the structure of weld deposit is dominated by austenite phase (bright area) with few delta ferrite (darker area). For the HAZ area, the structure is also dominated by austenite phase, as seen in figure 2 (HAZ of AISI 304) and figure 3 (HAZ of AISI 316L). The grain size of the HAZ is typically bigger than that of the base metals. This is mainly due to heating process during welding.



(a)



(b)

Figure 1. Microstructure of weld deposits, the dominant vermicular (a) and lathy (b) structure.

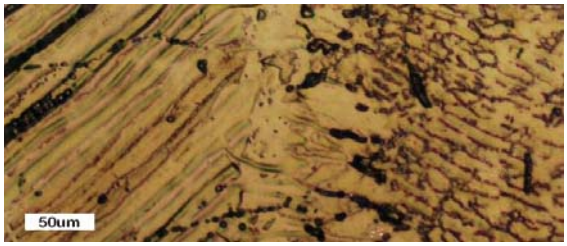


Figure 2. HAZ microstructure of AISI 304

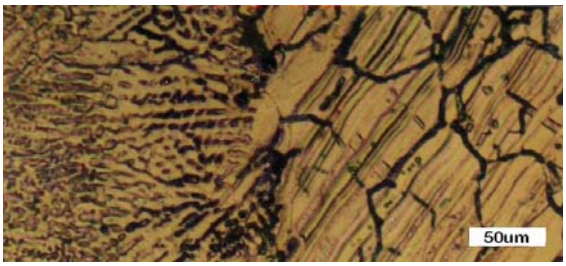

Figure 3. HAZ microstructure of AISI 316L

The weld deposit of AISI 300 steels can be classified into 3 types A, B, C based on their microstructure and the morphology of delta ferrite structure [3]. Nickel equivalence (Ni_{eq}) is the term used for the cumulative effects of austenite stabilizing elements as a weighted summation of their respective concentration levels while chromium equivalence (Cr_{eq}) is similarly the term used for the ferrite stabilizers [4]. The ratio of the two terms, i.e., equivalency ratio, is usually taken as Cr_{eq}/Ni_{eq}, based on the actual chemical composition of the steels involved, and can be used as a quantitative indicator for predicting the primary mode of solidification for arc (fusion) welded 300 series stainless steel. Since a small but finite amount of ferrite in the finished weldment is desired, weld pool solidification as primary ferrite is preferred to prevent the likelihood of encountering hot cracking during welding.

The use of applicable formula to calculate Cr_{eq} and Ni_{eq} is critical to predict the resulting microstructure [5]. A low Cr_{eq} / Ni_{eq} ratio produces austenitic solidification mode with type-A microstructure, while a high Cr_{eq} / Ni_{eq} ratio can produce a primary ferrite solidification mode with type-C microstructure. However, due to limited specimen availability in this research, only one method was applied for analysis of the microstructure.

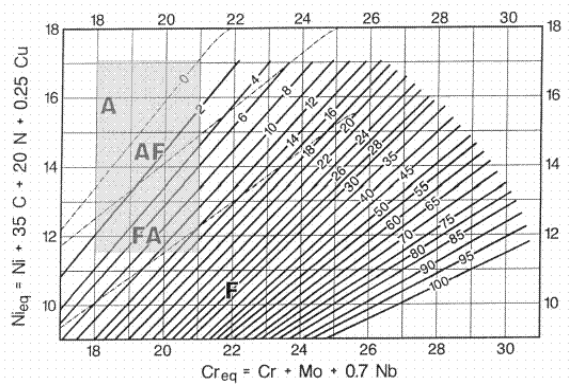

Figure 4. the WRC-1992 diagram for Cr_{eq} / Ni_{eq} of AISI 300 stainless steels

According to the specimen chemical composition and welding parameters, calculated heat input at 0.3 – 0.8 kJ/mm, the Cr_{eq} / Ni_{eq} ratio can be estimated at ~1.67 using Schaeffler formula. Hence, the microstructure can be classified as type B using the criteria proposed by Suutala [3], with ferrite content up to 10% dominated by vermicular morphology [6]. Moreover, using the WRC-1992 diagram [7-8] shown in figure 4, the weld deposit is predicted to have FN (ferrite number) ~10.

Referring to the Fe-Cr-Ni constitution diagram and putting the Cr_{eq} / Ni_{eq} ratio value to the diagram at the figure 4, the solidification mode of weld deposit is predicted to be Ferritic-Austenitic (FA). The FA solidification starts with delta-ferrite formation situated at the dendrites' axis and prefers to have vermicular or lathy structure depended on the value of Cr_{eq} / Ni_{eq} ratio.

The type B solidification starts with primary delta-ferrite solidification followed by

ternary phase reaction between liquid metal, delta-ferrite and austenite. Austenite formed between the ferrite dendrites through peritectic or eutectic reaction and then grew towards liquid metal and ferrite. The growth of austenite towards liquid metal promotes segregation of microstructure, while the growth towards ferrite through equiaxial or acicular mechanism caused drastic drop of ferrite volume fraction.

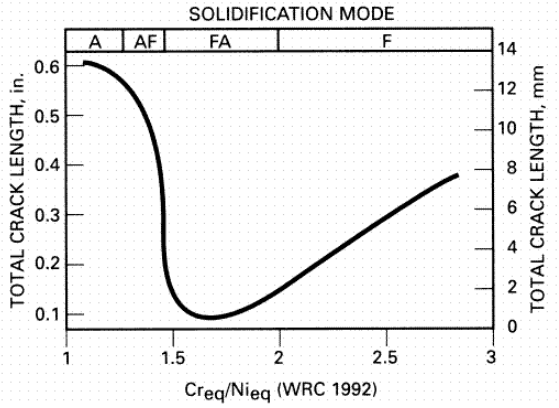

Figure 5. Cracking susceptibility based on WRC-1992 and Cr_{eq}/Ni_{eq} ratio [8]

Refer to the diagram shown in figure 5, the type-B solidification weld deposits produced in this research can be predicted to have good cracking resistance. The welding handbook describes the possibility for encountering weld solidification cracking increases dramatically at Cr_{eq}/Ni_{eq} ratios slightly less than 1.5 as the total crack length increases [9].

CONCLUSION

1. Welding of dissimilar stainless steels AISI 304\E308/316L and AISI 304\E316L/316L was carried out successfully.
2. Microstructure of the welds consists of ferrite at 10 vol-% in the austenite matrix.
3. The weld deposit has a Cr_{eq}/Ni_{eq} ratio ~1.67, which gives a type-B solidification. The ferrite number (FN) value was 10 and the morphology shows a *vermicular* structure.

ABSTRACT

Lateral control rod, which is a part of automotive differential system were failed during services. The lateral control rod system consists of a single rod with mass dumper welded and two joint at each side attached to the wheel system. Experiment procedure begins with examination by visual method followed by chemical composition of base metal. In addition, cross section of failed part was prepared for metallographic evaluation with hardness profile measurement accomplished by micro Vickers method. SEM equipped with EDS analysis was used for fractography and microanalysis examination. Observation of the fracture surface showed brittle fracture mode with beach mark propagation and chevron mark along the rod circumference. The lateral control rods at one point have a direct surface contact to the mass dumper which later on becomes a stress concentration. Lateral rod failure was initiated from the bottom area between the rod and the mass damper. The repeated load receive creating a radial or beach mark pattern and followed by chevron mark as the final fracture.

Keyword :
Lateral control, welding, stress concentration, brittle fracture

1. INTRODUCTION

Lateral control rod, which is a part of automotive differential system were failed during services. The unit was failed after three months in services. No information regarding the serviceability of the part or operational condition. The rod was made from carbon steel complied with JIS G 3445 - STKM 11A [1]. The lateral control rod system consists of a single rod with mass dumper and two joint at each side attached to the wheel system, as seen in Figure 1. The failed section of the rod was located at the area adjacent to mass dumper, as seen in Figure 2. The lateral rod part system was joined by welding method.

Figure 1. Lateral control rod (pointed) position in rear wheel system

Figure 2. As receive condition of failed lateral control rod

2. EXPERIMENT

Experiment procedure begins with examination by visual method and macro photograph on the failed part. Chemical composition of base metal was analyzed by optical emission spectrometer. In addition, cross section of failed part was prepared for metallographic evaluation with Nital 2% used as etching agent. Mechanical properties were conducted by performing tensile testing and hardness testing which accomplished by micro hardness Vickers method. SEM equipped with EDS analysis was used for fractography and microanalysis examination of the failed surface section.

3. RESULT AND DISCUSSION

3.1 Visual Examination

Visual observation of the failed part showed that the main fracture took place at the rod, above the mass dumper plate, as seen in Figure 3. Fracture area occurs at 1/3 of the total length of the rod, adjacent to the mass damper.
Observation of the fracture surface showed brittle fracture mode with beach mark propagation and chevron mark along the rod circumference. The fracture started from the bottom area of the rod, which can be noticed from the dark color of the fracture surface (mark by a circle), as seen in Figure 3. The dark color at fracture area indicated that corrosion already occurred.

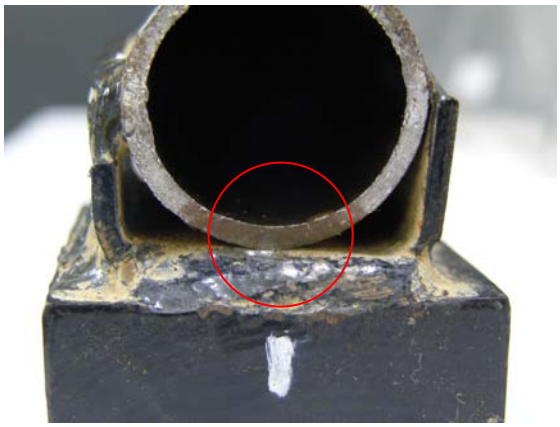

Figure 3. The main fracture showed at the bottom area of the rod. Dark color (corrosion product) covered the area of crack origin

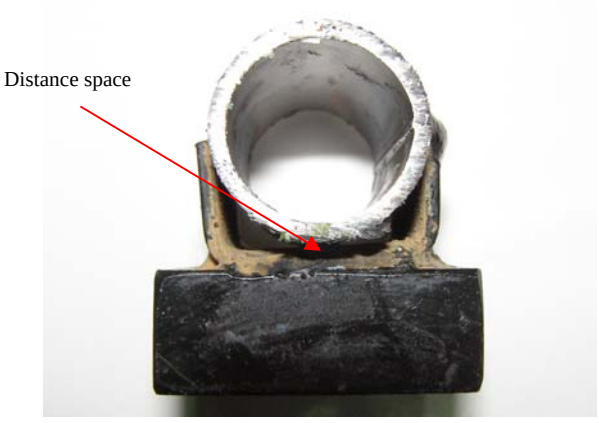

Figure 4. The gap between rod and mass damper

Visual observations also revealed there was a distance space approximately 2 mm between the rod and mass dumper, as seen in Figure 4. However, at the failed location those spaces were not existed. Observation at fracture origin showed an area indicated as point contact between the rod and mass dumper, as seen in Figure 5.

Figure 5. Point contact between the rod and mass damper, notice the bright appearance and slightly deformed

3.2 Chemical Analysis/Identification and Mechanical Properties

Some portions of the lateral control rod were subjected to the chemical analysis using optical emission spectrometer (OES). Chemical composition was complied with the specification JIS G 3445-STKM 11A.

Table 1. Chemical composition result of the failed sample in comparison to the standard JIS G 3445 - STKM 11A

	% C	% Si	% Mn	% P	% S
JIS G 3445-STKM 11A	0.12 max	0.35 max	0.6 max	0.04 max	0.04 max
Failed sample	0.042	0.011	0.192	0.013	0.007

The tensile testing was conducted at the base material of failure rod using a Shimadzu Universal Testing Machine. The average result of the tensile testing is 372 MPa for ultimate tensile strength (UTS) and 274 MPa for yield strength with the elongation of 38%. The ultimate tensile strength and the elongation conform to the specification of JIS G 3445 which minimum tensile strength required is 290 MPa and minimum elongation is 35%.
The hardness test was carried out on the cross section of lateral rod. This test was carried out in accordance with Vickers hardness testing method. The result, showed a value of 126 HV in average.

3.3 Metallography Examination

The microstructures of lateral rod were taken at the base metal, under a magnification of 100x and 500x, respectively. Based on the results, it can be seen that the microstructure of low-alloy carbon steel is dominated by ferrite and small amount of pearlite, as seen in Figure 6 and 7. No indication of abnormal non-metallic inclusion was found.

Figure 6. Microstructure in base metal of rod, mag 100X, 2% Nital etched, consist of ferrite and small amount pearlite

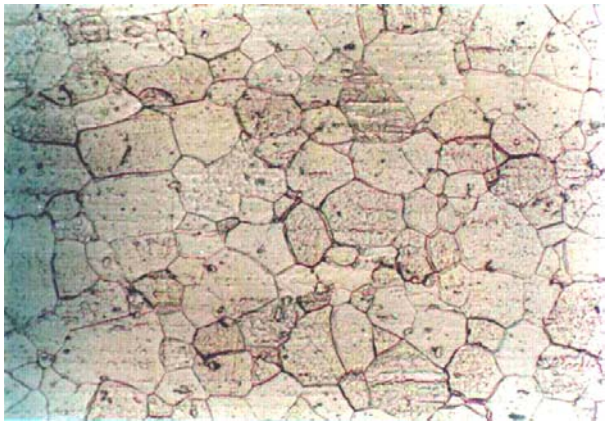

Figure 7. Microstructure of rod with higher magnification (500x) showed ferrite phase matrix.

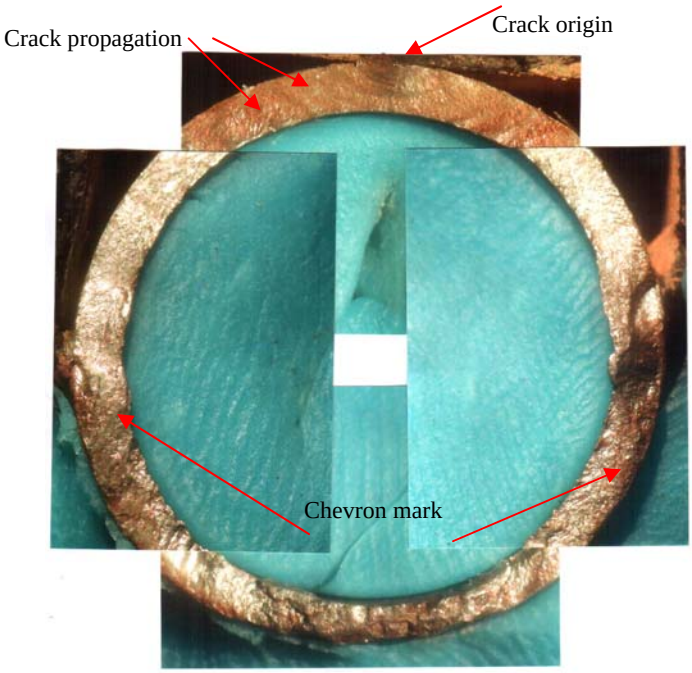

Figure 8. Surface fractography of failed rod, notice arrest line at crack origin and followed by chevron mark, mag 7x.

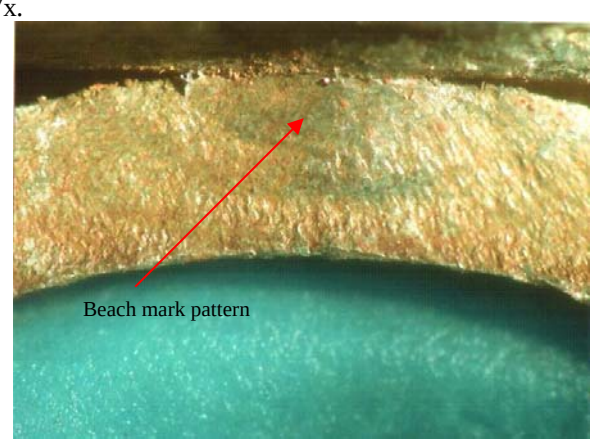

Figure 9. Closer examination at the crack origin showed a beachmark pattern, mag 20x

3.4 Fractography Examination

Fractography examination revealed that the facture occurred in two different modes, the fracture was initially a brittle mode, which can be recognized from the fracture mark creating a repeated line or beachmark as seen in Figure 8 and 9, and this was subsequently followed by chevron mark pattern. However, the SEM macrofractography result indicated that the surface of failed part was already covered with the corrosion product which makes it difficult to determine and examined the fracture origin, as seen in Figure 10 and 11.

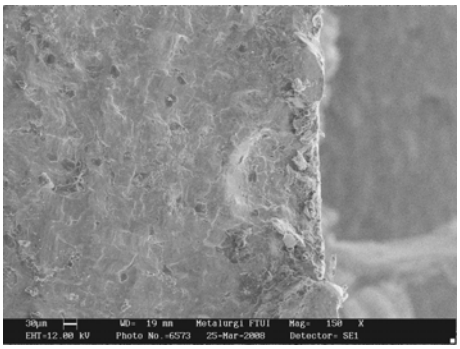

Figure 10. SEM fractography of the failed surface, taken at the chevron mark region, mag 150x.

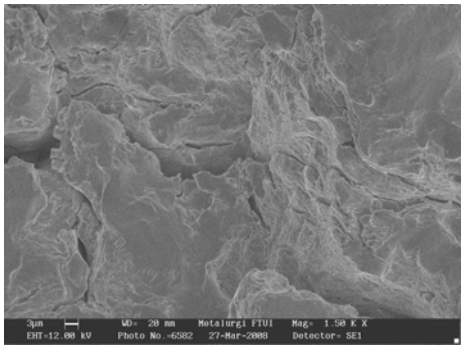

Figure 11. Closer examination revealed micro crack at the failed surface, mag 1500x.

A lateral control rod is a unit attached to the axle (differential) house and car body (chassis). It functions as a wheel stabilizer and therefore it has a vertical load modeling to balance the movement of the back wheels. Ideally, load or stress in the lateral control rod will be distributed uniformly along the lateral rod. The mass damper as a vibration reducer will help stabilizing the movement to prevent the damage caused by vibration. Mechanical testing and metallographic examination of the rod found conformity to the material standard.
Based on visual examination, the crack initiated from the bottom of rod adjacent to the mass damper then propagates upward until final failure occurred. Visual examination showed indication of fatigue failure. Fatigue damage result in progressive localized permanent structural change and usually occurs in materials subjected to fluctuating stress and strain [2]. Fatigue failures are caused by the simultaneous action of cyclic stress, tensile stress, and plastic strain. If any of one of theses three is not present, fatigue crack will not initiate and propagate [3-4].

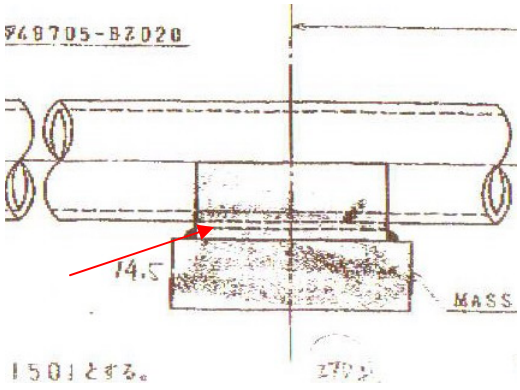

Figure 12. Clearance indication in the mechanical drawing of the lateral rod (mark by dash line).

Referring to the technical drawing of the lateral control as seen in Figure 12, it has been found that there is a differentiation between schematic and actual condition. The observation from the failed part showed that there is no clearance in one side of the mass damper as in the schematic. In other words, the mass damper is in outright position. This condition indicated that improper manufacturing process has already occurred. The lateral control rod which directly connects to the mass damper in one point contact will give a number of forces to the rod and mass damper themselves and therefore it become a stress concentration initiator.
When the car wheel moves, the cyclic (up and down) stress or load is received by the lateral control rod and is distributed evenly across the rod. However, in this failure case, the stress is disturbed and can not be distributed properly to the whole rod. One point contact becomes the point which receives the highest stress. As the wheels move, the cyclic stress or load will be frequently transmitted until the crack initiated. Load received at the lateral rod can be seen in Figure 13.
Crack initiation occurred in the body that has lower strength than other parts in the system. In this case, the mass damper has a better strength than the lateral control rod.

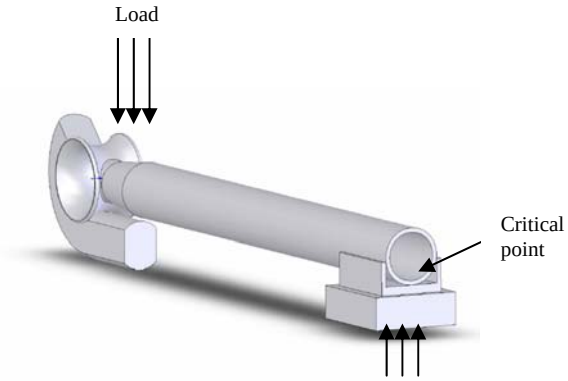

Figure 13. Schematic of load system received at the lateral rod.

The repeated load receive creating a radial or beach mark pattern and then they propagated slowly upward until the rod cannot accommodate the stress and failed in brittle manner indicated by chevron mark at the final fracture.

4. CONCLUSIONS

Based on the results of investigation, it was found that the lateral rod failure due to fatigue mechanism. The crack was initiated from the bottom area between the rod and the mass damper. This condition was occured due to the lack of clearance between them which created a high stress point at the rod. The stress received from the normal service condition was concentrated at that point, instead of being distributed along the rod. The repeated load receive creating a radial or beach mark pattern and followed by chevron mark as the final fracture. Improper and lack awareness in manufacturing during the welding process of lateral rod joint lead to this failure.

ABSTRACT

A bovine bone has been sintered at temperatures up to 1100°C and the mineral content examined in detail by powder X-ray diffraction (XRD), energy dispersive X-ray spectroscopy (EDX) and scanning electron mcroscopy (SEM). XRD profile analysis data has been determined to characterize the microstructural features of the bovine bone at varying temperatures from 500 to 1100°C. The best XRD profile of bovine hydroxyapatite (HA) was obtained upon sintering treatment in vacuum at 1000°C for 3h. The crystal structure of HA from powder bovine bone is refined on powder XRD using the Rietveld analysis with molecular formula of $[Ca_{10}(PO_4)_6(OH)_2]$. The unit cell of HA is hexagonal with space group $P6_3/m$, a = b = 9.435 Å and c = 6.895 Å, v = 531.60 $Å^3$ and Dx =3.13 g cm^{-3}. The powder pure bovine bone had the interconnecting pore network in the surface structure. The findings are discussed in the context of potential bone substitute as well.

ISSN 114-1284

1. Introduction

Bone is a complex, composite material with a mineral matrix commonly thought of as carbonated calcium hydroxyapatite (CHA) [1]. Because of the role of calcium phosphate in many biological processes they have been extensively investigated. This mineral has microstructural characteristics such as crystallite size, strain and stochiometry that are critical to bone physiology and function [2]. Operative treatment to replace bone that is lost due to accident or bone defects resulting inflammantion has remained a challenge for orthopedic surgeons. Due to the limited supply of natural bone for grafting, the need for bone substitutes which has the similar physicochemical and biological properties as a nature bone is ever increasing [3]. For example, the alternative treatment for bone defects is the use of xenogenous bone which is morphologically and structurally similar to human bone. Xenogeneous bone is usually from bovine bone and it is low cost.

The bovine bone is easy to obtain as a bio-waste, and available in unlimited supply. The organic part of bovine bone contains collagen and proteins while the inorganic part is mainly hydroxyapatite (HA) [4]. HA was derived from powder processing route has a great potential for bone substitute owing to its excellent biocompatible and high osteoconductive and osteoinductive non-toxicity, non-inflammatory behavior and non-immunogenicity properties [5,6].

Two factors important that can be affect the HA properties, i.e. (i) the temperature, and (ii) duration of heat treatment [7]. Therefore, the influence of heat treatment on bovine bone at low and high temperatures is of great important, thus it is not disrupt the HA phase stability.

In the paper we report the effect of sintering on bovine bone and phase purity of the HA by powder X-ray diffraction studies. The HA directly was prepared from bovine bone through sintering treatment. This study also attempted to investigate the physicochemical properties of the resulting HA when sintered in vacuum at different temperatures. The resulting HA is expected for use as a potential bone substitute.

2. Experimental

2.1. Sample preparation

A femur of an adult bovine (2 years 9 months old) was procured from Darma Jaya (Jakarta, Indonesia). The bone samples were cleaned to remove visible tissues and substances on the bone

surface. The clean bovine bone samples were defatted using a boiling followed with sun drying to remove the organic substances. This was done to avoid soot formation in the material during the heating treatment. The dried bovine bone samples were cut into rectangular prism shape of approximate size 10 mm x 10 mm x 10 mm. The bovine bone samples were sintered in vacuum by an electric Bohler furnace an automatic digital and rotary vacuum pump with pressure of 10^{-3} torr at different temperatures between 500°C and 1100°C using heating rate of 5°C/min for 2, 3 and 4 hours. The bovine bone pieces were cooled to room temperature by a slow furnace cooling followed by crashed using a mortar pestle and that sieved to obtain bovine HA powder (60 mesh).

2.2. Characterization

A powder specimen was spread on a non-reflective quartz specimen holder with a well depth of 0.2 ram. X-ray diffraction (XRD) intensity patterns for Rietveld refinement were obtained from an automated X-ray diffractometer. Phase analysis of bovine HA samples by XRD Shimadzu ZD 610 was carried out at room temperature using Cu Kα as the radiation source at a scan speed of 7°/min and a step scan of 0.05°. The crystalline phase compositions were identified with reference to standard JCPDS data available in the system software [8]. Crystallographic parameters of HA were determined based on the refinement of these XRD data by the Rietveld analysis and a computer program developed by Izumi [9] and Rigaku Limited Company. The unit cell parameters were refined together with several non-structural parameters; a zero correction of the 2θ experimental scale, the U, V, W and m profile function parameters defining the FWHM (full width at half maximum). The values of the refined non-structural parameters and the unit cell parameters are listed in Table 1. The refined fractional atomic coordinates and the occupation for the resulting HA when sintered at 1000°C for 3h are summarized in Table 2.

The microstructure of the sintered bovine bone was performed using a scanning electron microscopy (SEM Philips XL 30 series). Chemical analysis was also carried out using an energy dispersive X-ray spectroscopy (EDX) at 20 kV.

Table 1 Summary of crystallographic data for HA

Recording conditions

3. Results and Discussion

3.1. Characteristic and general observation

The properties of HA produced by sintering in vacuum was evaluated over temperatures range from 500 to 1100^{o}C. A direct observation that was made upon sintering treatment at different temperatures was the color change of the bovine bone powder. The color of bovine bone at room temperature is light yellow. Upon sintering treatment at temperatures of 500, 600 and 700°C the color of bone samples changed to black and grey. After sinter treatment in the ranges 800-1100°C, the color of bone samples is white, indicating that complete removal of organic matrix (e.g. collagen and proteins).

3.2. XRD studies

The XRD profiles of HA between 900°C and 1100°C were similar and showed a substantial increase in peak height and a decrease in peak width. There is a marked decrease in peak widths between 500°C and 600°C and then a steady decrease to 800°C. Apparent at the higher

temperatures, the peak widths is sharper than at the lower temperatures. This indicates an increase in crystallinity and crystallizes size [3]. All the XRD data of the bone samples were in good agreement with the earlier report of the XRD structure of HA characteristic pattern (XRD JCPDS file No. 9-432) [8]. Comparison XRD profiles of synthetic HA and the resulting HA when sintered at 1000°C for 2, 3 and 4h are shown in Figure 1.

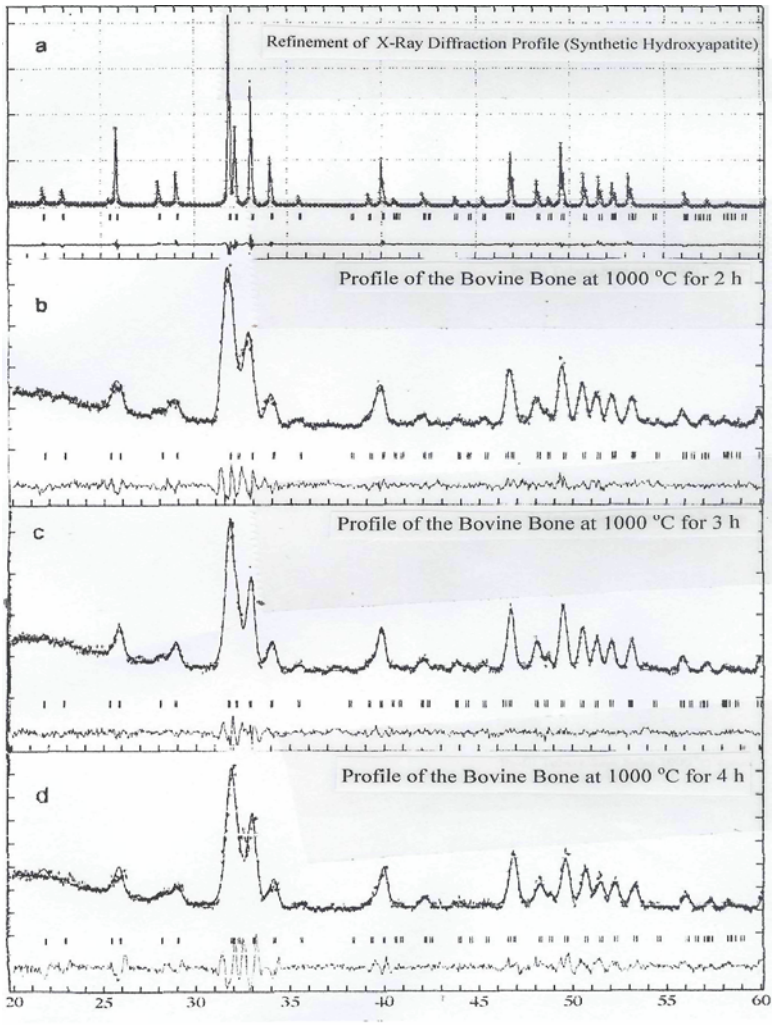

Figure 1 Comparison X-ray diffraction profiles of synthetic HA (a) and HA at 1000°C for 2h (b), HA at 1000°C for 3h (c) and HA at 1000°C for 4h (d)

ISSN 114-1284

Although decomposition of HA phases was not observed in bovine bone powder sintered up to 1100°C, dehydoxylation of HA has taken place. This can be observed by simply comparing the XRD peaks position of the sintered HA with the standard JCPDS data for stiochiometric HA [10]. The position of three diffraction peaks which corresponds to the (211), (300) and (202) reflection of sintered HA are very similar in position at temperatures between 900°C and 1100°C. These results indicate that dehydroxylation of the HA phase in bovine bone has occurred during sintering. The sintered bovine bone is hydroxyl carbonate apatite, which is benecial for biomedical purposes due to its similarity with the bone apatite. The position XRD peak of bovine bone exhibited 2θ angles of 31.65, 32.50 and 34.55° with the (211), (300) and (202) reflection, respectively. Upon sintering treatment at 1000°C for 3h, the position of XRD peaks of HA showed peak shifting due to dehydroxilation with 2θ angles of 31.85, 32.90 and 34.00° with the (211), (300) and (202) reflections, respectively (Figure 2). The best XRD profile of HA was obtained when sintered in vacuum at 1000°C for 3h.

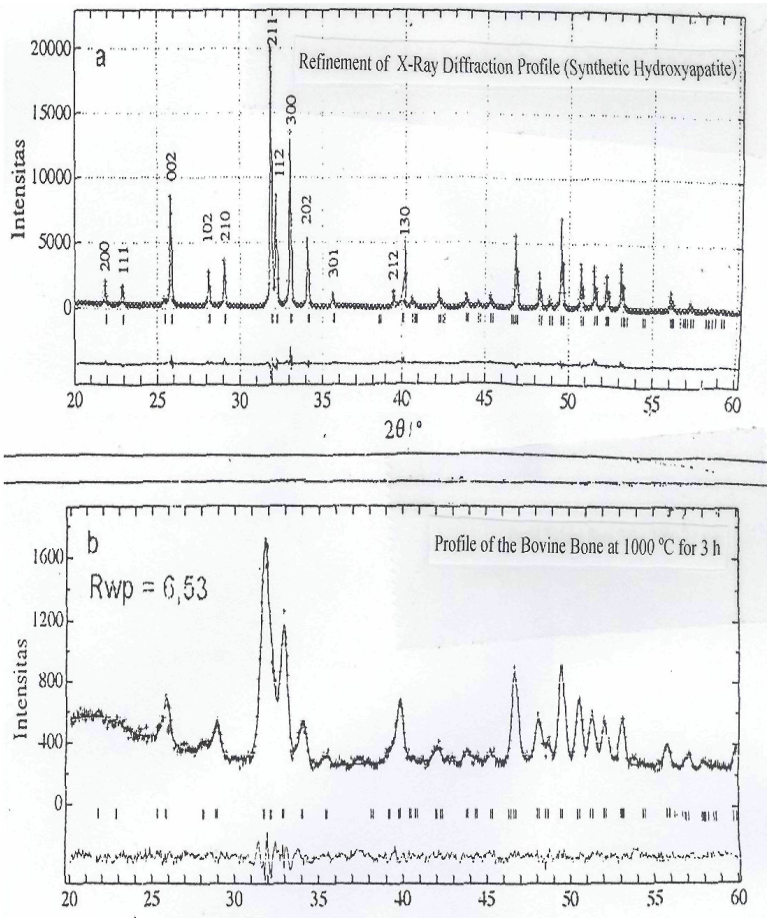

Figure 2 Comparison XRD patterns between the synthetic HA (a) and the resulting HA when sintered at 1000°C for 3h.

As the sintering temperature increased to 1100°C, the intensity of the characteristic peaks for β-tricalcium phosphate (β-TCP), which are located at 2θ angles of 27.75°, 31.65°, 45.55° and 48.0°, were observed to gradually increase. There is no evidence of β-TCP at lower temperatures. The present powder XRD data results suggest that the resulting HA stability in the bone matrix was not disrupted when sintered in vacuum up to 1000°C. XRD analysis also indicated the absences of secondary phases, such as calcium oxide (CaO). Thus, it suggested that bovine HA powder results in high crystallinity and single phase HA and is also believed to be pure natural HA as indicated by the peak of the diffraction patterns (XRD JCPDS file No. 9-432) [8].

All of the carbonated calcium hydroxyapatite (CHA) peaks (002) are clearly broader than those of the IRF (instrument resolution function). Line profile XRD analysis produced quantitative estimates of crystallite size at each temperature. The CHA peak is described in Figure 2 for the (002) diffraction peak.

In the present study, the crystal structure of natural HA is only observed upon sintering treatment at 1000°C for 3h. It is therefore interesting to compare the present results with previously refined cell parameters from HA. The refined values of a and c are in agreement with the earlier reported in the structural analysis of HA [11]. The crystal structure of HA has been reported by Aoki [11]. The bovine HA is crystallized in hexagonal with, $a = b = 9.43505$ Å and $c = 6.89557$ Å, $\alpha = \beta = 90°$ and $\gamma = 120°$, space group $P6_3/m$ and $Z = 1$ (Table 1). Molecular formula of HA from bovine bone has been characterized by powder XRD using the Rietveld analysis that is $[Ca_{10}(PO_4)_6(OH)_2]$ with number of calcium (Ca) = 10, phosphor (P) = 6, oxygen (O) = 24 and hydroxyl ion (OH^-) = 2 (see Table 2). The Rietveld analysis is particularly useful for obtaining accurate estimates of the unit cell parameters since they result from an overall optimization process involving strongly correlated effects such as the zero correction. The crystalline phase composition of sintered bovine bone is

similar with the natural bone mineral which is composed by [$Ca_{10}(PO_4)_6(OH)_2$], [hydroxyapatite, HA] of about 93% and $Ca_3(PO_4)_2$, [β-tricalcium phosphate, β-TCP] of 7% has been also reported by Martin [12].

The Ca(1) atom is lying on the threefold axis and coordinated to six oxygen atoms, which forms a twisted triangular prism. The Ca(2) atoms are situated around the hexagonal screw axis and are in an irregular sevenfold coordination with six phosphate oxygen atoms and the hydroxyl ion. The position of hydroxyl oxygen is shifted above or below the centre of the Ca(2) triangles. Only the one molecule HA in unit cell dimension was observed.

3.3. EDX analysis

A typical EDX spectrum shows the various elements that are present in the powder bovine bone matrix. The analysis indicated that the inorganic phases of pure powder bovine bone composed mainly of Ca and P as major constituents with some minor components comprising that are Na, Mg and O. The chemical compositions of pure bovine bone and human bone were similar. Thus, the resulting HA from pure bovine bone can be used for medical application as a potential bone substitutes. According the molecular formula of the standard HA, the Ca/Pa molar ratio is approximately 1.67 [3]. The Ca/P ratio of natural HA from bovine bone is approximately 1.65. This value lies within the acceptable for the HA.

3.4. Microstructure analysis

The microstructure of the pure powder bovine bone appears to be dense due to the presence of organic substances in the bone matrix. The morphology of pure bovine bone showed a porous network. From the surface morphology, the porous structure appears to be interconnected.

4. Conclusion

The natural hydroxyapatite (HA) has been obtained from the bovine bone bio-waste. The crystal structure of resulting HA is hexagonal with space group $P6_3/m$. The powder XRD data of HA shows that the intensity of major three peaks of HA which corresponds to the (211), (300) and (202) reflection are very similar in position at temperatures between 900°C and 1100°C which may be indicative of the dehydoxylation of HA during

sintering. The resulting HA can be used for medical application as a potential bone substitutes.

ABSTRACT

Due to declining of oil and gas production and increasing the demand, in 2006, the Government of Indonesia issued Regulation Number 033/2006 to encourage the development of Coalbed methane (CBM) for alternative energy sources. Regarding to this issue, some specific terms and conditions must be applied for the CBM contract, therefore, an economic calculation model is needed to be used as a reference in evaluating or appraising CBM working area blocks in bid. In this study, a suitable model for CBM Production Sharing Contract (PSC) scheme is developed by modifying appropriate terms and conditions in economic model for oil and gas contract. CBM development scenario in South Sumatra is used for an example case with two base scenarios. In this case, total gas production during 23 years of operation is estimated to be 609,000 MMScf, while total expenditures is about US$ 745,130,000. In South Sumatra - Case I, where First Trenched Petroleum (FTP) is set 5% (shareable), Cost Recovery Ceiling (CRC) is 100% for 1-5 years and 90% for 6-end years, Split (after tax) is 55:45, Tax 44%, and Price of Gas is US$ 4.3 /MMBTU, the results show that Internal Rate of Return (IRR), Pay Out Time (POT), Net Present Value (NPV) @ 10% p.a and % profit for contractors are 12.9%, 15.4 years, US$ 44,000,000 and 41.87% respectively; while NPV @ 10% p.a and % profit for Government are US$ 160,000,000 and 58.13% respectively. Furthermore, our sensitivity analysis shows that yearly gas production and gas price are very sensitive economic parameters upon the change of IRR, NPV, and Government take, while Split and CRC are sensitive policy parameter upon the change of IRR and Government take. In order to make IRR close to 20%, the only way is to increase the wellhead price gas to be US$ 7.00/MMBTU. No policy parameters can be used to obtain this value.

1. INTRODUCTION

Indonesia possesses in place CBM resources potential to a number of 453 TCF [1,2,3]. Assuming 10% of this value, or as much as 45 TCF, can be produced, Indonesia will not be bothered anymore with the issue of increasing energy demand. Therefore, to boost the development of CBM for alternative energy sources, the Government of Indonesia issued Regulation Number 033/2006.

The regulation for CBM production is similar to the one applied in the production of oil and conventional natural gas, using a production sharing contract (PSC) scheme. The only difference is that in the CBM development, specific characters such as cost and longer time needed for production need to be considered. Therefore, an economic calculation model is needed as tool for the government to evaluate and to estimate the value of the blocks offered. This model can be developed from an economic calculation model usually used for conventional natural gas by modifying the model with specific requirement and characteristics for the CBM production. This model should be able to simulate the best scheme for the CBM production sharing contract that can satisfy both government and investor.

2. METHODS OF STUDY

The scheme of the study can be illustrated in Figure 1, and described as folllows.

a. Collecting data of typical CBM dewatering and gas production, estimated cost parameters which has been evaluated based on a pilot project. These data include the data obtained from the CBM field development in South Sumatra [4,5]. The cost parameters considered in this study include:

- Number of wells
- Annual gas production
- Water gas production
- Production facilities (well facilities, piping network, future plan (compressor, process facilities, etc)
- Project investment cost, including:
  - Well drilling and related facilities
  - Gathering station
  - Low pressure compressor
  - Production tools and gas sales compression system
  - Tangible, intangible, capital and non capital project cost applied to the *PSC* accounting

- Depreciation schedule for tangible and capital cost according to *PSC*
- Operating Cost including:
  - Well maintenance
  - Production cost
  - Processing unit
  - Water treatment and Compression/ gas transportation

b. Reviewing the above data, and selecting appropriate production and development cost parameters.
c. Modifying the model from oil and gas economic calculation by using appropriate parameters applied for CBM production
d. Economic evaluation of CBM field development including IRR, POT, and NPV.
e. Perform sensitivity analysis of economic calculation to obtain the most affecting variables upon economic parameters.
f. Making conclusions an recommendations

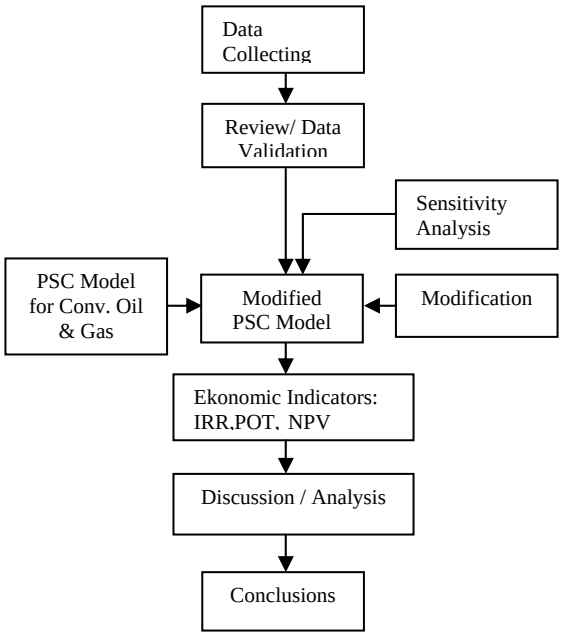

Figure 1. Research methods Scheme

3. RESULTS

Based on the cost components usually encounter in conventional gas development together with the data obtained from the CBM, the CBM field development, its production facilities and input data used in the economic evaluation can be described as follows.

3. 1 Field Development

In this study, 367 wells will be drilled in two steps of development. In the first step, about 210 wells will be drilled. Pilot wells will also be used as a part of development system. Horizontal pilot scale wells will also be made in the development step. The main target of this development step is to obtain the optimum production.

In the second step, the number of wells is expanded. The main goal of this step is to maintain production rate during the contract time. The addition wells are around 10 to 24 wells annually. Horizontal drilling and special treatment might be applied to support gas production and sale.

Production Facilities

The CBM production facilities are slightly different from the conventional gas production. These include:

- *Well facilities*
  Well production system consists of *PCP screw* type pump moved by electrical motor set on surface to produce water from tubing and gas from annulus. This pump type is selected because of four reasons: (a) big capacity, (b) intermittent, (c) resist on high gas concentration and coal flakes and (d) cheaper than other types.
- *Piping Network*
  Gas compressor at capacity of 2-3 MMSCFD is needed near the well hole and set at the gathering station. Inlet pressure is 10 to 20 psig and the outlet is 150 psig to gather gas from 10 to 20 wells to the sales point. P*olyethylene* (PE) pipe is used at low pressure section to reduce investment cost.
- *Future Plan*
  Main compressor for gas sales will be set near the field. Several clusters with the capacity of 5 to 10 MMSCFD processing gas will be set up in the project area. Each cluster will serve 20 wells.

Input Data

Input data needed in the model includes investment data, annual gas and water production , number of wells and number of production facilites needed. Furthermore, two cases are studied based on the specified above data.

***Case* I**

In this case, the following conditions are considered:

a. *FTP* = 5 % (shared for government and contractor)
b. *CRC* = 100 % for year 1 to 5,
   90% for year 6 to the end of the contract
c. *Split* = 55 : 45 (after tax)
d. *Tax* = 44 %
e. Gas and water production is shown in Table 1 and Tabel 2.

f. Wellhead gas price is US$ 4.30/MMBTU

***Case* II**

In this case, the following conditions are considered:

a. *FTP* = 10 % (only for government)
b. *CRC*= 90 % for year 1 to the end of contract, or 80% for year 1 to the end of contract
c. *Split* = 55 : 45 and 60 : 40 (after tax)
d. *Tax* = 44 %
e. Gas and water production is shown in Table 1 and Tabel 2.
f. Wellhead gas price is US$ 4.50/MMBTU or US$ 5.00/MMBTU.

3.3.1 Production Rate

Annual gas and water production are estimated based on the reservoir simulation as shown in Table 1 and Table 2 [4,5].

Table 1. Annual Gas Production Estimation (MMSCFY)

Year	Gas Production	Year	Gas Production
2008		2023	32000
2009		2024	32000
2010		2025	32000
2011		2026	32000
2012	1500	2027	32000
2013	1500	2028	32000
2014	1500	2029	32000
2015	3000	2030	32000
2016	3000	2031	32000
2017	15000	2032	32000
2018	15000	2033	32000
2019	25000	2034	30000
2020	25000	2035	26500
2021	25000	2036	26500
2022	32000	2037	26500

3.3.2 Investment Cost and Operating Cost

In general, operating cost of CBM production is higher than a conventional gas production at the early stage. This is because CBM production has longer dewatering stage (5-7 years compared to 1 year in conventional gas). After this stage, the CBM production cost is estimated US $ 0.03/MCF lower than a conventional one. Exploration cost for one well in CBM is estimated about US$ 400.000 [6,7], lower than the one in oil or conventional gas (US$ 1 – 2 million).

Table 2. Annual Water Production Estimation (Thousand of Barrel)

Year	Water Production	Year	Water Production
2008		2023	20000
2009		2024	19000
2010		2025	17000
2011		2026	16000
2012	33000	2027	15500
2013	36500	2028	15000
2014	42000	2029	14500
2015	39500	2030	14000
2016	36000	2031	13500
2017	34000	2032	13000
2018	30000	2033	13000
2019	27500	2034	11000
2020	25000	2035	10700
2021	24000	2036	10600
2022	22000	2037	10500

Meanwhile, compression and power plant cost is about 2-8 % and 5 % of the total production respectively. Therefore, only 87-93 % of the total production can be sold. Transportation and distribution cost should be covered by *end user*.

Project investment starting from year 1 up to year 23 consisting of drilling related facility cost, gathering pipeline, low pressure compressor, production and sales compression system is described in Table 3.

Detail description of the above cost parameters is as follows:

a. Well and facilities
- Core and *coring* analysis is US$ 125.000 per well
- Well and facilities is US$ 425.000 per well consisting the following components:
  - Access road, US$ 50.000. *Flow line*, US$ 25.000
  - Drilling, completion and cracking, US$ 250.000 per well
  - *PCP* pump and installation, US$ 100.000 per well.

b. Pipelines and production facilities (including water treatment)
- Low pressure gas gathering and compressor for each station consisting of modulo system @ 5-10 MMSCFD, US$ 1.200.000
- Water-gas separation system for 100 MMSCFD of gas, US$ 15.000.000

Year	No of Wells	Descriptions

Tabel 3. Biaya Investasi dan Operasional Proyek

c. *Pipelines* and Compressor for gas sales
The following data is used for information only, and not used for calculation, because we use *wellhead price* in this study.
   - Compressor with the capacity of 100 MMSCFD, US$ 45 million
   - Piping, US$ 12 million, consisting of:
     - 25 km of 24 inch piping to send the gas to PGN & PLN pipe, US$ 9 million.
     - Piping for other market (5-6 location @ 5 MMSCFD), US$ 3 million.

Because CBM gas content high purity of methane (>90%) with N2 and CO2 impurities (without H2S), investment for gas treating facilities is not included [9,10].

Operating cost consists of existing well maintenance, production cost, water treatment cost, and gas compression/transportation. Those cost components are:
- Well maintenance and production cost, US$ 25.000 per well per year.
- Water production and treatment, US$ 0.30 per barrel.

Other cost component is US$ 15.000 for restoration per well per year.

3.4 Economical Calculation of CBM Contract

Economical evaluation of the CBM production is calculated based on the PSC model as shown in Figure 2 [8].

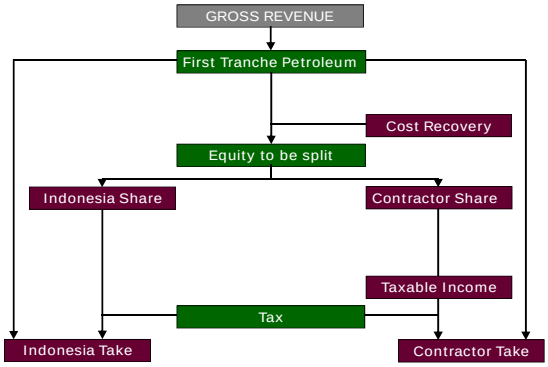

Figure 2. PSC Model for CBM Production

3.4.1. Results for *Case* I

Using conditions described in Case I, the following Tables 4 and 5 show the economic indicators results.

Table 4. Economic Indicators of CBM Development on Case I

Economic Indicators	Value
Expenditure, MM US$	745.13
NPV @ 10% p.a, MM US$	44.00
% Gross of Revenue	30.00
Internal Rate of Return (% IRR)	12.90
Profit to Investment Ratio (PIR), Fract.	2.82
Pay Out Time (POT) Year	15.40
Contractor Take, % of Profit	41.87
GOI Take, % of Profit	58.13
NPV @ 10% p.a MM US$	160.00
% Gross of Revenue	41.59

Table 5. Revenue Distribution on Case I

Revenue Distribution	Contractor (MM US$)	Government (MM US$)
Gross Revenue	2618.70	
Net Cash Flow	784.48	1089.09
Cost Recovery	632.95	0
Total FTP Share	105.22	25.72

Table I shows that, based on Case I, contractor does not get reasonable IRR, i.e. 12.9%.

3.4.2. Results for *Case* II

Using conditions described in Case II (*CRC* 90%, Split 55:45 and Gas price US$ 4.50/MMBTU), the following Tables 6 and 7 show the economic indicators results.

Table 6. Economic Indicators of CBM Development on Case II

Economic Indicators	Values
Expenditure, MM US$	745.13
NPV @ 10% p.a, MM US$	29.00
% Gross of Revenue	25.9
Internal Rate of Return (% IRR)	12.00
Profit to Investment Ratio (PIR), Fract.	2.54
Pay Out Time (POT) Year	15.00
Contractor Take, % of Profit	35.52
GOI Take, % of Profit	64.48
NPV @ 10% p.a MM US$	194.00
% Gross of Revenue	46.95

Table 7. Revenue Distribution on Case II

Revenue Distribution	Contraktor (MM US$)	Government (MM US$)
Gross Revenue	2740.50	
Net Cash Flow	708.73	1286.64
Cost Recovery	625.38	0
Total FTP Share	0	274.05

As on Case I, the results shown in Table 6 also shows that, based on Case II, contractor does not get reasonable IRR, i.e. 12.0% (lower than Case I). For gas price US$ 5.00/MMBTU, IRR is obtained 13.4%.

3.4.3 Results on Sensitivity Analysis

Effects of economic variables on economic parameters are studied further to observe the sensitivity of each variable, following are the results.

a. Sensitivity Analysis on Case I

Figure 3 shows effect of gas production rate, gas price, Capex, and Opex on IRR. This figure shows that gas production rate and gas price give very sensitive effect on the IRR, while both Capex and Opex do not give significant effect on the IRR. For instance, increasing production rate or gas price by 20 % will increase the IRR from 12.9 to 15.3%.

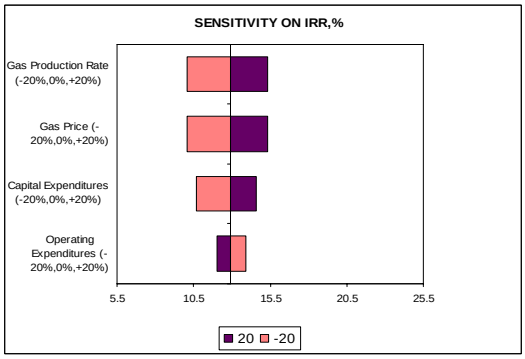

Figure 3. Effect of Gas Production, Gas Price, Capex and Opex on *IRR* in Case I

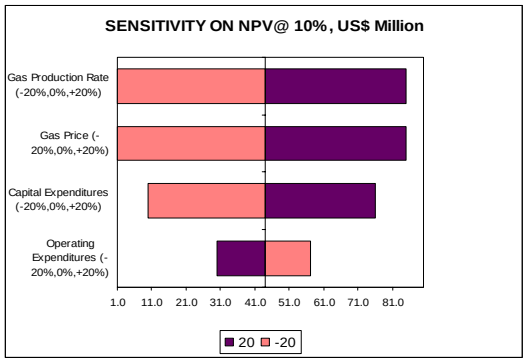

Figure 4. Effect of Gas Production, Gas Price, Capex and Opex on *NPV* in Case I

Figure 4 shows effect of gas production rate, gas price, Capex, and Opex on NPV for contractor. This figure shows that gas production rate and gas price give very sensitive effect on the NPV, while both Capex and Opex do not give significant effect on the NPV. For instance, increasing production rate or gas price by 20 % will increase the NPV from US$ 44 million to US$ 85 million.

Table 8 shows the sensitivity of the policy parameters on IRR. From the investor side of view, Split ratio is a very sensitive parameter on IRR. If the investor wants 19% of IRR, the Split ratio (Government: Contractor) should be 10 : 90, which is practically impossible, or the CRC is increased up to 120%, which is also impossible. Meanwhile FTP is not a significant factor on the change of IRR.

Table 9 shows the sensitivity of the policy parameters on Government Take. Similar to the above results, Split and CRC are important factors affecting the Government Take (in the reverse direction), while FTP is not a significant factor.

b. Sensitivity Analysis on Case II

Figure 5 shows effect of gas production rate, gas price, Capex, and Opex on IRR in Case II. As in Case I, gas production rate and gas price also give very sensitive effect on the IRR, while especially Opex does not give significant effect on the IRR. For instance, increasing production rate or gas price by 20 % will increase the IRR from 12.0 to 14.4%.

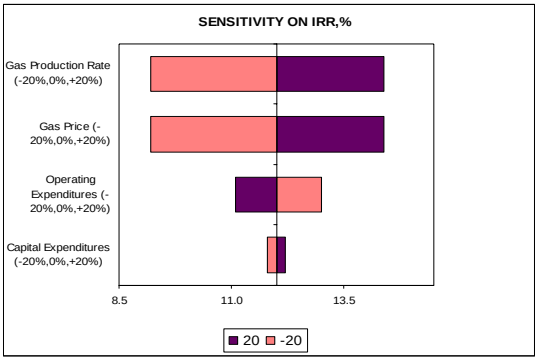

Figure 5. Effect of Gas Production, Gas Price, Capex and Opex on *IRR* in Case II

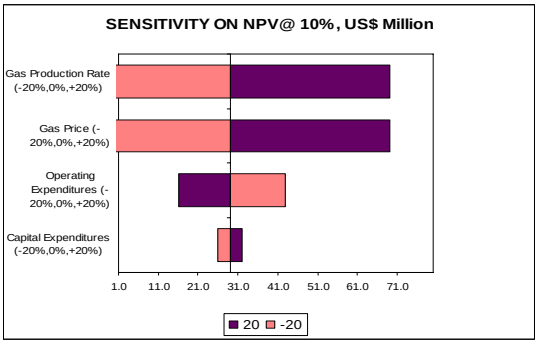

Figure 6. Effect of Gas Production, Gas Price, Capex and Opex on *NPV* in Case II

Figure 6 shows effect of gas production rate, gas price, Capex, and Opex on NPV for contractor. This figure shows that gas production rate and gas price give very sensitive effect on the NPV, while especially Opex does not give significant effect on the NPV. For instance, increasing production rate or gas price by 20 % will increase the NPV of contractor from US$ 29 million to US$ 65 million.

Table 10 shows the sensitivity of the policy parameters on IRR. As in Case I, split ratio is the most sensitive parameter on IRR for Case II. If the investor wants 19% of IRR, the government will gets nothing, or the CRC is increased up to 125%, which is also impossible. Meanwhile FTP is not a significant factor on the change of IRR.

Table 11 shows the sensitivity of the policy parameters on Government Take. Similar to the

above results, Split and CRC are important factors affecting the Government Take (in the reverse direction), while FTP is not a significant factor.

.

4. CONCLUSIONS

1. Base on Case I, IRR for CBM development in South Sumatra is 12.9%, and on Case II, IRR is obtained 13.4% at CRC = 90% and gas price US$ 5.00/MMBTU (the highest reasonable CRC and gas price).
2. Sensitivity analysis shows that Gas production rate and gas price give more significant effect on IRR and NPV, compared to the effect of Capex and Opex. Meanwhile, among the policy parameters, Split and CRC give significant effect on IRR, and FTP shows the least effect, both for Case I and Case II.

Tabel 11. Change of Government Take on Policy Parameters In Case II

3. From the government point of view, Split and CRC give significant effect on Government take, and FTP shows the least effect, both for Case I and Case II.

4. In order to get IRR = 20%, the following schenarios can be used:

Base Case I :

a. Gas price is increased to US$ 7,53/MMBTU, IRR = 20,6%
b. Gas price US$ 6,88/MMBTU, CRC = 100%, IRR = 20,2%

Base Case II :

a. Gas price is increased to US$ 8,10/MMBTU, IRR = 20,2%
b. Gas price US$ 7,65/MMBTU, CRC = 100%, IRR = 20,2%
c. Gas price US$ 6,75, FTP=10% (shared), CRC=100%, IRR = 20,0%

ABSTRACT

Coalbed Methane (CBM) is a new methane resources abundanty available in Indonesia. In this study, we evaluate the possibility of developing a small LNG plant from CBM at Rambutan Field through purification process and liquefaction. Due to low impurities and low pressure characteristic of CBM, we selected to use Pressure Swing Adsorption (PSA) method with eight columns in rows for purification process. Meanwhile, we used a Single MRC (Single Mixed Refrigerant Cycle) of Black and Veatch PRICO for liquefaction processes which are more suitable for a small scale LNG plant. Our economic analysis shows that the small LNG plant needs an investment as much as US$ 438.031.452,06. At the price of coalbed methane raw material US$3/MMBTU, the price for LNG product should be sold at US$8/MMBTU in order to get Internal Rate of Return (IRR) value 24.34 %, and payback period of 5.49 years from starting the construction or 3.49 years after operation of the plant

Keywords: *Coalbed Methane, PSA, LNG Process, Natural Gas Purification, Economic Evaluation*

1. INTRODUCTION

Coalbed Methane (CBM) is a new methane resources abundanty available in Indonesia. Only at one location (Rambutan Field), in South Sumatra, 0.8 TCF of methane reserve from CBM has been indicated with the purity of more than 90 % of methane [1]. This methane reserve might be potentially produced as energy resources for transportation need in Palembang which is 165 km away from the CBM resources. Considering the distance from the consumer and the rate of production which is estimated to be 50.9 MMcfd, this methane resources might be utilized through a small LNG (Liquified Natural Gas) plant and transported using LNG trucking [2].

In this study, economic feasibility of developing a small LNG plant from CBM source at Rambutan Field involving purification and liquifaction units is analyzed. This is a unique case, considering its specific CBM gas contents and conditions.

2. METHODS OF STUDY

This study is initiated by collecting the characteristics of the gas produced by CBM, including its condition and composition. The requirement of the LNG, which will be produced, should also be specified. Then, types of suitable unit processes are selected according to the above conditions and specifications.

Once the process is selected, the simulation is performed manually and by using Hysis software in order to obtain the specific size of each unit process and its energy consumption. This information will be used to calculate the CAPEX (Capital Expenditure) and OPEX (Operation Expenditure). All the prices are extrapolated for year 2015 as a reference year when the plant is expected to be built.

Profit is obtained by subtracting revenue from LNG sales and the OPEX, depreciation, and tax. Therefore, cash flow of the company can be determined and analyzed its economical feasibility. In this case, IRR, NPV and Payback Period, are calculated using suitable formula [3] and evaluated. Sensitivity analysis is performed using spider chart and tornado chart method [4].

3. RESULTS

The plant is designed for the average capacity of 50,9 MMcfd, which is enough for transportation energy need in Palembang and vacinity. Considering the methane reserve available at Rambutan field, which is 0.8 TCF, and 50% recovery, this plant is expected to operate up to 21 years. The life time of this LNG plant also agrees with the normal life time of typical LNG plant in the world [5]. The *small scale* LNG *Plant* at Rambutan Field is assumed to be constructed in 2015 and start producing LNG in the beginning of 2017.

The average temperature and pressure of CBM source at Rambutan Field are 43 ^{o}C and 7.83 atm, and its composition is shown in Table 1 [6,7]. Meanwhile, the specification of the LNG produced should meet the requirement shown in Tabel 2 [8].

H_2O	<1 ppmv
Hg	max 0,01 μgr/Nm3

3.1 Selected Proses

Figure 1 shows Block Flow Diagram of the LNG plant selected based on the condition and composition of the CBM available. Due to its low pressure and low nitrogen and carbondioxide contents, the CBM gas is purified using Pressure Swing Adsorption (PSA) process in molecular sieves 5 A at pressure 300 psia and temperature of 25 ^oC. Eight adsorption columns are used for the adsorption process and the other eight columns are used for regeneration. The capacity of adsorption is calculated based on the adsorption isotherm obtained by Wakasugi [9].

Total gas of 940,63 ton/day or 48,46 MMCFD will be produced from the PSA unit. As much as 12 % of total gas (112,87 ton/day) is used for fuel consumption in the gas turbine to generate electricity and 6,16 ton/day is used for regeration purpose in the PSA unit. Therefore, only 821,6 ton/day will be processed further in the liquifaction unit.

Liquifaction process uses a *single mixed refrigerant* method patented by Black and Veatch PRICO [10]. Table 3 shows the composition of mixed refrigerant used.

Tabel 3. Mixed Refrigerant Composition

MR Component	% Mole
N2	10
C1	24
C2	28
C3	16
i-C4	5
i-C5	17

3.2 Economic Analysis and Sensitivity

The CAPEX needed [11] for building a small scale LNG plant is listed in Table 4. Total CAPEX is $ 157.152.784,50 for total LNG production of 821,6 ton/day or 0,299 MTA (Thousand of Ton Annual). Ratio of CAPEX to the LNG production is $ 524,03 MM/MTA, which is higher than normal ratio for building a *base load* LNG *plant* ($ 300 MM/MTA) [5]. This result is not unexpected, considering that unit cost for bigger scale plant always less than the smaller scale.

Tabel 4. CAPEX Esitmation

UNIT	Investment (US$)	%
PSA Purification	4,323,551,57	2.69
Liquefaction Process	4,220,691,35	2.69
Power Plant	75,246,062,76	47.88
Piping, Instrumentation & Control	3,333,011,37	2.12
Land	15,000,000,00	9.54
Service Facilities	14,505,386,17	9.23
Site Development	2,901,077,23	1.85
Contractors	14,505,386,17	9.23
Engineering, Supervision, Start Up	8,703,231,70	5.54
Others	14,505,386,17	9.23
TOTAL CAPEX	157,152,784,50	100.00

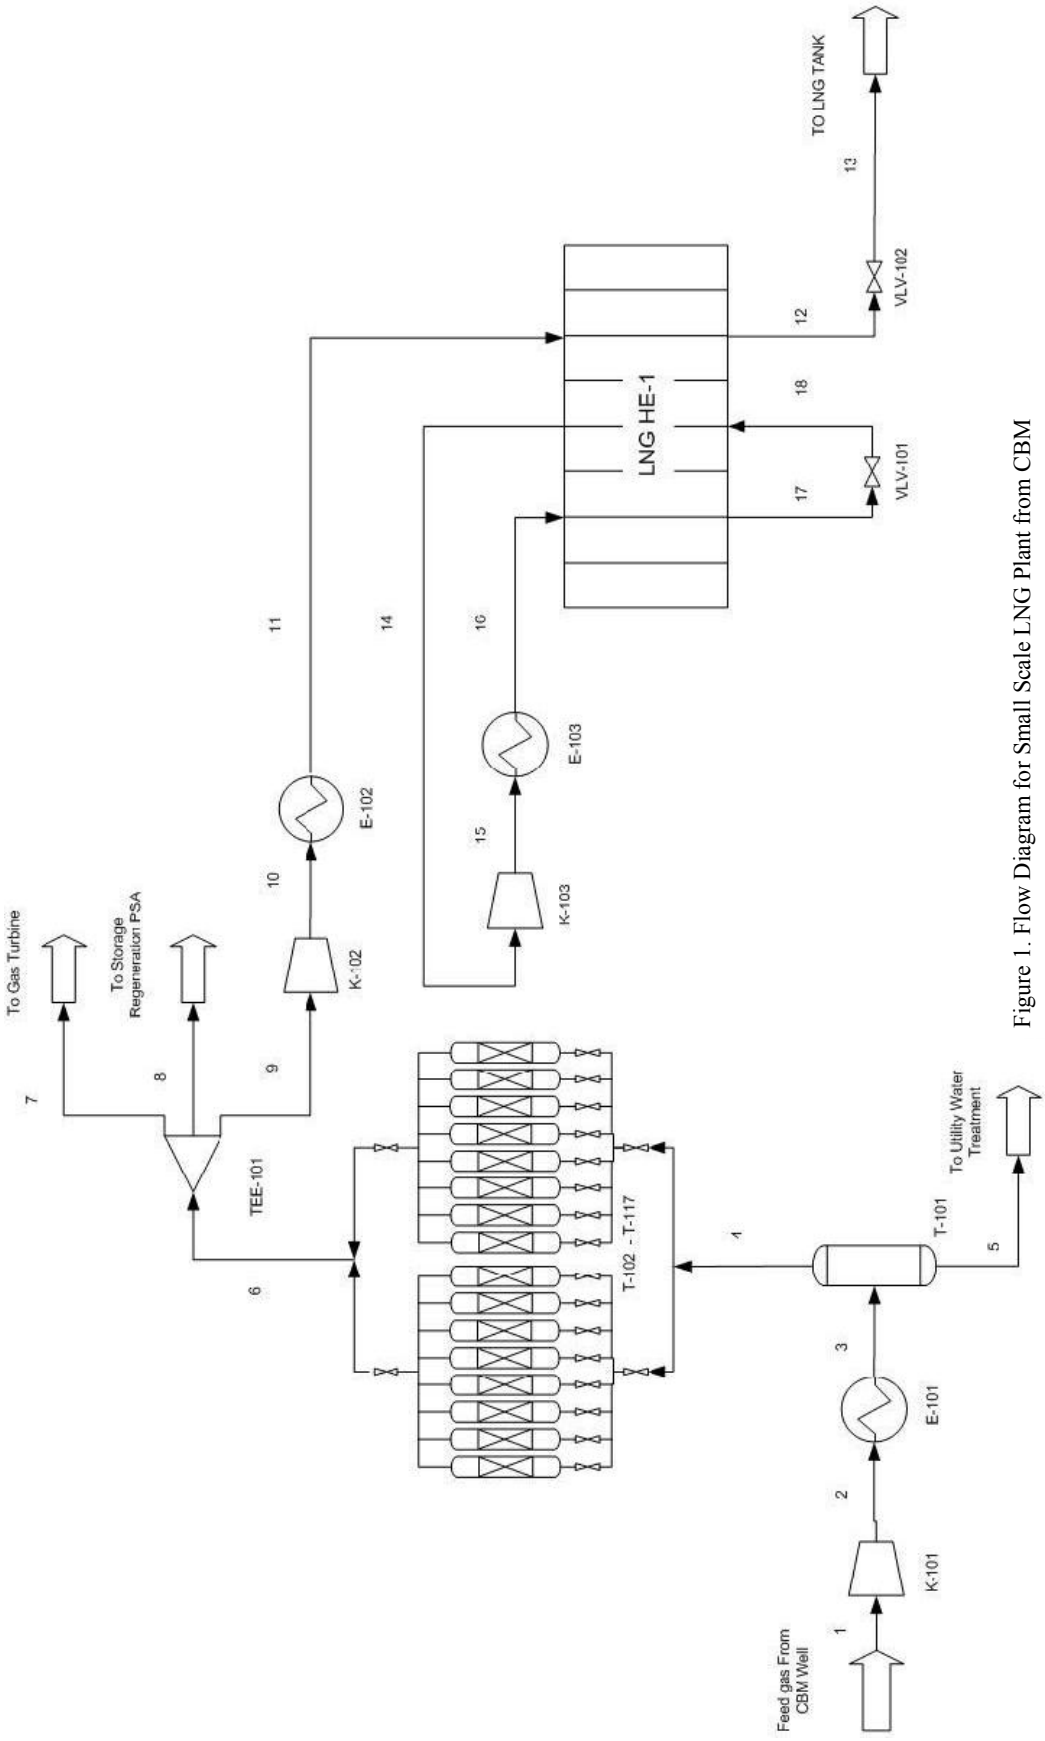

Figure 1. Flow Diagram for Small Scale LNG Plant from CBM

Estimation of OPEX and its components can be seen in Table 5. This estimate is calculate based on literature [11] and recent market situation.

Tabel 5. OPEX Estimates

Component	Cost (US$)
Direct Cost & Utilities	5,563,014,59
Insurance	1,813,173,27
Marketing & Administration	3,000,00
Labors & Office	553,200,00
TOTAL OPEX	7,932,387,86

OPEX per MMBTU production can be calculated as $ 0,54 / MMBTU. According to literature [5], OPEX per MMBTU for base load LNG plant is about $ 0.2 / MMBTU (excluding purification process). Comparing the two values, and considering the difference in scale and cost in purification process, the OPEX estimates in our small LNG plant is quite reasonable.

Assuming the price for raw natural gas is $ 3/MMBTU and the selling price is $ 8/MMBTU based on Free On Board (FOB), profit can be calculated by substructing revenue with the operating cost and depreciation. The profit is obtained as much as $ 4 / MMBTU.

Based on the calculated CAPEX, OPEX and depreciation, the cashflow can be made, assuming that equity of this plant comes from 100 % self funding, the inflation rate is 2,8% and government tax (PPH No 22) is 30%. The IRR for the above standard price is obtained to be 24,34%. The NPV at 2015 is obtained as much as $ 438.031.452,06. *Payback period* is 5,49 years since the construction begin, or 3,49 years after LNG production. Therefore, this small LNG plant is feasible to be developed.

Changing -20% to 20% upon selling price of LNG, CBM price, CAPEX and OPEX gives the following effects on IRR:

IRR increase up to 35.5% by changing 20% of LNG price and decrease to 12.5% by changing
-20% of LNG price.
IRR increase up to 29% by changing -20% of CBM price and decrease to 19% by changing 20% of CBM price.
IRR increase up to 31% by changing -20% of CAPEX and decrease to 20% by changing 20% of CAPEX.
IRR increase up to 25% by changing -20% of OPEX and decrease to 23% by changing 20% of OPEX.
The above results show that the LNG price is the most sensitive parameter in the economic feasibility of the plant studied, and the OPEX is the least sensitive one. Similar results are also obtained for the effect of NPV on the change of -20% to 20% upon selling price of LNG, CBM price, CAPEX and OPEX.

Simulation on the cash flow based on the fixed OPEX and CAPEX and varying GMB and LNG prices gives the following equations (in US$) for different IRR:

For IRR = 20%
Selling LNG price = CBM price + 4,13

For IRR = 15 %
Selling LNG price = 1.03 CBM price + 3,85

For IRR = 10 %
Selling LNG price = 1.02 CBM price + 3,60

The above equations can be used to estimate the price of LNG for a specific price of CBM price and at the rate of return required.

4. CONCLUSIONS

1. Based on the CBM price of US$ 3 and the selling price of LNG at US$ 8, the IRR for the above standard price is obtained to be 24,34%. The NPV at 2015 is obtained as much as $ 438.031.452,06. *Payback period* is 5,49 years since the construction begin, or 3,49 years after LNG production. Therefore, this small LNG plant is feasible to be developed.
2. Sensitivity analysis shows that the LNG price is the most sensitive parameter in the economic feasibility of the plant studied, and the OPEX is the least sensitive one.

3. Feasible price for the LNG produced can be estimated according to the price of the CBM at a certain IRR required, as follows:

   For IRR = 20%
   Selling LNG price = CBM price + 4,13

   For IRR = 15 %
   Selling LNG price = 1.03 CBM price + 3,85

   For IRR = 10 %
   Selling LNG price = 1.02 CBM price + 3,60

CERN – Lyon, France
E-mail : mohamadhardiyanto@ yahoo.com

ABSTRACT

The functional of a multi purpose research nuclear reactor control rod blade nuclear reactor is stabilized and controlling devices for nuclear chain reactions, the existing of Cerenkov's radiation impact and thermal neutron flux in reactor chamber. This research was conducted in Large Hadron Collider (LHC) – Muon Hadron Division at CERN, Lyon – France under International Research between Canadian Deuterium Uranium (CANDU) – Nuclear Reactor and Betha Group Section for sub-particles for nanomaterial. Using Juergen Model with quantum states approaching and testing by Muon-Hadron Stirrer equipment had determined the Th_xDUO_2 derivatives materials. This material shown the strength of thermal neutron flux absorbed about 2.1 x 10^5 – 1.8 x 10^6 Ci/mm, the value of Electrical Conductivity is 26.62 – 29.98 in 800º - 890º C temperature, however at 2.1 x 10^5 Ci/mm thermal neutron flux condition is 29.44 – 37.88 in IAEA standard. At 450 tesla magnetic field and 2.1 x 10^5 Ci/mm thermal neutron absorber, the crystalline structure reduction is 6.88% until 10.95% for 25 years period in 45.7 megawatts with UO_2 more enrichment and Pu_2O also Th_2O_y nuclear fuel element matrix.
Keywords : Cerenkov's Effect, Quantum states, Fast neutron floating, Juergen Model, Muon-Hadron Stirrer

1. INTRODUCTION

This research involves a multi purpose research nuclear reactor with increasing of its adjusted power from 30 megawatts (MW) to 50 MW. This process has changed the nuclear fuel element matrix from UO_2 to be UO_2 more enrichment with Pu_2O and Th_2 O_y buffer element. This matter could be increasing of thermal neutron flux up to 2.1 x 10^5 currie/mm in normal condition, much more Cerenkov's radiation figure out and several quantum states in reactor chamber (Stuart, Thomas P., 2001).

The shape and dimensions of control rod blade include 5 meters length, 0.80 meters diameter and thickness fit on 0.10 meters. Moving on normally with 76 mm/second speed and reached above on reactor yield is 1.6 meters for normal condition. These values have fixed on International Atomic Energy Agency (IAEA) regulation (CANDU, 2001).
At present time, the control rod blade material is Zircalloy-4, and according of IAEA recommendation, this material have to change with best substance fitted on 50 MW adjusted power. The eliminary investigations show that material has found from Sr_2 Al_xO_y types (Moh Hardiyanto, 2001) consists are three types including Th_x DUO_2 , Th_{x-1} DUO_2 and Th_{x-2} DUO_2 materials. From basic testing with Super Muon-Magnetic equipment in few conditions ; normal, sub critical, critical phase 1 and phase 2 have eliminary result such as the highest thermal neutron flux absorber value could reached by Th_x DUO_2 with much more stability in graduation points. Another thing, when the Cerenkov's radiation shown up, this material expression the more ordered electron clouds track, then could be count to facing neutrino, μ, and anti-neutrino particles bombarding around the reactor chamber.

2. LITERATURE AND FORMULATION

2.1 Juergen Model

The IAEA standard for software and programming to multi purpose nuclear research reactor was written in Modula's language consists are 4 main programmes including numerical processing, begin to simulation, advanced simulation and establishing calculations also display. Additional for this software, Ising Model has 38,700 sub-programmes consists are 8,700 formulations and calculations especially in physics, chemistry and other nuclear reactions. Thereby, include 10,000 sub-programmes for various databases. More completed with 15,000 sub-programmes for making simulations. After that working, this software was completed with 5,000 sub-programmes to display with interactive processing, specific in nuclear chain reactions at reactor chamber with all devices (Durant, W.C., 2001).

2.2. Super Muon-Magnetic

The equipment has developed especially for multi purpose nuclear reactor. Advanced devices will be connected and integrated with reactor chamber and shielding of its reactor and generates with 150 kilowatts power non-stop electrical force, commonly by 2.1 grams Thorium-331, one isotope species from Trans-Uranium series (Waghmare, Y.R., 2001). Various parts will be connected with this equipment test including premier properties such as:

- Thermal neutron flux luminosity between 1.9 x 10^4 currie/mm to 2.1 x 10^6 currie/mm with Na_2SO_3 liquid moderator.
- Magnetic field between 400 tesla up 610 tesla of thermal neutron flux existence in reactor chamber when adjusted power increasing around 50 MW.

- The magnetic frequency around 410 MHz until 550 MHz for each chain reaction based on UO_2 more enrichment nuclear fuel.
- Existing of v and v$^-$ particles and more muon-hadron particles when Cerenkov's radiation coming up in reactor chamber.
- The value of temperature around 800° - 890° C, when adjusted power increase to 50 MW.

This part was connected with special device, *catch-nuc power*; the equipment will be generated electrical power amount 70 kilowatts per hour.

Through by Super Muon-Magnetic and Juergen Model will be determined the derivation of Th_x DUO_2 covering are Th_x $DUO_{1.7,}$ Th_x $DUO_{1.8}$ and Th_x $DUO_{1.9}$ types with involving the quantum states.

2.3. Quantum States Approaching

Most formulations will be used in this research based on relativistic quantum mechanics, Einstein's condition, and a few interstellar quantum statistics until the derivation from BCS theory in super-conductivity state (Gomiez, J.A., 2001).

Begin from standard formulation for relativistic wave length, forward to spectrum of nuclear analysis up to super-conductivity state with Fermi, Fermi-Hall condition (Beiser, Arthur, 1998). The first of Compton's wave length in Einstein-Dirac state expressed by:

$$\frac{\{hf_0 - hf + m\}^2}{c^2} - m_0^2 c^2 = \left\{\frac{h}{\lambda_0}\right\}^2 + \left\{\frac{h}{\lambda}\right\}^2 - \frac{2h^2}{\lambda_0 \lambda}\cos\theta \qquad (1)$$

Considering the total energy in relativistic states is:

$$E^2 = p^2 c^2 - m_0^2\ c^4 \qquad (2)$$

Meanwhile the formulation of Einstein-Dirac could be written in muon-hadron particle with:

$$E_\varphi = \frac{e^4 \sin\phi}{4\pi\varepsilon_0 c^2 r} \qquad (3)$$

In this case, considering that the speed of the electron is small in comparison it the speed of neutron particle, the electric field of Electrical Conductivity (EC) flowing at Einstein-Sommerfeld field in an point H_{11} with polar coordinates

$$\left(\frac{E_\varphi}{E}\right)^2 = \frac{e^4 \sin^2\phi}{(4\pi\varepsilon_0)^2 m_n^2 c^4 r^2} \qquad (4)$$

As the intensity is directly proportional to the square of the electric field. The total amount of energy scattered per unit volume of the scattered per second is given by

$$U_s = \int_0^\pi I_s (2\pi r^2 \sin\theta) d\theta \qquad (5)$$

$$U_s = \left(\frac{1}{2}\right)\left[\frac{2\pi n e^4 r^2}{(4\pi\varepsilon_0)^2 m^2 c^4 r^2}\right] \int_0^\pi (1+\cos^2)\sin\theta\, d\theta \qquad (6)$$

The first formulation investigated by Arthuro J. Gomiez (Gomiez, J. Arthur, 2001) shown that the crystalline structure will be derived from BCS theory such as

$$H_1 = \sum_i J\left\lfloor C_{ki\uparrow}^F C_{ki\downarrow}^F \right\rfloor \qquad (7)$$

The early equation was given by Abrikosov, Balseiro and Russel in matched on superconductivity crystalline structure (Kempster, M.H.A., 1999) using Fermi's state non reactive electron cloud and Fermi-Hall reactive electron cloud. The completed equation was given by

$$H_{II} = \sum_i J\left\lfloor C_{ki\uparrow}^F C_{ki\downarrow}^F \right\rfloor + k\sum_i \sum_j \left\lfloor C_{kij\uparrow}^F C_{kij\downarrow}^F \right\rfloor \qquad (8)$$

Consider of quantum relativistic field and existence of Gell-Mann's specification particles (Valli, G., 2000) and based on Bose-Einstein state. Begin from electron potential energy up to Rydberg's constant, derived such as:

$$K = \frac{1}{8}\frac{me^4}{\varepsilon_0^2 h^2 n^2} \qquad (9)$$

$$V_{(r)} = \frac{-1}{4}\frac{me^4}{\varepsilon_0^2 n^2 h^2} \qquad (10)$$

From both Equations (9) and (10) will be found total energy on the *n*-th shell in crystalline structure displacement (Chattopadhyay, C., 1998) at semi-relativistic quantum condition, is:

$$\frac{1}{\lambda_c} = \frac{1}{8}\frac{m_e e^4}{\varepsilon_0^2 h^3 c}\left\{\frac{1}{n_2^2} - \frac{1}{n_1^2}\right\} \qquad (11)$$

Reviewing from a few formulations, it is clear that by measuring σ the value of *n*-th can be determined

$$n = \left(\frac{3}{8\pi}\right)\left[\frac{(4\pi\varepsilon_0)^2 m_n^2 c^4}{e^4}\right]\sigma \qquad (12)$$

At 2.1 x 10^4 currie/mm thermal neutron flux absorption for minimal condition in reactor chamber, the value of *n*-th stage begin from 1 up 2 according the Fermi's interference condition, expressed :

$$E_{n1} - E_{n2} = \frac{1}{8}\frac{m_n e^4}{\varepsilon_0^2 h^2}\left\{\frac{1}{n_2^2} - \frac{1}{n_1^2}\right\} \qquad (13)$$

In this Equation found the value of Rydberg's constant for thermal neutron flux at reactor chamber, the amount is 1.097373 x 10^7 m^{-1}. Based on the Rydberg's constant and wearing the Compton's nuclear wave length for thermal neutron flux scattering in crystalline structure, Pfund at Princeton University (Vasudeva, D.N., 1999) found the new

series near in "Doublet-Natrium" red-infra closest with derivation of Dirac's Mirror equation such as:

$$E(eV) = -\frac{1}{e_c}\frac{m_e e^4 z^2}{8\varepsilon_0^2 h^2}\frac{1}{n^2} \qquad (14)$$

When "z" is value for moment-magnetic spin of angular electron in solid state.

According these equations and seem to reactor chamber flow from nuclear fuel reaction until shown up the Trans-Uranium series with DUO_2 fuel element, then a few device of Super Muon-Magnetic will be recorded a lot of data with many serial repeated reaction. For precisely calculations, many equations will be transferred in group-theory, one of modern mathematical tools in quantum-relativistic phenomena.

In this part will be described the changing of the semi-relativistic formulation to quantum's group-theory, develop by Dirac, Gell-Mann, and other famous physicians (Beiser, Arthur, 1998). Start by the steady force law in relativistic magnetic field up to the connection of phonon-electron cloud in solid state structure. Describing such as:

$$H_{II} = \sum \varepsilon_k C_{kt}^F - \hbar\Delta\sum\left\{C_{k\uparrow}^F\, C_{k\downarrow}^F x\hbar c\right\} \quad (15)$$

Derivation of BCS's theory break by Abrikosov-Balseiro-Russel formulation energy potential expressed as:

$$\Delta = g_{BCS}\sum_k \left\langle C_{k\downarrow} \bullet C_{k\uparrow}\right\rangle \qquad (16)$$

Analysis by Vitalli Ginsburg (Harold, Thomas S., 2001) using with Superconducting Quantum Interference Device (SquID) shown that Fermi's interference displacement caused by UO_2 nuclear fuel in 400 tesla magnetic field reactor chamber.

3. RESULT AND DISCUSSIONS

Ultimate testing for the three types materials including are $Th_x\ DUO_{1.7}$, $Th_x\ DUO_{1.8}$ and $Th_x\ DUO_{1.9}$ covering the Cerenkov's radiation impact existence at reactor chamber. This moment was happened at moderator pool, so to be reactive with Na_2SO_3 liquid. The element of nuclear fuel matrix was using UO_2 with Pu_2O and Th_2O_y buffer element could be increasing for thermal neutron flux until 4.7 x 10^9 currie/mm. In this picture on below, has shown the Cerenkov's radiation was happened at reactor chamber, when the nuclear fuel element covered UO_2 more enrichment.

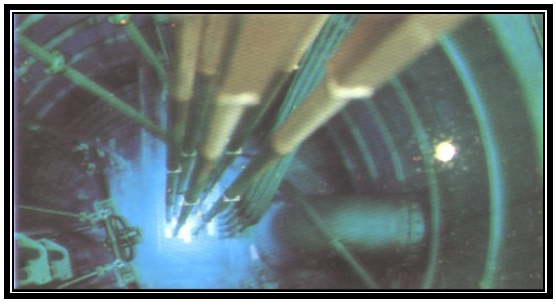

Figure 1-Cerenkov's radiation moment at 45.7 MW with DUO_2 more enrichment

(Courtesy and special permission of CERN, Lyon)

From the picture above, it has shown the blue color deep at reactor chamber, if look from reactor's yield bottom. It has biggest thermal neutron flux until 5.3 x 10^{10} currie/mm and coming up of v,v^- particles in amount is 2.6 x 10^4 mol per 1 activation reaction. This particles has known as Dirac's particle couldn't shield or barrier with Pu or Th up to 10^{10} light-years thickness.

After through the ultimate test by Cerenkov's radiation, the material of $Th_x\ DUO_{2-x}$ derivatives has tested in quantum magnetic-spin and magnetic-resonance at 450 tesla magnetic field on 45.7 MW and detecting by *Electron Spectroscopy for Chemical Analysis to Neutron* (ESCA-N). The picture from its tested has figured out below.

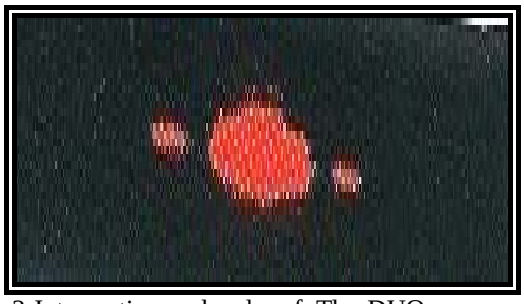

Figure 2-Intersection molecular of $Th_x\ DUO_{2-x}$ in 450 tesla magnetic field
(*Courtesy of CERN, Lyon*)

Looking forward the picture, find out the nucleus of greatest mass from $Th_x\ DUO_{2-x}$ assemble to making a center of gravity's mass surrounding by two interstellar mass. Hosted by Dirac, these interstellar are phonon-electron's active cloud and always pairing together. It will be explained how the quantum magnetic-spin keep on steady state for long period as long as there isn't loosing mass, however a much little bit value. The value is 2.426 x 10^{-12} m and to converted to relativistic-mass unit by Bose-Einstein multiplier.

Based on a few Equations shown that the post result by Super Muon-Magnetic experimental with magnetic-spin frequency at 550 MHz and rolling shield of 450 tesla magnetic field, the quantum density from inactive Fermi-Hall's paired cloud has connected with plane wave is homogenous state. Figure out by Bohr-Sommerfeld's formulation has calculated wrote by

$$\mu_{BS} = \frac{e\hbar}{2m_e}$$

$$= \frac{1.6021892x10^{-19}\,x\,6.626176x10^{-34}}{4\pi\left(9.109534x10^{-31}\right)}$$

$$= 9.274078\ \ x10^{-24}\ JT \qquad (17)$$

Comparison by the value of Magneton-Bohr's formulation

$$\mu_B = eh/2m_e$$

= magneton Bohr
= 9.273 x 10^{-24} J/T (18)

there is very tight difference, but a much little value has enough to making Fermi's effect on intersectionthe value of

nucleus magneton, μ_N, has described by Equation (15) but in group-theory of quantum relativistic, for seem not to be complicated, take a look for semi-relativistic formulation, using :

$$|\mu_N| = |g_N| \frac{e}{2m_p} \sqrt{I(I+1)\hbar} \qquad (19)$$

When $\sqrt{I(I+1)\hbar}$ is quantum moment magnetic-nucleus as describing by Einstein and Sommerfeld (Weigner, Karl P., 2002)0 took place of the v particle, and making a good simplify calculation for nucleus magneton such as

$$\mu_N = \frac{e\hbar}{2m_p}$$

$$= \frac{1.6021892\,x10^{-19}\,x\,6.626176\,x10^{-34}}{4\pi\,1.6726485\,x10^{-27}}$$

$$= 5.50824 \text{ x}10^{-27} \text{ JT}^{-1} \qquad (20)$$

Therefore nucleus magneton $\approx \frac{1}{1836}$

From Bohr's magneton, it can be divided of interstellar ensemble for a few micro-substances. These was explained how the thermal neutron for 450 tesla magnetic field could reach the quantum boundary layer and affected the Fermi's effect increasing so depth in the crystalline structure.

The phenomena about this matter could see for picture below making by *Kaon* detector, which is integrated by Gell-Mann spectroscopy and connected to Magnetic Stirrer for reactor chamber, was adjusting its power.

The picture has shown one magneton nucleus and five interstellar consists are thousands phonon-electron's paired making a barrier for thermal neutron luminosity and its bombarding, was given such as

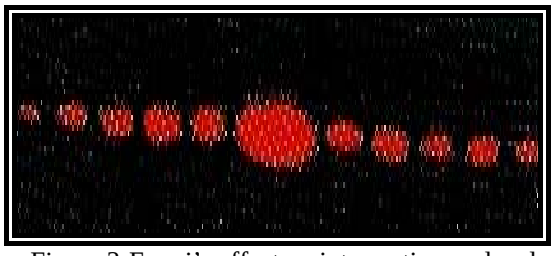

Figure 3-Fermi's effect on intersection molecular of Th_x DUO_{2-x} in 450 tesla
(*Courtesy of CERN, Lyon*)

Remaining of Anderson's tunnel fields has found the fluxoid and based on Equations (19) and (20) for deflection requirement crystalline structure, having found the value for distance between one interstellar to other side as written by

$$R_e = \sqrt{\frac{I}{\mu}} = \sqrt{\frac{2.643x10^{-47}}{1.62668x10^{-27}}} = 1.275x10^{-10}{}_m \quad (21)$$

In quantum magnetic-spin for relativistic field, the reliability of crystalline structure depends on Bohr-Sommerfeld formulation, Fermi-Dirac's state, and Bose-Einstein statistic condition, and reference to Equations (15) and (21), will have investigated each interstellar by :

$$N_i = g_i e^{-\varepsilon_{1/kT}} / \sum_i g_i e^{-\varepsilon_{1/kT}} \qquad (22)$$

Remaining those impact and based on the study about reliability of crystalline structure of substitution material, Th_x $DUO_{1.8}$, then this substrate made to a pellet and to be testing in Super Muon-Magnetic tray connected to reactor chamber. According to Equations (10) until (18) above, there is must be existing of quantum magnetic-rotate also magnetic-spin simultaneously from crystalline structure caused by EC effect at the 10^3 nm area depth. Using with ESCA-N, involves bombarding the surface with high-energy of thermal neutron in 45.7 MW adjusting power to emit phonon-electrons cloud pairing together, then making of Fermi-Dirac's state in outer-boundary layer, so it could be analyzed for information on the elemental of the depth surface.

The picture below could be shown how the enough strongest of Th_x $DUO_{1.8}$ material facing the impact of the EC's value at semi-relativistic quantum magnetic-spin and magnetic-rotate for reliability of its crystalline structure, and also facing to thermal neutron flux bombarding at 2.1 x 10^5 currie/mm amount. For better viewing, take a look about its graph comparison between present material, Zircalloy-4, and the substances at thermal neutron bombarding for IAEA standard around is 1.9 x 10^5 currie/mm and just only 400 tesla quantum magnetic-rotate and magnetic-spin frequencies, when moderator liquid has still same condition, Na_2SO_3 and the state of muon-hadron particles there weren't detected by *Kaon* and Gell-Mann detectors, and the picture on below

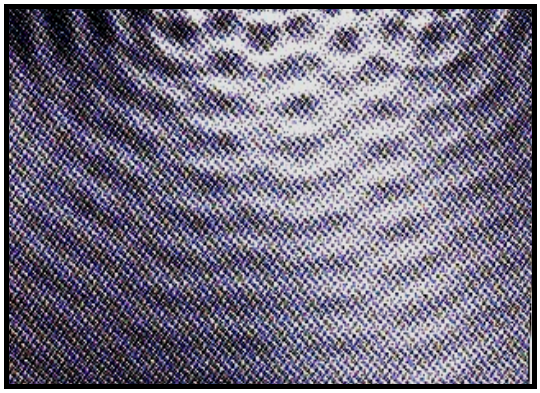

Figure 4-Cross-section effect of EC on sub critical phase based on Th_x $DUO_{1.8}$
(*Courtesy of CERN, Lyon*)

Observing that picture, and concerning of crystalline structure for Th_x $DUO_{1.8}$ material for it's crystalline structure reliable value, there is a few points for analyzing that phenomena such as:

a. The Compton's displacement wave length has very smooth waving on top side, it means for 0.811752 / 10^{-3} amu magneton's nucleus, the phonon-electron cloud together with Fermi-Dirac state and neither of one pieces of thermal neutron could be breaking the barrier on 10^3 nm depth area.

b. At adjusted power 45.7 MW and 2.1 x 10^5 currie/mm luminosity of thermal neutron, the interstellar of this material able to conduct of quantum semi-relativistic electrical charge, the amount is 7.8114/eV. It can be calculated by Equations (2.45) and (2.47) in group-theory, but with quantum coupling rotation for magnetic-rotate has shown by

$$P^2 = J(J+1)\hbar^2;$$

requirement : **J** = 0,1,2,… (23)

$$P_Z^2 = M^2\hbar^2 \quad ; \text{requirement:}$$

M = 0, ±1, ±2, …**J** (24)

$$P_k^2 = K^2\hbar^2 \quad \textbf{;} \text{ requirement:}$$

K = 0, ±1, ±2, …**J** (25)

$$E_{FD} = J(J+1)\frac{\hbar^2}{8\pi^2 I_{FD}} + K^2\left(\frac{1}{I_F} - \frac{1}{I_D}\right)\frac{\hbar^2}{8\pi^2} \quad (26)$$

c. At bottom side it looks that the electron-neutron cloud in active reaction, then the electrical charge line could be an ensemble together with notation C ; which one of parity coefficient is up arrow, there is possibility to grew up much more interstellar neighboring as far as 0.001127 x 10^{-10} meter, and fixed on Einstein-Sommerfeld predictable.

d. For magnetic field has reached 450 tesla, the value for quantum magnetic-spin of Th_x $DUO_{1.8}$ is 7.8114/eV thereby the resonance of spin-rotate has matched with formulation and more completed in quantum states. Additional result, after testing Th_x DUO_{2-x} derivative, there is tabulation to indicate that the Th_x $DUO_{1.8}$ has bigger value than another derivative themselves.

Table 1 : The properties of quantum magnetic field states

Materials	Quantum magnetic-spin value	Quantum states
Th_x $DUO_{1.7}$	7.1006/eV	$C^F_{kij\uparrow}; E_{(FD,J)}$
Th_x $DUO_{1.8}$	7.8114/eV	$C^F_{kij\uparrow}; E_{(FD,P,J)}$
Th_x $DUO_{1.9}$	7.7221/eV	$C^F_{kij\uparrow}; E_{(FD,J)}$

Source: Experimental test at 1.0 μ m Fermi-Dirac area (*Courtesy of Betha Group LHC, CERN, Lyon*)

According of quantum magnetic-spin and magnetic-resonance which are expressed by Equations (11) until (22) that was describing about how strongest impact from thermal neutron bombarding to Fermi-Dirac interstellar area wide. However, the wide is 0.001127 x 10^{-10} meters having magnetic field deflection on resonance of spin-rotate around 6772.55 cm per each Fermi's cloud active reaction. This matter in 500 MHz up to 550 MHz magnetic-spin frequency with Na_2SO_3 liquid moderator's water cooling at reactor chamber. For show up the impact and existing of Fermi-Dirac's surface effect caused by Anderson's tunnel for floating of thermal neutron electrical charge in quantum magnetic-spin also resonance, it has figure out from Gell-Mann spectroscopy and ESCA-N devices below

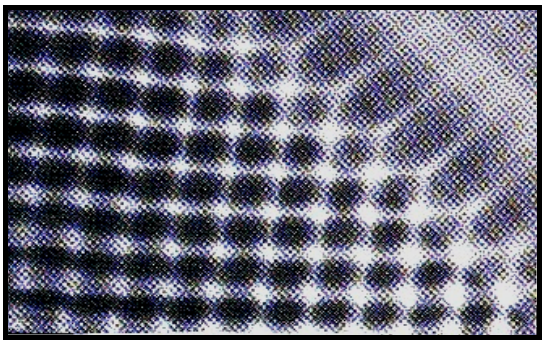

Figure 5 – Flux of thermal neutron effect cross-section caused by Fermi-Hall state at 2.1 x 10^5 currie/mm on 450 tesla in critical phase based on Th_x $DUO_{1.8}$ in 45.7 MW (*Courtesy of CERN, Lyon*)

Based on the resonance of magnetic-spin and is rotate. Then using a few formulation will be found the joining between Coulomb nuclear force with Bohr's centripetal force in relativistic quantum area, which is 2.1 x 10^4 currie/mm thermal neutron flux absorption for minimal condition in reactor chamber, the value of *n*-th stage begin from 1 up 2 according the Fermi's interference condition. Based on the formulation for Fermi-Dirac's active cloud in coherent Compton's wave length, will be adjoined of critical modulation phonon's vibration and Cooper's pair cloud, there was written by $\varpi = \exp(-i\vec{p} \bullet \left[\vec{r}\, x\, \hbar\right])$ (27)

If using the Einstein-Sommerfeld deflection requirement for the thermal neutron flux from Compton's nuclear wave length after first chain ordered reaction, could be wrote by

$$\oiiint_J \vec{p}\, x\hbar\, x\left[-\vec{i}\, x\left\{\vec{j}\, x\hbar\right\} dr\, dl\, dS\right] \bullet \oiiint_p \Phi < \xi_F > \quad (28)$$

Through by Anderson's tunnel field could be found of fluxoid value with Einstein-Sommerfeld deflection effect of mesonic in positive charge and lambda point in magnetic field, bring the Equations (18) until (27) in simple value, written by

$$\Phi = \frac{2\pi\ \hbar\ c\ S_{II}}{q^{\pm}_{\uparrow}} \quad (29)$$

$$\Phi^{\pm}_{\uparrow\downarrow} = \vec{\Phi}_0 \bullet S_{II} \quad (30)$$

When the value is 2.0678 x 10^{-7} gauss cm^2 and was called the earlier fluxoid reaction in quantum magnetic-spin and magnetic-rotate just like the Figure 5 especially in bottom plane.

In a few Equations (27) until (30) have shown Ae^{ik_0x} represents the wave traveling along the *x*-axis with amplitude A and Be^{-ik_0x} represents the reflected Compton's wave along negative *x*-axis with amplitude B for quantum resonance state.

4. CONCLUSIONS

Investigations and research using by Juergen Model programming also Super Muon-Magnetic equipment based on Th_x $DUO_{1.8}$ material for control rod blade nuclear reactor 45.7 megawatts have a few result, expressed:

a. The strength of thermal neutron flux absorbed is 2.1 x 10^5 – 1.9 x 10^6 currie/mm.
b. The values of Electrical Conductivity (EC) about 26.62 – 29.98 in 800º - 890º C temperature for IAEA standard. At thermal neutron flux amount 2.1 x 10^5 currie/mm then the value of EC is 29.44 – 37.98 in IAEA standard. For magnetic field has reached 450 tesla, the value for quantum magnetic-spin is 7.8114/eV and Anderson's tunnel between interstellar area around 0.001127 x 10^{-10} meters, then the thermal neutron electrical charge could be flowing smoothly.
c. For magnetic field is 450 tesla and thermal neutron absorption exactly 2.1 x 10^5 currie/mm, the crystallization structure reduction is 6.88% - 10.95% for 25 years period in 45.7 megawatts.

ABSTRACT

Prior Austenite is an important phase in high strength low alloy (HSLA) steel , before it being transformed by cooling to room temperature from austenite temperature of reheating process. in Thermo Mechanical Control Process.(TMCP) . However, the observation of prior austenites is limited due to the difficulty to find an appropriate etchant solution. The present study is aimed at overcoming this problem therefore the behavior of the austenite grain during hot working, can be monitored.
In this experiment, a single composition of HSLA-0.037Nb with 0.048%C, was heated to various austenization temperatures of 1000, 1100, 1200 and 1300°C, fast cooling by water quenching. .Metallography. examination were performed using five different composition of picric acid , aquadest or Alcohol, $CuCl_2$, HCl and wetting agents .
Visual observation shows that the higher the reheating temperature, prior austenite grain boundaries can be observed more clearly as can be observed in samples reheated to 1300°C for all etchant solution composition and techniques .
The most optimum etchant solution for revealing prior austenite grain boundary for this type of steel is supersaturated picric acid solution in alcohol, with small amount of HCl and modified with additional of small amount of Dodecylbenzenesulfonat (DBS) as the wetting agent . More over, additional of Dodecylbenzenesulfonat (DBS) makes picric acid solution works better significantly.

1. INTRODUCTION

High Strength Low Alloy Steel (HSLA) or Microalloy Steel with small amount of Nb,V or Ti has high structural Strength, with minimum tensile strength of 350 MPa[1,2]. The strength of this kind of steel can be improved by various mechanism such as solid solution strengthening,grain refining, precipitate strengthening and work hardening (dislocation hardening) [2].. The Strength of HSLA steel is affected by the final microstructure and final grain size. For this purpose, Thermo Mechanical Control Process (TMCP) has been applied to control the microstructure and mechanical properties of HSLA Steel

The Interest in controlling the thermomechanical process on the materials mainly has the following reason [3,4];

a. To have the higher quality of product by a precise control process.
b. To reduce the cost production,especially in the development of new production techniques or improvement of existing techniques.

These reason become more important since with increasing demand of metallic products, and energy crisis is increasing worldwide , saving energy during hot forming has attracted to do.
For this purpose, the quantitative metallographic method can be used to calculate the austenite grain size . However, the observation is limited with the difficulty to find an appropriate etchant solution. The present study is aimed at overcoming this problem so that the behavior of the austenite grain during hot working, can be monitored.
Metallography techniques to reveal the prior austenite grain boundaries is unique since the observed austenite structures actually had been transformed to ferrite or martensite. Various prior austenite etching techniques had been applied by some researchers , but those techniques applied to HSLA with higher Carbon content and only at a certain reheating temperature[5,6] . The present study focuses on the effect of reheating temperature of steel and composition of etchant solution to the metallographic quality of prior austenite of HSLA-Nb.

2. EXPERIMENT

In this experiment, a single composition of HSLA-0.037Nb with 0.048%C, was heated to various austenization temperatures of 1000, 1100, 1200 and 1300°C, holding for 30 minutes in the Muffle Furnace with heating capability up to1600°C,follows with fast cooling using cold water quenching .Metallography examination wew performed using five different composition of picric acid , aquadest or Alcohol, $CuCl_2$, HCl and wetting agents .

The composition of HSLA Steel is as follows;

Table 1. HSLA Steel observed in research (wt%)

Ti	C	Si	Mn	P	S	Al
0,002	0,048	0,266	0,706	0,01	0,007	0,037
Cu	*Nb*	**V**	**Ni**	**Cr**	**N**	**Cu+Cr+Ni**
0,052	0,037	0,003	0,022	0,018	0,004	0,092

The material is HSLA steel slab**,** with dimension of working samples are cubes with axes of 1 cm as follows;

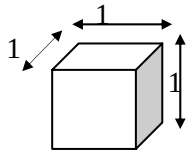

Figure 1. Working samples dimension

After heating and quenching process with cold water (0^oC), metallographic sample preparation starts with grinding,polishing and etching. Fast cooling from austenization temperature is to have martensite microstructure which according to some literatures , will makes easier to reveal the prior austenites grain boundaries. Etching solution and techniques applied in this research are as follows;

•

Etching Solution composition has adopted from previous researchers which had applied to different composition steels [7,8,9,10], while etching time and temperatures applied with trial and error in this observation. One of these techniques also modified with additional of wetting agents like dodecylbenzenesulfonat (DBS)

After etching process, metallographic examination under optical microcope with some magnification has done, and austenite grain boundaries appearance were observed and compared each other.

3. RESULT AND DISCUSSION

Metallography examination with five different etching solution and techniques shows prior austenite appearance as photomicrographs as follows;

3.1 Prior Austenite with various etching techniques of samples with heating temperature of 1000^oC

3.1.1 Saturated Picric Acid 30%

3.3.5. .Saturated Picric acid 10% Etchant solution

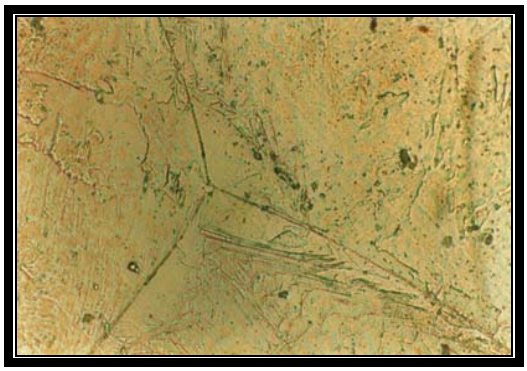

Figure 20. Prior Austenite Grain Boundaries saturated ,picric acid 10%etching, sample no 4,500x Magnification

Photomicrographs aboves, shows that the prior austenite grain boundaries can be revealed by all the etching solutions and techniques observed, but in different qualities.

A very good prior austenite grain boundaries appearance can be obtained by saturated picric acid 30% modified by additional of wetting agent Dodecylbenzenesulfonat(DBS). This etching solution not only reveal the prior austenite grain boundaries , but also the grain structures.Besides this kind of etching, Japanese etching solution also reveal austenite grain boundaries, however It also reveal some phases with brown colours at the grain boundaries of austenites. Super picral solution and its modification can reveal the austenite grain boundaries, although it looks like should be at the longer etching time, as it looks as only thin grain boundary appearance. Saturated picric acid 10% etching solution also reveal thin grain boundaries appearance, as it is difficult to reveal in photomicrograph with low magnification.

These visual observations shows that prior austenite grain boundaries are very sensitive to the etchant solution composition, methods and in the same time also affected by austenization temperature of steel. .

For HSLA-0.037Nb which was previously austenized at 1000 °C, the prior-austenite grain boundaries almost can not be clearly revealed by any etchant solution composition and methods.(figure 2 to figure 5). Almost the same appearance can be observed for samples with

austenizing temperature of 1100°C, which prior austenite revealed with low quality appearance (figure 6-figure 10) With higher austenization temperature, as samples with austenization at 1200°C and in the first place at 1300 °C , austenite grain boundaries become easier to reveal and can be observed clearly (Figure 11-figure 18). This observation also shows that an etching solution consisting of saturated picric acid 30% in alcohol with an additional of small amount of HCl is the most effective etchant solution to reveal the prior austenite grain boundaries in comparison to other combination of etchant solution , at almost all austenizing temperature except at 1000°C. It was also found that a modification on that etching solution with small amount of dodecylbenzenesulfonat (DBS) as the wetting agents , is significantly more effective in revealing the prior-austenite grain boundaries of high metallographic quality

4.CONCLUSIONS

Based on analysis to these photomicrographs aboves, it was found that reheating temperature in Thermo Mechanical Control Process (TMCP) influences the ability of etchant solution in revealing prior austenite grain boundaries. The higher the reheating temperature, prior austenite grain boundaries can be observed more clearly as can be observed in samples reheated to 1300°C.

The most optimum etchant solution for revealing prior austenite grain boundary for this type of steel is supersaturated picric acid 30% solution in alcohol, with small amount of HCl and modified with additional of small amount of Dodecylbenzenesulfonat (DBS) as the wetting agent . Additional of Dodecylbenzenesulfonat (DBS) makes picric acid solution works better significantly.

ABSTRACT

Carbon can be used in many applications for example: as electrode of energy device, conductive material, reinforced plastics, as well as structural composites. Natural carbon can be in the form of the diamond, graphite, or coal with possessed the different carbon rate. The aim of this research is to analyze and produce carbon by High Rise Combustion of Palm Fibre. This carbon will be used for electrode of energy device. Carbon has been processed by using high rise warm-up technique. The carbon produced then analysis using EDS and SEM techniques to observe the element content and morphology of carbon as well as the diameter. Results showed that after obstetrical warm-up of carbon element gyrate contain of 32% - 57%. While in the form of good hollow tube before and after warm-up, the diameter of carbon was approximately 2μm - 8μm, and there were a hole at the tube wall with the size of 1μm - 2μm. Based on the specification of the carbon analysis currently was probably matched as a carbon to be used for an electrode materials conducting gas.

Key words: *carbon, pyrolysis, palm fibre, fixed carbon*

1. INTRODUCTION

Carbon is an element that resides in several polymorphic forms, thus, it can be in an amorphous form [1]. Carbon is not always in one certain group, it can be in a metal, ceramic, polymer. Several types of carbon: charcoal, active carbon, graphite and diamond. A carbon element can be found anywhere, in solid matter (human being, animals, plants), liquid (alcohol), gas (methane) and its existence is in a connection, forming a compound, such as hydrocarbon. Carbon can occur from a result of a decomposition process. The public better knows it as charcoal. Charcoal or active charcoal usually occurs as it is deliberately made, whereas coal and diamond is naturally formed in the nature. A natural fiber consists of several compounds, including cellulose, lignin and hemicelluloses. These compounds contain an element of carbon that can be decomposition by a certain process of heating, thus it can produce charcoal of approximately 35% with a porosity of 70%, whose carbon content is approximately 80 to 90% [2].

Technological development enables carbon to be applied for various types of needs, among others, hydrogen storage, biomedical, medical treatment for broken bones [3], super-capacitor, textile industries [4], conductive or reinforced plastics [5], energy storage, conductive adhesives and connectors, molecular electronics, thermal materials, structural composites (aircraft, spacecraft, and suspension bridges), catalyst supports, air, water and gas filtration, reinforced tennis rackets, baseball bats, field emission, field-effect transistors, fibers and fabrics [6], batteries and fuel cell.

Carbon, when it is used a fuel cell PEM electrode component, resembles a "frame", forming porous or hollow sheets or plates or composite sheets/plates that are arranged from a line of carbon in a solid cylinder or tube. Pores are needed in fuel cell electrodes to conduct and distribute gas fuel in all electrolyte surfaces, Figure 1 [7]. Various forms of carbon as “frames” of this PEMFC electrode can be made using a chemical vapor deposition (CVD) method [8, 9, 10], laser ablation, arch method, ball milling, plasma-enhanced chemical vapor deposition [11], usually from powder of pure carbon materials.

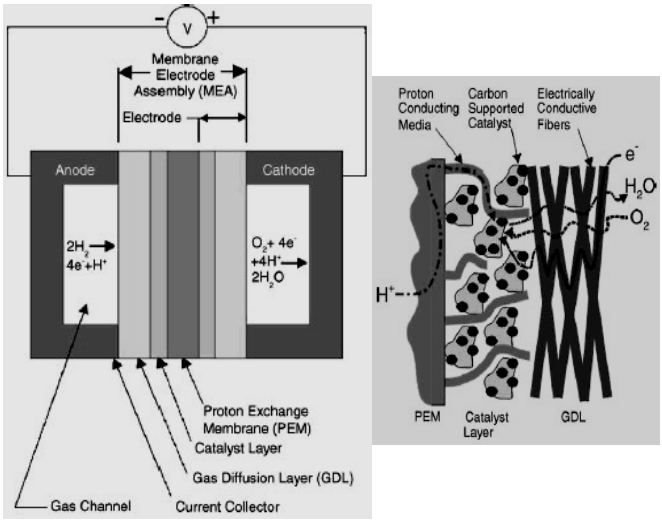

Figure 1: Electrode frame that has a function to conduct and distribute gas

In this research carbon is made from palm fibers through a process of carbonization or pyrolysis. As natural fibers contain several compound (including lignin, cellulose and hemicelluloses) whose existence may form a line along its stem, the leveled heating it is estimated or expected to be in a

form of "carbon wire" or "carbon tube." The use of carbon in this form in the creation of electrode sheets is estimated to form a frame or texture that has large porosity and is evenly distributed, of which it is a requirement as a PEMFC electrode.

2. EXPERIMENT

The basic material for the carbon making is palm fibers. Before being processed, palm fibers as natural materials, an thermal analysis is carried out in a room with a temperature of up to 900^0 using DTA-TG to find out at what temperature and what reaction that occurs, and to find out the percentage of weight loss due to the heating.

Carbon is made of palm fibers using a heating method in limited air (pyrolysis) in the temperature of 275^0 for 2 hours. The carbon content of the charcoal that occurs is analyzed using a fixed carbon method (ASTM D 1762-64) and EDX, and a microstructure is observed using SEM and XRD. Heating is continued in the temperature of 500^0 for 1 hour, and the same analysis is carried out.

3. RESULT AND DISCUSSION

A DTA TG analysis result on palm fibers with a temperature of up to 900^0C can be seen in Figure 2, showing there are 2 large peaks of an exothermic reaction in the temperature of between 272^0C - 324^0C and between 399^0C - 530^0C with a weight loss of 45% and it drops to 75%. According to Euro Sjostrom [12] in a range of the first peak of hemicelluloses and cellulose, this is degraded in the range of the second peak of degraded lignin. Heating of between these temperatures, natural materials are disentangled gradually, producing a large number of distillates, especially acid acetate and methanol, and then a number of tar and gas products.

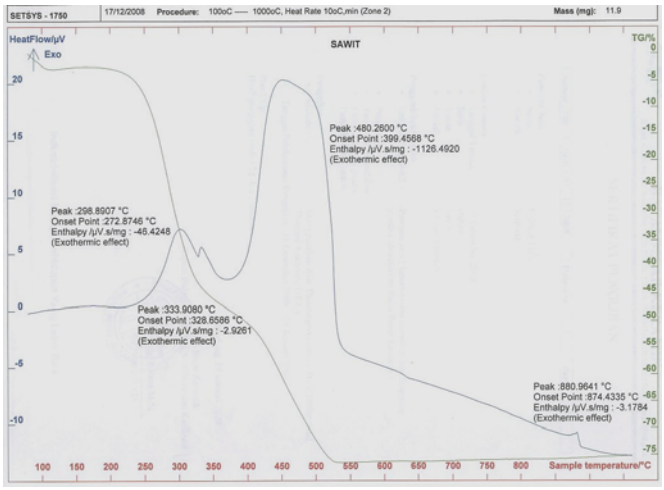

Figure 2: A curve of palm fiber DTA-TG analysis is carried out on a room temperature of 900^0C.

A result of a microstructure analysis suing XRD is shown in Figure 3, showing that charcoal, which is made, has an amorphous structure, and sharp peaks can be seen and they are most likely minerals or compounds that are contained in the palm fibers. The compounds are natural compounds in natural materials, thus it is difficult to be removed although they are heated up to 900^0C. The diffraction curve, which forms a hill or hillock, shows that the structure of the materials is amorphous. The 2θ position of the peak of the hill or hillock (amorphous structure) is nearly the same with the 2θ position of the graphite crystal structure in accordance with the XRD analysis of the graphite materials (Figure 4). This indicates that charcoal that is made dominantly contains an element of C and has an amorphous carbon structure.

Figure 3: Photos of the palm fiber basic material (left), after being carbonized (right).

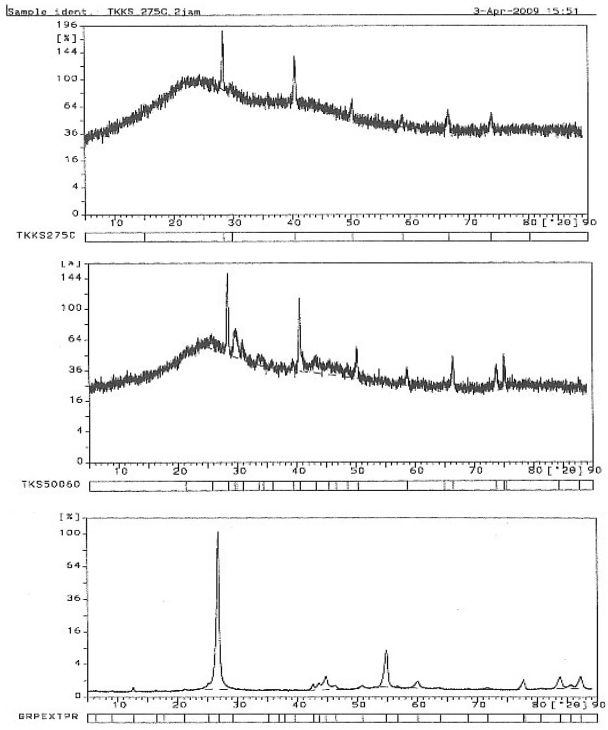

Figure 4: Diffraction curve and data on a palm fiber sample that has been heated (in limited air) at the temperature of 275^0 for 2 hours (above) 500^0 for 1 hour (middle), and pure graphite materials (below).

Palm fibers and charcoal of a leveled heating result with limited air are shown in the Figure 5. This charcoal of the heating result is observed using SEM and it shows that diameters of the palm fiber charcoal vary between 100μm and1000μm. A morphology from the palm fiber charcoal shows that there are hollows in the form of alleys or tubes, which are parallel with the fibers with various diameters of hollows or tubes, between 2μm - 8μm, and at alley wall there are hole with the diameter about 1μm - 2μm. Morphology and a lot of pores in this charcoal/carbon are very attractive, it can be likely applied for a basic material of electrode in PEMFC.

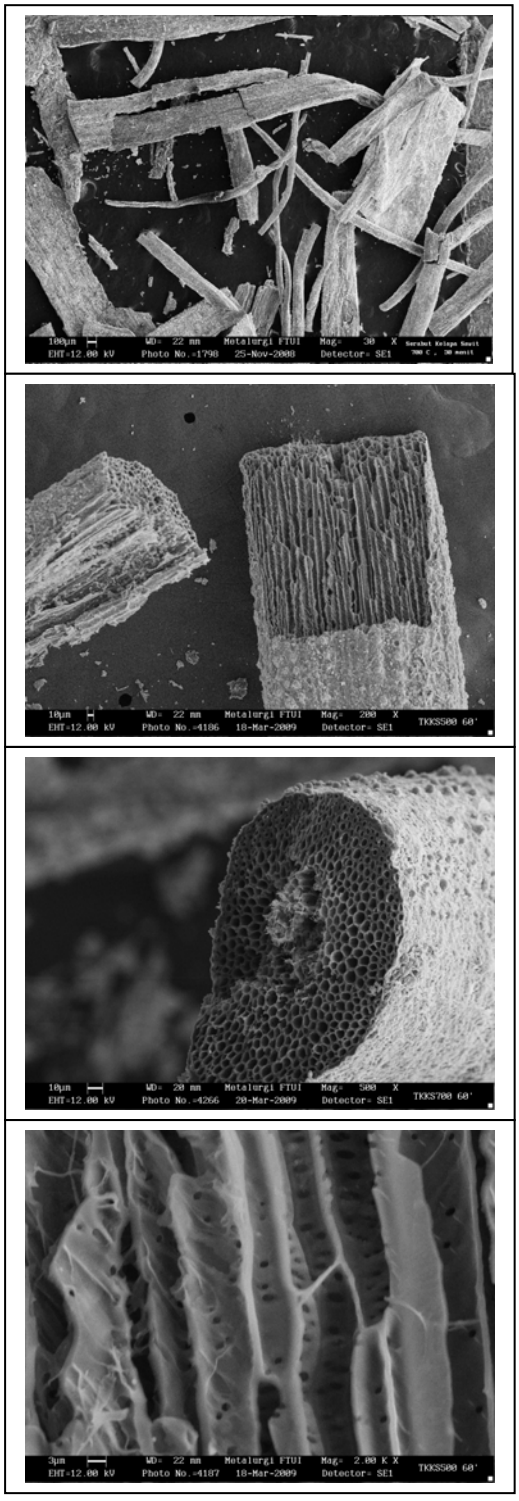

Figure 5: SEM observation result on palm fibers that have been heated , Enlargement of 30X, 200X, 500X, 2000X (from top to downwards)

An ash analysis result of palm fiber charcoal, which has been heated with a temperature of 500^0 for 1 hour, shows that its carbon content is between 56.4% - 58.6%, the average is 57%. The rest is in accordance with a qualitative and quantitative analysis result using EDX, showing there are several compounds that are contained in the palm fiber

charcoal such as K_2O, CaO, SiO_2, MgO, ZnO and other. Table 1 shows a comparison of the total weight percentage (Wt%), which is detected for carbon from materials that are heated with a temperature of 275^0C, having an average C content of 47%, and Table 2 for carbon from materials that are heated at the temperature of 500^0, having an average C content of 32%. As a comparison, pure graphite is analyzed using the same equipments EDX, and data of the analysis result in the Table 3 shows that graphite has an average C content of 91%.

IV. CONCLUSION

Charcoal that is made from palm fibers forms an amorphous carbonic structure, and the diameters of the palm fiber charcoal vary between 100µm - 1000µm. The morphology of the carbon/charcoal from palm fibers is in a form of alleys, which are parallel with the stem of the palm fibers, with diameters of between 2µm - 8µm, and the wall of the alleys has holes of between 1µm - 2µm in diameter. The carbon content in the charcoal, which is made from palm fiber is 32% - 57%.

DEVELOPMENT AND CHARACTERIZATION OF MAGNETIC MATERIAL BARIUM HEXAFERRITE FOR MICROWAVE ABSORPTION

Priyono and Azwar Manaf
Material Science Study Program PPS - FMIPA University of Indonesia
Kampus UI, Jl. Salemba Raya No. 4, Jakarta, Indonesia

Abstract

Ferrite is widely known as a material which is used as hard magnet and soft magnetic materials and for various applications such for magnetic data storage, computer, radio wave tools, television and microwave. In addition, ferrite is also used as electromagnetic impedance (EMI) particularly for the ultra high frequency. This research develops Type-M hexaferrite as an absorbing material through nanostructure engineering by the method of mechanical milling route. The formation of phase $BaFe_{12-2x}(MnTi)_xO_{19}$ (x varies from 0.0 to 2.5) is through a two-stage mechanism which starts with the formation of $(Fe,Mn,Ti)_2O_3$. The synthetic result is tested by X-ray Diffraction and TEM to determine its structure and formation phase. Meanwhile, the magnetic characteristic is tested by permeagraph in saturating field of up to 2.15 Tesla. Network Analyzer (1 GHz to 6 GHz) is used to compute the reflection and transmission coefficients as well as reflection loss in that range of frequency. Formation through a two-stage mechanism occurs perfectly at the temperature of 1200 C. The Synthetic result shows that the partial substitution of Fe^{+3} ions with Mn^{+2} ions and Ti^{+4} influences the change

in the lattice parameter from c = 23.2093 nm to c =22.8146 nm, meanwhile the value of a tends to be constant. The research result shows that there is a change in magnetic properties particularly coercivity which significantly decreases as the number of Mn^{+2} and Ti^{+4} ions increase. Besides, there is a shift in resonance microwave absorption in the frequency range 1 GHz to ~ 4Ghz and it is characterized as multiband.

Keywords*: M-Type Barium Hexaferrite, Substitution, Microwave Absorption*

1. Introduction

The development of high frequency microwaves experiences an expository growth particularly the one which applies wireless technology. The development of electronics and electronic devices with high frequency application should always be accompanied with technology of electromagnetic absorption. To remove the bias field which normally occurs in various electronic tools, in a relatively low frequency it can be done by placing a ferromagnetic metal which can reduce the low frequency electromagnetic interference (EMI); however, it cannot be used for very high frequency such as application microwave and ferrite material becomes one alternative to reduce it. Although various ferrite materials are known as permanent magnet, ferrite is also used as a soft magnet such as in high frequency transformers, circulators, isolators, tunable filters and phase shifters, antenna and radar absorbing material (RAM) and stealth material, [1][2]

Spinnel Mn-Zn ferrite magnet is frequently used for application in microwave with lower frequency and Garnet is used for applications with higher frequency [3], meanwhile Hexagonal magnet class is mostly promoted for even higher frequency. Hexaferrite structure has six classes

which are distinguished on the basis of their chemical composition and structure. Type Y and Type Z are often utilized for applications with high frequency, yet only few research has used Type M because Type M has a higher crystal anisotropy which is more suitable for permanent magnet. Research on single crystal by Karim et all [4] shows that the resonance frequency of $BaFe_{12}O_{19}$ takes places in the frequency range of ~ 42 GHz. Thus, substitution of Fe^{+3} ion with various transitional metals can reduce the magnetocrystaline anisotropy[5][6].

Addition of a small number of additive ions from other transitional metals can significantly change magnetic properties such permeability, magnetic saturation, remanence, magnetic cooercivity, as well as the Curie temperature.

2. EXPERIMENTAL PROCEDURE

Barium ferrite which is substituted by Mn^{+2} ions and Ti^{+4} ions is synthesized through two mechanisms. The first mechanism begins with the formation of $(Fe,Mn,Ti)_2O_3$ by using the components forming $MnCO_3$ and TiO_2 as well as Fe_2O_3 in the heat of 1300 C and the next stage is the formation of $BaFe_{12-2x}Mn_xTi_xO_{19}$. The two stages are conducted by using mechanical alloying method.

The study on the formation of $BaFe_{12-2x}Mn_xTi_xO_{19}$ is conducted by heating it in various temperatures from 850 C to 1200 C at the pressure of 1 atm. The phase formation result is analyzed using XRD C_0 K_α (PW-1830 Philips Netherlands) at the angle of $2\Theta = 20^0$ to 80^0 with the step width of 0.02^0. Magnetic properties are analyzed using Permeagraph in the external field up to 2.15 Tesla. Nanostructure material is conducted by using Transmission Electron Microscope (TEM) which is equipped with electron diffraction tool, whereas the transmission and reflection of electromagnet waves is examined by using Network Analyzer (HP8735ES) at the frequency range of 1 GHz to 6 GHz.

3. RESULTS AND DISCUSSIONS

The substitution using Mn^{+2} ions and Ti^{+4} ions in Fe_2O_3 uses the oxide components of Fe_2O_3, TiO_2 and $MnCO_3$ in various temperatures have been conducted and analyzed deeply and the result shows that the optimum temperature in which the substitution takes place is at 1300 C[7].

3.1 Structural Analysis

Ionic substitution process may occur when the balance of ions can be achieved. Ion balancing process is achieved when the number of Fe^{+3} ions are substituted by the same number of ions and those ions are from Mn^{+2} and T^{+4}. As a result, the substation process is likely to occur to 2 Fe^{+3} ions which are substituted by one Mn^{+2} ion and one Ti^{+4} ion. It has been proved previously that if the number of fractions of Mn^{+2} ions exceeds the number of fractions of Ti^{+4} ion atoms there will be formed two $(Fe,Mn,Ti)_2O_3$ and $MnFe_2O_4$ and if the number of fractions of Mn^{+2} atoms is fewer than the fraction of Ti^{+4} atom ions, $(Fe,Mn,Ti)_2O_3$ and Fe_2TiO_5 are formed. This condition may be maintained until the number of Fe^{+3} ions which are substituted reach 21.8% of the atoms [8].

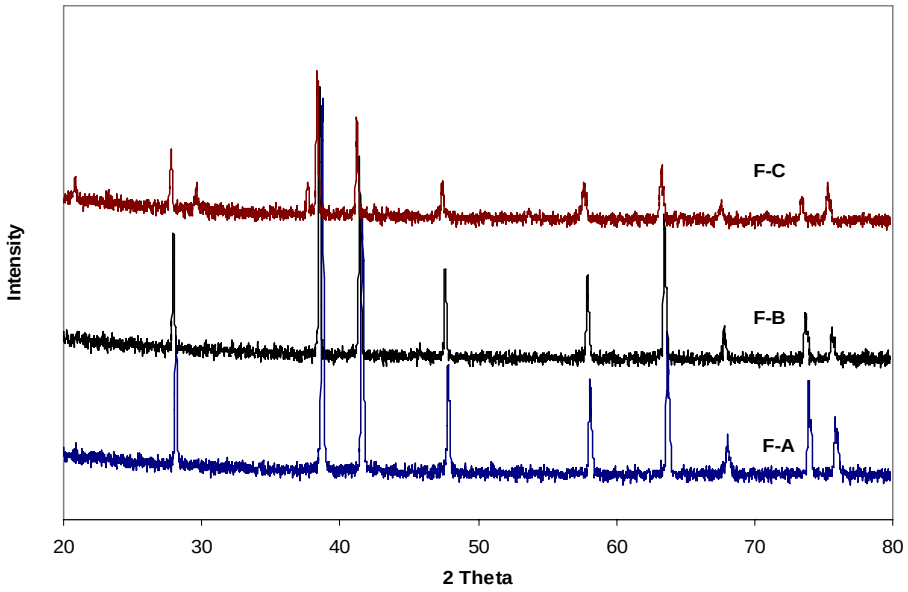

Figure 1 Diffraction pattern of substitution of Mn ions and Ti ions in phase Fe_2O_3. F-A represents Fe_2O_3, F-B represents $Fe_{1.5}Mn_{0.25}Ti_{0.25}O_3$ and F-C represents $Fe_{1.10}Mn_{0.45}Ti_{0.45}O_3$ with the heating of 1300 C for 4 hours.

Figure 1 shows the result of partial substitution of Mn ions and Ti ions for the formation of $Fe_{1.5}Mn_{0.25}Ti_{0.25}O_3$ and $Fe_{1.25}Mn_{0.325}Ti_{0.325}O_3$ and Fe_2O_3. Fe^{+3} ions which are partially substituted by Mn^{+2} ions and Ti^{+4} ions, Mn^{+2} ions on the subskin of $3d^5$ more prefers to substitute in the spin down position of Fe^{+3} ion in the subskin of 3d0, meanwhile Ti^{+4} ion in the subskin of $3d^0$ will substitute the position of Fe^{+3} in its spin up position. The difference of position of ions partially substituting Fe ions will have an impact on the lattice parameter in the previous condition[9].

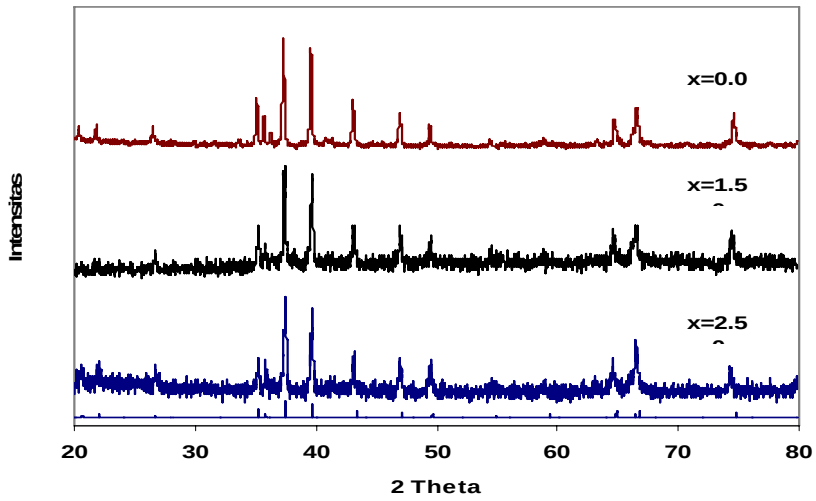

Figure 2 and X-Ray powder difraction patterns of $BaFe_{12-2x}Mn_xTi_xO_{19}$ (x=0.0 and 1.5 as well as 2.5) in 1200 C

ISSN 114-1284

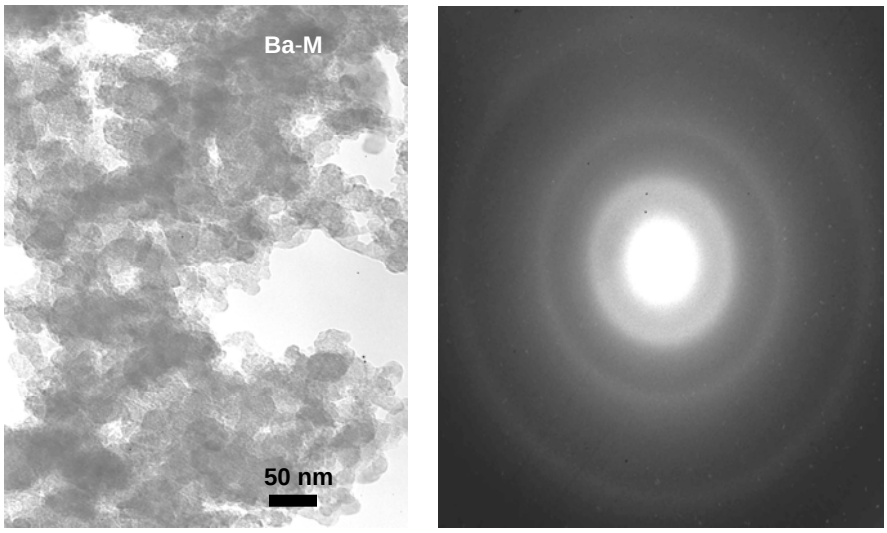

Figure 3. Braigh fild image and Selected Area Electron Difraction (SAED) of TEM $BaFe_{12-2x}Mn_xTi_xO_{19}$ (x = 1.5) in 1200 C

Figure 2 shows the diffraction pattern of compound $BaFe_{12-2x}Mn_xTi_xO_{19}$ for various composition of x =0.0 and 1.5 as well as 2.5. Generally, the three substitute compounds have the same diffraction pattern as the diffraction pattern of compound BaO.6 (Fe_2O_3), which is a single phase with magnetoplumbit structure. The presence of the substitute ion only results in a change in the intensity pattern. This result indicates that the formation of temperature of barium ferrite formation can be done in the temperature of 1200 C. Whereas according to Ghasemi[10] formation through composing compounds directly can only take place if the temperature is above 1250 C. The difference in the formation temperature is likely to be caused by the difference in the methodology used. In the first method, the substitution is conducted first while in the second method the substitution is conducted simultaneously. Using the first method, the growth of the size of crystal particle can be slowed down to the size of nanocrystal. The photo result of TEM shows that using the first method, the size of crystal particle is smaller than 50 nm.

Based on the result of calculation on the change in lattice parameter it is found that the presence of Mn^{+2} ions and Ti^{+4} ions do not significantly change in lattice parameter a = 5.8487 nm, yet the same thing does not happen to value of lattice parameter c = 675,8681 (for x = 0 the result is 5,8862 nm and c = 696,4060 nm[7]. Consequently, the change in the lattice parameter has an impact on the constant value of crystal anisotropy so that the magnetic properties of a material such as coersivity and magnetic saturation will change.

3.2 Magnetic Properties

Hysteresis loop of the magnet sample $BaFe_{12-2x}Mn_xTi_xO_{19}$ in which x = 0, 1.5, and 2.5 is shown in Figure 5. It is obvious that as the number of Mn^{+2} and Ti^{+4} atom fractions increase, the remanence and the saturation magnetization linearly decreases, unlike the decrease in the coercivity value.

ISSN 114-1284

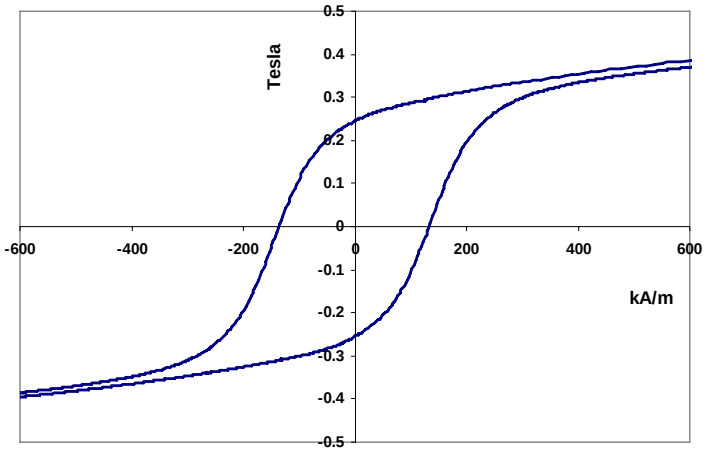

Figure 4. Hysteresis $BaFe_{12-2x}Mn_xTi_xO_{19}$ (x=0.0) with the growth temperature of 1200 C.

Systemically decrease in magnetic properties in the structure of $BaFe_{12-2x}Mn_xTi_xO_{19,}$ which is shown in Figure 5 results from the substitution of Fe^{+3} ions with Mn^{+2} ions and Ti^{+4} ions. Mn^{+2} ions occupy the spin down position of Fe^{+3} ions ($3d^0$) in tetrahedral (4fl), while Ti^{+4} ions position themselves in the position of Fe^{+3} in its octahedral lattice. Since Mn^{+2} is paramagnetic in nature, it is suspected that it may cause the decrease in total magnetic moment which has an impact on the decrease in magnetic properties particularly in its coercivity and magnetic saturation. It also applies on the substitution by Ti^{+4} ions in the oxtahedral position of F_e^{+3} ions. The substitution of Fe ions with Ti and Mn ions which has caused the decrease in the volume of cell units, by referring to the research result by Mones, it can be concluded that the pace of the decrease in the total magnetic moment of the main phase because of substitution of Ti ions is bigger than the pace of the decrease in the volume of cell units so that the total magnetization of the main phase becomes lower.

3. 3 Losses Study in Microwave frequency

Figure 6 shows that reflection coefficient (S_{11}) and transmission coefficient (S_{21}) for x = 1.5 and 2.5 at the frequency range of 1 GHz and 6 GHz. Both values indicate a difference in resonance. Both of the samples are multyband because they have a number of resonance peaks. At the frequency range of 1 GHz and 2 GHz, both samples have relatively similar resonance frequency, meanwhile for x=2.5 there is a shift in frequency, exceeding 4 GHz. The transmission coefficient which is relatively high compared to the transmission coefficient is more likely to be caused by the size of the sample which is quite thick (~12 mm) so that more radiation is absorbed.

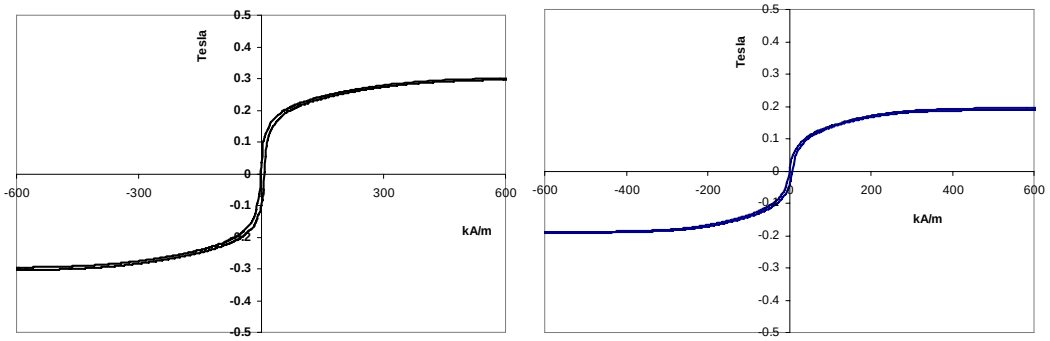

Figure 5 Hysterisis $BaFe_{12-2x}Mn_xTi_xO_{19}$ (x = 1.5 and 2.5) with the growth temperature of 1200 C

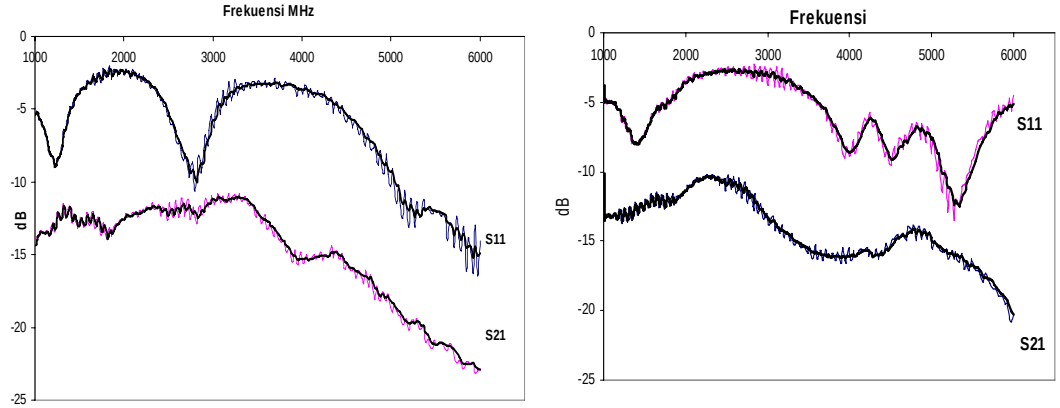

Figure 6 The graph of reflection coefficient (S11) and transmission coefficient (S21). The electromagnetic wave of $BaFe_{12-2x}Mn_xTi_xO_{19}$ ((a) x = 1.5 and (b) x = 2.5)) is measured by Network Analyzer using Coaxial wave guide

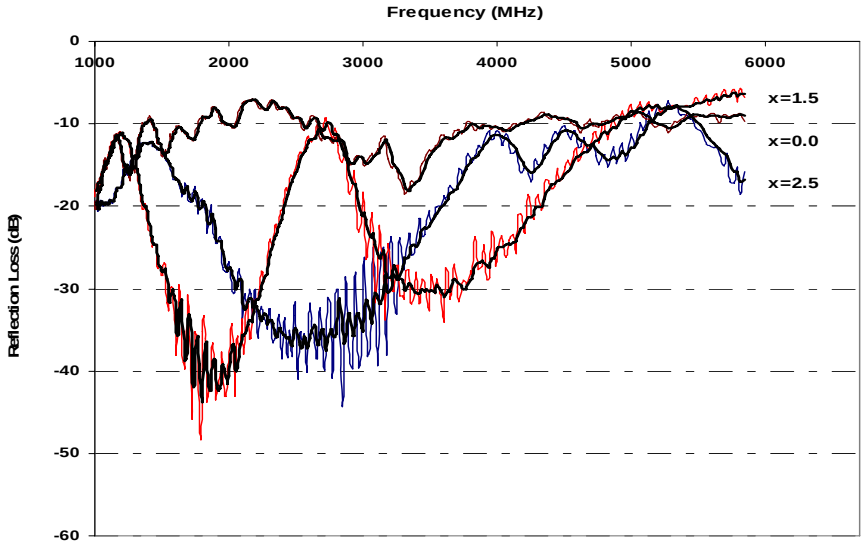

Figure 7 Reflection loss in material $BaFe_{12-2x}Mn_xTi_xO_{19}$ (x=y= 0.5; 1.0 and 1.5) in the thickness of ~ 12 mm

The calculation of reflection loss in total is shown in figure 7. Material which is not substituted has the lowest reflection of the other materials which have been substituted.

Conclusions

Formation of $BaFe_{12-2x}Mn_xTi_xO_{19}$ can be achieved by mechanical integration from the composing components Fe_2O_3, $MnCO_3$ and TiO_2 and $BaCO_3$ which is conducted through two stages of treatment can be perfect in the heating of 1200 ^{0}C. The synthetic result which is preceded with the formation of $(Fe,Mn,Ti)_2O_3$ has a lower temperature formation of $BaFe_{12-2x}Mn_xTi_xO_{19}$ than the temperature in one-stage treatment.

$BaFe_{12-2x}Mn_xTi_xO_{19}$ has a lower volume of unit cells as the number of Mn^{+2} ions and Ti^{+2} ions compared to materials which are not substituted. The decrease in the value of the lattice parameter from c = 23.2093 nm to c = 22.8146 nm with the value of a which is relatively the same can have an impact on a number of properties particularly on the magnetic properties and electromagnetic wave absorption particularly in the microwave frequency.

A change in the lattice parameter is accompanied with the decrease in coercivity and the total magnetization value as well as the shift in the microwave absorption frequency. Microwave absorption in the magnetic material barium ferrite which is substituted by Mn ions and Ti ions in the range of 1 GHz and 6 GHz is multiband and occurs in the range of 1 GHz to 4 GHz.

Development of Pt-Ni/C Alloy Nanocatalysts For The Proton Exchange Membrane Fuel Cell

Rusnaeni N.[1], Hendrajaya L.[2], Purwanto W.W.[3] and Nasikin M.[3]
[1] Indonesia Institute of Sciences
[2] Institute of Technology Bandung
[3] University of Indonesia

ABSTRACT

Pt-Ni/C alloy nanocatalysts synthesized by polyol method with atomic ratio, are investigated to find the origin of the enhanced activity of the oxygen reduction reaction (ORR) for fuel cell applications. Prepared catalysts are characterized by various techniques, such as X-ray diffraction (XRD), Scanning Electron Microscopy (SEM-EDX), and cyclic voltammetry (CV). XRD analysis shows that all prepared catalysts with different atomic ratio exhibit face centered cubic and have smaller lattice parameters than pure Pt catalyst. The mean particle size of the catalysts are between 4.3 to 6.3 nm. Electrochemical experiments using CV, are conducted to test the ORR activity of the Pt-Ni/C catalysts. Cyclic voltammograms (5 mV s^{-1}) at 25°C obtain the electrochemical active area and activity of electrocatalysts Pt-Ni/C in the potential range 900 mV versus RHE.

Keywords : *alloy catalyst; oxygen reduction reaction (ORR); fuel cell*

1. INTRODUCTION

Fuel cells are becoming a subject of intense applied research for portable, stationary and electric vehicle applications due to their high conversion efficiencies, high power density and low pollution. Among the various types of fuel cell, the proton exchange membrane fuel cells (PEMFC) are attractive power sources and the most suitable candidates for electric vehicles and residential applications as they can be operated at a low temperature of <100°C. Platinum supported on a carbon is widely used as the electrocatalyst in PEMFC. However, platinum is expensive and the world's supply of Pt is limited and to promote alternatives for reducing the use of Pt.

Therefore, how to improve the electrocatalytic activity is a very important issue [1,2,3]. The search for oxygen reduction reaction (ORR) catalysts that are more active, less expensive and with greater stability than Pt has resulted in the development of Pt based transition metal alloys [4, 5]. Some platinum-based binary alloys have the best prospect for use as a cathode catalyst such as PtCr, PtZr, PtTi exhibit a higher catalytic activity for ORR in pure acid electrolytes than pure platinum [3]. Although for improved performance from the Pt-based metal alloys, it is necessary to taylor the electrocatalyst layer to achieve the optimum Membrane Electrode Assembly water balance under the selected PEMFC operating conditions. Such alloy catalysts could improve the activity toward oxygen

ISSN 114-1284

reduction by a direct four-electrons reaction without involving the intermediate hydrogen peroxide step. The mechanisms for the enhanced activity of platinum alloy catalysts toward oxygen reduction have been studied extensively in recent years [4]. Mukerjee S. have explained the improvement in the PtCo catalytic activity based on an increase in the d-orbital vacancy promoting a stronger metal-oxygen interaction, particle size, and the inhibition of formation of Pt-OH at potentials above 800 mV vs RHE [5]. The stronger Pt-O_2 bond can cause a weakening and lengthening of the O-O bond and an easier scission of the O-O bond resulting in an increase in the reaction rate. But the other side, an increase the d-band vacancy in Pt makes it difficult to loose an electron for oxygen reduction. The enhanced electrocatalytic activity of the PtCr, PtCo, PtCu and PtNi can be explained by an electronic factor, i.e. the change of the d-band vacancy in Pt upon alloying and/or by geometric effects (Pt coordination number and based on the decrease in the Pt-Pt distance) [6].

In the present research, we use transition metal nickel, which has received little attention, to synthesize the Pt alloying catalyst because nickel has similar atomic radius to Co, Fe or Cu. Ni had been studied for oxygen cathode in anode PEMFC but the critical issues of improving the ORR activity was not analyzed completely. Therefore, we prepare Pt-Ni/XC-72R and characterize by various techniques. X-ray diffraction (XRD) characterization is carried out to determine the mean crystalline size and the lattice parameter of these Pt-Ni/C catalysts. Energy Dispersive X-ray spectroscopy (EDX) is used to investigated the bulk composition. Electrochemical experiments including cyclicvoltammetry (CV), are also conducted to characterize these Pt-Ni/C catalysts, to determine the electrochemical area of the catalysts, and to test the ORR activity of the catalysts.

2. EXPERIMENT

2.1. Preparation of the electrocatalysts

The carbon supported Pt-Ni catalysts are prepared by the Ethylene Glycol Method. H_2PtCl_6 and transition metal precursor solution is mixed well and added to carbon ethylene glycol solution alloy metal loading : 30 wt%, Pt:Ni = 1:1; 3:1; 4:1 in atomic ratio) under mecanically stirred conditions. 2.5M NaOH is added to adjust the pH of the solution to about 10. The temperatur is then increased to 190^{o}C for 2 hour.

2.2. Characterization

All catalysts are characterized by recording their powder XRD pattern on an X-ray diffractometer using CuKα radiation with a Ni filter and step scanning. The tube current is 30 mA and tube voltage is 40 kV. Using XRD we can do qualitative analysis. The Pt diffraction peaks are used to calculate the mean size of the Pt particles according to Scherrer's formula.

$$D = 0.9\lambda_{K\alpha 1} / B_{2\theta} \cos\theta$$

D is mean size of Pt particles, λ is the X-ray wavelengh, B is the half-peak width for the peak in radians, θ is the maximum angle of the peak. The metal composition of these PtNi/C catalysts determined by EDX. Electrochemical characterization is performed on a Instruments , in which reference working and counter electrodes are separated, is used for CV measurements. An Ag/AgCl electrode is used for the reference electrode and a platinum wire is used for the counter electrode. The catalysts layer of the working electrode is prepared as follows : a mixture containing PtNi/C catalysts, ethanol and 5 wt% Nafion are ultrasonically blended in a glass vessel for half an hour to obtain a homogeneous ink. The ink is spread on the surface of Carbon electrode and dried in an oven at 80°C for 10 min to obtain a thin active catalytic layer. The electrolyte is 1 M $HClO_4$ solution. CV is obtained after using high purity nitrogen to clean the electrolyte solution for 20 min. The scan rate is 50 mV/s and scan range is from -0.2 to 1.2V (Ag/AgCl). ORR tests are obtained after oxygen bubbling for 20 min. The scan range is from 1.2V to -0.2V (Ag/AgCl)

3. RESULT AND DISCUSSION

The metal bulk composition of these PtNi/C catalysts determined by EDX are shown in Table 1. From this table, the sample 13 can be found to have higher Pt loading than sample 2 and 12. The Pt loading of all samples are lower than the setting value. Figure 1 compare the X-ray diffraction patterns of the Pt/C and PtNi/C catalysts. The diffraction peaks of the PtNi/C alloy catalysts shift to higher angles as compared to that of Pt/C, indicating a lattice contraction arising from the substitution of the smaller Ni atoms for the larger Pt atoms. All the XRD peaks can be indexed as face centered cubic (FCC) structure [7, 8]. The lattice parameters and the mean PtNi/C particle sizes were calculated from Scherrer's formula based on Pt(111) peak and listed in Table 1.

Table 1. Metal composition of Pt-Ni/C

Sample Number	Pt:Ni atomic ratio	Lattice parameters (°A)	Particle size (nm)
Sample 2 Pt : Ni = 1 : 1	23 : 77	3.64	5.7
Sample 13 Pt : Ni = 3 : 1	37 : 63	3.66	6.3
Sample 12 Pt : Ni = 4 : 1	29 : 71	3.81	4.3
Pt/C Commercial	-	3.93	5.9

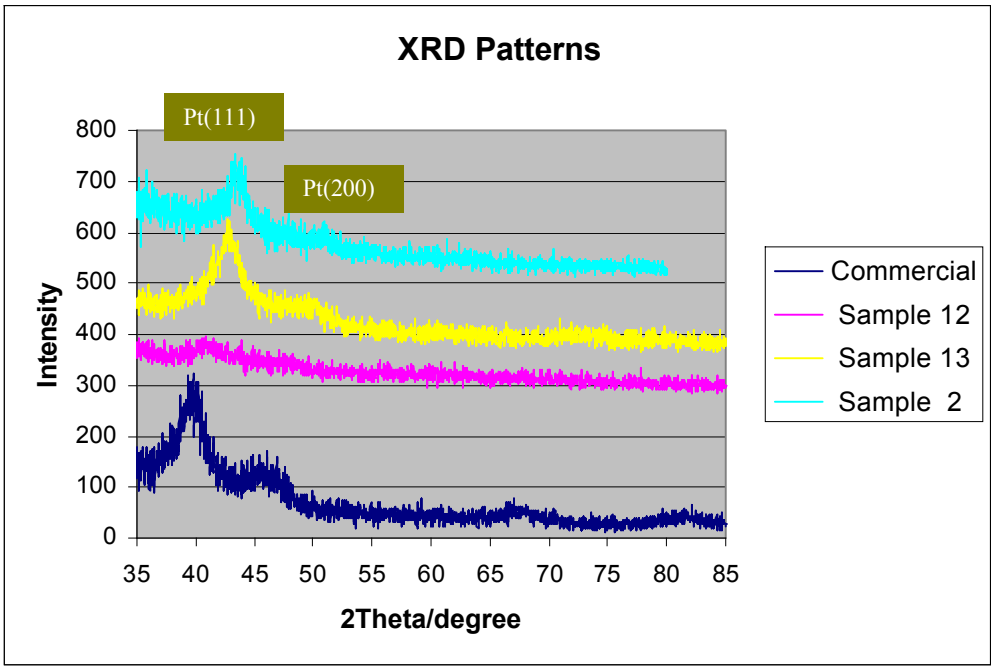

Figure 1 : XRD patterns of Pt/C and Pt-Ni/C prepared by EG method

With the data given in Table 1, the lattice parameter and hence the average Pt-Pt distance is decrease as the ratio atomic Pt is increased. The PtNi system under this composition is known to exhibit a $PtNi_3$ type structures for sample 13 as evident from the phase diagram, an for sample 2 and 12 exhibit a PtNi type structure. The $PtNi_3$ and the PtNi have a cubic structure in which the Pt atoms occupy all corner positions and the Ni atoms occupy all the face centered positions [9, 10, 11]. Because the shoulder around $2\Theta = 71^{o}$ do not appear in the XRD results, we speculate that the Pt-Ni has a disordered phase of face centered cubic structure in which the Pt and Ni atoms are randomly distributed at the corner and face centered positions.

ISSN 114-1284

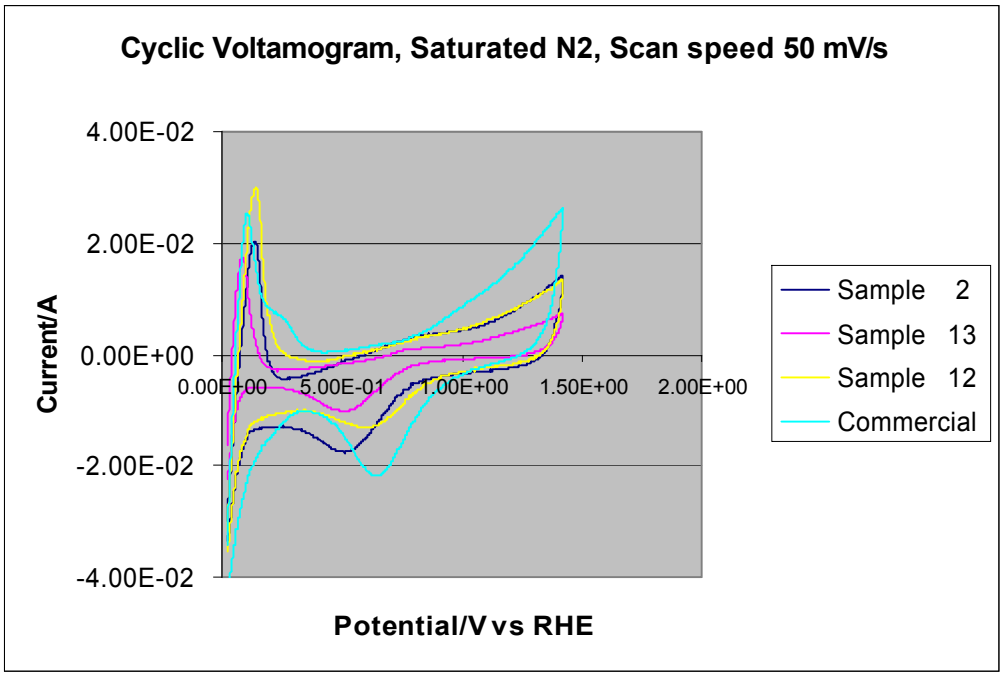

Figure 2 : Cyclic voltammograms for Pt/C commercial and Pt-Ni in 1M $HClO_4$, saturated N_2, The potential scan is 50 mV/s

Figure 2 compare the voltammetric behavior of the sample 2, 13, 12, and commercial. The cyclic voltammetry (CV) tests are performed in 1.0M $HClO_4$. From hydrogen desorption peak areas in yhe CV curve and the Pt single crystalline activity surface area transition constant Q_m = 0.21 mC/cm2Pt, the electrochemical surface area for these catalysts can be calculated. The results are shown in Table 2. Pt/C commercial has the largest surface area. But when the transition metal is added, the surface area becomes smaller. ORR tests are conducted in 1.0M $HClO_4$, which is a weak anion adsorption acid and can be used to evaluate the catalytic activity [12]. There are generally two ways to express the catalytic activity : One is mass activity (MA), which is the current per unit amount of catalyst and MA has practical implications in fuel cells because the cost of the electrode is largely dependent on the amount of platinum used.

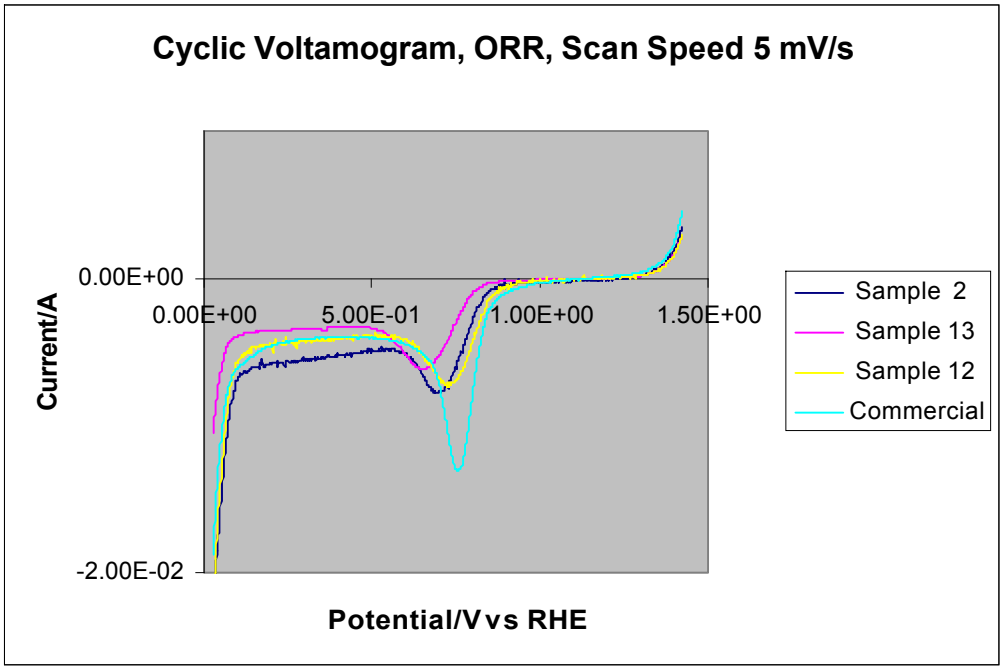

Figure 3 : The polarization curves for ORR on Pt/C commercial and Pt-Ni in 1M $HClO_4$, The potential scan is 5 mV/s

Table 2. Electrochemical characterization for Pt/C and PtNi catalysts, scan speed 5 mV/s

Catalysts	H_2 desorption (Q_H) mC	Ic pd 0,9V mA	Electrochemical Surface area (EAS)(cm^2/mg)	At 900 mV vs RHE)	
				Mass Activity (MA) (mA/mg Pt)	Specific Activity (SA) (mA/cm^2)
Sample 2	2.38	1.01	40.66	3.61	0.09
Sample 13	1.78	0.47	123.38	6.71	0.55
Sample 12	4.1	1.01	164.16	8.42	0.05
Pt/C Commercial	7.4	1.05	160.54	4.77	0.03

The other is specific activity (SA), which is the current per unit surface area of catalyst and the specific activity provides a measure of the electrocatalytic activity of platinum atoms in the particle surface. The MA and SA can be obtained through equation below :

MA (mA/mg) = $i_{0.9V}$ / W, W is the mass of Pt calculated

SA (mA/cm^2) = $i_{0.9V}$ /S, S is the electrochemical surface area

The ORR current is negative, the absolute values of ORR for these catalysts are used. The activity results are shown in Table 2. The ORR test results of the catalysts are shown in Figure 3. Since we are concerned with the electrichemical kinetic effects, the attention will be focused on

the region where the potential exceeds 0.9 V vs RHE. From Figure 3 and Table 2, it is found that Sample 12 has the highest MA of 8.42 mA/mg and the highest EAS of 164.16 cm^2/mg, but Sample 13 has the highest SA of 0.55 mA/cm^2. Moreover PtNi/C show a higher ORR activity than that of Pt/C. This may be attributed to the adition of Ni to Pt/C catalyst. The more electropositive transition metal Ni,

to which the oxygen species is attached, provides an electrochemical force that favor the four electron oxygen reduction electrochemical pathway, and consequently improves the ORR activity of the catalyst. This phenomenon results from the adsorption property of oxygen on Pt surface by dual site mode. Therefore the Pt-Pt nearest-neighbor distance plays an important role in determining the adsorption behavior. The addition of Ni to Pt/C catalyst not only reduces the Pt lattice parameter, but also enhances the catalytic activity. Therefore the alloying effect is an important factor affecting the catalitic activity toward ORR.

4. CONCLUSIONS

In this study, we use transition metal nickel to synthesize Pt alloying catalyst. X-ray diffraction (XRD) characterization is carried out to determine the mean crystalline size, these Pt-Ni/C catalysts. Electron Dispersive X-ray Spectroscopy is used to determine the bulk composition of catalyst. Electrochemical experiments including cyclic voltammetry (CV) are also conducted to characterize these PtNi/C catalysts, to determine the electrochemical area of the catalysts and to test the ORR activity of the catalysts. Samples 2, 13, and 12 produces by the lattice parameter, and the PtNi alloy effect of using EG method, has a competitively mean size particle, EAS, MA and SA value than that of Pt/C commercial.

ABSTRACT

Atomic force microscopy (AFM) was used as a lithography technique to create nanoscale oxide patterns for nanoelectronic device fabrication. The AFM lithography has been performed using a conductive AFM tip to produce the silicon oxide nanopatterns on silicon on insulator (SOI) wafer. The parameters such as tip-sample voltage, writing speed and oxidation time were well controlled to form silicon nanowire transistor patterns. The tetra methyl ammonium hydroxide (TMAH) was used as the etching reagent for silicon machining, whereas, hydrofluoric acid (HF) for oxide removal. A silicon nanowire transistor with structures of a nanowire channel, a source (S) and a drain (D) pads, and a lateral gate (G) has been successfully fabricated via AFM lithography followed by chemical etching processes.

Keywords

AFM lithography, chemical etching, silicon nanowire, transistor

1. INTRODUCTION

Nanotechnologies had become one of the promising research areas by which might bring a significant progress into material and device development. To get specific nanoobjects and their properties, particular techniques should be selected. For the surface microscopy, scanning probe microscopes (SPM) has been using in fabrication of nanostructures and nanodevices as well. The microscope worked in standard SPM modes as in the STM mode, contact, non-contact and tapping AFM mode, magnetic mode (MFM) and lateral force mode (LFM) [1]. Atomic force microscope (AFM) had become useful tools not only for observing surface morphology and nanostructure topography but also for fabrication of various nanostructures. There were several methods for nanopatterning such as dip-pen nanolithography (DPN), chemo mechanical surface patterning and local anodic oxidation (LAO) patterning.

For local anodic oxidation (LAO) patterning method, the oxide will grow on a chemically reactive substrate by the application of a voltage between a conductive AFM tip and a substrate surface which acted as an anode. There was a threshold voltage at which the anodic oxidation started. The water molecules adsorbed on a substrate dissociates due to high electric field ($E > 10^7$ V/m) into fragments (e.g. H^+, OH^- and O^{2-}) and acted as an electrolyte [1]. The reaction of the LAO patterning was happened as shown by Equation 1:

$$Si + 2OH^- + 4H^+ \rightarrow SiO_2 + 2H^+ \quad (1)$$

LAO method was influenced by some parameter such as tip radius, air humidity, tip sample voltage, tip writing speed and oxidation time [2-7].

2. EXPERIMENTAL

Silicon oxide (SiO_x) pattern was formed on silicon-on-insulator (SOI) wafer by means of AFM nanolithography, which is, localized anodization induced by a conductive AFM tip followed by etching processes. These anodic SiO_x patterns could serve as masks for the chemical etching of Si in alkaline solution. The commercially available SOI wafer (Soitec) has the top Si layer of 100 nm in thickness, buried oxide (SiO_2) layer of 200 nm, and bottom Si substrate of 6.25μm. The SOI wafer was cut to smaller size of 1 cm x 1 cm followed by cleaning process from any contaminant and native oxide that could influence the performance of the device fabrication. Briefly, the RCA cleaning procedure was used to clean the SOI wafer and then followed by the surface passivation with 2% HF for 1 min. The objectives of this treatment are to remove the native oxide naturally existing on the wafer surface and passivating the silicon layer by metastable hydrogen terminated surface. During this step the Si–O bonds are replaced by low energy Si–H bonds.

After wafer cleaning and passivation process, the nanoeletronic devices were designed on SOI surface by AFM lithography via local anodic oxidation patterning. Experimental work was carried out using an environmentally controlled scanning probe microscope (SPM) machine (SII SPI3800N). This SPM is equipped with CAFM mode with a nanotechnology software package to control the tip-sample voltage and tip movement according to pre-designed patterns. The anodic oxidation process was performed in the chamber with relative humidity in the range of 40-50% at room temperature. A conductive AFM with a gold-coated conductive tip (diameter ~ 20 nm) was operated at -7 to 9V bias relative to the sample at writing speed of 6 to 9 μm/s.

Wet chemical etching process was performed to the patterned sample to obtain silicon nanowire transistor devices. Tetra methyl ammonium hydroxide (TMAH, $(CH_3)_4NOH$)) containing no alkaline metal was used as the etching reagent for Si machining, whereas, hydrofluoric acid (HF) for oxide removal. In the first etching stage, patterned sample was etched in an aqueous solution of 25 wt% TMAH at 60°C for 10s to remove Si layer that not cover by oxide patterns. In this process, TMAH reagent is choosing due to its etching behavior that very high selectivity ratio between Si/SiO_2 (etching rate ~ 2000:1). After TMAH etching, the patterns were characterized by AFM and FESEM. The second etching stage is removing the oxide mask layer by HF etching process. Sample was immersed in 2% HF solution for 20s to produce a SiNW transistor device.

The size, topography and microstructure of device were characterized by AFM and FESEM analysis. Figure 1 shows a schematic diagram of the fabrication of SiNW transistor device.

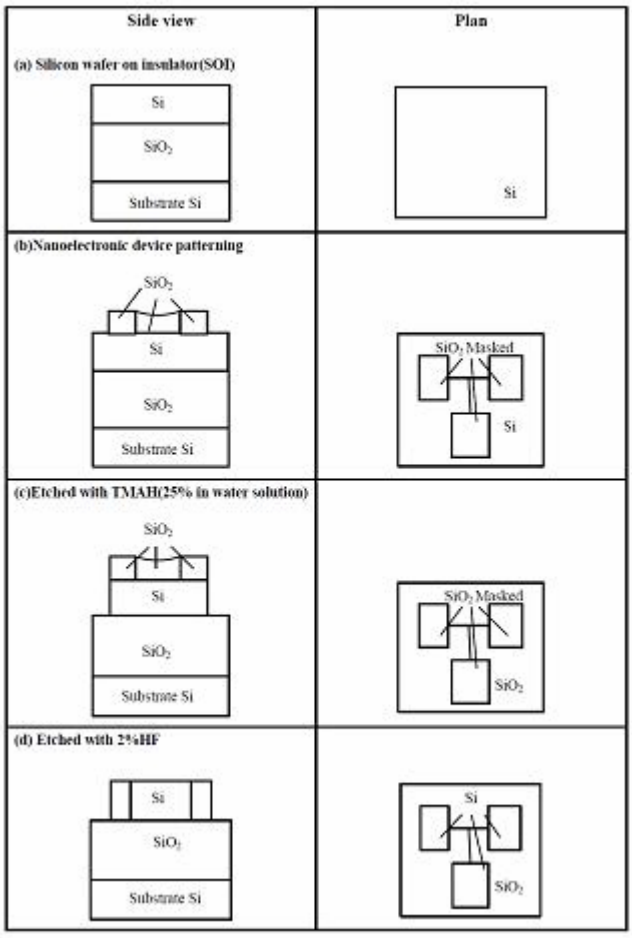

Figure 1: Schematic procedure of silicon nanowire (SiNW) transistor fabrication.

3. RESULTS AND DISCUSSION

The applied tip-sample voltage is one of the important parameter that will influence the local anodic oxidation (LAO) patterning result [1-7]. It was found that the tip-sample voltage will affected the size (width and height) of the patterned nanoscale oxide where the width and height of the pattern are increases with the tip-sample voltage [1].

Figure 2 shows the effects of applied tip-sample voltage and tip writing speed to the size of the patterned oxide nanowires. In this case, the nanowire patterns were drawn by applied tip sample voltage from 7 to 9 V at two different tip writing speed, 6um/s and 9um/s. The measurement results indicate that the width of the oxide nanowires is increasing linearly with increment of the tip sample voltage. For tip writing speed of 9 um/s, the width of the oxide wires is increase from 86.91 nm at tip sample voltage 7 V to 175.17nm and 290.81 nm for tip sample voltage 8 V and 9 V.

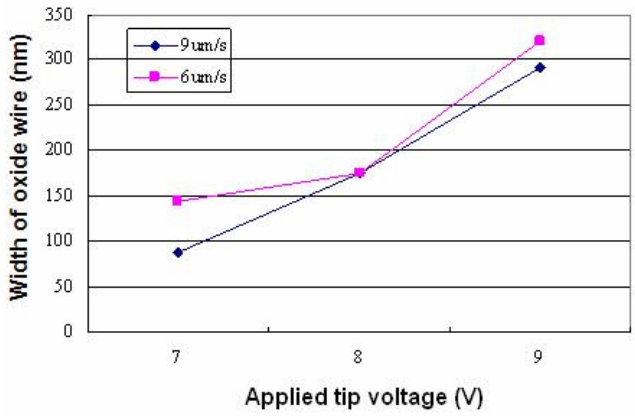

Figure 2: Graph of the width of the oxide nanowires at different applied tip sample voltage for two different tip writing speed, 9 um/s and 6 um/s.

Figure 3 shows the graph of the height of the oxide nanowires that drawn by tip sample voltage from 7 to 9 V at two different tip writing speed, 9 um/s and 6 um/s. From the measurement, the height of the oxide wires also increase linearly due to the increasing of the tip sample voltage. For tip writing speed of 9 um/s, the height of the oxide nanowires increase from 1.25 nm to 2.35 nm for tip sample voltage 7 V and 8 V. The height of the oxide wires further increase to 4.50 nm for tip sample voltage 9 V.

Tip writing speed also influenced the result of the local anodic oxidation patterning. Cervenka *et al.* [1] has found that beside the tip sample voltage, tip writing speed also affected the width and height of the oxide nanowires. It was found that the tip writing speed and applied tip sample voltage have to be well controlled in order to produce good result of oxide nanowires via local anodic oxidation patterning. Therefore, the suitable tip writing speed and applied tip sample voltage with other parameters should be found during the patterning process.

As shown in Figure 2 the lower tip writing speed of 6um/s produced bigger of the oxide nanowires if compared to the higher tip writing speed of 9 um/s at the same applied

tip sample voltage. For tip writing speed 6 um/s, the width of the oxide wires increase from 144.89 nm at tip sample voltage 7 V to 174.49 nm and 321.40 nm for tip sample voltage 8 V and 9 V. The result shows that the 6 um/s tip writing speed was produced more highly in the width of the oxide wires compare to the tip writing speed 9 um/s. But, the more lower the tip writing speed, the more of the time had been taken for patterning.

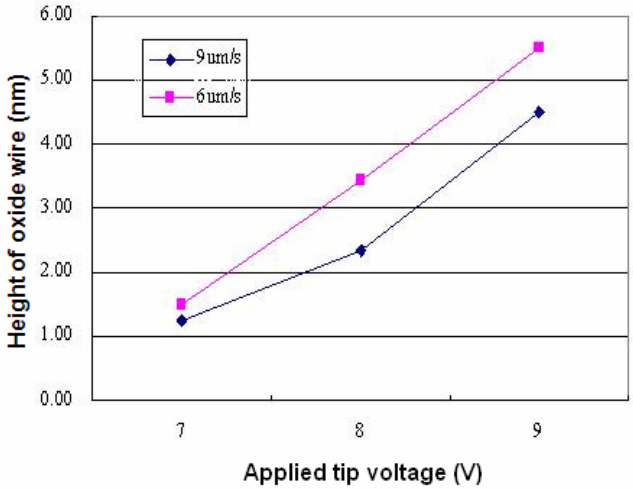

Figure 3: Graph of height of the oxide nanowires at different applied tip sample voltage for two different tip writing speed, 9 um/s and 6 um/s.

Figure 3 shows the graph of height of the oxide wires which had been drawn by tip writing speed, 6um/s and 9um/s with tip sample voltage from 7 to 9 V. From the graph in the Figure 3, the height of the oxide wires will increase due to lower down the tip writing speed which applied to the same tip sample voltage. The graph also shows that the height of the oxide wires will increase due to the increase of the tip sample voltage for the two different tip writing speed. So, the more lowly the tip writing speed, the more highly the height of the oxide wires

Figure 4 shows that the two dimensional (2D) and three dimensional (3D) images of the simple nanoelectronic structure drawn by AFM lithography patterning via local anodic oxidation (LAO) method. The designed of the nanoelectronic (Silicon nanowire transistor) was patterned at tip sample voltage of 7V with tip writing speed of 6um/s. The device has the source (S), drain (D) and lateral gate (G) with a silicon nanowire as a channel. The size of patterned oxide wire are 3 nm in thickness, 160 nm width and 1.744 µm in length which determined in situ by AFM topographic analysis. Meanwhile, the square pad size is about 5µm x 5µm. These oxide patterns will be used as mask system to protect Si layer underneath during the chemical etching process by using TMAH.

The TMAH etched of unmasked Si layer produced the oxide covered device structure as shown in Figure 5. Lastly, a completed SiNW transistor device was formed by removing the oxide layer via HF etching process. Figures 6 and 7 show the AFM and FESEM images of completed formation of silicon nanowire transistor after final stage of etching process by HF.

(b)

Figure 6: (a) 2D and (b) 3D AFM images of completed formation of silicon nanowire transistor after final stage of etching process by HF.

4. CONCLUSION

As a conclusion, a simple nanoelectronic device (silicon nanowire transistor) using a silicon nanowire as a channel with source (S), drain (D) and lateral gate (G) pads has been successfully fabricated by AFM nanolithography process. The lithography process via LAO using conductive AFM is influenced by certain parameters such as applied tip sample voltage, tip writing speed, and environment humidity. In this work, the lithography patterning of simple nanoelectronic device had been drawn at 7 V tip sample voltage and 6 um/s tip writing speed. These parameters have been chosen based on the optimum condition from experimental results of the height and width of the oxide nanowires at different applied tip sample voltage and tip writing speed.

ABSTRACT

Metal foams or also known as cellular materials are widely used in many applications due to their attractive properties, especially in excellence good damping capacity, high impact energy absorption and very high specific stiffness. In this paper, aluminium metal foam was manufactured by powder metallurgy process route and dissolution in water. NaCl particles were added up to 90%wt and employed as cell structure former. The aim of the study is to produce and to characterize the properties the aluminium foam. The results show that aluminium foam was successfully fabricated by this method. In general, the density and porosity increase with the higher addition of NaCl to the mixture. Addition of 50wt% of NaCl to the mixture gives the density of 0.81 g/cm^3 compared to 2.25 g/cm^3,i.e. the density of the sintered product without NaCl addition. The porosity shape is almost similar with that of NaCl particles. It can be distinguished from the porosity due to imperfection during compaction by its shape.

Keywords

Cellular materials, Al, metal foam, metallic powder, lower density, porosity

1. INTRODUCTION

Metallic foam materials or also known as cellular metallic materials are categorized as new materials since a few decades with unique properties combination [1]. There are many applications of metallic foam in a great diversity industrial field, such as in automotive, energy, chemical, aerospace industries and so on [1-3]. The manufacturing process of this material is available practically in several routes for many kinds of metallic materials, for instance aluminium, copper, iron, titanium and others [2,3].

In case of aluminium foam, it can be manufactured, for instance by gas injection, foaming agent addition, powdered metal [1-4]. Zao and Sun (2001) have developed a powder metallurgy and dissolution process, which is also known as sintering and dissolution process (SDP) [5]. This process consists of three steps. Firstly, the mixture of Al, NaCl and additives is compacted to form a green compaction at a certain pressure. Secondly, the green is sintered at above or below the melting temperature of Al to form well-bonded structure. Finally, the NaCl particle is removed from sintered by leaching in hot water, leaving a foam structure of Al. Further study of SDP process optimization has been also conducted [6, 7]. Zao et al. (2004) showed that the optimum range of compaction pressure is 200 – 250 MPa and sintering temperature at 670 – 680^{o}C [6].

Based on the previous works of Zao et al. [5], the present study aims to produce aluminium foam by using powder metallurgy and dissolution process. The raw materials morphology used in this study is flake aluminium powder and acicular NaCl. It is different from Zao *et al.*'s works, which utilized atomized aluminium particles and round NaCl [6]. Physical and mechanical characterizations of aluminium foam are undertaken to the products after finishing the process.

2. EXPERIMENTAL METHOD

2.1 Materials

Aluminium powder (purity > 90%) and NaCl (technical grade) were used as main raw materials in this study. Al_2O_3 particles was also added to

the mixture in a certain amount as matrix strengthener. Zinc stearate was added in the mixture as a lubricating agent.

Fig. 1 shows the morphology of aluminium (flaky) and NaCl powders (acicular). The mean size of aluminium particle was 65.9 μm, whereas the size range of NaCl was 67 -667 μm.

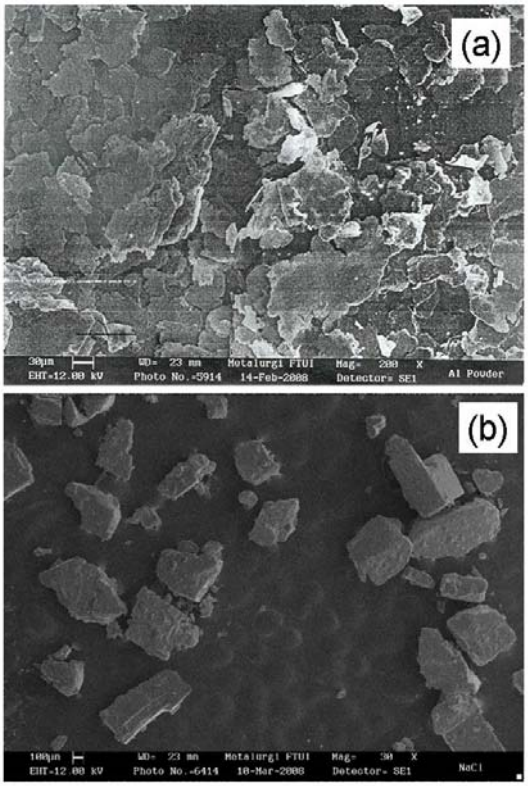

Figure 1: Raw materials utilized in this study. (a) aluminium and (b) NaCl powders.

2.2 Procedures

The aluminium powder was mixed with NaCl in the proportion of 0, 30, 50, 70 and 90 mass%. The additives were also admixed to the mixture by using rotary mixer for about 5 minutes. The homogenous powder mixture was then compacted at 200 Bar at room temperature. The sintering process of green compacted powder was conducted at 650^{o}C for 2 hours. After cooled down in room temperature, the sintered product was dissolved in warm water to remove NaCl from the products.

The metallic foam products were characterized their density and porosity. Scanning electron microscope (SEM; Leo, Oxford Instruments) was utilized to observe the structure of metal foam.

3. RESULTS AND DISCUSSION

Fig. 2 shows the sintered product (a) and leached product (b) of aluminium foam. It was also observed in some of the sintered product that a little portion of Al melts out on the surface of the sintered product in the form of globule. It is because actual sinter temperature in the furnace is still higher than aluminium melting point, even the heating element was set at 650^{o}C. Some part of the sample product was degraded during water dissolution. To avoid these conditions, attention should be paid during the process to obtain optimum condition.

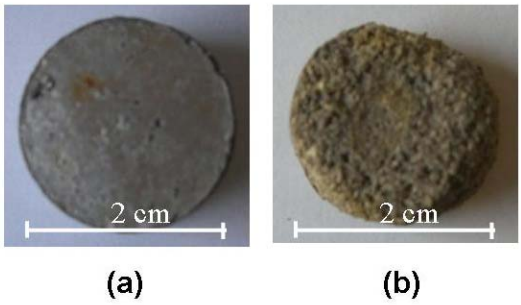

Figure 2: The sintered product (a) and the leached product (b) of aluminium foam.

Fig. 3 illustrates the structure of the foam after water dissolution process for 50% NaCl addition. It is observed that foam or cell structure was produced by using this process. The cell shape is relatively similar with the shape of NaCl, i.e. acicular form. The cell size, in case of 50% NaCl addition, is in the range of 350-687 μm, which is still in the range of NaCl size. Qualitatively, the amount of cell structure increases with increasing in addition of NaCl in the mixture. Some interconnection cell in the structure is also observed. It means that open cell structure was partly produced in this study.

Fig. 4 shows the effect of NaCl addition to the metal foam density. Actually, without NaCl addition, the density of sintered aluminium powder (2.25 g/cm^3) was still lower than that of aluminium bulk density (2.70 g/cm^3). It indicates that the porosity was formed as a defect of powder metallurgy process. Gradually, the density of aluminium foam is decreased with increasing in NaCl addition. Addition 30-90% NaCl into

aluminium powders mixture decreases the density of aluminium foam to the range of 1.58 – 0.22 g/cm^3.

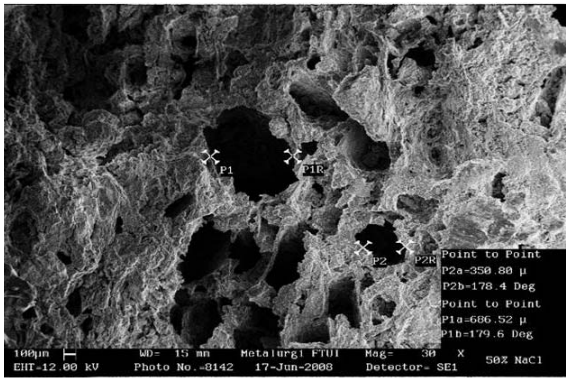

Figure 3: Microstructure of aluminium foam with 50% addition of NaCl.

On the contrary, the population of cell structure, in term of porosity percentage, is increased with increasing in NaCl portion in the mixture, as shown in Fig. 5. About 17% of porosity was formed as the defect of powder metallurgy process. Addition of 30 – 90% NaCl increases the porosity in the form of cell structure to the range 41.37-91.7%. The percentage of the measured porosity is still higher than NaCl addition in each condition. It indicates that the porosity in aluminium foam consists of defect porosity of powder metallurgy process and porosity which is formed during dissolution process. It also means that most of NaCl was removed during dissolution process.

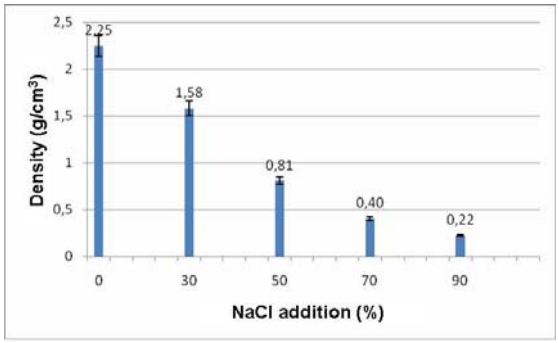

Figure 4: Effect of NaCl addition to the aluminium foam density.

4. CONCLUSION

The results of the present study show the reproducibility of the powder metallurgy and dissolution process to produce aluminium foam. More than 41% of density reduction compared with aluminium bulk density can be produced in the form of aluminium foam. The morphology and size of NaCl, as perform cell structure, should be considered to obtain a certain form of cell structure.

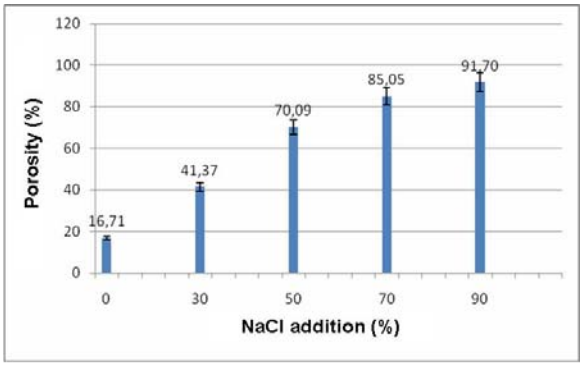

Figure 5: Effect of NaCl addition to the porosity in the aluminium foam.

ABSTRACT

We report on the deposition by Langmuir-Blodgett process of thin film monolayer organic Tetraether lipids were transferred onto Silicon wafer substrates. Langmuir experiments were performed with the Langmuir trough from a commercial film balance (Riegler & Kirstein GmbH, Mainz, Germany) . The surface pressure was measured with a filter paper Wilhelmy balance. The experiments were performed at a temperature of 19˚C ± 1˚C. The subphase was pure water. The Tetraetherlipid were dissolved in chloroform in concentration 1 mMol for the film balance experiments. Thin film monolayer organic were made onto substrate Silicon wafer which Hydrophobic, Hydrophilic and Aminosilanisated properties. Ellipsometry Measurements show that the thickness and optical properties of monolayer films, The surface morphology with Atomic Force Microscoy (AFM) as results showed that in all films domains are present and that the thickness of the observed domains films varies between 2 nm and 5 nm. From all films the hydrophobically transferred showed the most homogeneous organization on the substrates. After transfer on hydrophilic and aminosilanisated surfaces the lipids are arranged in small islands on the substrates.

1. INTRODUCTION

Organized molecular films at the air-water interface as well as on solid substrates of great importance to a number of nanotechnology , nanoelectronic, biosensor, material science, biomimetic chemistry, biomedical and drug-delivery applications.

The application of nanotechnology principles and methodology is providing an exciting will generate a revolution of novel applications in several arenas. Applications of nanotechnology range from novel nanosensors, to novel methods for sorting and delivering bioactive molecules, to novel drug-delivery systems. Supported membrane systems are key features of emerging nanotechnologies.

Self-assembled phospholipid membranes play an important role in biological processes. Mimicking these natural thin films lipid-coated surfaces are of great importance to a number of biomedical applications, including intravenous drug delivery, biomaterials, and biosensors. Surface-supported lipid layers are also interesting as model surfaces in studies of protein adsorption or biophysical membrane studies.

Regarding the behavior at the air-water interface, monofunctional amphiphilic molecules are the most commonly used model compounds which have been extensively studied. In a monolayer of amphiphiles, the hydrophilic headgroups are immersed in the water and the hydrophobic tails jut out into the air. Supported membrane systems are key features of emerging nanotechnologies, because these tetraether lipids self-assemble into ordered structures with extraordinarily stability against chemical and microbial degradation.

Our work has several flavors, indicated in the title. The first how large area the homogeneous of monolayer film organic onto Silicon wafer substrate with some kind properties of substrate (Hydrophobic, and Aminosilanisated) which using Langmuir-Blodgett technique and also characterization using Atomic Force Microscopy and Ellypsometric equipment the reason of the present investigation was to find out while bolaamphiphiles tetraether lipids may also great potential in applied science especially in the field of nanotechnology a detailed physicochemical characterisation of tetraether lipid films at the air-water interface or after deposition onto solid supports (Silicon wafer subtrate).

2. MATERIALS AND METHODS

2.1 THE LIPIDS AND OTHER MATERIAL

The archaea were grown in semicontinuous fermentor (Biostat 50D, Braun, Melsungen, Germany) cultivation according to Freisleben et al. (1994) at temperatures between 39°C and 59°C in sulfuric acid medium at pH 2. The main tetraether glycolipid (MGL) was extracted and purified from H.-J. Freisleben and E. Antonopoulos as described by Blöcher et al. (1984) modified by a two-step chromatography with DEAE-cellulose and silica columns eluted with chloroform/methanol. Analyses of the lipid composition was carried out by a high performence liquid chromatography (HPLC). The purity of the MGL fraction was 99%. The Langmuir film balance experiments were accomplished with MGL-extracts from cultures grown at 39°C (MGL39) and 59°C (MGL59). The lipid was lyophilized at 10^{-2} torr overnight and stored at room temperature over phosphopentoxide in an exsiccator. All chemicals were obtained from Merck (Damstadt) or Sigma (Deisenhofen) at the highest purity available.

2. 2 LANGMUIR-BLODGETT (LB)

The monolayer investigations were carried out with a commercial film balance (Riegler & Kirstein GmbH, Mainz, Germany) with a rectangular thermostatted Teflon trough. The surface pressure was measured with a filter paper Wilhelmy balance. The lipids were dissolved in chloroform in a concentration 1 mMol for the film balance experiments. The subphase was pure water of Milli Q quality (18.2 MΩ, pH 5.6). The experiments were performed at a temperature of 20°C. After spreading, the lipid films were equilibrated for different times at zero surface pressure before starting the measurements. All films were compressed with a constant speed of 0, 1 mm/s.

2.3 WAFER MODIFICATION AND PURICATION

The Hydrophobic substrates were prepared using SiO_2 wafer which were cleaned with Piranha Method. For activation of the wafer surface a Hydrophobisation Method was used. Put into Dimethyl C_{18} – Chlorsilan. The hydrophobicity of the substrates thus prepared were reasonably good with the layer should be 1,5 nm and a contact angle 90˚ resulted.

The aminosilanisated substrates were prepared using SiO_2 wafer which were cleaned with Piranha Methode. For activation the wafers were cleaned using UV-lamp (Xeradex, Lampenwerk

Wipperfürth, Germany) for 5 minutes and than put into aminopropyldimethylethoxysilane. An aminosilanisation ot the substrate a layer of 1 nm and a contact angle 70˚ resulted.

2. 4 ELLIPSOMETRY MEASUREMENTS

Ellipsometry Measurements were accomplished with a mapping single wavelength ellipsometer SE–400 (Sentec Instrument, Germany, Berlin). As light source a He/Ne laser with a wavelength $\lambda = 632,8$ nm was used. The angle of incidence was 60˚. A substrate refractive index of 3,874 used for Silicon. The upper layer refractive index were determined by 1,46. The bolaamphiphiles (Archaebacterial tetraetherlipid) were transferred onto Silicon wafers (1cm x 1cm). The surface was scanned in a single line direction from the pure silicon oxide layer into the lipid layer. The distance between the measurement points is 200µm, the are of one spot is 250 μm^2.

2. 5 ATOMIC FORCE MEASUREMENTS

The morphology of the transferred film were investigated in the contact mode using an AFM image were obtained on NanoWizard (JPK Instruments, Berlin, Germany) under atmospheric conditions. The samples were examined within one our after preparation.

3. RESULT

3. 1. FILM BALANCE

We have transferred the bolaamphiphiles from air/water films on silicon substrates by Langmuir Blodgett technique at the highest surface pressure. Caldarchaeol in concentration 50µl 1 mMol at temperature 20°C had surface pressure about 20 mN/m.

We have transferred the monolayer Bolaamphiphiles on silicon substrates by Langmuir Blodgett technique at various type of transfer (Y-type for Aminosilanisated substrates and X-type for Hydrophobic substrates).

We have attempted to transfer the monolayer films onto hydrophobic (X-Type) and aminosilanisated substrates (Y-type transfer). The monolayer of these bolaamphiphiles are transferred at the surface pressures given in Figure 1

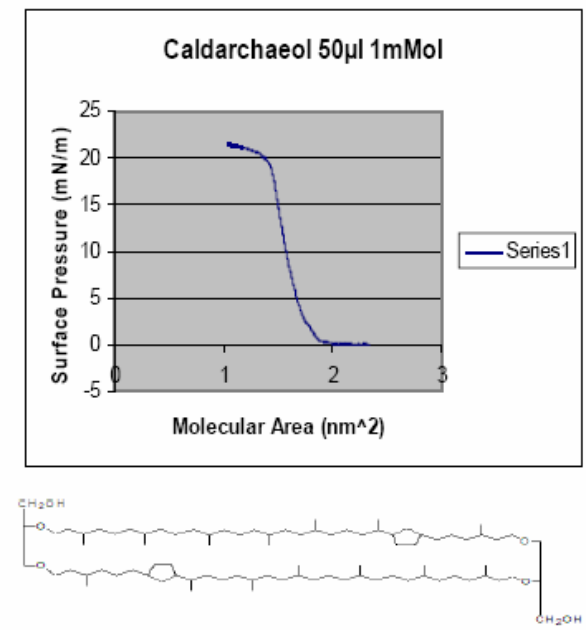

Figure 1 Representative Surface Pressure/ Area isotherms at 19°C,for Caldarchaeol 50µm 1mMol

3.2. ELLIPSOMETRY

he ellipsometry gives a mean film thickness over a large spot area of 250 μm^2 and therefore can not discriminate between different morphological substructures. Therefore, only 75% of the total surface areas of the substrates were covered by the lipid layer. The surface was scanned in a single line direction from the pure silicon oxide layer into the lipid layer.

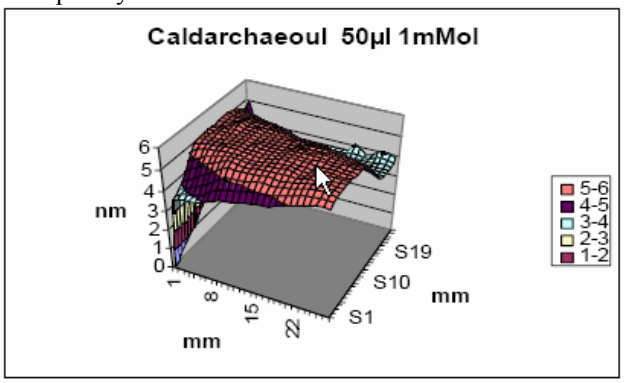

Figure 2. Ellipsometry for Caldarchaeol 50µm 1Mol YType transfer onto Amino-silanisated wafer

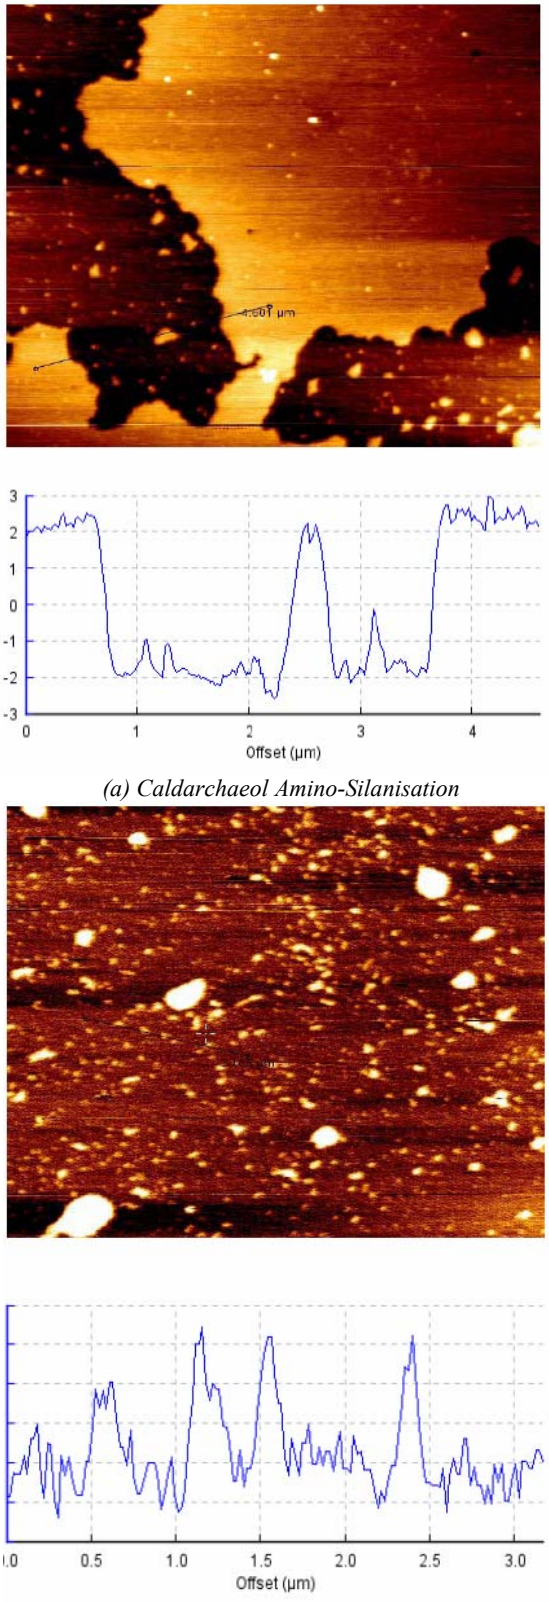
3. 3. ATOMIC FORCE MICROSCOPY (AFM)

The surface morphology of monolayer films were studied by means of AFM. The AFM images for the Langmuir-Blodgett monolayer films of bola amphiphiles on hydrophobic substrates and aminosilanisation substrates with the respective height profiles along a chosen line are shown in Fig 3.



(a) Caldarchaeol Amino-Silanisation

Figure 3 (a) Caldarchaeol Amino-Silanisation (Y-Type Transfer) and (b) Caldarchaeol Hydrophobic (X-Type Transfer)

4. DISCUSSION AND CONCLUSION

The phase behavior and the molecular organization of natural and synthetic archaeal tetraether lipids has been investigated for more than 20 years . At present the phase behaviour and the molecular organization of the tetraetherlipids from thermoacidophilic archaea become of special importance, because these lipids can be form very stable monomolecular model membrane systems . To establish a organization-model for natural tetraether lipids in dependence on the living conditions of the archaea we investigated monomolecular films of these lipids on the air-water interface by using a combination of Langmuir-Blodgett film balance, ellipsometric and AFM experiments.

The Surface pressure vs Area per molecular isotherms (Fig.1) for caldarchaeol in our experiments, bolaamphiphiles form metastable liquid-expanded monolayers where one molecule occupied an area of nearly 1, 4 nm² forms a stable liquid-expanded monomolecular film. Compression of the monolayer leads to a homogeneous condensed phase and then to a collapsed state.

For the symmetric bolaamphiphile Caldarchaeol the film collapsed at a pressure near 20 mN/m and a molecular area of about 1,4 nm². Caldarchaeol gives the most instable lipid films therefore we could not plot a compression-decompression curve. Nevertheless a transfer has been tried. The ellipsometric data showed a thickness of the film after hydrophobic (X-Type) transfer of about 2,8 nm, whereas the film-thickness after transfer onto amino-silanisated (Y-Type) wafer the thicknes reached only 1,5 nm. This points for all films to a horseshoe-conformation.

Ellipsometry even in the mapping technique is unable to resolve single higher standing domains, because the smallest spot cover an area of 250 μm^2 and therefore the data only represent a combined mean value of horseshoe and upright standing domains.

According to the ellipsometric data our AFM results showed that for Hydrophobic substrates had in all films domains are present and that the thickness of the observed domains films (almost 100% was covered lipids) varies between 2 nm and 5 nm. This is consistent with the assumption of coexisting upright standing and horse-shoe like conformations. But for Aminosilanisated substrates had only 40% was covered lipid. From films the hydrophobically transferred showed the most homogeneous organization on the substrates than transfer on amino-silanisated surfaces the lipids are arranged in small islands on the substrates. The large area was covered films onto Slicon Wafer Substrates which importants for applications.

ACKNOWLEDGEMENTS

This study was supported by the DAAD. The authors would like to thank the group of Dr. Ulrich Rothe (Institute of physiological chemistry University Halle) for the technical support.

Abstract

Has been done research of the effect of ultrasonic wave (sonication) on reduction of particle size of domestic silica of kalimantan (SDK) to produce silica nanoparticles. In this research, sonication was done at frequency 20 kHz with dissociation energy intensity (power) ± 60 watts. In order to observe the effect of sonication, the samples were sonicated using time variable of 0 minute, 180 minutes and 300 minutes which were then named as SDK0, SDK180 and SDK300 sample, respectively. The obtained samples were then characterized using X-Ray Diffractometer (XRD), Scanning Electron Microscope (SEM) and Particle Size Analyzer (PSA). The comparison of XRD analysis of the samples shows no significant crystal structure change on each sample. SEM analysis of SDK0 sample shows microstructure in the form of relatively big agglomerate. Whereas, the microstructure of SDK180 and SDK300 sample show the scale tendency of smaller agglomerate. In addition, PSA analysis shows quantitatively the occurred reduction of particle size process. PSA analysis shows the reduction of average particle size of SDK0, SDK180, and SDK300 samples, where the longer sonication time the smaller particle size is. Besides, the sonication was observed can conduct reduction of particle size without making any crystal structure damage of the samples.

Keywords : ultrasonic wave, reduction of particle size, silica, sonication

INTRODUCTION

Silica is the oxide form of silicon which usually found in nature in the form of quartz and opal [1]. Silica (SiO2) was known to have abrasion resistance, electrical insulation and high thermal stability properties which has been applied widely in industry. This mineral has great abundance in Indonesia, however still not utilized maximally. Silica nanoparticle posses superior novel properties which cannot be achieved in bulk particle size. Besides, silica nanoparticle is a real expensive material ($10000/ton) [2] and cannot be produced in Indonesia. Therefore, the research to yield silica nanoparticle absolutely have a real strategic and high economic value.

One of common way utilized to yield nanoparticle is mechanical milling method. This method can yield nanoparticle by giving mechanical force in the form of collision, shear, and strain. However, though this method is applicable to yield nanostructured material, the utilization of this method often less effectively in yielding nanoparticle which primarily caused by agglomeration phenomenon causing particle size exactly bigger and bigger. Therefore, another method is required to yield nanoparticle more effectively which one of them is sonication method using ultrasonic wave.

The main advantage of sonication method is its ability in breaking the agglomeration. In solution, ultrasonic wave generate cavitation phenomenon. Cavitation is the event of formation, growth and implosive breakage of bubble in fluid. According to Suslick (1998), the event of bubble collapse produce an intense local heating (~ 5000 K), high pressure (~ 1000 atm), high heating and cooling rate (> 109 K/s), and fast liquid flow (~ 400 km/jam) [3]. This process sequence finally will break particle and also agglomerate in the sample.

EXPERIMENTAL SETUP

The samples used for this experiment were obtained from local silica rocks. The silica rocks were crushed manually to yield smaller size of about 1 cm. The crushed silica rocks were the milled using disk mill for 20 minutes. The yielded powder was then dissolved in techinal ethanol solution. The solution was then sonicated with energy intensity of 60 W for 0, 180, and 300 minutes. The obtained samples were then characterized using XRD, SEM, and PSA.

RESULTS AND DISCUSSION

XRD pattern comparison SDK0, SDK180, and SDK300 samples is shown in Figure 1. From Figure 1, it can be seen that sonication process gives no significant on XRD pattern of the three samples. Neither the appearance of new peak nor disapperance of initial peak was observed from those three XRD pattern. This condition imply that there is no mechanical reaction like usually it is in common mechanical milling process. Moreover, there is no significant intensity decrement which shows no deformation on the crystal structure of the processed samples. There is also no peak shifting which shows no significant lattice strain.

ISSN 114-1284

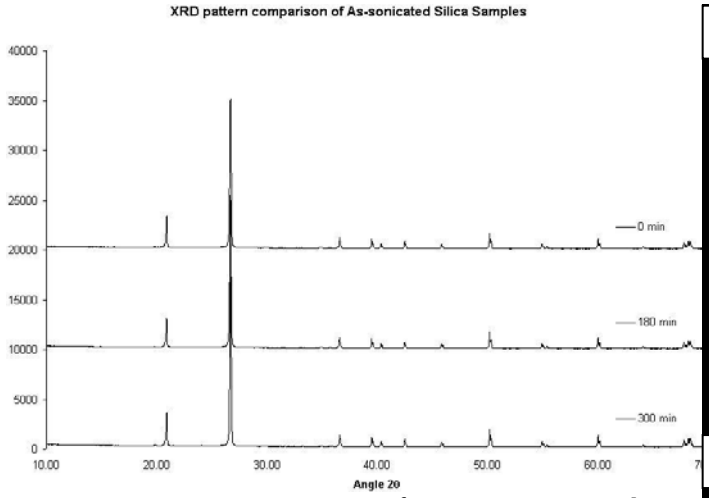

Figure 1. XRD pattern comparison of SDK0, SDK180, and SDK300 samples

Microstructure of the three samples is compared using SEM photograph as shown in Figure 2. From the comparison of the three SEM photograph, it can be seen clearly that separation process and breakage of particle were happened. It also can be seen from Figure 2(a) that unsonicated sample seems to form particle groups with morphology showing that there are still weak bondings between particles. After 180 minutes sonication, those particle groups seem to break and change into particle clusters with various size, from 19µm to some hundred nanometers. This breakage process was continued for 300 minutes sonication time, yielding smaller size particle clusters. In general, it can be seen that the breakage process of weak bondings and reduction of particle size was happened simultaneously for 300 minutes sonication time. The yielded particle size is relatively more homogeneous compared to 180 minutes-sonicated sample. However, reduction process of particle size was still incomplete so that there are still relatively big particle clusters remaining compared to average particle size.

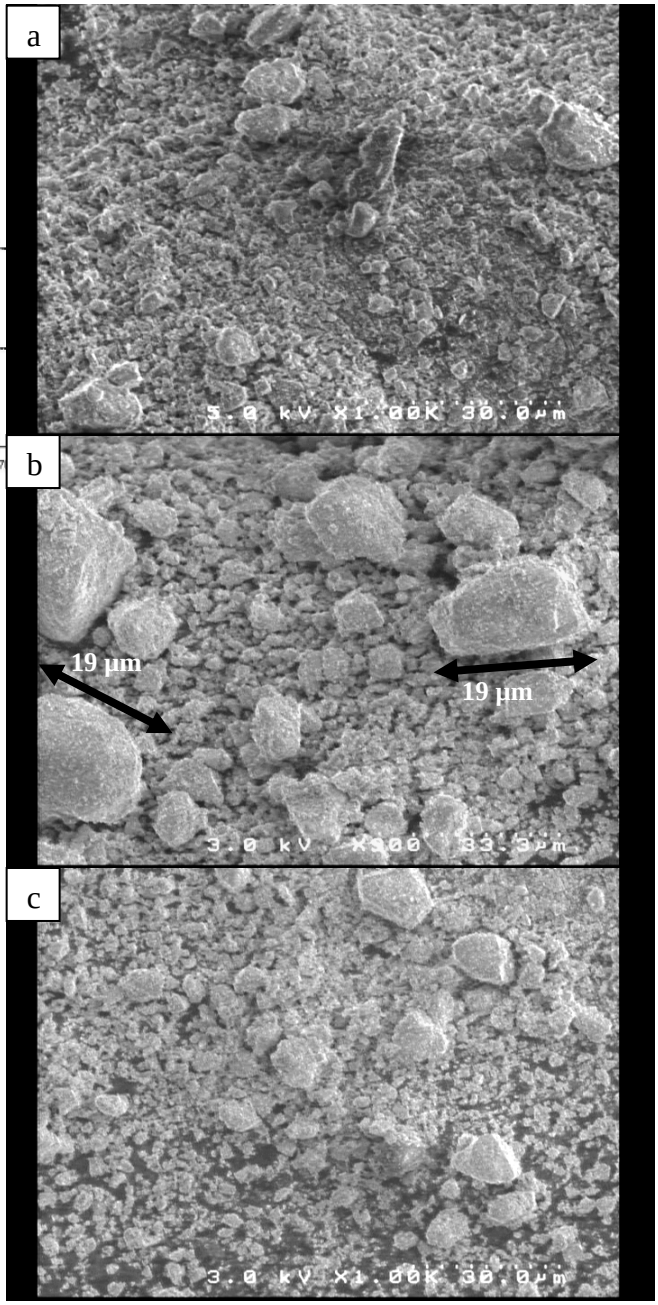

Figure 2. SEM photograph of sonicated samples for: a. 0 minute b. 180 minutes c. 300 minutes

SEM photograph of the sonicated sample with magnification of 25000X is shown in Figure 3. From Figure 3, it can be seen that unsonicated sample has particle clusters which are tied by weak bondings among particles as also shown in Figure 2. After 180 minutes sonication, those weak bondings are broken, caused the disconnection of particle clusters from the bonding. However, reduction process of particle size was still not happened effectively because the dissociation energy of sonication process is applied firstly to break the bonding among the clusters. The circle parts of Figure 3(b) indicate that there are some particle which still in process of disconnection of weak bonding among particles. The disconnection process of weak bonding among particles was continued with the next step e.g. reduction process of

ISSN 114-1284

particle size after 300 minutes sonication time as shown in Figure 3(c). It can be seen clearly in Figure 3(c) that there are particle size distributions, showing clearly the occurrence of reduction process of particle size. However, as can be seen from Figure 2(c), the reduction process of particle size was still incompleted so that some relatively large particles are still remaining.

The results of particles size measurements using PSA are shown in Figure 4 and Figure 5. From those measurements, the initial sample has particle size of about 2.25 µm. After 180 minutes sonication the average size was reduced to 478.7 nm. Whereas, 300 minutes-sonicated sample has average particle size of about 207.7 nm. It is then clear reduction of particle size has already happened. However, though reduction of particle size has already happened, the XRD shows no crystal structure transformation on the samples. This can be happened because reduction process of particle size during sonication doesn't include plastic deformation process which usually can be observed on conventional mechanical milling process [4-9]. Thereby, reduction process of particle size prepared by sonication method has an advantage over conventional mechanical milling process in avoiding the crystal structure of the sample from destruction.

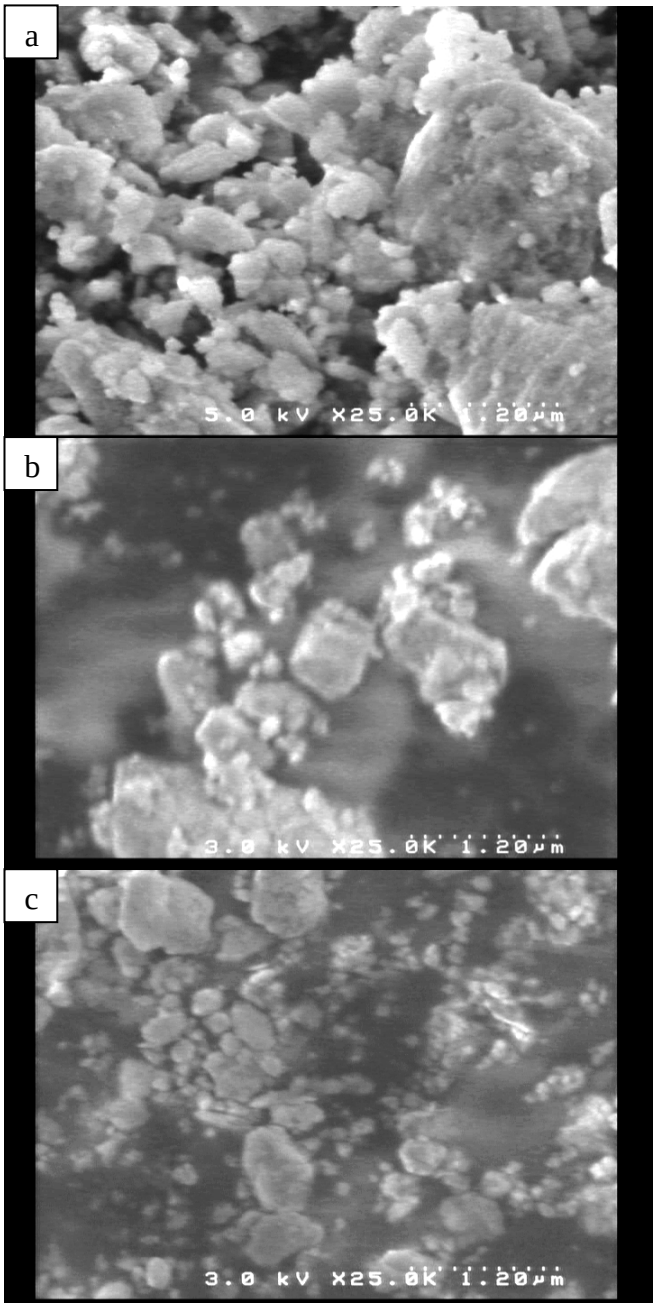

Figure 3. SEM photograph of sonicated sample with magnification 25000X: a. 0 minute b. 180 minutes c. 300 minutes

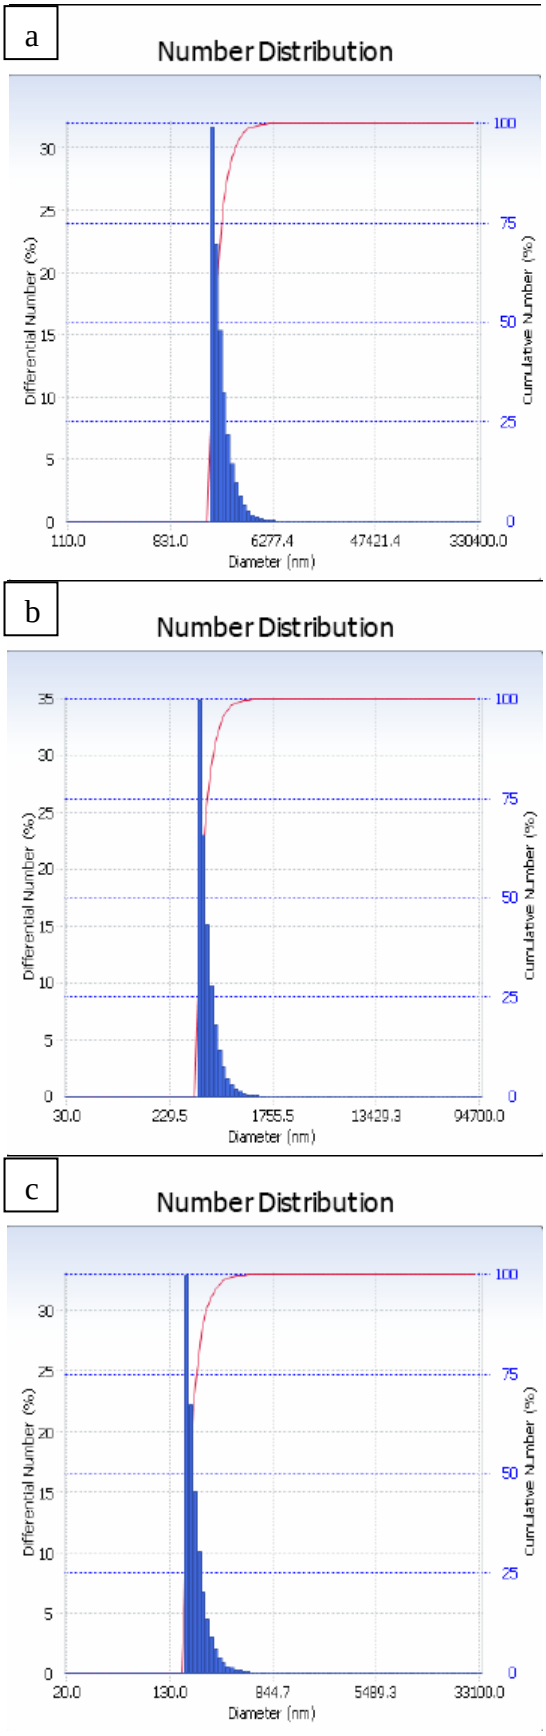

Figure 4. Result of particle size measurements: (a) 0 minute (b) 180 minutes (c) 300 minutes

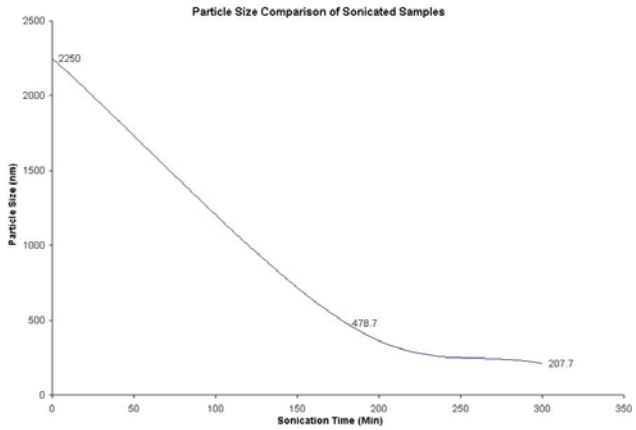

Figure 5. Comparison of sample particle size which has been sonication during 0, 180, and 300 minutes.

CONCLUSION

1. The ultrasonic wave gives micro scale effect on sonication process in term of reduction of particle size which correlates linearly with sonication time.
2. The conducted sonication process was able to do reduction of particle size without changing crystal structures of the processed sample.

Performance of Portland-Blended Cement as future's *'Green Cement'*

V.Indrawati and A.Manaf

Postgraduate Program of Materials Science, University of Indonesia
e-mail: vera.indrawati@ui.ac.id

ABSTRACT

Supplementary cementing material (SCMs) of local resources was used for partial replacement of the Portland clinker in attempt to reduce CO_2 emission in the cement production. Replacement of Portland clinker up to 20 wt.% with SCMs in the normal cement has reduced CO_2 emission by 0.18 Ton CO_2/Ton cement. However, when compared with that of normal cement, the property is still comparable in which almost 80% of the mechanical strength of the normal cement was achieved (32 MPa vs 40 MPa). In this paper, performance of portland blended cement was evaluated through mechanical strength, phase identification and microstructure.
Key words: portland cement; SCMs; CO_2 emission; portland-blended cement; mechanical strength

INTRODUCTION

Since 19th centuries, Portland cement has been commonly used in the construction. Its performance in term of mechanical strength and durability are assumed as the best. Unfortunately, its sintering process has negative effects to the environment because of CO_2 emission. Research on cementing materials which refers to Roman cement has given a new direction to new type of cement which is called blended cement. This kind of cement is not only related to the environment aspects but durability of concrete structures is also included[1]. Blended cement is produced by mixing Portland clinkers with other Supplementary Cementing Materials (SCMs). These SCMs could be natural or artificial such as slag, flyash, silica fume, metakaolin[1][2]. Trass is natural SCM which its deposit abundantly in the country. In this paper, we report results of replacement of up to 40 % trass to portland cement

EXPERIMENT

Trass from two different sources were characterized by XRF and XRD to identify the chemical and mineral compositions. Trass materials were ground together with portland clinker and gypsum to produce blended cement. Replacement of 20, 30 and 40% of portland clinker were prepared. Compressive strength of its cement mortar were measured and microstructures of cement pastes were investigated by SEM. Water to cement ratio(W/C) used is 0.485

RESULT AND DISCUSSION

Figure 1 showed the compressive strength of blank portland cements compared with that of blended cements of 20, 30 and 40% trass. Refer to 40 Mpa as mechanical strength of normal cement, replacement up to 20 % trass has values of 32 and 40 Mpa strength at 28 and 56 days curing. By calculation, CO2 reduction of 20, 30 and 40% clinker replacement are 0.18, 0.27 and 0.36 T/Tcement respectively. Microstructures by SEM of cement pastes at 56 days age also showed insignificant difference between portland and blended cement. Figures 2 to 5 showed microstructures of calcium silicate hydrate (CSH) originated from hydration of calcium silicate (C3S) from portland clinker which responsible for mechanical strength of cement. In portland blended cement deduction of C3S portion is replaced by CSH formed from reaction of silica in SCMs with Ca(OH)2 as site product of C3S hydration.

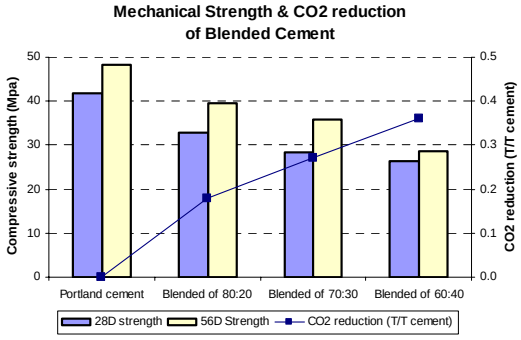

Figure 1. The compressive strength of cements

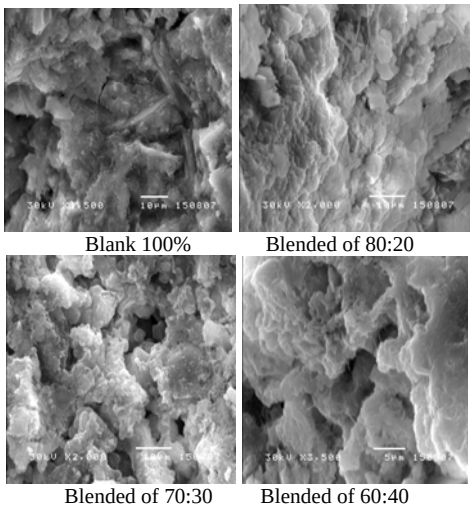

Blank 100% Blended of 80:20

Blended of 70:30 Blended of 60:40

Figure 2-5 Micrograph of cement pastes at 56 days

ISSN 114-1284

CONCLUSION

Replacement of up to 30 % trass to portland cement still gives good mechanical strength makes portland blended cement is promising for future's cement as well as contribute in reducing CO_2 emission.

ABSTRACT

High speed steel (HSS), widely used for tools, because of excellent hardness, wear resistance, and high temperature properties. HSS rolls consist of martensitic matrix, hard carbide such as MC, M_2C, M_7C_3, and M_6C and secondary carbides the matrix. The most decisive microstructure in HSS fracture toughness is intercellular carbide and their distribution together with matrix characteristics. Direct micro fracture observations show that micro cracks initiate at hard carbides formed along in cell boundaries, and that fracture proceeds along these carbides [1]. Connected carbide can easily propagate the microcrack on the cell boundary. In order to develop HSS fracture toughness without decrease the wear resistance, boron is used for alloying element. We investigate the boron effect on the HSS properties using HSS alloy with ± 0.04 wt% boron. Boron can segregate in austenite cell boundaries and occupy vacancy sites induced by deformation so as to prevent the formation and propagation of microcracks at boundaries [2]. Bending test was performed to study the effect of boron on HSS strength. Microstructure characterization; phase identification, carbide identification, boron segregation and fractography of the materials was performed using SEM/EDS, XRD. The cell size and carbide volume fraction is examined using image analysis software. Boron addition increase around 10% bending strength of the material. Matrix hardness and overall hardness also increased. There are no differences of carbide morphology with addition of boron.

Boron addition, high speed steel, segregation, bending test, cell refining

1. INTRODUCTION

High speed steel has excellent hardness, wear resistance, and also high-temperature properties. These properties make HSS become suitable material for roll material. Roll material must have excellent wear resistance because of the application of this material. These HSS rolls have different microstructure and characteristic from high speed tool steels. When manufacturing tool steels, the structure is destroyed in the subsequent deformation such as forging, and the final microstructure after heat treatment consists of tempered martensite containing fine and well distributed carbide [1]. The cast structure of HSS contains of coarse carbide, and the matrix will transform to temper martensite after heat treatment.

Carbides on HSS material contribute to the hardness of HSS. If volume fraction of carbide increases, the hardness of the HSS also increases. Coarse carbides are generally segregated along cell boundaries, therefore, overall roll hardness increases, but fracture toughness tends to deteriorate [1]. Consequently, the microstructural factors such as size, volume fraction, distribution of coarse carbides, and the characteristics of the martensitic matrix play important roles in enhancing the roll properties.

Boron has a strong tendency to segregate to the grain boundaries but not to cavity (free) surfaces, and enhance grain boundary cohesion [3], segregation of boron can be found as a component of Fe2B [4]. Segregation of boron and enhancing of the grain boundary cohesion causes cell refinement and winding of grain boundaries. Boron is enhancing of the grain boundary cohesion that obstructs grain growing at annealing course [5]. K.N.Kim [5] investigated that with the increase of boron addition the RT bend strengths also increase. S.H Song [6] investigated effect boron on the C-Mn steels and austenitic stainless steels. It has been shown that boron can segregate to

austenite grain boundaries and occupy vacancy sites induced by deformation so as to prevent the formation and propagation of micro cracks at boundaries and in turn improve the steel hot ductility.

The complexes diffuse from the matrix to the boundary causes the boundary segregation since the boundary is a sink for vacancies. Therefore, when a specimen is cooled to a lower temperature from a higher temperature, solute atoms will segregate to austenite grain boundaries. Since the diffusion rate of B-vacancy complexes is far faster than that of P-vacancy complexes [8], B vacancy complexes arrive at the grain boundary more quickly than P-vacancy complexes do in the process of continuous cooling, which suppresses the segregation of phosphorus. As shown in [8], the binding energy of boron with the grain boundary is approximately twice of that of phosphorus.

In order to develop HSS fracture toughness without decrease the wear resistance, boron is used for alloying element. The purpose of this study is to investigate the effect of boron on the casting HSS alloy sample properties. The addition of boron is 0.04 wt %.

2. EXPERIMENTAL PROCEDURE

Materials used in this study were four HSS manufactured by casting method, whose chemical composition listed in table 1. The basic composition of the HSS is 1.9C-6.5V-6Cr-0.8Si-0.4Mn-3-Mo-5W (wt. %) and this alloy design to be able to investigate the effect of boron addition by addition 0.04 wt % boron in some alloy. The HSS alloys were manufactured by a laboratory scale induction furnace casting apparatus with the capacity 2.5 kg. The melt was charged into the mold and then equilibrium solidified.

The samples were polished and etched in vilella and marble's [10] (10 g CuSO, 450 mL HCl, 50 mL water) and were observed by an optical microscope and scanning electron microscope (SEM). Compositions of carbides and the matrix were quantitatively analyzed by energy dispersive spectroscopy (EDS). Carbides were examined using Murakami etchant [10] (10 g K3Fe (CN), 10g NaOH, 100 ml water), in which M2C (black), M7C3 (light pink), and M6C (pink) carbides are selectively etched but not the matrix and MC carbides. The cell size and the volume fraction of respective carbides were quantitatively analyzed using an image analyzer.

An X-ray diffractometer was used to confirm the kind of carbides and to measure the amount of retained austenite (γ). Microhardness of the matrix was measured by a vickers hardness tester under 25 g loads.

Sample with dimension 3x3x30 mm were used for room temperature bend testing using three point bending method.

3. RESULT AND DISCUSSION

Fig. 1(a) through (d) are optical micrographs of the four as-cast HSS. It is known that boron generally has major effect on cell size. Figs. 1 show the effect of boron on the cell size for the foundry samples. In alloy 1, sample with boron (Fig.1 (a)) produce smaller cell size than sample without boron (Fig.1 (b)). This phenomenon also happened in alloy 2, sample with boron (Fig.1 (c)) produce smaller cell size than sample without boron (Fig.1 (d)). Boron has a strong tendency to segregate to the grain boundaries but not to cavity (free) surfaces, and enhances grain boundary cohesion [5]; segregation of boron can be found as a component of Fe_2B [4]. So the segregation of boron and enhancing of the grain boundary cohesion causes cell refinement. Increasing of boron content can reduce the solubility of carbon on γ phase (reduce the γ loop) [16]. Boron also can make C replacement on γ phase and also cementite. Another mechanism of cell refining is because of boron act like C, together with C and high contain of V, W it will promote MC carbide formation on the liquid in high temperature. The formation of MC carbide became nucleating agent for solidification process. So additional of boron will increase the MC carbide content on the liquid, it means that increasing nucleating agent on the liquid. From what has been mentioned above, it will refine the cell size gives cell size refining effect. The calculation of cell size shows in table 2. In alloy 1, the addition of boron reduces the cell size 46 %. In alloy 2 the addition of boron reduces the cell size 17 %.

Boron has lower solubility on the Fe matrix for ± 10 ppm on 900°C, confirm by T.B.Cameron [4]. T.B Cameron found that the solubility of boron in the austenite is higher than in the ferrite at the invariant temperature. Therefore it will produce eutectoid reaction. During cooling, eutectoid reaction will happen because of the difference of boron solubility on austenite and ferrite (Fig.3). The reaction is:

$$\gamma \rightarrow Fe_2B + \alpha$$

In alloy 1 and alloy 2 with boron sample we found formation of Fe_2B that confirm from the XRD data (Fig 7 (a) and (b) with low peak intensities.

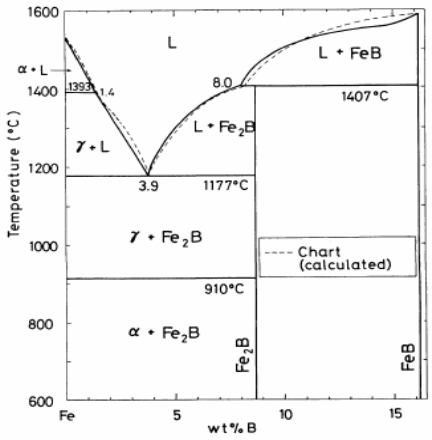

Figure 3: Calculated equilibria in Fe-FeB phase diagram [16]

In Table 3, the average hardness values of the four HSS samples are provided in HV units (Hardness Vickers). The hardness values of without boron samples are observed to be lower than those of with boron samples. This is because samples that contain boron have smaller cell size compare with without boron sample. And also in boron sample there are $M_{23}(C,B)_6$. From the XRD results (Fig.7), we found the formation of $M_{23}(C,B)_6$. It has been reported [11] that only soluble B can segregate and then later precipitate as $M_{23}(B,C)_6$ at grain boundaries. These particles act like other interstitial alloying elements which are able to fill the unfavorable gaps on grain boundary and stabilize the grain boundary surfaces [11]. Likewise, it has been shown that boron atoms tend to migrate to austenite grain boundaries (segregation), a fact that can be associated to B-vacancies interactions [8,11]. Boron can also act as interstitial atom in Fe site that can also increase the hardness of the material.

MC carbides are V-rich carbides (V_4C_3 in chemical stoichiometry) containing mostly V with small amounts of W, Mo, Cr, and Fe. M_2C and M_6C carbides are carbides containing Mo and W, and M_7C_3 carbides are Cr-containing ones. Because of high content of Cr, W and Mo, M_7C_3 type or M_2C type carbides are located along solidification cell boundaries (Fig.1). Most of MC type carbides are formed inside cells (Fig.1). This is happened for entire samples. HSS with boron samples contain higher % carbide volume fraction than HSS without boron samples (Table 4).

Table 6
Effect Boron on Bending Strength

Sample		Size of the samples (±0.005)(mm)	Most load (average) (kgf)	Bending Strength (Mpa)
Alloy 1	With boron	3 x 3 x 30	243.45	270.50
	Without boron	3 x 3 x 30	219.44	243.82
Alloy 2	With boron	3 x 3 x 30	130.43	146.64
	Without boron	3 x 3 x 30	118.00	128.61

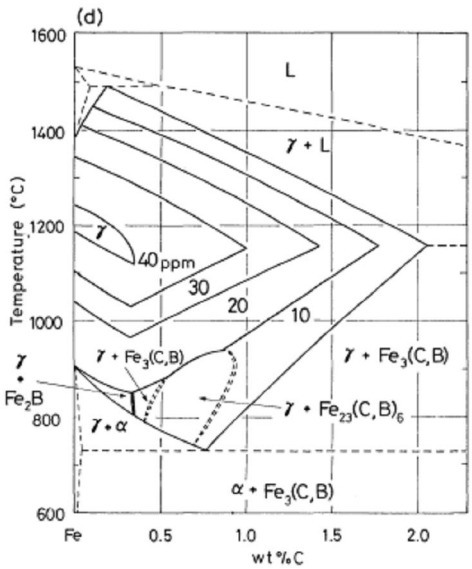

Figure 5: C-B system and carbon limitation for pure austenite [16]

In alloy 1, with boron sample produce 1.13 % higher carbide volume fraction than without boron sample. In alloy 2, with boron sample produce 1.38 % higher carbide volume fraction than without boron sample. This is because boron decreases the solubility of the carbon on austenite phase (Fig.5) [16]. Rejected carbon will tend to form carbide. So additional of boron will increase the carbide content. It was confirm from the XRD data (Fig.7) that with boron samples have higher peak intensity of carbide than without boron sample. For entire samples, from the calculation, the quantity of M_7C_3 type or M_2C carbides is higher than MC carbide. This is because of high containing of Cr, W and Mo, so M_7C_3 type or M_2C carbide is easier to form.

Fig.2 (a) and (b) are SEM micrographs of matrices of Alloy 1 with boron (a) and without boron (b). It can be confirmed that the as-cast matrix is lath martensite in both alloy. The carbon content in the HSS rolls is generally 1.5–2.0%, most of which is combined with such strong

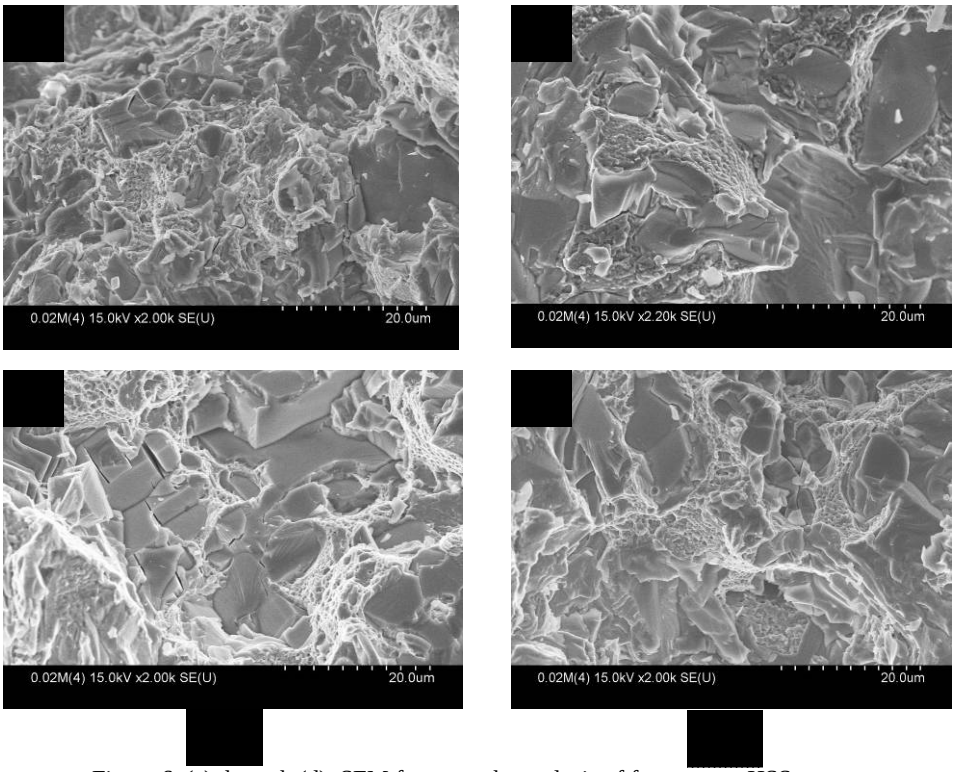

Figure 6: (a) through (d); SEM fractographs analysis of four as-cast HSS.
(a) alloy 1 with boron (b) alloy 1 without boron (c) alloy 2 with boron (d) alloy 2 without boron.

carbide formers as V, W, and Mo [1]. The rest of carbon,0.3–0.6%, is contained inside the matrix, and forms lath-type martensite when the carbon content is below 0.4%, while plate-type martensite when it is above 0.4% [1]. Fig.2(c) and (d) are SEM micrographs of matrices of alloy 2 with boron (c) and without boron (d). It can be confirmed that the as-cast matrix is lath martensite in both alloys. Evenly distributed inside the matrix are quite fine spherical carbides (Fig. 4). This fine carbide analyzed using EDS. The result of qualitative and quantitative EDS analysis shown in Table 5. This fine carbide contains higher vanadium, tungsten, and molybdenum than the matrix. The fine carbide formed during slow cooling on solidification process. This fine carbide distributed on the matrix.

The result of room temperature bend test of sample made form casting are shown in table 6. From the table shows that sample contain of boron tend to have higher bending strength than without boron sample. The RT bend strength of with boron alloy is higher than without boron alloy by about 10 % in alloy 1 and alloy 2. It shows that additional of boron improves the ductility of the alloy; the mechanisms of boron ductilizing effect may include: (1) boron enhances grain boundary cohesion [3]; (2) boron modifies grain boundary structure that allows slip accommodation and transmission across the boundaries at lower levels of stress accumulation [5].

We analyze the fractographs of bending sample. For entire sample bending-tested at room temperature. As we know, HSS contain high carbide volume fraction. Fracture easily happen on the eutectic carbide that segregated on the grain boundary. In alloy 1 with boron (Fig.6 (a)), when the specimen is fractured there appears to be ductile fracture with small and large dimples and with small apparent grain boundary facets. In alloy 1 without boron (Fig.6 (b)), the material exhibit intergranular failure on the carbide site and also there are small dimple. Fracture most happened on carbide. In alloy 2 with boron (Fig.6 (c)), when the specimen is fractured there appears to be mix between ductile fracture with small and large dimples and also we can find intergranular fracture in some part. In alloy 2 without boron (Fig.6 (d)), the material exhibit mix between intergranular failure and also ductile fracture, but with boron sample has more dimple than this sample. From the fracture surface appearance shows that for material with boron tend to has fracture on the matrix (ductile fracture) with small and large dimples, but for the material without boron fractures tend to happen on the carbide site (intergranular). It shows that boron tend to increase the ductility because of boron enhances grain boundary cohesion.

Fig. 7(a) through (b) are X-ray diffraction results of alloy 1 and 2 after casting. At the as-cast state, peaks of martensite, MC, M_2C, and M_7C_3 are dominant, together with a small amount of austenite for entire samples. We found the peak of $M_{23}(C,B)_6$ and Fe_2B in with boron sample(Fig.7(a) and (b)). In this alloy, the peak intensity of retained austenite is very small, shows the small contain of retained austenite in the samples.

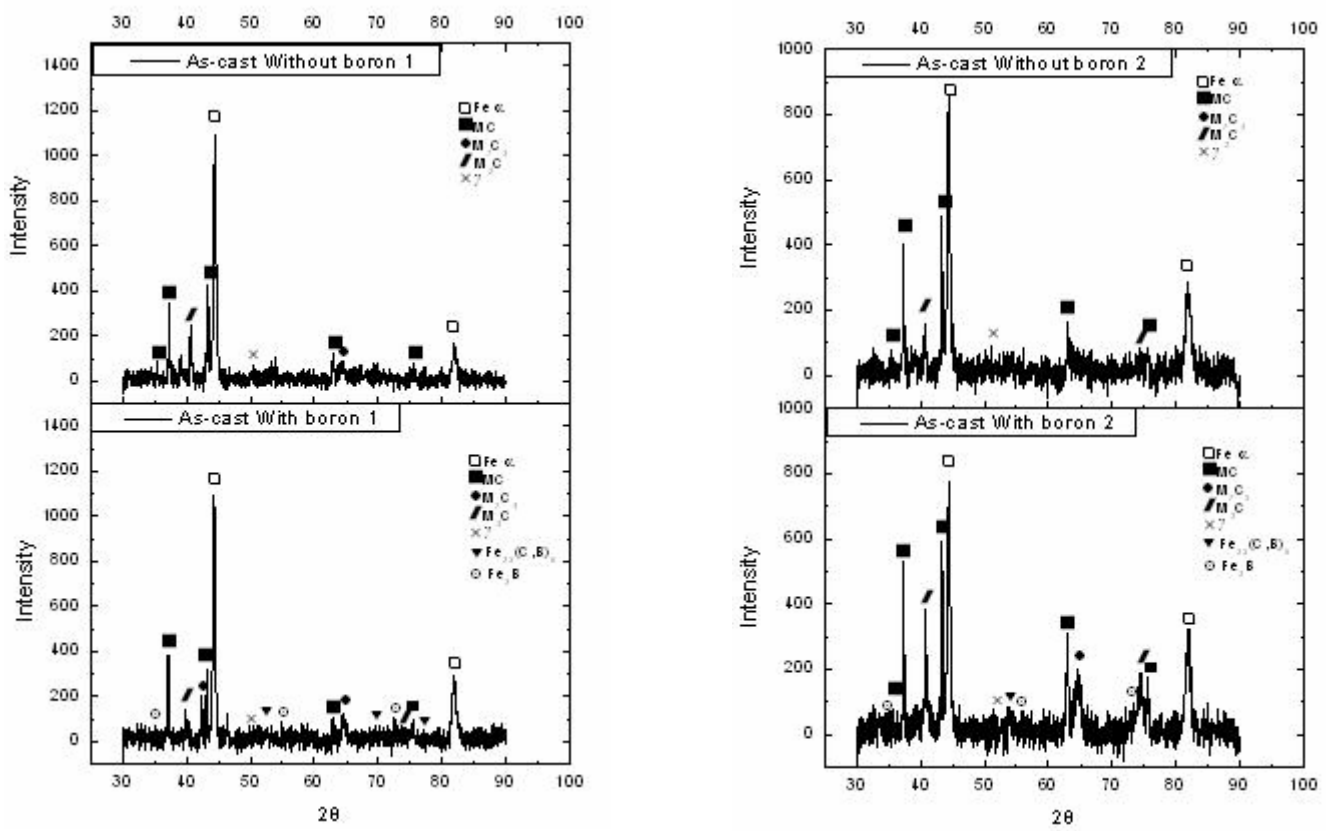

Figure 7: XRD Result (a) Alloy 1 (b) Alloy 2

4. CONCLUSION

In this study, the effect of Boron on properties of HSS alloy was investigated.

1. Additional boron 0.04 % on the HSS alloy shows cell refining effect on the sample. With boron sample produce cell size ± 30 % smaller than without boron sample. This is because boron increase nucleating agent by increasing formation of MC carbide. It is also increase the % carbide volume fraction for with boron sample.
2. Additional boron 0.04 % on the HSS alloys increases the bending strength ± 10 %. The improved ductility for the studied alloy is because of the enhanced grain boundary cohesion by boron.
3. Additional of boron tend to increase the hardness of the material. This is because boron gives cell refining effect and also boron can act as interstitial atom on Fe site.

ABSTRACT

Mostly, duralumin is used extensively as a material in aerospace, automotive, and other industry, i.e. petroleum to cryogenic materials. Porosity defect until now consists in metals casting especially in duralumin that would reduce its mechanical properties. The Researchers and Foundry mans reports about porosity had conclude that it is affecting solution hydrogen in casting. Several processes; fluxing, vacuum following induced argon gas, high isostatic pressure, and high pressure die casting have been tried to eliminate the hydrogen solution in duralumin casting. This article will explain the method to reduce hydrogen solution by vacuum system in casting process to eliminate hydrogen absorption in metal melt and trapped in solidification, respectively. The objective of this experiment research is to compare porosity defect included porosities density and morphology on duralumin casting process by melting, followed by solidification in atmosphere and vacuum conditions. Pure aluminum ingot (99.5%Al) and pure copper scrap (98.5%) as raw materials are melted on stainless-steel crucible and pouring at 700 ^{o}C for cooling in isothermal process. Specimen casting made by permanent mold to near net shape is aimed to lessen removed materials and reduced its thermal effect. The porosity was studied with Picnometry method, and then would be confirmed with optic method and scanning electron microscopy. Present work is focusing on qualitative and quantitative analysis (QQA) of casting product specimens. The experimental result also gives explanation of birthed casting defect especially in duralumin casting.

1. Introduction

Metal casting is one method of manufacturing process, and this method history has begun since 4000 BC, but aluminum casting was not founded until 1825 and its major usage was to produce kitchen tools. Research and products development of aluminum casting continuously running to explore aluminum alloys, so in 1901-1906 Dr. Alfred Wilm succeed to find Al-Cu with spectacular characterization and it is named Duralumin [1]. Because, it is Duralumin is significant properties for strength to weight ratio (σ_t: 190 MPa for O, and σ_t: 470 MPa for T4), good quality in corrosion resistance and thermal conductivity, and *fracture toughness* and *fatigue* is excellent. In 1973 – 1999 periods, several experiments have been tried vacuum casting method to improve the quality of aluminum alloys casting products [2]. And now, casting of aluminum alloys especially duralumin is commonly used in automotive and aerospace industries, and in petroleum industry for cryogenic pipe. However, Designer and Foundry-man have constrains with porosity defects that is difficult to eliminate.

The matter of porosity formation must be detected and avoided in melting and solidifying processes, in order to produce high quality of Duralumin casting. When aluminum alloy casting is done in atmospheric condition, oxygen, nitrogen, hydrogen gases always follows it. The atmospheric humidity and the mixture of additions, such as constitute element ingots to increase its gasses contents in casting process. And then hydrogen is the only gas dissolved to a significant extent in the melt that would affect fatally on Duralumin casting. In the literatures, porosity forms when there is a gas entrapment, solidification shrinkage due to failure of inerdendritic feeding, and/or precipitation of dissolved gas from the molten metal. Most research jobs have been done until now to decrease of porosity with several methods, i.e. fluxing, continued vacuuming, only

to melting process, and can would to optimal produce. This article is an innovative process that hopefully would be an improvement of Duralumin casting of melted and solidified is done by simultaneously.

Porosity is casting defect especially in duralumin, it includes morphology and density and would effected on mechanical properties. Generally, porosity in metals would be reduced in mechanical properties is where some incident because it's unknowable. It's is always consist of every aluminum alloy casting and nothing null but only decreased or elimination. Now, urgently some question about of porosity is first questions, limits of porosity casting is allowable in duralumin. The second question is the length of term effect Duralumin porosity in atmospheric and vacuum casting conditions. For, the answered of important two questions is needed statistic knowledge to explained porosity phenomenon. So then descriptive in qualitative and quantitative test, and statically interpretation until inferential is crucial to explored thus comparison.

2. Materials and Experimental Setup

2.1. Material Processing

Initially, the research design is to compare between duralumin porosity at atmospheric condition and vacuum condition to determine quality and quantity of porosity in metallograpy, i.e., using microstructures, so information from its porosity can be correlated with mechanical properties. However, the actual research until now just for duralumin casting from aluminum ingot and copper pipe as the raw materials in reveberatory furnace, and this is done as the pre research on dissertation. This involves; a). Measurement of element content substance will be done with spark spectrometry, b). Casting of raw materials to made duralumin, c). Measurement of duralumin casting mass will be done with digital electric balance, and d). Porosity characterization is done with picnometry and optic microscopy. Each of the above experiments for duralumin casting while three replications to data precision, and made data accuracy would be uncertainty test is to compared of research instruments with it's in metal laboratory at University of Indonesia. Result of uncertainty test is multiplying factors would used in research data.

2.2. Casting Procedure

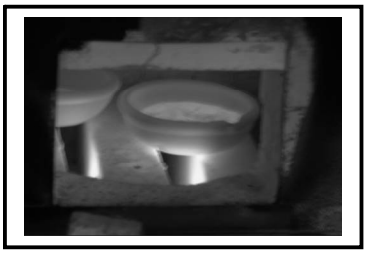

Figure 1: Duralumin melt in crucible.

There are preparations to make duralumin casting products in this research which are mass analysis, melting process, pouring, and solidification, and testing of the specimens. The calculation and weight balance of one kg aluminum ingot which contains 995 grams of pure aluminum to produce Al-Cu with composition of 2.5, 3.0, 3.5, 4.0, 4.5 % Cu need addition of 25.90, 31.24, 36.64, 42.09, 47.60 grams of copper scrap in a series. To simplify the analysis, other elements will be ignored since the composition is less than 0.5% in the raw materials i.e.; Mg, Fe, Si, Zn etc. Raw materials which have been measured with the same proportion will be put in a ceramics crucible for melting process in reveberatory furnace. The first period raw materials will be melted in seventy five until eighty five minutes and the next periods of raw materials will be melted in twenty minutes. Then, melted duralumin in crucible will be poured and solidified by gravity and atmosphere condition in permanent mold. As presented on the figure 1 is duralumin melt in crucible on casting process.

2.3. Porosity Test

Qualitative and quantitative of porosity defect of duralumin casting are respectively measured by microscope optic and Picnometry apparatus (mass balance). Microscope optic by 50 magnitude is used to get image, and Picnometry to determine the percentage of porosity defects. The experimental are the Picnometry apparatus for density test of duralumin cast can be expressed as; $\gamma_C = \frac{Wa}{Wa - Ww} x\gamma_W$ (1)

where Wa and Ww is specimen weight on air and specimen weight in water, γ_c dan γ_w is casting density and water density. And experiment porosity test of duralumin cast can be expressed as;

$$P = \frac{\gamma_{IC} - \gamma_C}{\gamma_{IC}} x100\% \qquad (2)$$

where γ_{IC} is ideal casting density is find analytical from chemical content of specimen from spark spectrometry. As presented on the figure 2 the Picnometry apparatus as measured weight balance on experiment. The measured weight of specimen is dipped in water media

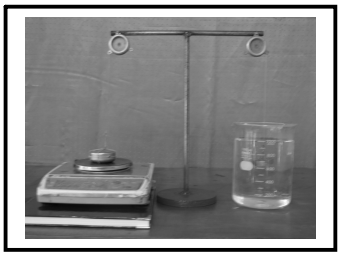

Figure 2: Picnometry apparatus

3. Data and Discussion

A. Chemical Content

The material balance data of this experiment are appearance on the chemical composition of raw material and duralumin shown in Table 1.

Shown Table 1 is proportion goal of alloyed Al-Cu not yet success because copper and aluminum are decrease, and increasing of ferrous. Effect of alloy elements and density measure density by Picnometry is shown of Figure 4a. Highest heating temperature and long period duralumin melt are caused reducing aluminum element. The ideal produce of casting is importance to added primary substance (Al and Cu) because in metal casting it's will be change to slag and gas specially materials with low melt point. Generally, aluminum alloy casting is added 10 to 15% primary material and 5 to 7.5% material alloy from mass balance account by stociometry [3].

Fluid flow in interdentritic capillary depend of primary dendritic arm spacing (PDAS) and secondary dendritic arm spacing (SDAS), it's crucial as variable in solidification mechanism to predict of formed microposity. The other factor is added alloy composition, content gas of air, casting dimension, thermal conductivity of mold is depended solidification process. In experiment of duralumin casting, added substance in raw material have high melting point like it ferrous and silicon is increased. It's will be made new compound (fe intermetalic) in aluminum alloy is harmed by complex marphology, i.e.; $Al_{15}(Fe,Mg)_3Si_2$ phase [4]. Certainty, $Al_{15}(Fe,Mg)_3Si_2$ and other phases on duralumin will be detected by scanning electron microscopy [5].

B. Microstructure and Porosity

Duralumin microstructure or porosity of the optic microscopy is shown in Figure 3. They generally consist of structural grains and porosities is differential in fraction volume, which exhibits relatively smaller contrast compared to casting area. By figure 3, increased trend of porosities on each added copper ratio in duralumin is cleared.

Figure 3 and 4b showing optic microscope of duralumin micro porosity and porosity of duralumin. Aluminum alloy, bronze, eutectic Al-Si alloy have short-freezing-range to make excellent surface of casting. To make the channel open wider we have to make first solidification and continuing to fill in the liquid. In the end of the internal pressure become lowest cause by the minimize fill in inside the pore of liquid nucleation.

Solidification and nucleation continuously to driving force on the growth of inside the pore beside the casting surface. The casting area porosity generally consists of the smallest and contrast round grains. In the lowest temperature (on solidification) porosity as the sign of solubility(hydrogen).According to (6), porosity inside the casting solidification cause to liquidation or the capable porosity inside the casting solidification cause to liquidation or the capable to fill in interdendritic out-let finally became shrinkage.

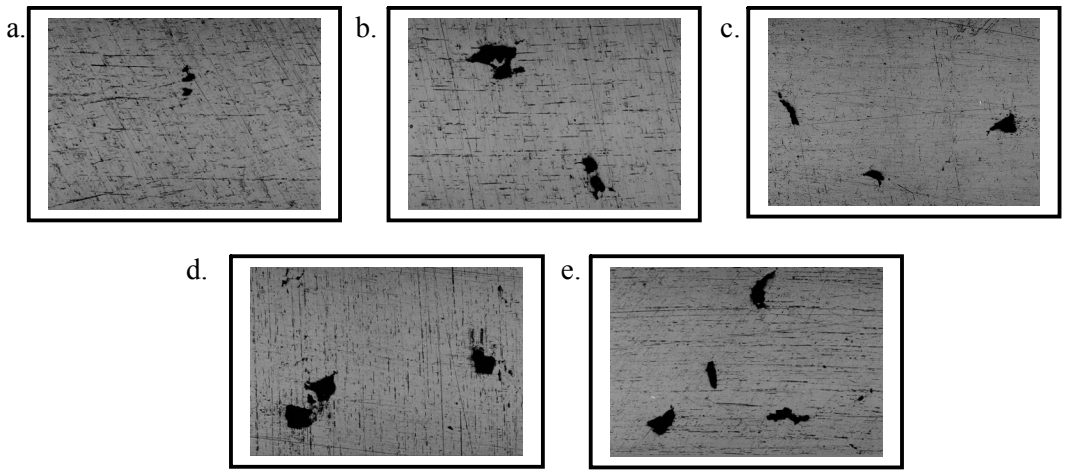

Figure 3: Porosity in duralumin casting, a. alloyed 2.5% Cu, b. alloyed 3.0% Cu, c. alloyed 3.5% Cu, d. alloyed 4.0% Cu, e. alloyed 4.5% Cu

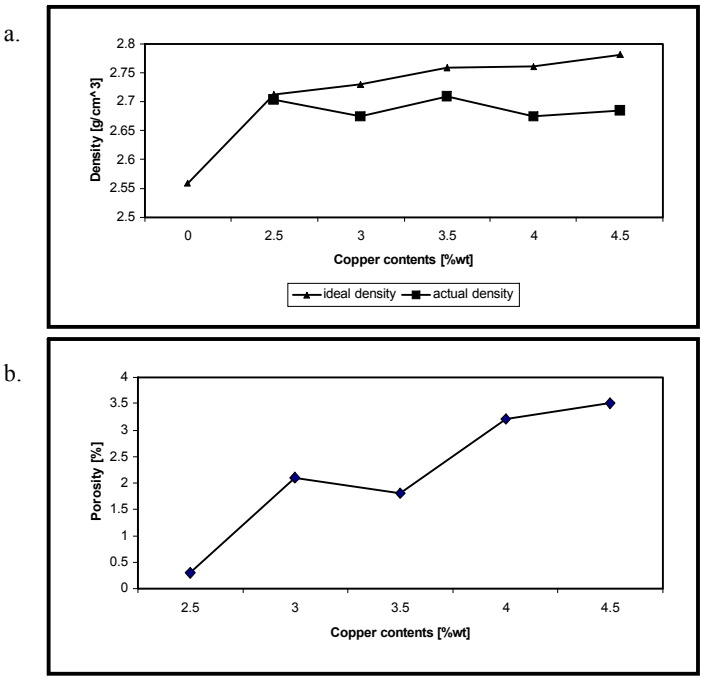

Figure 4: Physic performance of duralumin casting diagram, a. density comparison, b. porosity vs copper on duralumin

4. Conclusion

The melt recycling of Aluminum ingot the variations of added copper scrap in reveberatory furnace with respect to density and porosity was done. The contents of aluminum and copper in duralumin decreased and ferrous increased from casting designs. But it's copper continuously to trend be promote of higher copper ratio each alloying. The trend of porosity will be increase of high than low copper ratios, and aluminum has trend inversed.

wahyubw@gmail.com

Formation mechanism of nanosized geometry in Mechanical Alloying process is very interesting field of study which hasn't revealed and studied intensively. Compared to the micro-structured bulk material, nano-structured material has large surface energy which gives significant influences to the thermal stability. Many previous researches have reported the increases of strength and hardness of nano-crystalline materials which have been consolidated into bulk material, compared to the conventional large-grain size bulk material. In order to study the formation mechanism of nanosized geometry, we proceed Mechanical alloying experiment of stoichiometric composition of Bi-50%atMn from pure Bi and Mn powder using High Energy Milling (HEM) for different specified time. The processed powders were then characterized using X-Ray Diffraction (XRD), Scanning Electron Microscopy (SEM) and Energy Dispersive Spectroscopy (EDS). The X-ray diffraction pattern shows structural change and formation of new phase which then became rapidly since 32 h. The comparison of SEM images gives better visualization which can be concluded for overall process as process evolution from the existence of mechanical bonding into chemical bonding.

Keywords: *Nanosized geometry, Mechanical Alloying, Bi-Mn system.*

Introduction

Bi-Mn has been known as a metallic alloy with suitable characteristics to be applied as permanent magnet. This alloy is affected easily by external magnetic field because of its high magnetic anisotropy energy [1]. The phenomena of highly negative Kerr Polar rotation (-1.2˚) in the range of UV spectrum and high perpendicular magnetic anisotropy of MnBi, the stable phase of Bi-Mn system up to 550˚C, is the characteristics that makes MnBi good candidate for magneto-optic data recording [2-3]. $BiMnO_3$ and $BiMn_2O_5$ as possible phase of Bi-Mn or Bi-Mn-O system are known to have rare multiferroic phenomenon that has novel functional potential for micro/nano devices[2]. On the other hand, Mechanical Alloying is one method of material synthesis which is very interesting to explore for some phenomena such as particle refinement, amorphous formation, and solid solution [5]. However, there are still limited studies which discover the formation mechanism of nanosized geometry, conducted by mechanical alloying process. For those purpose, this paper describes the formation mechanism of nanosized geometry in correlation of mechanical alloying process. This study is aimed to study the microstructural evolution of Bi-Mn system alloy during mechanical alloying process.

Experimental Procedure

The material used for this experiment is 99.5% purity needle-shaped Bi flakes which were firstly powdered using Siebtechnik blast mill (disk mill) to reach micron-size powder. The powdered Bi then mixed with 99.5% purity manganese in initial composition of Bi-50%atMn and were MA-ed using High Energy Milling E3D (HEM E3D). The process was carried in argon condition with BPR (Ball to Powder Ratio) of 10:1 at normal speed of 300 rpm. The mixed powders were sampled for MA time of 1, 4, 8, 16, 32, and 64 jam which then characterized using Digital Rigaku Geigerflex XRD, ESEM tipe XL30CP- Philips, and HR-SEM (JEOL JSM-6510LA). The overall step of the experimental is shown in Figure 1.

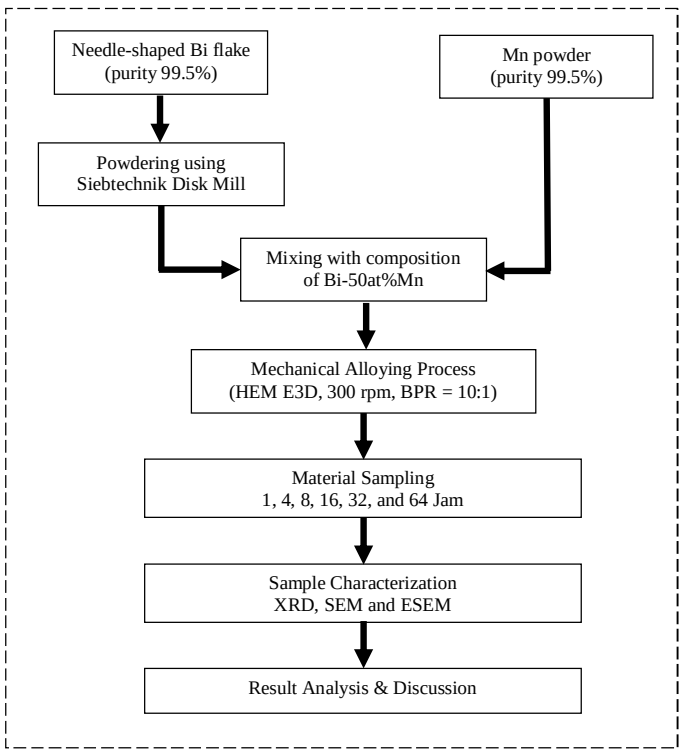

Figure 1 Experimental Flowchart

Results and Discussion

X-Ray Diffraction pattern of MA-ed Bi50at%Mn is shown in Figure 1. Before MA process, the pattern is dominated by Bi peaks and there's only one strongest Mn peak detected, relative to overall peak intensities. After 1 hour MA, there can be seen the occurrence of new phases which identified as $Bi_{24}Mn_2O_{40}$ (222) and Bi_2Mn (002). This shows the mixing and initial reaction between Bi and Mn particles has occurred since 1 h MA time. The processes were accompanied by the inclusion of oxygen particles through the process, resulted the formation of new phase.

There is no drastic change on the XRD pattern alter 4 h milling, yet some peaks intensity started to decrease. Meanwhile, new phase peak which occurred firstly afear 1 h milling experienced no significant change after 4 h milling. The similar result was also happened after 8 h milling time, yet the intensity decrement of Bi main peaks continued to occur. After 16 h milling, $Bi_{24}Mn_2O_{40}$ (310) which close to Bi (012) peak and Bi_3Mn_2 (002) started to occur, whereas $Bi_{24}Mn_2O_{40}$ (222) and Bi_2Mn (002) peaks were getting higher. As new phases occurred, almost all Bi and Mn peaks decreased accompanied by peak broadening. This could happen because of advanced reaction among powder particles, including oxygen particles.

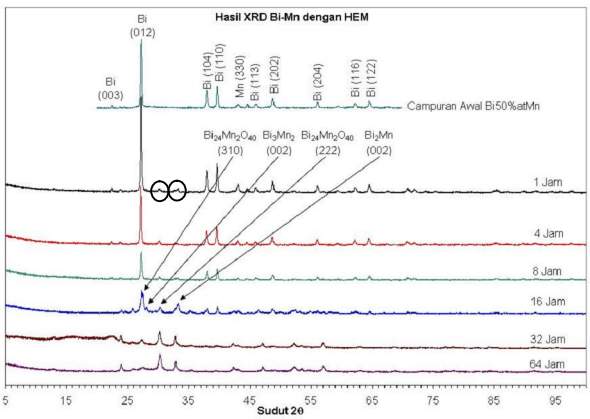

Figure 2. XRD pattern of Bi50at%Mn prepared by HEM

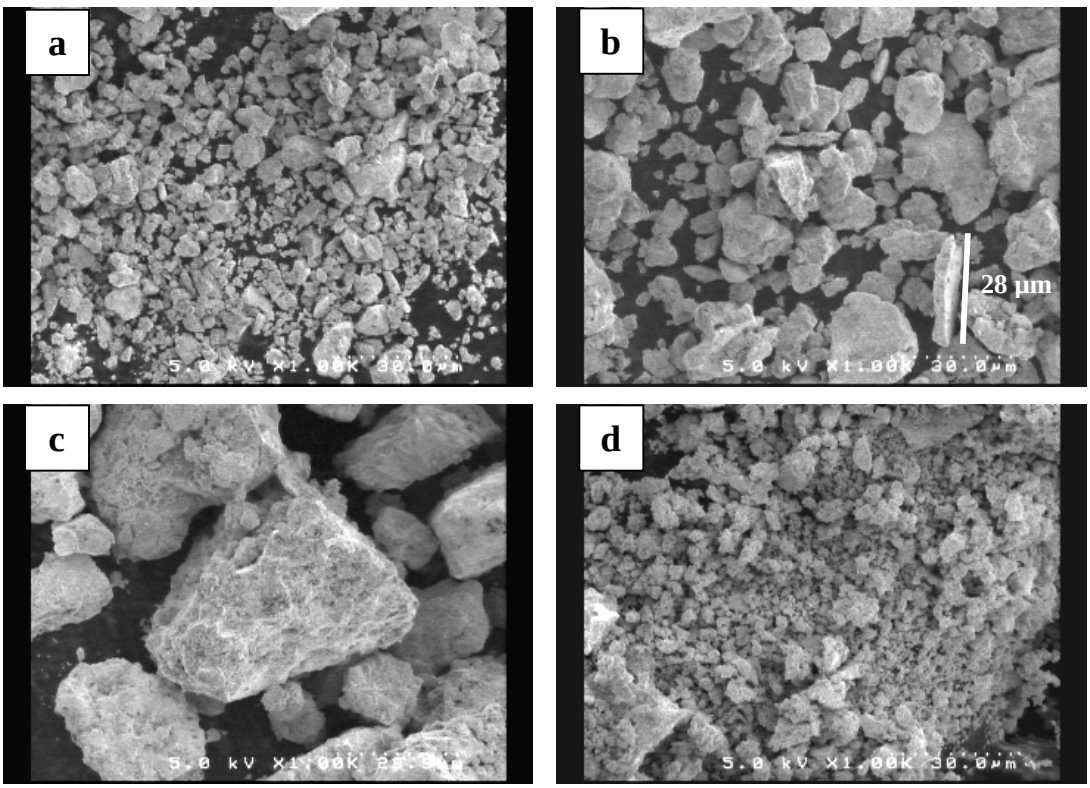
After 32 h milling time, $Bi_{24}Mn_2O_{40}$ (310) and Bi_3Mn_2 (002) phases were vanished which followed by significant intensity decrement and peak broadening of Bi (012), whereas $Bi_{24}Mn_2O_{40}$ (222) and Bi_2Mn (002) peaks were getting stronger. The

occurrence of $Bi_{24}Mn_2O_{40}$ (310) and Bi_3Mn_2 (002) phases were then triggered the decrement of Bi (012) intensity and not the advanced reaction for phase formation. On the other hand, Bi (104) and Bi (110) peaks were also vanished without pre-formation of new phase. In advance, there is no significant XRD pattern difference between 64 h simple and 32 sample, except for the broadening of Bi (012) peak. In addition, there is little increment of $Bi_{24}Mn_2O_{40}$ (222) peak. By analyzing these result, it can be concluded that the formation reaction of $Bi_{24}Mn_2O_{40}$ (222) started to stop. The process was then stepped to the next process i.e. grain refinement process.

Figure 3 shows the microstructure evolution of as-milled Bi-50%atMn. After 1 h milling the powder grains began to mix heterogeneously, yet the individual particles still dominated the microstructure. However, after 4 h milling there are many kind of morphologies which dominated by flaky shape with maximal length of around 28 µm and only small amount of particles which still in their original shape. This could happen because of the plastic deformation from the collision of milling balls which is the initial stage of milling process. By comparing the difference of morphology size between 1 h and 4 h, it can be proved that almost all parts of particles grain have made clusters instead of exist individually. Therefore, the process after 4 h milling is plastic deformation which conducted by balls collision.

After 8 milling microstructure photograph shows many lumps which form big cluster. There are no flaky shapes as we can seen for 4 h milling remaining and replaced by big cluster which came from the joining of those flaky shapes. This joining was not followed by chemical reaction yet only included the process of morphology and particle structure deformation. This can be confirmed by comparing XRD pattern of 4 h and 8 h, where there is no significant difference between those two patterns. The intensity decrement of Bi (012) peak was caused by mechanical deformation on some structure of Bi (012) particles.



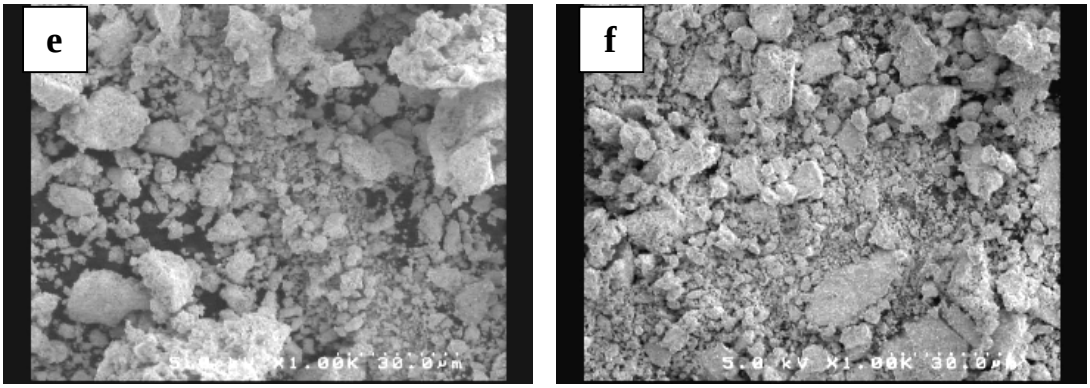


Figure 3. Microstructure evolution of as-milled Bi-50%atMn prepared by HEM E3D (1000X magnification) a. 1 h b. 4 h c. 8 h d. 16 h e. 32 h f. 64 h

After 16 h milling, the particles were broken into smaller cluster which inferred intensive particle refinement and the beginning of new phase formation if we compare with XRD pattern. This could be happen because the lump formation after 8H milling is the saturation point that makes further joining could not happen. Therefore, the actual process after particle agglomeration is particle fracturing which is the preliminary stage before reaction for new phase formation. This could be happen because the smaller particle size will increase surface to volume ratio which ismore unstable in thermodynamics point of view and makes chemical reaction easier to happen [6]. After 32 h milling, some of grains were going to re-agglomerate with brighter color compared to smaller grains and different morphology appearance compared to grains cluster in 8 h milling time. Compared to XRD pattern of 32 h milling, those grains cluster were predicted as new phase of $Bi_{24}Mn_2O_{40}$ (222) and Bi_2Mn (002). The description agree with sample's diffraction pattern where after 32 h milling, the main Bi peak of (002) decrease significantly meanwhile $Bi_{24}Mn_2O_{40}$ (222) and Bi_2Mn (002) phase peaks is getting higher. In conclusion, after 32 milling time most of Bi (012) particles and all of Bi (202) particles experienced particle refinement that make them able to react and change into $Bi_{24}Mn_2O_{40}$ (222) and/or Bi_2Mn (002) phases. After 64 h, bright phases seem increase in number with more homogeneous size, whereas darker particles seem not too dominant. XRD pattern of 64 h sample shows the disappearance of all of Bi and Mn peaks whereas new phase peaks show no significant intensity change. From the result, and by comparing XRD pattern of 64 h sample, it can be concluded that phase transformation was no longer happened and turned into particle size homogenization. The illustration of the process for each milling time is described globally in Figure 4.

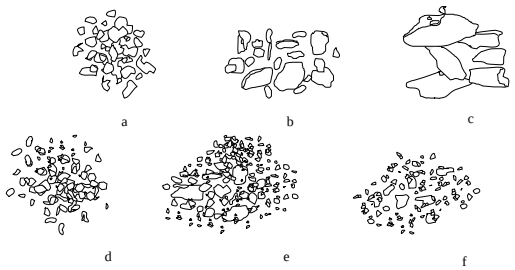

Figure 4. The illustration of the process for each milling time a. 1 h b. 4 h c. 8 h d. 16 h e. 32 h f. 64 h

The as-milled Bi-50%atMn micrograph with 50000X magnification is shown in Figure 5. After 4 h milling, the surface microstructure is dominated by fiber geometry that seems to attach because of collision force from milling balls that conduct morphology deformation. At that time, mixing and particle size refinement have not happened yet that can be concluded by looking the various morphology and wide distribution of particle size. Mixing and particle size refinement process which is accompanied by the formation of new phases was happened after 16 h milling, showed by the appearance of various morphologies such as fibers, flakes, rods, and spheres.

ISSN 114-1284

The particle size refinement and formation of new phase process was still continued after 32 h milling, showed by the appearance of two main morphologies i.e. spheres and fibers which is smaller than fiber geometry in 4 h milling. After 64 h milling, the geometry patterns appear more homogeneous and show no different morphology and no significant particle size. Size and particles morphology homogenization process can be seen more clearly as can be seen in microstructure photograph with 1000 X magnification.

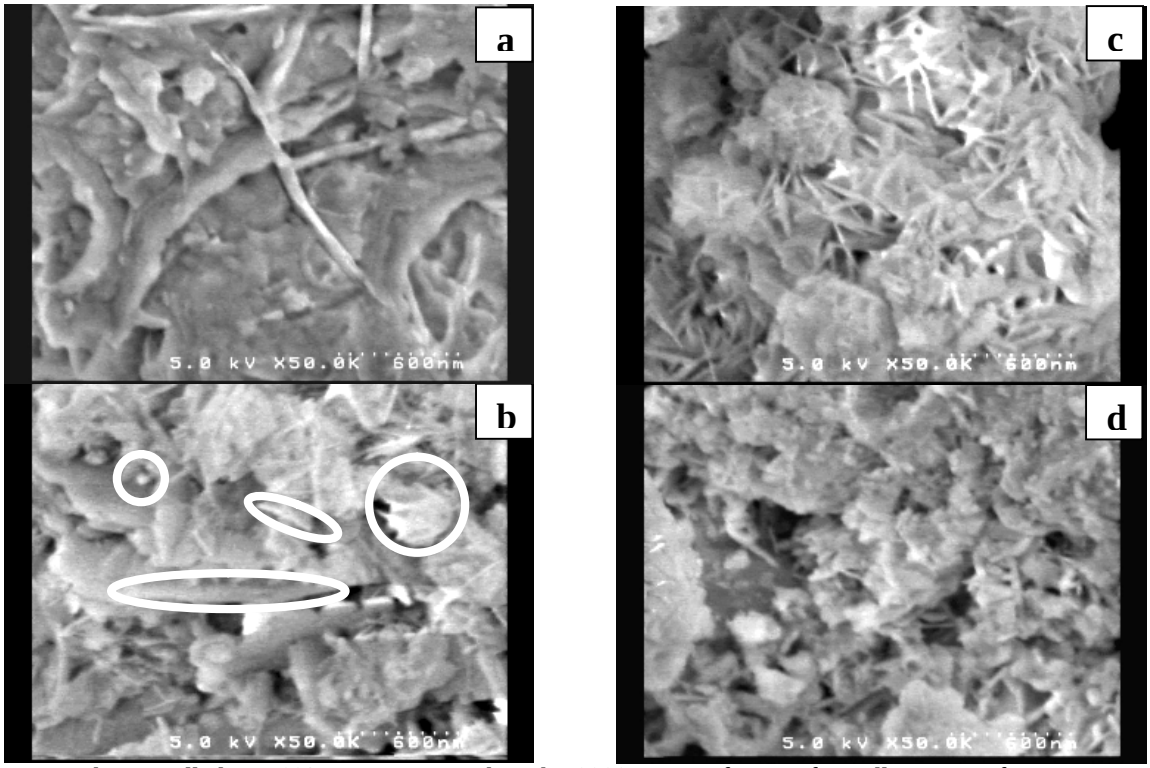

Figure 5 The as-milled Bi-50%atMn micrograph with 50000X magnification for milling time of a. 4 h b. 16 h c. 32 h d. 64 h

Conclusion

From the discussion of the obtained results, it can be concluded that the stages and processes by which the Bi-50%atMn samples experienced different microstructure change are:

1. Heterogeneous mixing process
2. Plastic deformation process
3. Agglomeration process
4. Particle size refinement process
5. The reaction process for phase transformation
6. Homogenization process of particle size distribution

ABSTRACT

In this experiment has been done processing of iron sand to be iron igot by direct reduction using electric arc furnace at 1700°C. The pellet was constituted by iron sand, graphite, limestone, and bentonite with composition of 74:20:5:1 wt % respectively. NaF was also added to composite pellet funcitioned as sludge catcher and aggregation agent. From the experiments, iron ingot in the form of pig iron with iron content of 96,58 % and carbon content of 3,40 % has been yielded. The metallization process yielded 61,47 %. In the sludge, there are still remain iron in the form of Fe_2TiO_4 and FeO compounds, which has proved that reduction process was still not conducted perfectly.

Keyword *: Iron sand, Iron ingot, Electric arc furnace, Sludge.*

INTRODUCTION

Steel or iron is a vital raw materials in industry, almost 95% of metal-made product is dominated by steel which is used in every dailly life activity, such as electrical power plant, building structure, bridge structure, car body etc. In correlation with the demand of steel as a raw material in every field, the lack of iron ores deposit was the most problem to solve in steel industry. Indonesia has an abundance iron ores resource, but existing technology can not be applied to process it. Indonesia's iron ores has no significant Fe content, or it is categorized as low grade iron ores.

Iron sand is availabled in Indonesia abundantly, but it is only used to produce low economic value purposes. Whereas is very potential to process to be special purposes, for example coloration [1], toner [2], magnetic recording [3]-[5], magnet ferit [6] and iron steel [7]. The goal of this experiment is to study possibility of direct reduction process of iron sand pellets into ingot iron and used graphite as reductant.

EXPERIMENT

Graphite powder and iron sand (after being purified by magnetic separator) were inserted with milestone and bentonite with composition of 74:20:5:1 wt % respectively. The mix component and then were refined by disc mill for 10 minutes. Whereas during being refined by disc mill 5 wt % (7.34 g) Sodium Flouride was added to the mix component. To make a composite pellet compact was used sugar cane extract which is dissolved in water with composition 1:1. Cylinderical composite pellet was shape used PVC pipe with about 3 cm diameter and 6 cm height. Pellet was burnt use electric arc furnace with 50 volt and 125 Ampere

for 20 minutes, and temperature during burning process was 1700-1800^{o}C measured by optical pyrometer. The ingot iron and sludge yielded from metalization were analyzed by XRF, XRD, SEM and EDS.

DISCUSSION

1. Preparation and Analysis of Raw Material.

Iron sand was separated based on magnetic properties by magnetic separator. Separation used magnetic separator is better than conventional process used sieve mesh. Elemental analysis of iron sand is shown by Table.1

Based on literature [8][9] iron oxide contented on iron sand after separation were magnetite (Fe_3O_4) and ilmenite ($FeTiO_3$). By varying magnetic field which was used, magnetite (Fe_3O_4) and ilmenite ($FeTiO_3$) could be separated. Compound analysis using XRD shown that magnetite is a major component and ilmenite as a minor component. By comparing with database ICDD every peaks shown can be define, and the comparing result is shown by Table. 2. From ICDD database Fe_3O_4 has cubic of crystal system and Fd3m of *space group* with lattice parameter a = 8,41 Å, in correlation with PDF no. 02-1035. Meanwhile $FeTiO_3$ Rhombohedral of crystal system and R3c of *space group* with lattice parameter a = 5,123 Å and c = 13,760 Å in correlation with PDF no 83-0192.

Table.1. XRF analysis of Iron sand before and after separation

No. Atom	Name of Atom	Iron sand before magnetic separation (wt %)	Iron sand after magnetic separation (wt %)
12	Mg	1.6856	1.6319
13	Al	1.4674	1.8889

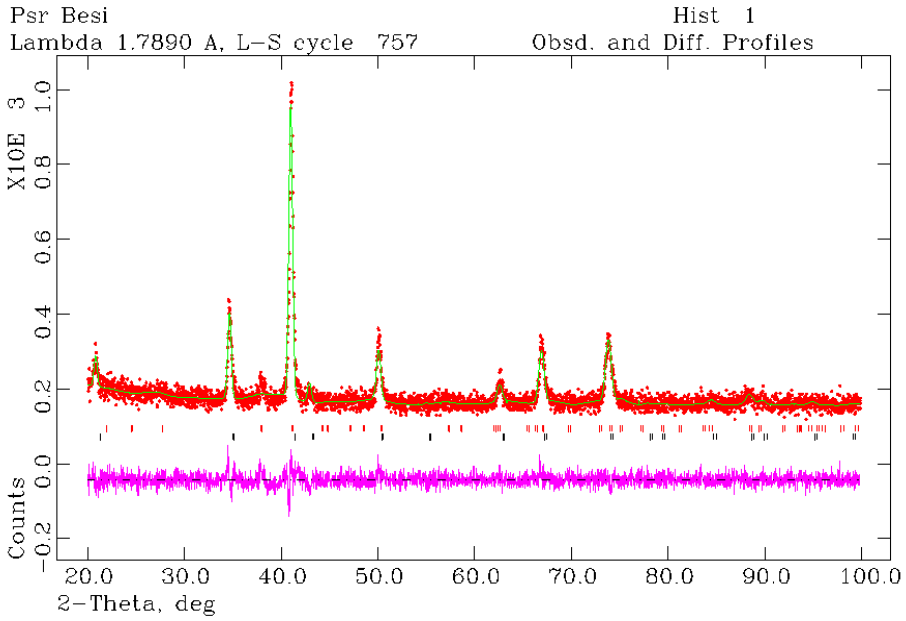
11	1,2600	1,2680	622	Fe_3O_4	021035

By using GSAS, the composition of $FeTiO_3$ and Fe_3O_4 can be known. Iron sand after separating by magnetic separator content of 8.96 wt % $FeTiO_3$ and 91.04 wt % Fe_3O_4. Result of GSAS Analysis is shown by Picture. 1. The picture shows that peaks result from GSAS analysis was correctly fit with the peaks result from XRD instrument.



Picture 1. GSAS plot analysis of XRD patern of iron sand after magnetic separation.

ISSN 114-1284

2. Production and Burning of Pellets.

Pellets composition which was made to produce hot-metal/pig iron with 1 kg capacity is shown by Table 3. NaF was added as aggregation agent to facilitate sludge separation from molten iron and increase hot metal viscosity. Nurul (2004) [10] reported that by adding aggregation agents and sludge catcher impurities can be separated from hot metal effectively.

On burning process of pellets, amount of pellets which is entered on furnace is shown by table 4.

Tabel 3. Composition of Pellets was Made.

	Iron sand (g)	Graphite (g)	Bentonite (g)	Limestone (g)	NaF (g)
Sampele of pellet	108.04	29.2	1.46	7.3	7.34

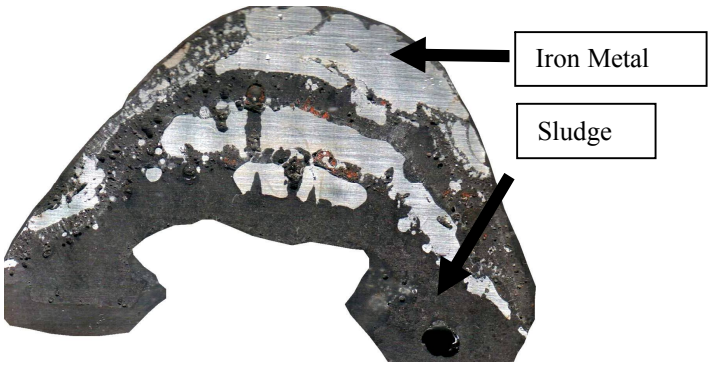
Picture. 2. Pellet with diameter of 3cm, and high of 6cm.

Table 4. Variation of Burning process of Pellets.

No	Pellet	Iron	Time	Current	Voltage	Temp
1	400 gr	103 gr	20 mnt	125 A	50 V	1700 ^{o}C
2	400 gr	95 gr	23 mnt	125 A	50 V	1700 ^{o}C
3	400 gr	98 gr	25 mnt	125 A	50 V	1700 ^{o}C
Average	400 gr	99 gr	23 mnt	125 A	50 V	1700 ^{o}C

Based on table 4, for every 400 gr pellets which was burnt, it would be yielded 100 gr metal iron. The Product of burning of iron sand pellets is shown by Picture 3.

ISSN 114-1284



Picture. 3. The Product of Burning of Iron Sand Pellets.

3. The Calculation of Metallization.

To calculate percent of metallization from process of pellets burning, consider two chemical reaction that represent two reaction of iron formation. Calculation by using stoichiometry on chemical reaction (1.1) dan (1.2)

Total of Pellets weight = 400 gr

Total of iron sand weight on pellets = 70,46% x 400 gr = 281,84 gr

Total of iron weight on iron sand (based on XRF data) = 83,38 % x 281,84 gr = 235,00 gr.

Weight fraction of Fe_3O_4 (Based on GSAS Resulted) = 91,04 %

Weight of Fe_3O_4 on iron sand = 91,04 % x 235,00 gr = 213,94 gr

Weight fraction of $FeTiO_3$ (Based on GSAS Resulted) = 08,96 %

Weight of $FeTiO_3$ on iron sand = 21,06

$$Fe_3O_4 + 4C \rightarrow 3Fe + 4CO_{(g)} \quad (1.1)$$

Weight of iron which is yielded from reduction reaction magnetite (Fe_3O_4) by graphite based on chemical reaction (1.1) is :

3 x mol Fe_3O_4 = mol Fe

$$3 \times \frac{wFe3O4}{Mr.\mathrm{Fe3O4}} = \frac{wFe}{Ar.\mathrm{Fe}}$$

$$\text{w Fe} = 3x\frac{wFe3O4}{Mr.\mathrm{Fe3O4}} \text{ x Ar. Fe}$$

$$\text{w Fe} = 3x\frac{213{,}94}{232} \text{ x } 56$$

w Fe = 154,92 gr

weight of iron resulted is 154,92 gram

$$FeTiO_3 + C \rightarrow Fe + CO_{(g)} + TiO_2 \quad (1.2)$$

Weight of iron which is yielded from reduction reaction ilmenite ($FeTiO_3$) by graphite based on chemical reaction (1.2) is :

mol $FeTiO_3$ = mol Fe

$$\frac{wFeTiO3}{Mr.\mathrm{FeTiO3}} = \frac{wFe}{Ar.\mathrm{Fe}}$$

$$\text{w Fe} = \frac{wFeTiO3}{Mr.\mathrm{FeTiO3}} \text{ x Ar. Fe}$$

$$\text{w Fe} = \frac{21{,}06}{152} \text{ x } 56$$

w Fe = 7,76 gr

weight of iron resulted is 7,76 gram

So that total of iron resulted from iron sand pellets which containt Fe_3O_4 and $FeTiO_3$ is 162,68 gram.

Total of metallization percent is:

ISSN 114-1284

$$\frac{wFeExperiment}{w.Fe.Calculation} \text{ x } 100\ \%$$

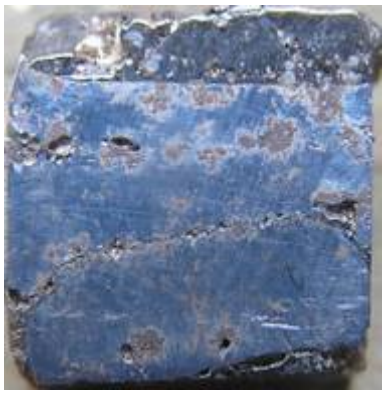
$$\frac{100}{154{,}92 + 7{,}76} \text{ x } 100\% = \frac{100}{162{,}68} \text{ x } 100\%$$

So that percentage of metallization process of burning of iron sand pellets is 61,47 %

4. Analysis of Pig Iron and sludge Resulted.

a. Analysis of Pig Iron

Pig iron which was resulted of iron sand burning at 1700°C in electric arc furnace is shown by Picture 4. Elements analysis of pig iron is shown by Table 5, and give information that pig iron contains 96,05 wt % of Fe, and contains Si as a major impurity. Another impurities was also existed but could be neglacted. Compounds analysis by XRD showed that pig iron which was resulted is closed to iron synthesis which is listed in ICDD database with PDF no. 01-1267. The correlation between pig iron resulted from experiment and iron synthesis from ICDD database is shown by Table 6.



Picture 4. Pig iron resulted

Table. 5. Pig iron element analysis by XRF

CONCLUSION

Pig iron was resulted from iron sand pellets by burning at 1700°C in electric arc furnace, and percentage of metallization process is 61.47 %. In the sludge, there are still remain iron in the form of Fe_2TiO_4 and FeO compounds, which has proved that reduction process was still not conducted perfectly.

ABSTRACT

In order to get capability in thermistor production in Indonesia, a study on electrical characterization of $CuFe_2O_4$ base-ceramics with Al_2O_3 addition has been performed.. The Al_2O_3 addition was done with various concentrations namely 0, 1 dan 5 mole %. Powder of CuO, Fe_2O_3 and Al_2O_3 was mixed and ground. The mixture was pressed with pressure of 3,9 ton/cm^2 to form pellets. The pellets was then sintered at 1100^{0}C for 2 jam in air. After sintering, two sides of some sintered pellets were coated with silver paste and fired at 600^{o}C for 10 minutes. Some of coated samples were heat treated at 500^{o}C for 5 minutes in N_2 gas. These pellets were analyzed using x-ray diffraction (XRD). R-T and ageing characteristics were evaluated. From the XRD data, it was known that the $CuFe_2O_4$ ceramics produced crystallized in tetragonal spinel. According to the electrical data, the thermistor constant (B) and sensitivity (a) increases due to the addition of Al_2O_3. It was known from the ageing test that only the ceramics with 0 and 1 mole % Al_2O_3 fit the electrical stability condition.

Keywords *: Ceramic, $CuFe_2O_4$, Al_2O_3, thermistor, NTC, ageing.*

1. INTRODUCTION

NTC thermistor are widely used due to its capability to be applied in many applications such as temperature sensor, electric current limiter, flowrate meter and pressure sensor[1]. It is known that generaly the NTC thermistor is made of ceramic having structure of spinel of AB_2O_4 where A is the ion occupies tetrahedarl position and B is the ion occupies octrahedral position[2-10]. Many works have been performed in order to improve the characteristic of the NTC thermistor having spinel structure [6,7,11]. Theoritically, the addition of additive such as Al_2O_3 may change the electrical characteristics of $CuFe_2O_4$ ceramic.

When the additive of Al_2O_3 is added to the $CuFe_2O_4$ ceramic, the characteristics of the $CuFe_2O_4$ ceramic may cange because two conditions may accur namely, the first, Al_2O_3 dissolves in the $CuFe_2O_4$ through substituting Cu ions or Fe ions, the second, Al_2O_3 does not dissolve and segregate at grain boundaries. When the substitution of Fe or Cu ions results in an increase of electron in the conduction band, the electrical resistivity of the $CuFe_2O_4$ will decrease. On the contrary, when the second condition occurs, the electrical resistivity may increase due to a change in microstructure. In this work, the effect of the Al_2O_3 addition on the electrical characteristics, especially the electrical stability, of the $CuFe_2O_4$ ceramic was studied.

2 . METHODOLOGY

Powder of CuO, Fe_2O_3 and aditive of Al_2O_3 (0, 1 and 5 mole %) were mixed and ground. The composition is shown at Table 1. After calcination at 800^{o}C for 2 hours, the mixture was ground. The ground powder was pressed with pressure of 3,9 ton/cm^2 to form pellets. The green pellets were sintered at 1100^{0}C for 2 hours in furnace air. Two sides of some sintered pellets were coated with silver paste. Some silver coated samples were heat treated at 500^{o}C for 5 minutes in N_2 gas. Structure of the sintered pellet was analyzed using x-ray diffraction (XRD). For electrical characterization, the electrical resistance of the pellets was measured at various temperatures. The measurement was done before and after ageing test. The ageing test was conducted by measuring the resistance of the pellet at room

temperature after heating at 150°C in every several hours. Thermistor constant (B) is the gradient of the ln Resistivity vs 1/T curve which is constructed based on equation (1) [2-11] expressing NTC characteristic. Sensitivity (α) was calculated using equation (2)[6].

$$R = R_0 . Eksp.(\frac{B}{T}) ……..(1)$$

where R = thermistor resistance (Ohm), R_0 = a constant (Ohm), B = Thermistor constant (K) and T = Temperature (K).

$$\alpha = \frac{-B}{T^2} ……(2)$$

where α = Sensitifitas termistor,

B = Koefisien termistor dalam °K

T = suhu dalam °K

Activation energy can be calculated using equation (3)[6],

$$B = \frac{\Delta E}{k} ……..(2)$$

Dengan B = Konstanta termistor (°K)

ΔE = Energi aktivasi (eV),

k = Konstanta Boltzmann $(\frac{eV}{°K})$

4. RESULTS AND DISCUSSION

4.1 XRD Analyses

XRD profiles of $CuFe_2O_4$ base-ceramics added with Al_2O_3 are shown at Fig. 1 and Fig.2 as the representative. All the $CuFe_2O_4$ base-ceramics crystallized in tetragonal structure (JCPDS No.34-0425). In all XRD profiles peak of Fe_2O_3 was observed indicating that a part of the Fe_2O_3 could not form $CuFe_2O_4$ solid solution. Peak from Al_2O_3 was not observed in all XRD profiles. This fact gives a possibility that the Al_2O_3 was dissolved.

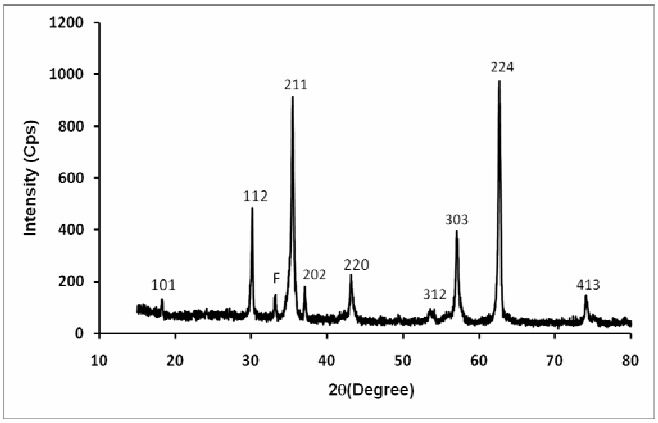

Fig.1. XRD profile of $CuFe_2O_4$ base-ceramic ($40CuO-60Fe_2O_3$) without Al_2O_3 addition. F is peak from Fe_2O_3.

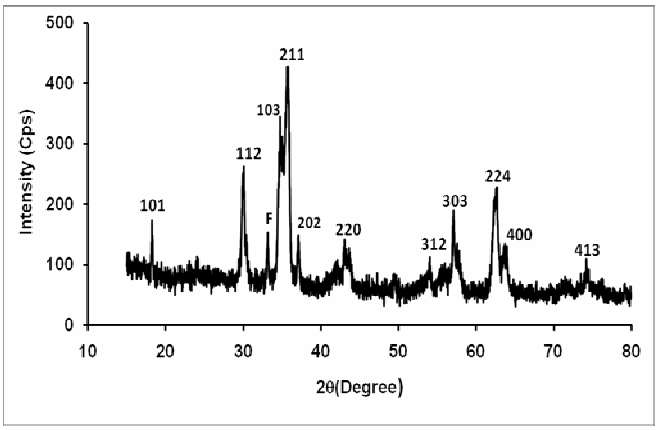

Fig.2. XRD profile of $CuFe_2O_4$ base-ceramic ($40CuO-60Fe_2O_3$) with 1 mole % Al_2O_3. F is peak from Fe_2O_3.

4.2 Electrical Characteristics

Curves of ln Resistivity vs 1/T in Fig. 3 are linear indicating that the $CuFe_2O_4$ base-ceramics obey the NTC characteristic of the thermistor. As shown in Table 1, thermistor constant (B) and sensitivity (alpha) of the ceramics added with Al_2O_3 are larger than those of the ceramics without Al_2O_3. This means that the addition of Al_2O_3 icreased the thermistor constant and sensitivity of the ceramics. Large B and α is good for the NTC thermistor. The value of B and α of the ceramics fit the market requirement

(larger than or equal 2000K(B) and 2.2%/K(α,alpha)). The mechanism of the increasing the thermistor constant and sensitivity is as follow. The Al_2O_3 segregates at grain boundaries and impeded grain growth during sintering. The ceramics then contains small grains or many grain boundaries. Because the grain boundaries are scattering center for electron, the electrical resistivity and thermistor constant of the ceramics increase.

The ageing test result is shown in Fig. 4. As can be seen, for sample without Al_2O_3, from 0 to 100 hours ageing test, the resistivity change rapidly following the aging time. From 100 hours to 1000 hours, the resistance tends to stable. Below 100 hours, the ions in the ceramics tend to rearrange during heating at 150°C[12]. Here, some Fe^{2+} oxidizes to Fe^{3+}. So, the resistance has not been stable. In the range 100-1000hours, the resistance tends to stable though slightly fluctuates. The time to reach a stability condition is different depending on the concentration of Al_2O_3. For sample added with Al_2O_3 the time to reach the stable condition is about 200 hours. It is clear that the addition Al_2O_3 worsen the stability. The fluctuation of the resistance becomes larger as the concentration of Al_2O_3 increases. The value of 200 hours can be taken as a time for preparing a stable $CuFe_2O_4$ base-ceramics for NTC thermistor.

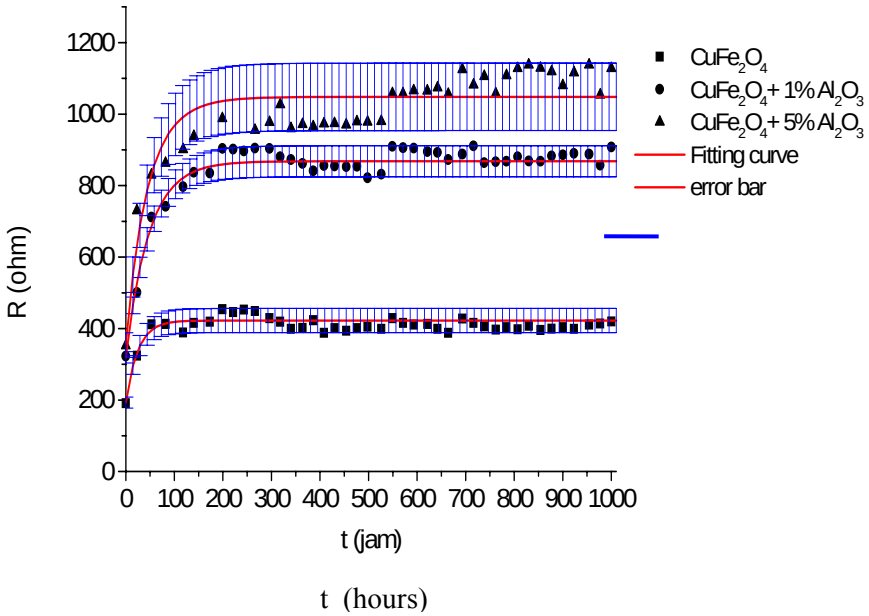
3.	5	3958	4,46



t (hours)

Fig. 4. Electrical resistance as function of time as the result of ageing test.

5. CONCLUSION

All $CuFe_2O_4$ base-ceramic crystallized in tetragonal structure. Thermistor constant (B) and sensitivity (a) of the $CuFe_2O_4$ base-ceramics increase with the increase of Al_2O_3 concentration. This means that the additionof Al_2O_3 can be used as a controlling parameter. However, the addition of Al_2O_3 decreases the electrical stability of the $CuFe_2O_4$ base-ceramics. Only sample without Al_2O_3 and that added with 1 mole % Al_2O_3 fit the electrical stability condition. Heating at 150^oC for 200 hours can be used to make $CuFe_2O_4$ base-ceramic stable electrically.

AKNOWLDGMENT

The authors wish to acknowledge their deep gratitude to DIKTI, Department of National Education of Indonesian Government for financial support under hibah PEKERTI program with contract No. 014/SPP/PP/DP2M/II/2006 April 24, 2006.

ABSTRACT

Cylinder heads of motorcycles are produced by low pressure die casting (LPDC) process using AC4B aluminium cast alloy. Rejects that are often found in this component are misrun due to the inadequate fluidity of molten metal to fill up cavity of LPDC die. Fluidity of molten metal may be enhanced through modification of microstructure by adding Sr. This research studied the effects of Sr addition of 0.004 wt. % on the as-cast properties of AC4B alloys.

Addition of Sr was conducted by adding rod Al-10 Sr master alloy in the holding furnace. Injection temperatures of LPDC process were varied 680, 700 and 720 ^{o}C. Fluidity of molten metal was measured by spiral method, and porosity was observed through vacuum porosity tests. Tensile and hardness tests were conducted as well as observation on the microstructure of the materials in as-cast condition by using light microscopy and SEM (scanning electron microscope) equipped with EDS (energy dispersive spectroscopy).

Fluidity of AC4B aluminium alloys increases by addition of 0.004 wt. % Sr. The higher the injection temperature, the higher the fluidity of the molten metal. Addition of Sr seems to increase the porosity level, which then decreases the hardness of the alloy. However, the distribution of porosity is random, and no particular mode is able to detect. The presence of Sr modify the accicular Si eutectic into fine fibrous. Injection temperature seems to have little effects on the modification of mircostructure by addition of Sr.

Keywords
AC4B, Sr, low pressure die casting, fluidity, modification

1. INTRODUCTION

One foundry alloy that is popular for use in automotive application is AC4B aluminium alloy, due to its excellent castability and mechanical properties. Its excellent corrosion resistance and low cost of recycling are also important considerations from an environmental point of view. Aluminium alloy AC4B is essentially a hypoeutectic Al-Si alloy with two main solidification stages, formation of aluminium rich dendrites followed by development of silicon phase. Two major disadvantages of these alloys. The first is the sharp edges of the coarse acicular silicon phase that occurs in the microstructure, promoting crack initiation and propagation which leads to poor mechanical properties. Another disadvantage is their long freezing range, which leads to feeding difficulties in the interdendritic region, resulting in increased porosity [1].

Strontium is added to hypoeutectic aluminium-silicon alloys in order to transform the morphology of the silicon phase from acicular flakes to a fibrous rodlike form, thereby improving mechanical properties, especially fracture toughness and elongation [2]. At a given cooling rate, Sr decreases nucleation and growth temperatures of the (Al)-Si eutectic and this effect is higher the higher the cooling rate [3]. Addition of Sr does not affect primary deposition of (Al) but apparently modifies reactions occurring after

the (Al)-Si precipitation. DTA work by Martinez *et al.* [3] confirmed that Sr addition has a direct influence only on the growth mechanism of the (Al)-Si eutectic. Small changes in overall eutectic kinetics due to Sr modification also results in subtle modification during final stages of solidification as well as in the precipitation of iron and manganese rich phases.

However, Sr addition is also associated with porosity formation. In this connection, Dahle *et al*. [4] suggested the change in the mode of eutectic nucleation – from that occurring near the a-Al dendrites in the Sr-free alloy, to that taking place within the eutectic liquid itself in the Sr-containing alloy. The mode in operation controls the distribution of the remaining liquid in the last stages of solidification when feeding becomes extremely difficult. This distribution, in turn, will define the connectivity of the feeding channels, and thus determine the resultant porosity profile in the solidified casting.

The aim of the present study is to understand the changes in the microstructure due to 0.004 wt. Sr addition to AC4B alloy produced by LPDC process. Fluidity of the molten metal and the resulting porosity was observed. Effect of injection temperature was also studied.

II. EXPERIMENTAL METHOD

An Sr-containing alloy was cast by using commercial AC4B as the base alloy and the resulting nominal composition is presented in Table 1. The charge materials consist of 70 % of ingot and 30 % of return scrap. These alloys were melted in an industrial furnace and gas bubble floatation process by using argon was performed for 8 minutes to remove trapped air from the molten metal. Master alloy Al-10Sr was added into the molten metal just before injection with the amount of 0.004 wt. % Sr. Injection temperatures were varied 680, 700 and 720 ^{o}C, and molten metal was injected into metal mould with resin-coated sand cores possessing the shape of cylinder head, therefore, it is expected that heat transfer in different position within the mould will be different. Hardness of the LPDC products was measured by using Rockwell B method with 1/16 inch diameter of indenter at 150 kg of load. Measurement was conducted around the studbolt region with 7 identation.

Fluidity test was conducted by using spiral mould with gravity method, in which molten metal was poured into the spiral mould, and the length of spiral was measured by using measuring tape. Microstructures at the tip of the spiral were observed to compare them with the LPDC structures.

Table 1. Nominal composition (wt. %) of alloys in this study

Alloy	Si	Cu	Mg	Fe	Mn	Sr	Al
Base	8.2	2.3	0.11	0.78	0.12	-	rem
Modified	8.9	2.6	0.13	0.88	0.13	0.004	rem

Tensile specimens were made by pouring molten metal into dog-bone-shaped metal mould in accordance with JIS Z2201, test piece no. 4. Hardness measurements were performed by Brinnel method at clamp area of the tensile specimens, by using steel ball indenter of 1/16 inch diameter. Seven indentations were taken for each hardness measurement.

Samples of each alloy were taken at three different positions of the cylinder head, representing area with high, medium dan low solidification rate, designated as area 1, 2, and 3, respectively. Samples were cut into 10 x 10 mm blocks for microstructural and microanalysis. Modification of microstructure was observed by means of a light microscope and LEO 420 SEM. Samples for microstructural analysis were prepared by etching with 0.5 % hydrogen fluoride.

III. RESULTS AND DISCUSSION

A. Effects of Sr on Fluidity and Porosity

Fluidity is an important factor in casting processes to reduce misrun. Results in Figure 1 show that at all injection temperatures, addition of 0.004 wt. % Sr increased fluidity of molten AC4B alloys. This is in correlation with previous studies that the role of Sr in solidification process is to decrease the eutectic temperature so that shorten the solidification range and resulting in higher fluidity [5]. Strontium is also known to reduce interfacial energy of molten aluminium that allows better fluidity [6]. As has been widely known, the higher the pouring temperature, the higher the fluidity of the molten metal. Another observation is that AC4B alloys containing Sr showed brighter silvery colour.

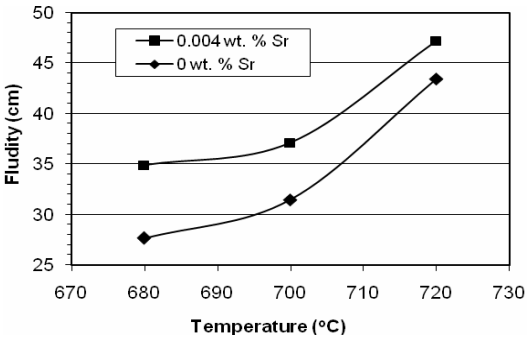

Figure 1. Effect of Sr addition and injection temperature on fluidity of AC4B alloys.

Figure 2 shows the intersection of vacuum porosity sample of the Sr-free and Sr-containing alloys. The presence of Sr seems to increase the amount of porosity. This has been shown by Amberg et al. [7] that modifier increase dissolution of hydrogen in molten metal, and decrease eutectic temperature that leads to longer period of solidification. The addition of 0.004 wt. % Sr increases porosity level from #5 to #7 in ASM standard. Figure 3 further confirms that the porosity increases in size and distribution by addition of Sr. This figure also shows that the porosity changes to transgranular and more rounded in the Sr-containing alloy.

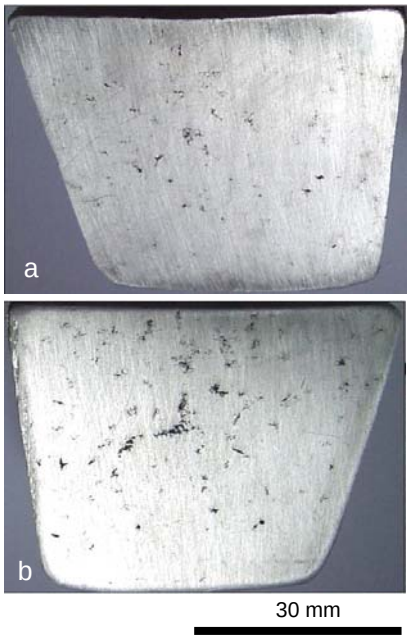

Figure 2. Porosity content in AC4B alloys with (a) 0 wt. %, and (b) 0.004 wt. % Sr.

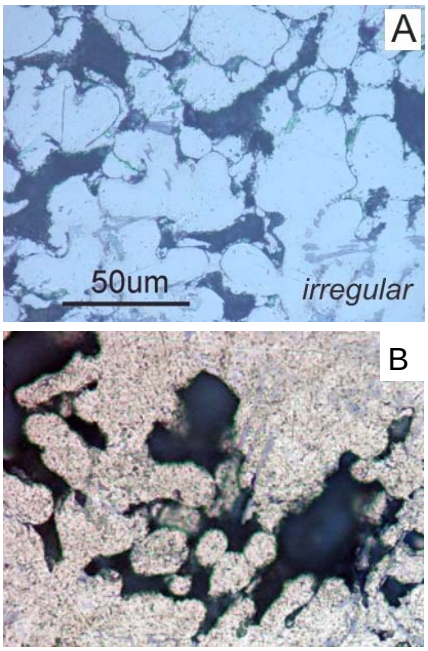

Figure 3. Morphology of porosity in (a) Sr-free, and (b) 0.004 wt. % Sr-containing AC4B alloys. Microstructures were taken from fluidity samples.

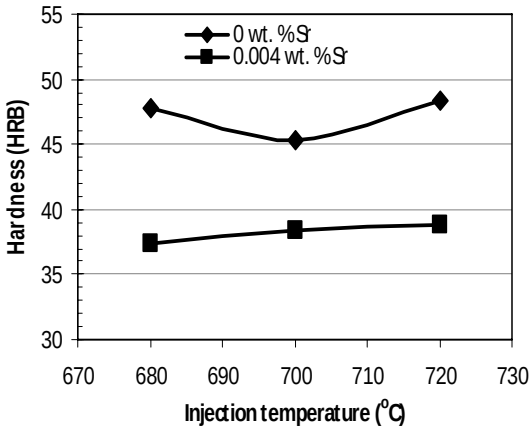

Figure 4. Effect of Sr content and injection temperature on the hardness of AC4B cylinder head.

B. Effects of Sr on Mechanical Properties and Microstructures

Figure 4 show the effect of 0.004 wt. % Sr addition on the hardness of AC4B alloys as LPDC products at different injection temperatures. It is clear that addition of Sr decreases the hardness for ~ 20 %, and there was no significant effect of injection temperature. This is in contrast with the

tensile strength which shows slight increase for 0.8 % from 196.1 MPa to 197.8 MPa (Figure 5). This peculiarity was further observed by measuring the hardness at the clamp area of the tensile samples. The result is provided in Figure 6. The hardness shows an increase by addition of 0.004 wt. % Sr, in line with the tendency in tensile strength. Observation on microscopy on the LPDC products and the tensile samples showed that LPDC products possess more porosities than the tensile samples. Different mould materials may be the reason for the difference.

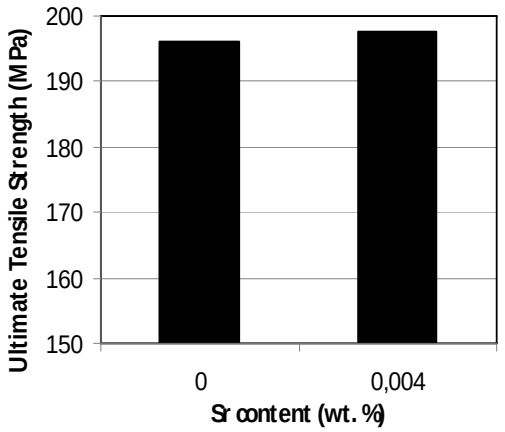

Figure 5. Effect of addition of 0.004 wt. % Sr on strength of AC4B alloy.

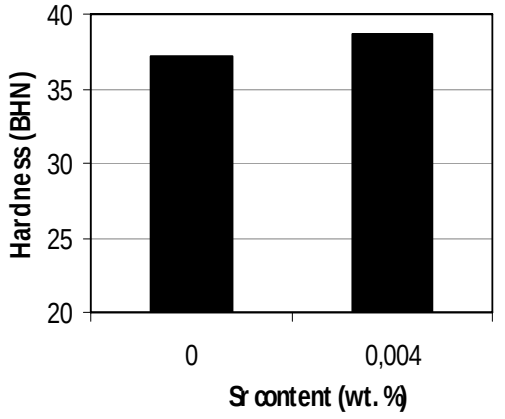

Figure 6. Hardness measured on tensile strength samples with different Sr content.

A series of microstructural analysis on the effect of Sr addition and injection temperatures is presented in Figure 7. These micrographs were taken from samples cast at 680 ^{o}C. In general, microstructure of AC4B alloys in as-cast condition consists of α-aluminium dendrites with interdendritic second phases. This is in correlation with the fact that solidification of hypoeutectic Al-Si starts with formation of α-aluminium dendrites, followed by eutectic reaction and formation of second phase particles, such as Mg_2Si and Al_2Cu. Aside from that, second phase particles containing Mn and Fe also form, such as Al_5FeSi (during slow solidification) and $Al_{15}(Mn,Fe)_3Si_2$ (during rapid solidification) [9]. As has been widely known, rate of solidification determines dendrite arm spacing (DAS), the higher the rate, the smaller the spacing, and this is confirmed in Figure 7.

Modification of microstructure by Sr can be clearly seen at position 3, which has the lowest solidification rate. Eutectic silicon structure was modified from coarse acicular into fine fibrous, similar to class C (modified) in accordance to ASM standard. At position 1, the microstructure is readily modified during high rate of solidification. Therefore, degree of further modification by Sr addition is not as apparent as that at positions 2 and 3. Quantitative measurement shows that modification also resulted in the decrease in DAS, which in turn increase the strength and hardness of the alloys. Observation revealed that varying injection temperature for 680, 700 and 720 ^{o}C did not affect the microstructure and level of modification of the alloys.

Detailed micrographs of AC4B alloys at position 1, which has the highest solidification rate, are presented in Figure 8. Identity of each phase was confirmed by EDXS analysis, tabulated in Table 2. Change of interdendritic structure due to modification is clearly revealed, in which the morphology of Al-Si eutectic transforms from acicular into fine fibrous structure. No alteration of morphology was detected in α-Al(Fe,Mn)Si phase (position 3 and 4). The small amount of Sr may be the reason for this. The pocket Al_2Cu structure was modified into massive blocks (position 1 and 2). This phase was initially well dispersed within the matrix, but upon addition of 0.004 wt. %, it tends to segregate at particular locations. This segregation may be caused by the lowering of eutectic temperature for $\pm$ 10 ^{o}C by addition of Sr, so that shorten remaining solidification time for Al_2Cu formation.

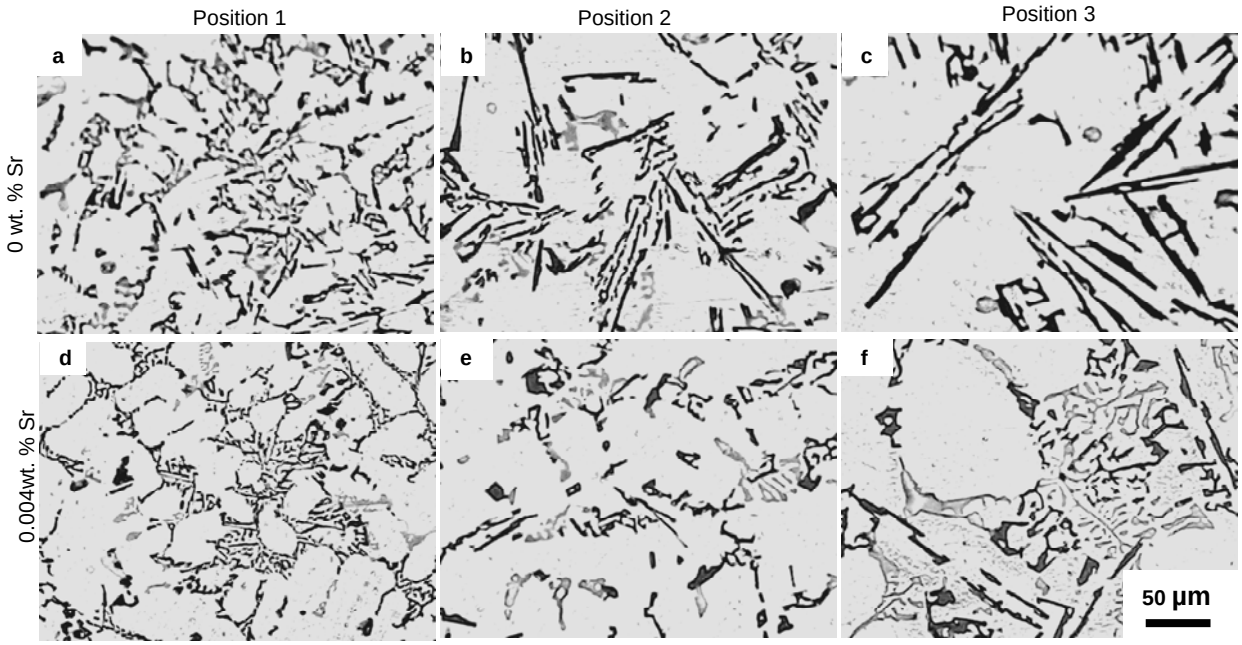

Figure 7. Effects of addition of (a-c) 0 wt. %, and (d-f) 0.004 wt. %, Sr on modification of AC4B alloys produced by LPDC process at 680 ^{o}C at different positions. Position 1, representing high solidification rate; position 2, representing medium solidification rate; and position 3, representing low solidification rate.

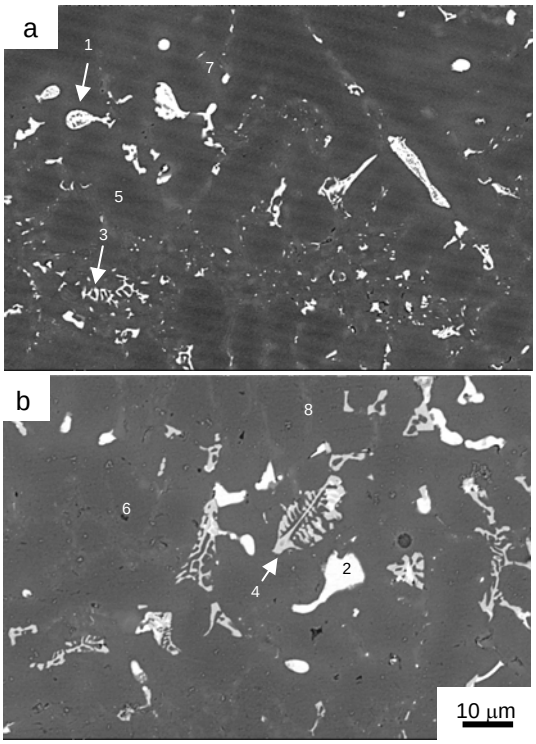

Figure 8. SEM micrographs of AC4B alloys added with (a) 0 wt. % Sr, and (b) 0.004 wt. % Sr, taken from position 1, which has the highest solidification rate.

Table 2. Microanalysis result on positions shown in Figure 8.

No	Element (wt. %)					Phase
	Al	Si	Cu	Fe	Mn	
1	81.60	5.73	12.67	-	-	Al_2Cu
2	84.55	2.41	13.04	-	-	Al_2Cu
3	57.00	6.50	0.62	32.40	3.48	Al(Fe,Mn)Si
4	61.00	6.29	0.57	30.19	1.94	Al(Fe,Mn)Si
5	7.91	92.09	-	-	-	Al-Si eutectic
6	29.97	70.03	-	-	-	Al-Si eutectic
7	98.32	1.68	-	-	-	Al matrix
8	98.59	1.41	-	-	-	Al matrix

CONCLUSIONS

1. Addition of 0.004 wt. % Sr to AC4B alloys processed by LPDC increases the porosity level from 5 to 7 (ASM scale), and reduces the hardness of LPDC products at all injection temperatures.
2. Addition of 0.004 wt. % Sr to AC4B alloys processed by gravity casting as tensile samples, increases tensile strength and hardness. Porosity in tensile samples was found less than in LPDC products.
3. Addition of 0.004 wt. % Sr increases fluidity of AC4B alloy. Increase in injection

temperatures also increases fluidity of the alloys.

4. Addition of 0.004 wt. % Sr modifies the silicon eutectic from acicular to finer fibrous in class C (modified).
5. Injection temperatures do not have significant impact to the microstructure and mechanical properties of the alloy.

ABSTRACT

Duplex stainless steels have a mixed microstructure consisting of ferrite (bcc) and austenite (fcc) phases. When duplex stainless steels have the optimum phase balance, which is usually approximately equal proportions of ferrite and austenite phases, they exhibit higher resistance to stress corrosion cracking and higher strength than austenitic stainless steels. However, the melting and solidification associated with fusion welding processes destroy the favorable duplex microstructure of these stainless steels, which causes the loss of low-temperature notch toughness and corrosion resistance in the weld. This situation suggests that the favorable duplex microstructure of the duplex stainless steel should be maintained, but there have been few papers dealing with the effect of cooling rate of solution annealing of duplex stainless steel. In this study, the microstructure and hardness properties of fusion welded duplex stainless steel were examined. High-quality welds were successfully produced in the duplex stainless steel by Gas Tungsten Arc Welding (GTAW) process. The base material had a microstructure consisting of the ferrite matrix with austenite islands, but weld annealed duplex stainless steel with water quench have a dominantly coarse grains of ferrite phases in the HAZ and weld metal zone in comparing with air cooling. The smaller grain sizes of the ferrite phases caused increases hardness within the HAZ and weld metal zone.

1. INTRODUCTION

Duplex Stainless Steels composed of ferrite and austenite in similar amount. They have good corrosion properties, high yield strength and good toughness in the temperature range -50 to 250°C. Above 400°C several structures changes occurs in duplex stainless steel during isothermal and anisothermal heat treatments.

Welding process usually change the phase composition balance between austenite and ferrite phase. The weldment phase balance highly influenced by the chemical composition and cooling rate at the weldment. At the HAZ region usually a coarse microstructure was formed with high fraction of ferrite phase. Numerous works already presented regarding the cooling rate and carbide phase formation. Work by Ogawa and Koseki [(1)] showed that equilibrium composition between ferrite and austenite are continually changing according to austenite and ferrite solvus line. Tavares *et.al* [(2)] studied the cooling rate effect morphology, toughness and microstructure of duplex stainless steel UNS S 31803. Solution treatment and furnace cooling remove the carbide from grain boundary and promote increase toughness. Work by Badji *et.al*[(3)] studied faster cooling rates affect the microstructure at fusion line even with same heat input.

Several papers regarding the duplex stainless steel failure attribute to welding process already well documented. Work by Battacharya and Sigh [(4)] studied the susceptibility Duplex Stainless Steel grade to Stress Corrosion Cracking can be attributed to heating process during manufacturing especially welding.

This paper focused on studied the effect of cooling rate on microstructure and hardness properties in the solution annealing of welded duplex stainless steel UNS S 31803 (SAF 2205) pipes, welded by manually TIG Welding process.

2. EXPERIMENTAL METHOD

The research was carried out using duplex stainless steel UNS S 31803 (SAF 2205) pipes, 10 inch diameter with 12.7 mm thickness. The sample then welded by GTAW method with welding parameter which refers to ASME sec IX as follow:

Method : GTAW (Gas Tungsten Arc Welding) manual type
Joint Design : Butt joint with 60 ° V- groove.
Filler type : ER 2209
Filler size : Diameter 2.0/2.4 mm
Interpass temp : 150°C max
Gas : Argon 99.995 %
Current : 80 – 130 Ampere (Root Pass) & 90 – 250 A (Filler Cap)
Voltage range : 8 – 15 Volts
Travel speed : 70 – 190 mm/min
Heat Input : 0.5 – 1.5 kJ/

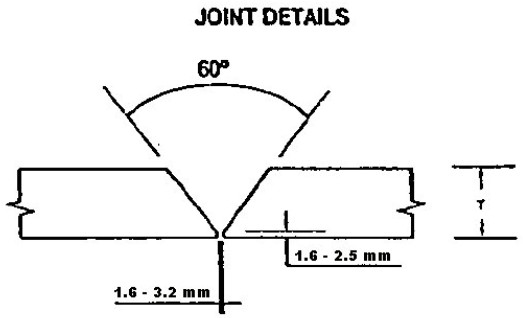

Fig 1. Schematic of weld joint design

The welded sample then cut into into three different heat treatment processes which are as-welded, water quench-annealed and air cooling annealed. The annealing process of welded samples was carried out at temperature of 1100°C and held for 90 minutes. After that those were quenched by water and air. Metallurgical characterization performed by micro vickers hardness test under 300 gr load for 15 second. Microstructure examination performed using light optical microscope. Ferrite content was measured by Scion™ image analysing sofware at 500x magnification on sample etched with electrolytic 50 mol KOH etching.

Table 1. Typical chemical compostion for S 31803 (SAF 2205) and Filler wire ER 2209

Material	C	Mn	Si	Cr	Ni	Mo	N
UNS S 31803	0.022	1.65	0.51	22.02	5.23	3.25	0.183
Filler ER-2209	0.014	1.63	0.53	22.55	8.94	3.11	0.13

3. RESULT AND DISCUSSION

3.1. Metallographic Examination

All the samples revealed the typical austenite-ferrite duplex structure, as can be seen in Fig. 2.

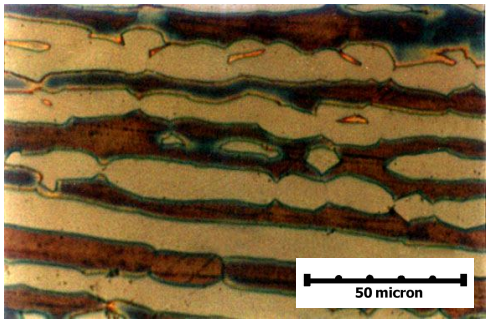

Fig 2. Microstructure of the base metal duplex stainless steel of UNS S 31803 (SAF 2205).

During solidification, basically duplex stainless steel solidified as ferrite, the transformation of austenite phase start below the ferrite solvus line along the ferrite grain boundaries [5]. Normally, welded areas have a high cooling rate which suppresses the austenite formation. However, multi pass welding process created a reheating condition and promotes secondary austenite formation.

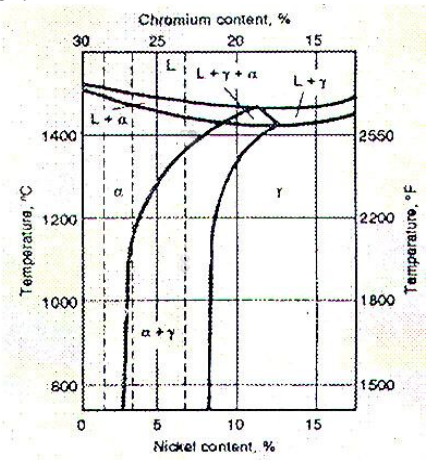

Fig 3. Diagram Pseudo-binary of Duplex SS (68% Fe)

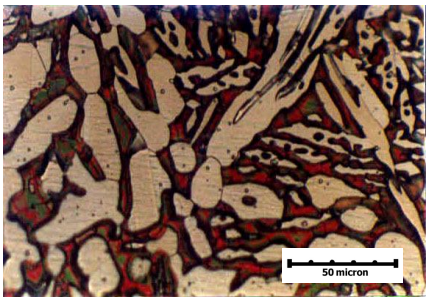
ISSN 114-1284

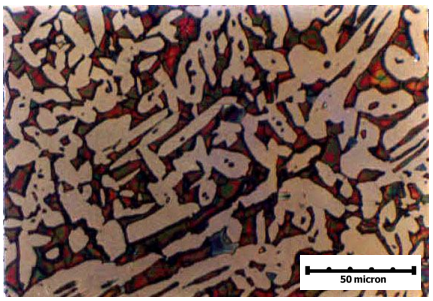
In water quenched samples (fast cooling) new grain of austenite start growing at the α/α grain boundaries. Due to rapid cooling austenite can not develop fully.

The performance of DSS can be highly influenced by welding process. Several parameter used during the process could alter and change the microstructure morphology of the duplex stainless steel joint. The proper welding method, filler metal and inter-pass temperature are needed to ensure proper phase balance and avoid the formation of precipitate or inter-metallic phase. Shielding gas also could play and important factor for obtaining optimal phase balance between austenite and ferrite [6-7]. Phase balance at the weld is required to avoid, excessively high ferrite content could cause brittleness, whereas a lack of ferrite could cause a loss of resistance to stress corrosion cracking [5].

Metallographic examination by light optical microscope was taken at weld and HAZ. Microstructure of the weld showed a different phase and balance between ferrite and austenite. The entire sample also showed secondary austenite at their joint area. Cooling rates have a significant impact to the welded microstructure morphology such as austenite – ferrite phase balance or precipitate and carbide formation, as seen in Fig 4 and Fig 5.



(a)



(b)

Fig 5. Microstructure of HAZ on UNS S 31803 welds with (a) water cooling and (b) air cooling

Microstructures at weld metal taken from air cooling sample have a vermicular appearance (Fig. 4) and finer dendrite of secondary austenite. Ferrite content analysis is 43.4 % which is lower compared to the water cooling sample (53.8 %). The cooling rates of water quenched samples are highly influenced by the capability of quench medium to drive out the heat of the sample. Normally, water quench have a higher cooling rate compared to air (atmosphere). The microstructures of HAZ taken from water cooling sample have a round and coarser appearance of secondary austenite (Fig. 5) and the ferrite content is 56 % which is higher than air cooling samples.

Table 2. Ferrite Content Calculation for S 31803 Welds

Weld Area	Water Quench		Air Cooling	
	% α	% γ	% α	% γ
HAZ	56.0	44.0	53.8	46.2
Weld Metal	52.3	47.7	43.4	56.6

3.2. Hardness Testing

The quench medium creating different cooling rate and lead to changes in different hardness value. In general assumption, the cooling rate from water medium is higher compared to air atmosphere.

The ferrite contents increase with increasing the cooling rate, hence the hardness increased with increasing cooling rate, as seen in Fig. 6.

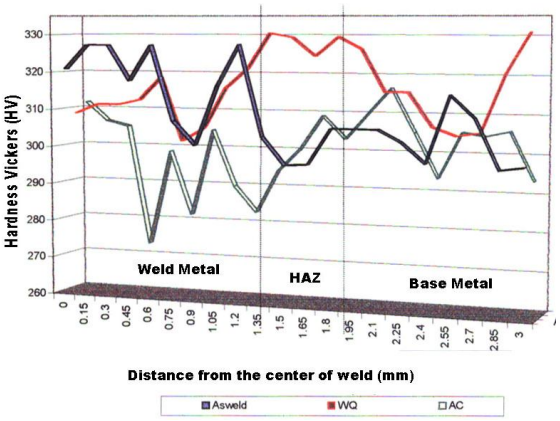

Fig 6. The effect of cooling rate to the hardness distribution of weldments UNS S 31803.

4. CONCLUSION

The cooling rate of solution annealing for welded duplex stainless steel of UNS S 31803 have a significant impact to microstruture morphology. This occured due to different cooling rate from each quenching medium. The changes can be seen for the microstructure shape and ferrite content. Higher cooling rate yields a secondary austenite growth, but the increasing the ferrite content. The hardness increased with increasing cooling rate.

ABSTRACT

Group technology (GT) has been proposed to increase productivity in manufacturing. The basic idea of GT is to exploit the similarity between parts and manufacturing processes. Parts similar in design and manufacture are grouped into part families. Machines are organized into machine cells to process part families. The problem of forming part families and machine cells is referred to as the GT. In this paper, we develop a new optimization algorithm that combines the simulated annealing and tabu search called the hybrid heuristic. The resulting hybrid algorithm retains the global perspective of the simulated annealing and the local search capabilities of the tabu search. We also present a detailed application of the proposed algorithm to solving cell load problem in GT and it is found empirically to outperform a pure simulated annealing algorithm implementation, particularly for large problems. The computational experience is also reported.

Keywords

Group technology, family, machine cell, cell load, hybrid heuristic, tabu search, simulated annealing

1. INTRODUCTION

Machine layout in a tradisional production system is mainly process (function) oriented where machines performing similar processes are grouped together. Parts requiring more than one process travel from one section of a production system to another until their operation requirements are completed. Long and uncertain throughput times are usually the major problems in such a system. Other problems include an increase in inventory holding cost, untimely product delivery and loss of sales [20]. Manufacturing firms have to look for better layout approaches to increase productivity.

Group Technology (GT) can be defined as a concept for increasing production efficiency by grouping various parts and products with the same or similar characteristics [12]. The set of similar parts can be called a part family. The application of GT results in the mass production effect to multi products and small-lot-sized production. The important areas of GT applications are classification and coding, process planning, part family and machine cell design, GT layout, group scheduling, and cell loading. For successful implementation of GT may involve the use of classification and coding which describes the basic characteristics of a given part with respect to its manufacturing process [11].

There are two type of machine layout in GT, namely, logical and physical machine layout [4]. In a logical machine layout, machines are dedicated to part families but their positions in a factory are not altered. In a physical machine layout, dedicated machine cells containing different machines are grouped together to exploit flow shop efficiency in processing part families. Although clustering concepts for physical layout are discussed in this paper, many of these concepts can be easily applied to a logical layout.

Ideally, all operations of parts in a part family should be completed within a machine cell. However, such ideal physical machine layouts are rare in practice. In most actual layouts, there are usually exceptional parts and exceptional machines. An exceptional part requires processing on machines belonging to more than one machine cell. An exceptional machine processes parts from more than one part family. To effectively implement GT, a good clustering algorithm is needed such that the number of exceptional parts and exceptional machines are minimized and improved measure for minimization of cell load variation within GT.

Many GT applications involve combinatorial optimization, that is, obtaining the optimal solution among a finite set of alternatives. Such optimization problems are notoriously difficult to solve. One of the primary reasons is that in most applications the number of alternatives is extremely large and only a fraction of them can be considered within a reasonable amount of time. As a result, heuristic algorithms are often applied in combinatorial optimization. Among the most successful such heuristics are evolutionary algorithms, genetic algorithms, tabu search, and neural networks. All of these algorithms are sequential in the sense that they move iteratively between single solutions or sets of solutions.

However, in some GT applications it may be desirable to maintain a more global perspective, that is, to consider the

entire solution space in each iteration. In this paper we propose a new optimization algorithm to address this difficult class of problems. The new method converges to a global optimum of combinatorial optimization problems in finite time and is very robust. We also present a detailed application of the method to a product design problem. Numerical results demonstrate the effectiveness of our proposed method.

In this paper, we use meta-heuristic such as simulated annealing and tabu search to evaluate several cases for the GT using minimization of cell load variation and Grouping efficiency as performance measurement. Minimization of cell load variation was proposed by Venugopal and Narendran [21], while Grouping efficiency proposed by Chandrasekharan and Rajagopalan [15].

2. PROBLEM FORMULATION

GT is an assignment-type problem and can be summarized as follows: given n items and m resources, the problem is to determine an assignment of the items to the resources optimizing an objective function and satisfying a stated set of additional side constraints. An objective function provides the basis for evaluating the machine groupings arrived at by a searching method. In the present work, one problem formulation (objective function) model was implemented. The model is based on the minimization of cell load variation.

2.1. Minimization of cell load variation model

This model is based on the model proposed by Venugopal and Narendran [21]. In this model we define m as the number of machines, k as the number of cell, and n as the number of parts. W = [w_{ij}] is an m*n machine component incidence matrix where w_{ij} is the workload on machine *i* induced by part *j*. X = [x_{ij}] is an (m*k) called as cell membership matrix, where

$$x_{ij} = \begin{cases} 1 & \text{if machine is in cell } i \\ 0 & \text{otherwise} \end{cases}$$

M = [m_{ij}] is an (k*n) matrix of average cell load, where

$$m_{jl} = \frac{\sum_{i=1}^{m} x_{il} w_{lj}}{\sum_{i=1}^{m} x_{il}}$$

The total load of cell i induced by part j is given as:

$$\sum_{i=1}^{m} x_{il} w_{lj}$$

The number of machines in cell i is given as:

The mathematical programming formulation of the grouping problem is as follows:

$$\text{Minimize } z_1 = \sum_{i=1}^{m}\sum_{i=1}^{k}\sum_{i=1}^{n}(w_{ij} - m_{ij})^2 \qquad (1)$$

Subject to:

$$\sum_{l=1}^{k} x_{il} = 1 \quad \forall i \qquad (2)$$

$$\sum_{i=1}^{m} x_{il} \geq 1 \quad \forall l \qquad (3)$$

The expression $\sum_{i=1}^{m}\sum_{i=1}^{k}\sum_{i=1}^{n}(w_{ij} - m_{ij})^2$ is the objective function. Equation (1) gives the extent of variation of the load on machine i in cell l (induced by all parts) from the mean load of cell i. The objective function z1 adds this quantity for all the machines and cells. Hence this formulation requires a solution for which the total cell load is minimized such that every machine belongs to exactly one cell and no cell is empty. Equation (2) ensures that for particular i, machine i is assigned to one cell only. Equation (3) ensures that no cell is empty.

2.2. Model Illustration

As an illustration, consider a 3x3 problem whose workload incidence matrix is given as:

$$w_{ij} = \begin{pmatrix} 0{,}3 & 0 & 0{,}2 \\ 0 & 0{,}9 & 0 \\ 0{,}5 & 0 & 0{,}5 \end{pmatrix}$$

where rows represent machines and columns represent parts. Suppose the machine grouping arrived at by the searching algorithm is:

Machine	1	2	3
Cell	1	2	1

This means that machines 1 and 3, respectively are in cell 1, while machine 2 is in cell 2. This implies:

$$x_{il} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix}$$

Since

$$Z= x_{11}(w_{1j} - m_{1j}) + x_{12}(w_{1j} - m_{1j}) + x_{21}(w_{2j} - m_{2j}) + x_{31}(w_{3j} - m_{3}) + x_{32}(w_{3j} - m_{3j})$$

and

$$m_{lj} = \frac{\sum_{i=1}^{m} x_{il} w_{lj}}{\sum_{i=1}^{m} x_{il}}$$

then:

$$m_{11} = \frac{x_{11}w_{11} + x_{31}w_{31}}{x_{11} + x_{31}} = \frac{0,3 + 0,5}{2} = 0,4$$

$$m_{12} = \frac{x_{11}w_{12} + x_{31}w_{23}}{x_{11} + x_{31}} = \frac{0 + 0}{3} = 0$$

$$m_{13} = \frac{x_{11}w_{13} + x_{31}w_{33}}{x_{11} + x_{31}} = \frac{0,2 + 0,5}{2} = 0,35$$

$$m_{21} = \frac{x_{22}w_{21}}{1} = 0$$

$$m_{22} = \frac{x_{22}w_{22}}{1} = 0,9$$

$$m_{23} = \frac{x_{22}w_{23}}{1} = 0$$

$$m_{lj} = \begin{bmatrix} 0,4 & 0 & 0,35 \\ 0 & 0,9 & 0 \end{bmatrix}$$

The matrix m_{lj} is then used to evaluate the objective function value.

3. HYBRID HEURISTIC

3.1. Motivation for the hybrid heuristic

Tabu search (TS) was introduced by Glover [8] as a technique to overcome local optimality. The strategic principles underlying TS have been more broadly formulated and extended which leads to the modern form of TS. Since then, TS has gained attention due to its potential for solving combinatorial problems including scheduling [6], transportation [3], layout [13] and telecommunications [14], etc. TS is a potential approach for solving the cell design problem.

Tabu search has its antecedents in methods designed to cross boundaries of feasibility or local optimality, which are normally viewed as barriers towards global optimality for existing optimal solution approaches. It systematically imposes and releases constraints to permit exploration of otherwise forbidden regions, thus, the search is able to move in and out of various intermediate local optima and explore good solutions closer to the global optimum.

A move in TS refers to a search action that perturbs the current solution to another solution. TS methods operate under the assumption that a neighbor-hood can be constructed to identify `adjacent solutions' that can be reached from any current solution through a move. Frequently, pair-wise exchanges (moves) are used to construct neighbor-hoods in permutation problems. To prevent the search from repeating exchange combinations tried in the recent past, potentially reversing the effects of previous moves by exchanges (moves) that might return to previous positions, the moves are classified tabu for a particular number of iterations called the tabu tenure. A tabu list is maintained to keep record of the attributes that are classified as forbidden (tabu). The size of the tabu list is equal to the tabu tenure and is simply referred to as tabu size. The attributes reside in the tabu list for a specified number of iterations and then are removed, freeing them from their tabu status. Several aspiration criteria may be used to override tabu status.

The tabu list is usually a circular list in which elements are added in sequence in positions 1 through tabu tenure and then started over at position 1. Empirical results have indicated that a robust range of values for tabu size exist for which such a simple tabu list performs very effectively for driving the search beyond local optima and obtaining progressively improved solutions [8]. The best value of tabu size seems to be an increasing function of the size of a problem. If it is too small, cycling will occur and if it is too big, it will constrain the search enough to skip the `deeper valleys' (i.e. better local minima) of the objective function value space [13].

Simulated annealing (SA) is a randomized version of local search that was first proposed by Kirkpatrick et al. [19]. It is based on certain analogies that exist between problems of combinatorial difficulty and large systems with many degrees of freedom, such as those normally encountered in statistical mechanics. Readers are referred to Kirkpatrick et al. [19], Van Laarhoven et al [16] and Jajodia et al [18] for the details of SA and its potential applications in solving optimization problems.

Traditionally, a sequential search method for finding an optimum begins with an initial solution and sequentially moves to a better solution in the neighbourhood until no improvements can be made. The search is frequently terminated at a local, not global, optimum. Simulated annealing (SA) is an algorithmic approach attempting to avoid the search being trapped at a local minimum by occasionally allowing unimproved moves. The generic SA procedure is outlined below.

Step 1. Define an initial solution *S*.

Step 2. Set an initial high temperature $T > 0$, cooling ratio $0 < r < 1$, and the number of times L.
Step 3. Do steps 4 and 5 until T approaches 0.
Step 4. Do L times for the following:
Step 4.1. Pick a random neighbouring solution S 0 of S.
Step 4.2. Compute Δ = cost (S') - cost (S)
Step 4.3. If $\Delta < 0$ then set $S = S$'.
Step 4.4. If $\Delta \geq 0$ then set $S = S$' with probability $\exp(-\Delta/T)$.
Step 5. Set $T = rT$ and go to step 4.
Step 6. Return solution S.
Note that the above generic SA algorithm returns only the last (best) solution obtained. In order to increase the probability of obtaining a global optimum, Rich and Knight [5] modified the generic SA to allow several good solutions to be kept in addition to the last. All these good solutions are candidates for future perturbations. The proposed algorithm utilizes a similar idea to increase the search space.

3.2. Proposed Procedure

As discussed in Section 3.1, tabu search has shown a lot of promise in the past in solving combinatorial optimization problems such as sequencing and facility layout. However, the direct application of TS to solve the GT problem requires a high degree of computational effort. In conventional TS all the pair-wise exchanges are evaluated and the exchange (move) that provides the best solution (lowest objective value) is chosen as the candidate move to perturb the present solution. For the GT problem, the neighbourhood is defined as the $\binom{n}{2}$ adjacent solutions that can be obtained by pair-wise exchanges (swaps).

Such a procedure is time consuming when applied to the integrated shortcut design problem, since ($\binom{n}{2}$-tabu size) separate optimization (GT design) problems need to be solved to identify the best move in each iteration (without considering the aspiration criterion). Moreover, some exchanges may result in infeasible sequences as discussed in Section 3. In addition, TS starts with an initial solution and improves it. Though it is a highly constrained neighbour-hood search method that overcomes the limitations of simple descent methods, some bias may exist due to the choice of the initial solution. Simulated annealing on the other hand has proven to be capable of overcoming the bias caused by different initial solution [17]. SA also requires less computation effort per iteration than TS.

The suitability of TS to solve the GT problem together with SA's computational efficiency and robustness to initial sequence motivated the development of a hybrid procedure that unites the features of these two search procedures. The hybrid procedure is likely to provide good solutions to the GT design problem in a timely fashion due to the highly constrained search process employed by the procedure together with the randomization aspects used to search the solution space. A detailed description of this combined TS and SA procedure is presented in Figure 1.

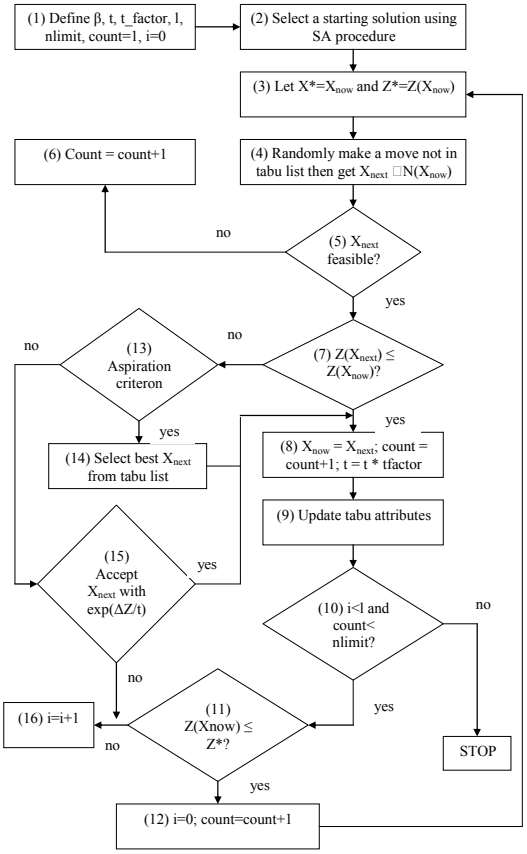

Figure 1: Flow-chart of the proposed procedure

4. COMPUTATION ANALYSIS

The proposed algorithm written in Pascal 7.0 and runs on PC with a Pentium 133 MHz. The proposed algorithm execution illustration is first given, then several set of problem types which were used are presented to compare the results with other algorithms.

		Parts														
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Machines	1	0	1	0	0	0	0	0	0	0	1	1	1	0	0	0
	2	0	0	1	0	1	0	0	1	0	0	0	0	1	0	1
	3	1	0	0	0	0	1	0	0	1	0	0	0	0	1	0
	4	1	0	0	1	0	0	0	0	1	0	0	0	0	1	0
	5	0	0	1	0	1	0	0	1	0	0	0	0	1	0	1
	6	1	0	0	1	0	1	0	0	1	0	0	0	0	1	0
	7	0	1	0	0	0	0	1	0	0	1	1	1	0	0	0

	10	0	1	0	0	0	0	1	0	0	1	1	1	0	0	0

Figure 2. Incidence matrix [11]

4.1. Algorithm execution illustration

This section provides an illustration of all internediate solutions arrived at in the solving of a machine grouping problem using the proposed algorithm. The set of input data used in this illustration is from Chan and Milner [11]. The input incidence matrix is shown in Figure 2. Number of machines is 10, number of parts is 15, minimum number of machines in a cell is 2, maximum number of machines in a cell is 6. The option for minimization of cell load variation is considered (objective function model). The results are plotted in Figure 3.

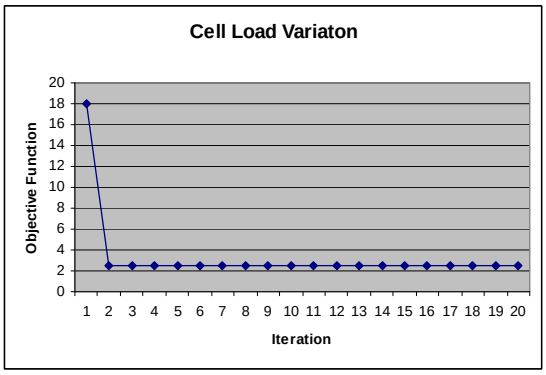

Figure 3. The proposed algorithm's objective function plots using Chan and Milner [11] data

The cell load variation drops from a value of 18 at the initial solution-state to 2.5 at the second solution state and settles at that value. This means that in the actual sense, the optimum solution was found at the fifteenth solution state even though the user indicated that the SA algorithm search through 20 solution states. The machine part grouping for the solution corresponding to the global is given in matrix form in Figure 4. The clustering efficiency is 92%.

	1	4	6	9	14	3	5	8	13	15	2	7	10	12

8						1	1	1	1	1				
1										1		1	1	1
7										1	1	1	1	1
10										1	1	1	1	1

Figure 4. Final solution

4.2. Extention computational results

We further tested the results of our algorithm with those of the TSP-based heuristic [4] and GA [9] for 5 data sets from literature. The detailed results of the further experiments are presented in Table 1. The measures frequently used in the literature are used in the present comparative study. One is grouping efficiency [15], which is defined as follows:

$$\eta = w\,\eta_1 + (1-w)\,\eta_2 \qquad (4)$$

where :
η = grouping efficiency (GE)
η_1= (o-e)/(o-e+v)
η_2= (M*P-o-v)/(M*P-o-v+e)
M= sum of machines
P = sum of parts
o= sum of 1's elements in solution matrix $\{a_{pm}\}$
e= sum of exceptional's elements in solution matrix
v= sum of *void* in solution matrix
w= weight (we use 0.5)

Table 1. Performance of the algorithm compared to TSP and GA

Number	Source	Size	Grouping efficiency (%)		
			TSP Cheng et al [4]	GA Onwubolu and Mutingi [9]	Proposed Algorithm
1	Seifoddini and Wolfe [10]	5 x 18	86.76	86.76	86.76
2	Kusiak and Chow [2]	5 x 7	87.5	87.5	87.5
3	Kusiak and Chow [3]	7 x 11	73.7	74.24	74.24
4	Boctor [7]	7 x 11	88.06	88.06	88.06
5	Carrie and Kusiak and Rajagopalan [15]	8 x 20	71.66	84.6	71.66

Table 1 shows that the proposed algorithm favorably competes with that of Onwubolu and Mutingi [9] and that both algorithms produce better solutions than Cheng et al [4], espcecially on third case [2], which is the commonly used reliable algorithm in comparative studies. In some cases our algorithm produces the same results as Onwubolu and Mutingi [9] for example solution in problems 1, 2, 3 and 4. The solutions from our algorithm in Table 1 are based on automatically generated cell size and there is the possibility that we can obtain better solutions by specifying different cell sizes and cell size capacities. Another point that needs to be addressed is that the authors of the TSP-based algorithm under the section of comparative study say:"it is not appropriate to use our objective function to evaluate the other solutions". This means that their objective function is solely dependent on the distance measures that belong to the family of Minkowski metric. In practice, a manufacturing systems engineer may want to consider only total cell load variation as objective function, or only intercellular moves as objective function, or a combination of both. This is what we have built into our algorithm: flexibility for the manufacturing systems designer.

5. CONCLUSION

This paper presents a hybrid tabu search and simulated annealing procedure for solving the GT design problem for fabrication facilities designed. A hybrid approach was developed to unite the best features of both TS and SA. This approach efficiently yields good solutions and tends to be insensitive to starting solutions. The proposed hybrid procedure can also solve many other cellular system design problems, since the cell formation, on which it is based, are commonly seen in practice. Therefore, the proposed design procedure promises to be a valuable approach for solving system design integration problems not only in GT but also in more general cellular manufacturing systems.

The Influence of Collaboration to the Supply Chain Performance (A Survey on Modern Retails at DKI Jakarta and Bandung City)

Agus Purnomo
Industrial Engineering Department
Engineering Faculty – Pasundan University Bandung 40153
e-mail : nrpsga@yahoo.com ; aguspurnomo@unpas.ac.id

ABSTRACT

The competition paradigm in modern retail has recently been changed, from the former, intercorporate competition into inter supply chain network. The improvement of Retail Supply Chain Performance seem to be the main demand to win high competition. Some questions of the study include : first, how does The Collaboration happen ? Second, how does The Supply Chain Performance happen ? And third, how far is the influence of Information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration to The Modern Retailer Supply Chain Performance either partial or simultaneous. The study was conducted as descriptive and verification method in which the causality was used as a type of investigation. This study was under taken in Hypermarket, Supermarket, and Minimarket. Number of sample are 207, while the empirical way of testing to examine hypotheses, the author used Structural Equation Modeling (SEM) processed by Lisrel 8.30 software for windows NT. Research findings indicate that; (1) There are some positive and significant influence between Information Collaboration to The Modern Retailer Supply Chain Performance; (2) There are some positive and significant influence between Decision Synchronization Collaboration to The Modern Retailer Supply Chain Performance; (3) There are some positive and significant influence between Incentive Alignment Collaboration to The Modern Retailer Supply Chain Performance; (4) There are some positive and significant influence between Organization Collaboration n to The Modern Retailer Supply Chain Performance; (5) There are some simultaneously positive and significant influence between Information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration to The Modern Retailer Supply Chain Performance. Based on the findings above the author concludes that Collaboration in Supply Chain between Modern Retailers and Key Suppliers are significantly able to enhance The Modern Retailer Supply Chain Performance.

Keywords : *Information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, Organization Collaboration, Supply Chain Performance.*

1. INTRODUCTION

Supply chain collaboration has become a new imperative strategy for companies to create competitive advantage [12]; [25]. A closer relationship enables the participating companies to achieve cost reductions and revenue enhancements as well as flexibility in dealing with supply and demand uncertainties [5]; [18]. Hewlett-Packard (HP), for instance, initiated collaboration with one of its major resellers [7]. These collaborative efforts, which focused on co-managed inventory by considering different levels of demand uncertainty, enabled both parties to improve fill rate, increase inventory turnover, and enhance sales. Similarly, Wal-Mart collaborated in demand planning and replenishment with its major suppliers to increase inventory turns, reduce inventory costs, reduce storage and handling costs, and improve retail sales [21]. Supply chain collaboration requires a reasonable amount of effort from all participating members to ensure the attainment of potential benefits [3]; [9]. The chain members also search for better practices and ideas through benchmarking their current collaborative practices to other collaborative supply chains. To achieve higher supply chain efficiencies, the various members of the supply chain are presumed to share information and trust one another. According to Supply Chain Management (SCM) theory, the level of collaboration depends on the nature of relationships (e.g., the frequency of the contact, the level of trust, etc.) and the application of advanced information technologies such as collaborative forecasting [11]; [19]. Improving relationships among the members of the supply chain in turn leads to cost reductions and higher levels of customer service [26].

The growth of modern retail in DKI Jakarta and Bandung is higher than the other cities in Indonesia. This certainly will cause the level of competition inter modern retailer become more and more tight. Thus the retail supply chain performance seems to be the most important demand to win the strict competition. The increase of retail supply chain performance would expectedly reached through collaboration with suppliers in form of information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration. Some questions of the study include : first, how does The Collaboration happen ? Second, how does The Supply Chain Performance happen ? And third, how far is the influence of Information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration to The Modern Retailer Supply Chain Performance either partial or simultaneous.

2. LITERATURE REVIEW

Collaboration between supply chain partners has been covered extensively in the strategic management literature [6]; [16]. Other researchers have examined the

theoretical implications of supply chain collaboration through unilateral supply policies [14]; [27]. Other researchers have employed theoretical models to examine bilateral information exchange rather than unilateral policy incentives [10]; [20]. The practitioner-oriented research into supply chain collaboration tends to focus on the emerging concept of Collaborative Planning, Forecasting and Replenishment (CPFR) and Vendor Managed Inventory (VMI) [1]. Though rigorously reported empirical data are rare, [15] presents results for 31 grocery retail chains that adopted Campbell's continuous replenishment process and showed a significant improvement in inventory turns and a simultaneous reduction in stock-outs. Sharing of physical assets as suggested by our concept of structural supply chain collaboration has been examined in pieces but not holistically. For example, [8] examine the benefit of coordinated shipments to improve truck utilization.

The definitions of collaboration made by researchers as well as column writers in business magazines are not incongruous, nor are they ever the same; it seems extremely difficult to develop a general one-sentence definition of collaboration [4]. Collaboration can (similar to [19]) understanding of the SCM term), be considered to contain two different things. First, collaboration can be characterized as a certain type of relationship between independent companies or functions in a company where trust, win-win thinking, commitment and openness are important ingredients [20]; [21]; [22]. Second, collaboration also consists of activities that are performed by the participating actors within the collaboration [19]. Collaboration within the logistics area, which is the focus in this dissertation, typically means sharing information and jointly negotiating and deciding upon logistics activities in the supply chain such as transportation and inventory. This means a two-way communication with jointly, voluntary agreed goals [23]. Since collaboration should contribute to improvements in the supply chain, the possibility for the involved parties to influence the collaboration is important; otherwise there is a risk that major opportunities for improvements can be lost as well as the win-win situation [13]; [24]

Collaboration variable in the research is grouped as follow :

1) *Information Collaboration*
   Cooperation amongst collecting and disseminating relevant and functual information using all resources to make decision, planning, and supply chain operation. The collaboration indicators include : Demand Forecasting, Sales Administration, Inventory level, Promotion Plan, Delivery Schedule, Information Technology [23].
2) *Decision Synchronization Collaboration*
   Cooperation of decision making is based on adjustment of planning and supply chain operation standard. Collaboration indicators include : Purchasing, Target Market, Price Policy, Service Level [22]; [2].
3) *Incentive Alignment Collaboration*
   Cooperation of risk equivalent regulation and benefit which is caused by planning and supply chain operation. Administrative fee and utilizing technology are normally handed together amongst members of supply chain to keep commitment. Collaboration indicator include: Discount Program, Research & Development, Inventory Management, Product Warranty [22]; [2]
4) *Organization Collaboration*
   Collaboration organization and making use of cross firm function focusing on planning and supply chain operation. The collaboration indicators are : Information Technology Implementation, Supply Chain Design, Customer Satisfaction Measurement [2].

Based on the problem faced by modern retailers and relevant literature study. The research paradigm shows as follow :

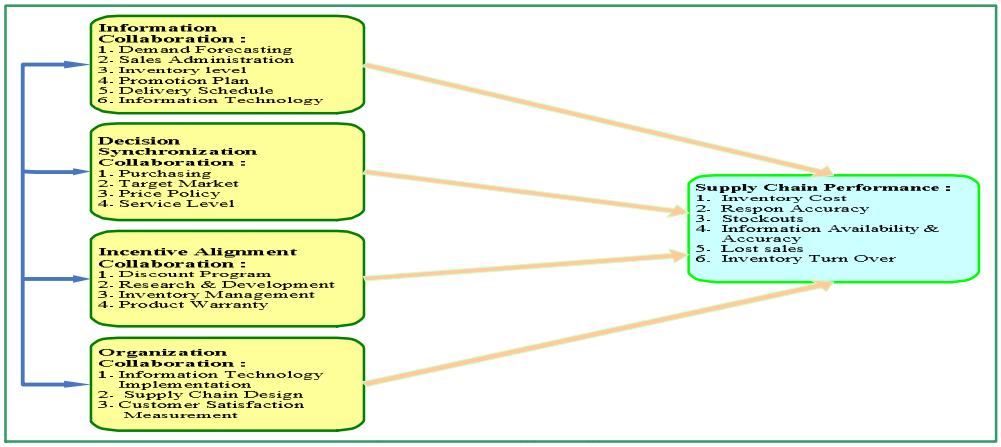

Figure 1. Research Paradigm

State of the art for this research presented in table 1 below:

3. RESEARCH METHOD

Research methods used in this study are descriptive and explanatory survey. In descriptive survey, the researcher wants to have a description about level of collaboration which aims to headwaters (key distributor). It has been conducted by retailers from DKI Jakarta and Bandung. Explanatory survey is captured out in to 250 head gerai hypermarket, supermarket, and mini market in DKI Jakarta and Bandung as sample. The purpose of the survey is to know how is the correlation inter variable amongst information collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration to The Modern Retailer Supply Chain Performance, through hypothesis test. Investigation type used in the research is causality, a kind of research type stating the existence of causal correlation of research variable between independent variable and dependent variable. Data analysis has been completed by using quantitative method. It is statistically tested the hypothesis used Structural Equation Modeling (SEM) processed by software Lisrel 8.30 for Window NT.

Stuctural Equation Model shows the correlation between endogenous latent variable and exogenous latent variable as following formula:

$$Y = \gamma_{Y1}X_1 + \gamma_{Y2}X_2 + \gamma_{Y3}X_3 + \gamma_{Y4}X_4 + \zeta_y$$
……..……(1)

Where : Y=Supply Chain Performance; X_1= Information Collaboration; X_2= Decision Synchronitiozan Collaboration; X_3= Incentive Alignment Collaboration; X_4= Organization Collaboration; $\gamma_{1y}\, s.d\, \gamma_{4y}$ = influence value exogenous latent variable to endogenous latent variable.

Figure 2 below describes a research model for all variables in SEM diagram form.

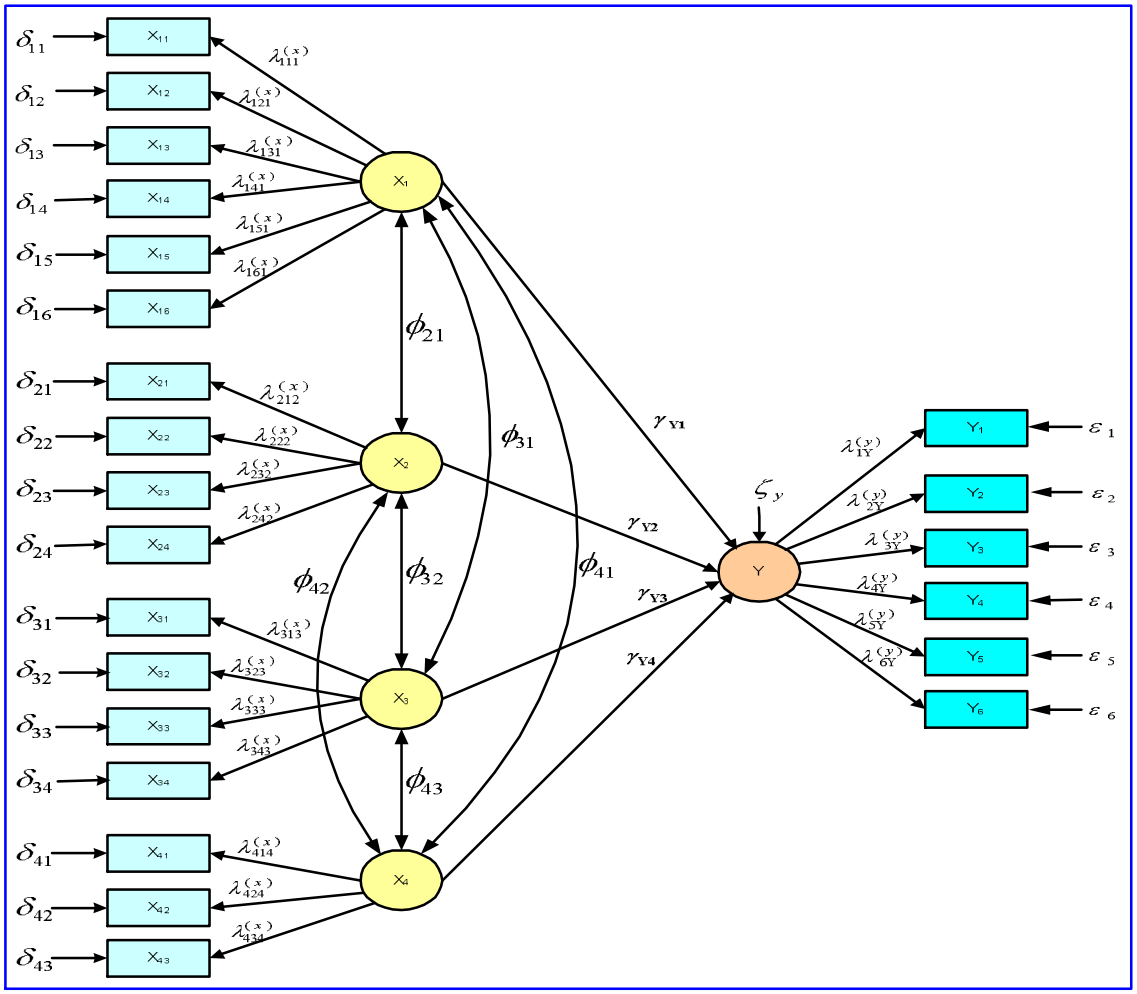

Figure 2. Research Model in the Form of SEM Diagram for All Variables

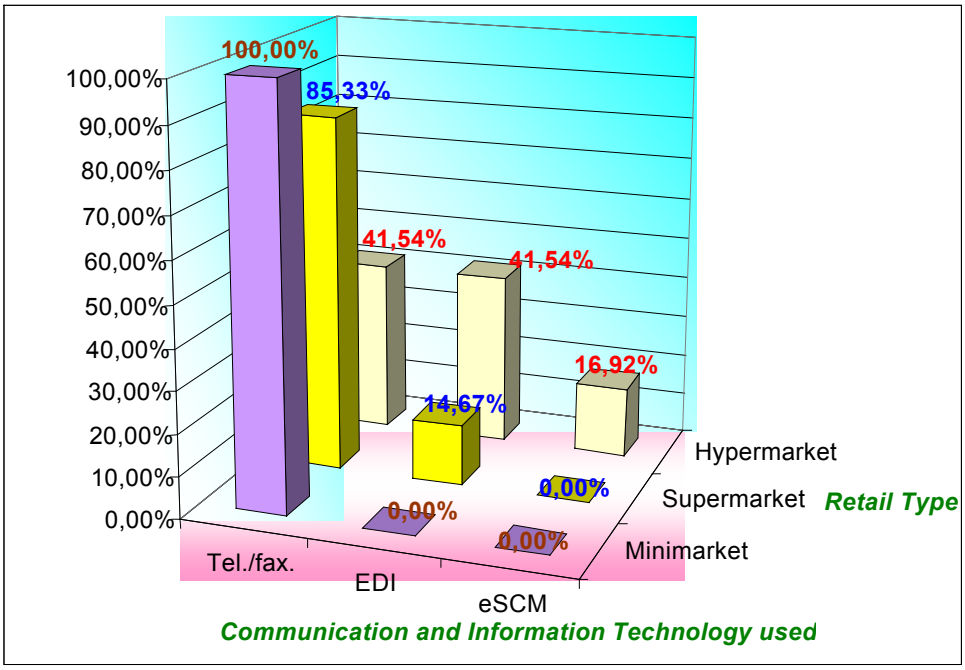
4. FINDINGS

Based on 207 respondent, the retailer characteristic description based on communication and information technology which is used in collaboration with key suppliers (figure 3) shows that 100% of minimarkets used telephone/facsimile to have communication and information exchange when they collaborate with their key suppliers. While 85,33% supermarket used telephone/facsimile in the same time with 14,67% electronic data interchange (EDI) to exchange information and communication when collaborating with key suppliers, 41,54% hypermarkets used telephone/facsimile, Electronic Data Interchange/EDI (41,54%) and 16,92% esupply Chain Management / eSCM to have communication and information exchange when collaborating with key suppliers.



Source : questioner (n=207), 2009

Figure 3. Characteristics of Retailers according to Communication and Information Technology used in Collaboration with Key Suppliers

The description of retailers characteristic according to arrangement collaboration constraint with key suppliers (figure 4) are: first, insufficiency of information and technology equipment (25,12%), second, unsynchronized in decision making (23,19%), third, unequivalency of giving risk and benefit (19,81%), fourth, interfims unreliability and fifth, less of logistic competency (14,01%). According to the description above, we find that the insufficient of information technology equipment has placed the first constraint in collaboration with suppliers. It is relevant to communication and information technology which is used by retailers collaborating with key suppliers mostly used telephone/facsimile.

NNFI	0.9725	NNFI > 0,9 : model *fit*	

Source : Processed from questioner (n=207) with *software* Lisrel 8.30, 2009

The result of computation influence decomposition between exogenous latent variable and endogenous latent variable supply chain performance (Y), can be concluded that exogenous latent variable (information collaboration (X_1) showed the bigger total causal effect (TCE) compared to endogenous latent variable supply chain performance (Y), namely 0,4269. Meanwhile, exogenous latent variable of decision synchronization collaboration (X_2) showed the smallest TCE compared to endogenous latent variable supply chain performance (Y), it is 0,2390. While exogenous latent variable organization collaboration (X_4) and incentive

alignment collaboration (X_3) showed the averaged TCE compared to endogenous latent variable supply chain performance (Y) one after the other, 0,3644 and 0,3010.

The explanation of hypothesis test found that information collaboration, decision synchronization collaboration positively and significantly influenced to the modern retailer supply chain performance, meaning that descriptively collaboration, decision synchronization collaboration, incentive alignment collaboration and organization collaboration have been applied and appropriately used by the modern retailer and key supplier in DKI Jakarta and Bandung. The successful of implementing collaboration, decision synchronization collaboration, incentive alignment collaboration and organization collaboration will hopefully increased the modern retailer supply chain performance inform of : lower inventory cost, accuracy respond, lower stock outs, information availability and accuracy, lower lost sales and higher inventory turn over.

5. Conclusion

The research has completely considered the collaboration aspect related to supply chain performance between the modern retailers and key suppliers namely about information collaboration, decision synchronization collaboration, incentive alignment collaboration and organization. The result of the study shows that there are some partial and simultaneously positive and significant influence between Information Collaboration, Decision Synchronization Collaboration, Incentive Alignment Collaboration, and Organization Collaboration to The Modern Retailer Supply Chain Performance. Based on the findings above the author concludes that Collaboration in Supply Chain between Modern Retailers and Key Suppliers are significantly able to enhance The Modern Retailer Supply Chain Performance.

Information Collaboration resulted the biggest TCE compared to supply chain performance, it means that employing the appropriate information and communication technology would become the main determination to improve the modern retailer chain performance.

ABSTRACT

In accordance with advancement of technology, so does incremental business interconnectivity of Bank D through Information Technology . This will bring along a larger amount and variation of threats and vulnerabilities towards IT security. Therefore, support system and IT resources enhancement becomes critical. With this concern, the requirements of ISO/ IEC 17799:2005 and ISO/ IEC 27001:2005 on Information Security should be integrated to Information Technology Department of Bank D Balanced Scorecard. This is known to be 4th generation of Balanced Scorecard. This research is dedicated to find methods of putting 4th generation of Balanced Scorecard into practice at Bank D.
The methods that we have developed is based on Analytical Hierarchy Process, which complementing the risk management process that is the heart of ISO requirements.

Keywords

4G Balanced Scorecard, Information Security, Risk Management, Analytical Hierarchy Process, ISO 27001:2005

1. INTRODUCTION

In order to attain the vision and mission while completing major duties of Bank D, information technology support is required. Therefore, vision and mission at Information Technology Department was established. The vision and mission make use of 3rd generation of Balanced Scorecard as management and measurement system of information technology. Balanced Scorecard helps organization to define key success, determine relationship between the key success, and develop the measurement that is appropriate to evaluate information technology performance.[1]

On the other hand, Bank D strives to increase information security performance by implementing Information Security Management System (ISMS) of ISO/ IEC 27001:2005 certification. The certification is able to control information technology based on practice guidance in ISO/IEC 17799:2005. [2]

If we could combine both requirements, the organization could benefits from more effective and efficient performance measurement which is related to risk management. The 4th generation of Balanced Scorecard which balance the profit earning strategy and the internal control strategy based on Sarbanes-Oxley do this. [3]

Fourth generation of Balanced Scorecard brings benefits to improve internal control, further understanding to entity of process, detect risk in internal process earlier, as tool of making effective internal audit program, increase transparency and accountability, show the gap between target and real condition of internal process, increase organization's value, and assure internal process control that is easy to be traced and improved in the next periods or is called Kaizen.

This research aims to obtain integration methodology of ISO/ IEC 17799: 2005 and ISO/ IEC 27001:2005 into Information Technology Department's Balanced Scorecard to become 4thBalanced Scorecard.

2. METHODS

Risk is the condition where there is a gap between result and expected outcome.[4] Risk of information technology based on Internasional Standard Organization is potential condition that threat will cause vulnerability to an asset or more so that the asset lost or broken.[5] Asset in information system is something that is attempted to be protected [6].

Operational risk is the lost risk of insufficient or failure of internal process, people, and system, or external events [7]. Components of operational failures are operational failure risk in running business and operational strategy risk from external factor [8]. Operational risk could be classified by people, relationship, process and technology, physical, and other external risks[9].

Threat is potential of vulnerability from threat source. Threat source is any condition or event that potentially causes lost in information technology. Vulnerability is the lack of security system in procedure, design, implementation, or internal control that can make security policy disruption. Likelihood is the probability where there is any potential vulnerability that can happen because of threat in an environment. Impact is the result of vulnerability that can be described as one or combination of integrity, availability, and confidentiality.

Steps of Information Security Management System (ISMS) implementation [5] are planning ISMS, implementing and conduction ISMS, monitoring and evaluating ISMS, and maintaining and improving ISMS.

Balanced Scorecard is a method to translate mission and strategy of company to a comprehensive measurement and give framework of strategic management and measurement. Four perspectives of Balanced Scorecard are financial, customer, internalbusiness process, and learning and growth.

The Balanced Scorecard for Sarbannes Oxley Act (4th generation of Balanced Scorecard) as the improvement of 3rd generation of Balanced Scorecard that has been applied by many companies. [3] The previous generations is as follows [10]:

a) 1st generation "Multimodal Assessment Tool" the additional nonfinancial perspectives to measure performance–learning and growth, internal business, process, and customers – to represent major stakeholders in business [11]
b) 2nd generation "Top Down Management Tool" that is the beginning of strategic goal concept where there is additional essential of organization strategy to each perspective of 1st generation of Balanced Scorecard [12]
c) 3rd generation "Knowledge-creating and Strategic Communication Tool" (based on strategy map) where there is strategy map that can give illustration of critical aim of organization and relationship between Key Performance Indicator from each perspective

Since risk that is related to daily operation changes everyday, company has to communicate important information and monitor every risk sign to prevent failure of external audit. Balanced Scorecard for SOX canhelp company, top management, director, and stakeholder. It makes use of 3rd generation of Balanced Scorecard as the basis. Profit earning strategy is still reflected but then added by internal control. Based on risk control matrix, key risk indicator (KRI) of each risk has a role as lagged indicator and key control indicator (KVI) of each control has a role as leading indicator.

The selection of indicators is important. Some consideration of indicator selection are metric that is suitable to risk, represent stakeholders, has support from senior management, understand risk indicator versus performance indicator, simple and understandable, consistent framework, quantifiable, invest in technology, use escalation criteria, and indicator as work in progress [13]. Other considerations include characteristics and effective key risk indicators are based methodology and consistent standard; related to risk factor: source, likelihood, impact, and correlation; quantifiable; could be traced by time; support goal, risk owner, and risk standard category; balance between leading and lagging indicators; useful to the decision and management action; could be compared internally and externally; time and cost efficient; and risk could be simplified without losing its real meaning [14].

Recommended steps to make indicator are identify indicators in organization, gap assessment, indicator improvement, validation and target level determination, dashboard design, make a control plan and escalation criteria [15].

In order to simplify the fulfillment of multiple criteria, we will use the priority matrix [16]

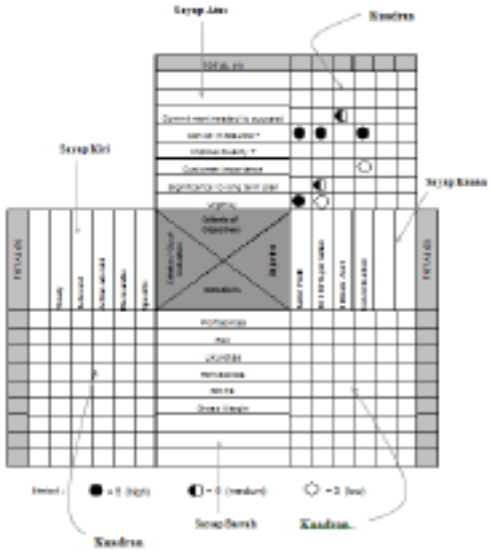

Figure 1: Example of Priority Matrix [14]

We can identify all potential indicators to measure each perspective.. Priority matrix was designed so that company just need 1 simple matrix to select the alternatives with

ISSN 114-1284

scoring: 9 for strong relationship, 6 for medium relationship, 3 for weak relationship, and 0 for no relationship.

Since Bank D is the 1st bank in Indonesia that has applied 3rd generation of Balanced Scorecard and ISO/ IEC 17799:2005 and ISO/IEC 27001:2005, research uses expertise judgment in those two fields. Experts criteria are very important in AHP. [17]

The respondents of research are:

a) Information Technology Department of Bank D that has been and had been KPI manager of Information Technology of Bank D and security officer ISO/ IEC 17799:2005 and ISO/ IEC 27001:2005
b) Project leader of ISO/ 27001:2005 certification project.

Based on the educational background, four respondents have information technology, Telecommunication and Balanced Scorecard background. They also have been employees there for 11 – 14 years with experience as KPI manager of Information Technology of Bank D for ±3 years. Beside that, the experience of ISO/IEC 17799:2005 and ISO/ 27001:2005 is ranging between 1 until 3 years.

Based on Saaty, (personal communication, October 12, 2003) if there is no expert in a subject of research, a lot amount of respondents won't be enough. If there is just 1 expert who knows everything, it is sufficient to make a good scaling.

3. DISCUSSION

Figure 2 show the complete methodology by combining all the elements necessary from all perspectives. Each process and aspect of ISO/ IEC 17799:2005 and ISO/ IEC 27001:2005 that is integrated into Balanced Scorecard to become 4th generation Balanced Scorecard used experts that make use of both qualitative – problem definition – and quantitative aspects – judgment and importance level.

Risk selection criteria determination was based on input from 1st step of ISMS implementation which is ISMS planning and 3rd step deliverable which is risk profile. On the other hand, indicator selection criteria alternatives are from Budgeting Planning and Performance Management of Bank D with flexibility of additional criterion.

Indicator selection criteria weighting was conducted by pair wise comparison from Analytical Hierarchy Process (AHP) method. From this weighting result, we could recognize the importance level of each criterion to be consideration of Information Technology Department to make decision of selecting implemented KRI and KCI.

After selecting risk, KRI and KCI determination made use of priority matrix. Input of KRI and KCI were from 4 steps of ISO/ IEC 17799:2005 and ISO/ IEC 27001:2005. Selected KRI and KCI would be the input for risk control matrix creation.

Risk control matrix is a requirement that is needed for developing Balanced Scorecard. It was from Risk Assessment of Policy Division, Operational Division, and Administration Division of Information Technology Department selected KRI and KCI.

Relationship determination between KRI, KCI, and KPI of Information Technology Department of Bank D is the basis for identifying and assessing ISMS implementation support to KPI from internal business perspective. It is also the development of 3rd generation of Balanced Scorecard to become 4th generation of Balanced Scorecard at Information Technology Department of Bank D.

Then criteria of risk and indicator were selected. Criteria for risk are risk happens to critical assets and it has to controlled risk. Criteria for indicator are align to strategic target of department and can be controlled, quantifiable, capable of illustrating previous performance and current performance, specific and explicit, data could be quantified periodically, realistic, time bound, and understandable.

Data processing for weighting indicator selection criteria was conducted by averaging all respondents' score by geometric average [18]. Then, by using Expert Choice Software, weight for each criterion and inconsistency ratio was assessed based on distributive mode.

Using priority matrix, all risks of Policy Division, Operational Division, and Administration Division of Information Technology Department 26 risks are selected based on criteria.

In indicator selection several steps were conducted:

a) Make total of 1st quadrant – respondents' assessment of selected risk and KRI- and 2nd quadrant – respondents' assessment and KCI. After that, sorting KRI and KCI which has highest and 2nd highest total with minimum score of 24.
b) Make total of 3rd quadrant – KRI and indicator selection criteria – and 4th quadrant – KPI and indicator selection criteria. Both quadrant are for assessing the ability of

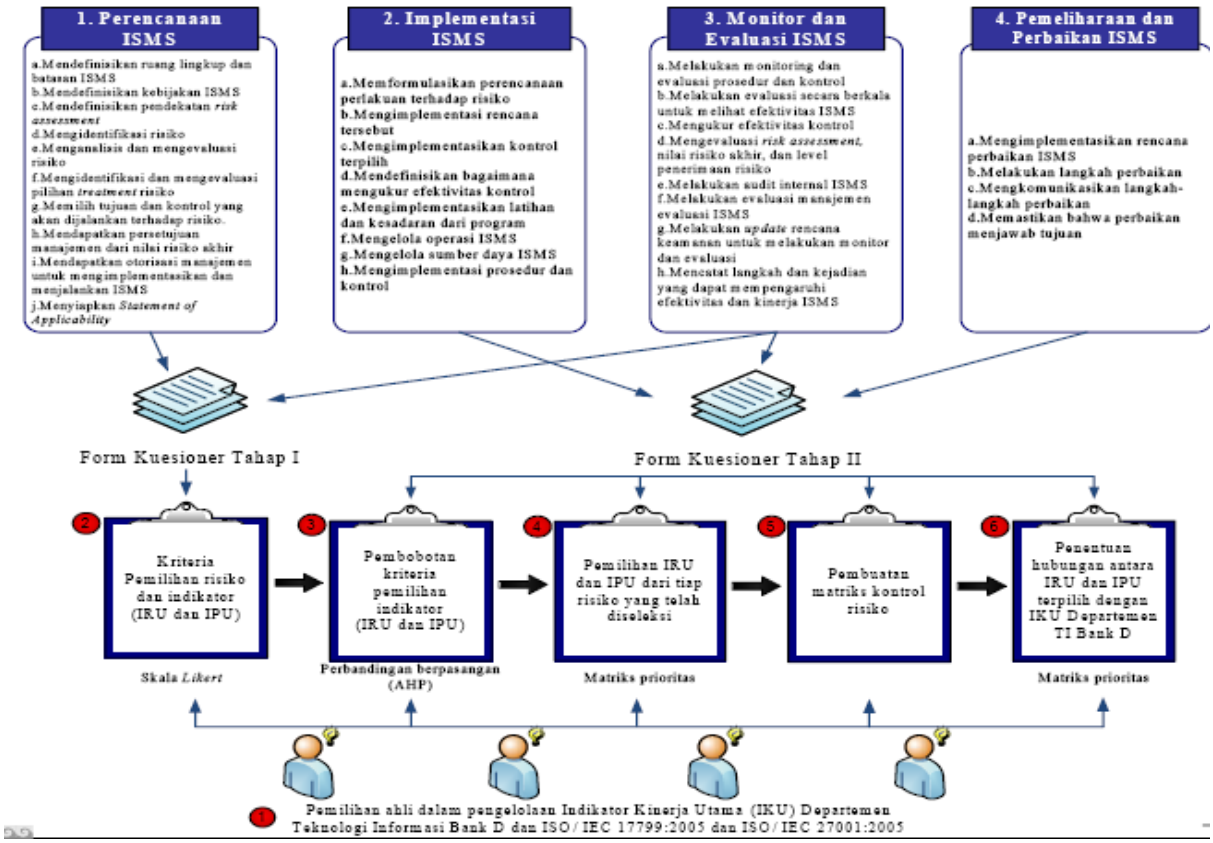

Figure 2 Methodology for the integration of Risk Management from ISO/IEC 27001:2005 into the Balanced Scorecard

c) KRI and KCI to fulfill indicator selection criteria. After that, the total was multiplied by weight of each criterion
d) Confirm those selected KRI and KCI to the respondents

Table 1 Example of Selected KRI and KCI

No	Risk	Key Risk Indicator (KRI)	Key Control Indicator (KCI)
1	The lack of physical security of Director's and Vice Director's Room causes unexpected access that affects authorization process	Measurement of Losing and Damaged Asset in Director's and Vice Director's Room	Measurement of Access Control Compliance
2	Unappropriate asset maintenance causes thermal control can not be used because of damaged components	Measurement of thermal Control Availability	Measurement of Asset Maintenance Level
			Measurement of Incident Corrective effectiveness

After KRI and KCI of each risk had been selected, risk control matrix of Information was constructed. The example of risk control matrix can be seen in table 2. The aim for creating risk control matrix is to identify KRI, KCI, and whole plan of risk mitigation.

Data processing to determine the relationship between KRI and KCI and KPI of Information Technology Department of Bank D was conducted by making total of 3rd quadrant that contains assessment of relationship between KRI and KPI and 4th quadrant that contains assessment of KCI and KPI.

The example of this relationship is the relationship between KRI "performance level of mainframe" and KCI "maintenance level of asset" with KPI "downtime percentage of critical applications and email".

No	Asset	Risk Classification	Description	Likelihood	Impact	KRI	Control Activities	KCI
9	Director and Vice Director's Room	Operational Risk	Lack of control in access control could potentially cause unexpected access to Director and Vice Director's room so that results in authorization process of Informatio Technology Department (e.g. missing information)	Level 7	Level 7	Measurement of Losing and Damaged Asset in Director's and Vice Director's Room	- Bank D Regulation about Registration and Nonactivation of Access Rights of User - Access Rights Evaluation Regulation - Physical Access Control	Measurement of Access Control Compliance

Table 2 Example of Risk Control Matrix

4. CONCLUSION

ISO/ IEC 27001:2005 into Information Technology Department Balanced Scorecard to become 4th generation of Balanced Scorecard could be applied by these steps:

a) Selection of Expert Respondents
b) Determine risk selection criteria (Likert scale)
c) Weighting of indicator (KRI and KCI) selection criteria based on pairwise comparison of Analytical Hierarchy Process (AHP) method.
d) Key Risk Indicator and Key Control Indicator setting that use priority matrix
e) Risk control matrix making
f) Determination of relationship between KRI and KCI with KPI of Information Technology Department of Bank D

Product Miniature Quality Design with Multi Responses Taguchi Method

Ali Parkhan[1], Ceria Mustika[2], I. D. Widodo[3]

[1,2,3]*Industrial Engineering Study Program,*
Islamic University of Indonesia

ABSTRACT

One of the important factors that influence the firm sustainability is product quality. The quality of temple miniature product can be measured using the product shrinkage and strength. Factors that influence the temple miniature are resin composition (A), cobalt composition (B), catalyst composition (C), talk composition (D), and mixing duration (E). Besides, there is an uncontrollable factor namely room temperature. Initial parameter setting is the factor level combination of $A_1B_1C_1D_1E_1$ (combination of 55% resin, 0.4 % cobalt composition, 0.6 % catalyst composition, 44% talk composition and 5 minutes mixing duration). For this combination, its shrinkage is 2.625 % and the strength average is 120.437 kg/cm^2. Taguchi method is applied to improve product performance. Based on Taguchi method, the optimal factor level combination is $A_1B_2C_2D_1E_2$ (55% resin composition, 0.3 % cobalt composition, 0.4 % catalyst composition, 44% talk composition and 10 minutes mixing duration). It can successfully improve quality and reduce cost. The shrinkage can be reduced to 1.875 % and strength average can be improved to 136.875 kg/cm^2. This combination also reduces cost to Rp. 30.5/ product.

Keywords: *quality, Taguchi, level factor combination, cost*

1. INTRODUCTION

In globalization era, product and process efficiency and quality have become main consideration for industry that aware of competition. Nowadays, many products have used fiber glasses, including temple/statue miniature. Temple miniature quality is determined by strength of getting impact and shrinkage.

By considering this phenomenon, temple miniature industry should be able to produce product that has maximum strength and minimum shrinkage with minimum cost/price. Therefore, industry must improve its product quality by maintaining its pricing. Taguchi method is applied to minimize experiment cost and time applied. Multi responses Taguchi method is used because there are 2 variables being involved, strength and % shrinkage.

2. LITERATURE REVIEW

2.1 Quality definition

Conventional definition of quality usually reflects some direct characteristics of product, such as, performance, reliability, easy to use and aesthetic. Whereas, strategic definition of quality is anything that can satisfy customer need [1].

2.2 Quality control

Quality control is defined as measurement process done in period of product and process design. Quality control involves every phase of product research and development, production process design and customer satisfaction. Quality control is divided into:

a. Off line Quality Control

Off line quality control consists of [2, 3, 4] three steps, as follow:

Step 1: Concept Design

In this step, product design and development idea from customer, are generated. Model and method applied in this step are Quality Function Deployment, Dynamic Signal-to-Noise Optimization, Theory of Inventive Problem - Design of Experiments, Competitive Technology Assessment -, Pugh Concept Selection.

Step 2: Parameter Design

This step is to optimize level of control factor to some effect appeared by other factors so that product will be robust from noises. Therefore, this step is also called by robust design. Model and method applied in this step are Engineering Analysis, The System P Diagram, Dynamic and Static Signal to Noise Optimization, And Crossed Array Experiment.

Step 3: Tolerances Design.

This is the last step of Taguchi method. Some methods are applied in this step such as Quality Loss Function, Analysis Of Variance (ANOVA), And Design of Experiment.

b. On Line Quality Control

On Line Quality Control is an activity to directly observe and control quality for every step of production processes. This is very important to maintain low production cost and high product quality. Statistical process Control, Static Signal to Noise Ratio, Compensation, Loss Function are some method that commonly used for on line quality control.

2.3 Experimental Design

Experiment design is an experiment phase/activity design so that all information of the experiment running can be collected [5]. There are two types of design experiment, conventional and Taguchi. Compared to conventional approach, Taguchi method is preferred because it needs smaller number of experiment so that it can minimize time, cost, and energy.

Taguchi method, introduced by Genichi Taguchi, uses orthogonal array to determine minimum experiment number that can produce as much as possible information of factor that influence parameter. The most important of orthogonal array is in selection of level combination from input variables for each experiment [2]. Taguchi philosophy consists of three concepts, they are [6]:

1. Quality must be designed into the product and not only checking the product. The best quality can be reached by minimizing deviation of target.
2. Product must be designed so that robust from uncontrollable environmental factors
3. Quality cost must be measured based on deviation function from the target and loss must be measured for all system.

2.4 Signal to Noise Ratio (S/N Ratio)

S/N ratio is logarithm of quadratic loss function and used to evaluate quality a product. There are three S/N Ratio types, they are:

1. Smaller- the Better

Quality characteristic where by smaller value it gets, the better quality it has, however the biggest S/N ratio is used to determined optimum factor level [4]. S/N Ratio function of smaller- the better:

$$S/N\_STB = -10Log\left[1/n \sum_{i=n}^{n} yi^2 \right]$$

n= number of trial

yi= respon value of sample i

2. Larger the Better

The bigger value it gets, the better quality it has. The function is

$$S/N\_LTB = -Log\left[1/n \sum_{i=n}^{n} 1/yi^2 \right]$$

3. Nominal –the Better

Quality characteristic where by a nominal value (target) is determined. The closer value to the target, the better quality it has. The S/N ratio function is

$$\eta = 10\log\left[\frac{\mu^2}{\sigma^2}\right] \qquad \sigma^2 = \frac{\sum\left(y_i - \bar{y}\right)^2}{n-1}$$

2.5 Taguchi Multi Response

Taguchi approach is divided into two types, namely single response and multi response. Single response Taguchi only has one single response variable, so that the optimum combination is directly found. Multi responses Taguchi involve more than one response variable (minimum 2), and each response variable has different factor combination. To get optimum combination, it must do multi attribute analysis tools such as Multi Response Signal to Noise (MRSN) and *Technique for Order Preference by Similarity to Ideal Solution* (TOPSIS)[7].

2.6 Multi Response Signal to Noise (MRSN)

Three MRSN steps are:

1. Calculate quality loss for every trial. It depends on quality characteristics.

Bigger the better

$$L_{ij} = k\frac{1}{n_i}\sum_{k=1}^{n_i}\frac{1}{y^2_{ijk}}$$

Nominal the best

$$L_{ij} = k\frac{1}{n_i}\sum_{k=1}^{n_i}\left(y_{ijk} - m\right)^2$$

Smaller the best

$$L_{ij} = k\frac{1}{n_i}\sum_{k=1}^{n_i} y^2_{ijk}$$

Where :

L_{ij} = *quality loss* for response -i, trial -j

Y_{ijk} = data for response-i, trial -j, replication -k

n_i = replication response-i

k = Coefisien of *quality loss*

m = target Value

2. Determine MRSN Ratio

a. Determine the maximum Quality loss for each response

b. Normalization

$$C_{ij} = \frac{L_{ij}}{L_i}$$

Where: C_{ij} = *normalized quality loss* for response i, trial –j

L_{ij} = max $\left\{L_{i1}, L_{i2}, ..., L_{ij}\right\}$

ISSN 114-1284

c. Calculate *total normalized quality loss* (TNQL) every experiment :

$$TNQL_i = \sum_{i=1}^{m} w_i x C_{ij}$$

W= weight of normalization response-i

d. Calculate MRSN Ratio for every experiment

$$MRSN_j = -10\log(TNQL_j)$$

3. determine optimum level factor combination based on the bigest MRSN Ratio by:
   a. developing response table and response graph of MRSN
   b. determining control factor that has significant effect to MRSN
   c. determining optimum level of control factor based on the bigest MRSN
   d. confirming the experiment

3. EXPERIMENT DESIGN AND PLANNING

3.1 Experiment Planning

Experiment planning is an information provider phase to run experiment. Some steps in experiment phase are :

1. Selection of Poduct Quality Charateristics
   Quality charateristics of temple miniature are "good" when its shrinkage rate is low and its strength value is high.
2. Identification and selection factors that influence product quality charateristics. Five controlable factors and a noise factor influence the experiment. They are:
   a. Resin composition
      Level used is in between 55% and 66%. If resin composition is lower than 55%, the mixture is difficult to be mold because its viscosity is too high. In contrary, if composition is higher than 65%, the mixture is too watery.
      This will influence the thick and the strength of product.
   b. Cobalt Composition
      The possible level used is in between 0.3 % and 0.4 %. Mixture that contains cobalt composition that lower than 0.3 % will take longer time in drying process. This is in contrast to mixture that contains cobalt to much (more than 0.4%). It will be too fast.
   c. Catalist composition
      Catalist composition level is in between 0,4 % and 0,6 %. Mixture that contains catalist composition less than 0.4 % will take longer time in drying process. This is in contrast to mixture that contains catalist more than 0.6%
   d. Carbonate Calcium (Talk) Composition
      The level used is in between 33,3 % and 44%. The mixture will be too watery if it is less than 33,3% and it is incontrary if the talk composition is more than 44%
   e. Mixing Process
      It is between 5 minutes and 10 minutes.
   f. Room Temperature
      It is noise because this factor cannot be controlled.

3.2 Experiment Execution

To test the product, two measuremet are applied. They are product strength (kg/m^2) and shrinkage (%) measurement. The strength test was done in Concrete Laboratory FTSP UII. The shrinkage test is done by comparing product length and the molt. The measurement results are presented in Table 1 and Table 2.

Table 1: Temple miniature strength data (kg/cm^2)

4. RESULT AND DISCUSSION

4.1 Normality Test

Strength test data follow normal distribution because. χ^2_{cal} is 4.7111 less than χ^2_{table} (7,81472776) so do shrinkage test data. χ^2_{cal} is 4.8328 less than χ^2_{table} (5,99147636).

4.2 Homogeneity and Analysis of Variance (ANOVA)

Both data are homogenous. Strength test data is homogenous because χ^2_{cal} (3.726) less than χ^2_{table} (3,841). Shrinkage test data that are also homogenous because χ^2_{cal} (0.0529) less than χ^2_{table} (3,841).

All factors (A, B, C, D, and E) influence both strength and shrinkage based on ANOVA.

4.3 S/N Ratio Analysis

S/N Ratio of both strength and shrinkage are presented in Table 3. Effect factor for strength and % Shrinkage are presented in Table 4 and 5.

Table 3: Strength and % shrinkage mean and SNR

rial	Strength		% Shrinkage	
	Mean	SNR	Mean	SNR
	120.4375	59.7922	2.625	-8.5278
	132.875	60.0043	4.375	-12.9281

Rank	**1**	**3**	**2**	**4**	**5**

4.4 Determination of Factor Level with MRSN

MRSN is applied because optimal combination of strength (A2 B2 C2 D2 E1) is different from optimum combination of % shrinkage (A1 B2 C1 D1). MRSN Ratio is calculated by stating % shrinkage and strength weight 1/3 and 2/3. The MRSN ratios are performed in Table 6.

Table 6: Multi Response Signal to Noise Ratio (MRSN)

No	A	B	C	D	E	MRSN
1.	1	1	1	1	1	1.3408
2.	1	1	1	1	2	1.8575
3.	1	1	1	2	1	1.1266
4.	1	1	1	2	2	1.5607
5.	1	1	2	1	1	1.7567
6.	1	1	2	1	2	2.1135
7.	1	1	2	2	1	1.1777
8.	1	1	2	2	2	1.3862
9.	1	2	1	1	1	2.8824
10.	1	2	1	1	2	3.1263
11.	1	2	1	2	1	2.5519
12.	1	2	1	2	2	3.0585
13.	1	2	2	1	1	3.1743
14.	**1**	**2**	**2**	**1**	**2**	**3.3779**
15.	1	2	2	2	1	2.4975
16.	1	2	2	2	2	2.8942
17.	2	1	1	1	1	1.4077
18.	2	1	1	1	2	1.828
19.	2	1	1	2	1	0.8686
20.	2	1	1	2	2	1.2218
21.	2	1	2	1	1	1.306
22.	2	1	2	1	2	1.6274
23.	2	1	2	2	1	0.7321
24.	2	1	2	2	2	0.9974
25.	2	2	1	1	1	2.7315
26.	2	2	1	1	2	2.984
27.	2	2	1	2	1	2.0295
28.	2	2	1	2	2	2.511
29.	2	2	2	1	1	2.5431
30.	2	2	2	1	2	2.6825
31.	2	2	2	2	1	1.8474
32.	2	2	2	2	2	2.2074

Conclusion: the best combination based on MRSN is A1 B2 C2 D1 E2. It gives highest MRSN Ratio (3.3779).

4.5 Prediction test and T Test

Optimum combination based on MRSN (A1 B2 C2 D1 E2) has not been done in the previous experiment, so it needs prediction for the combination result. Regression method is applied to predict the result based on experiment performed. Shrinkage percentage are (2, 2, 2, 2, 3, 2, 2, 3) and the confirmation result is (2,1,3,1,1,3,2,2). S/N Ratio is – 6.15, this value is in confidence interval – 10.6899 < SNR < - 5.5019. This shows that SNR from experiment confirmation result is not significantly different from experiment prediction.

Strength prediction is (134, 152, 147, 139, 171, 131, 181, 159) and the experiment confirmation is (117, 123, 135, 132, 121, 169, 143, 155). SNR Value is 60.85. This value is in confidence interval (29.2634 < SNR < 91.5056). It means that prediction and confirmation result is not significantly different.

Based on T Test, there are not significantly different both strength and % shrinkage between prediction and confirmation experiment result. T_{cal} for shrinkage is 1.11, this is in confidence interval (-2.145 and 2.145). T_{cal} for strength is 1.67 this is also in confidence interval (2.145 and 2.145).

4.6 Cost Reduction and Quality Improvement

Cost reduction for cobalt per temple miniature is 25% x 1liter x Rp 250.000,-/liter)/2000 unit = Rp. 32.25. Catalyst cost reduction per unit is Rp. 9.99. Work force cost increase is Rp. 10.71/unit so total cost reduction per unit is Rp. 30.53.

Reduction of Shrinkage percentage average is 0.75 (initial shrinkage is 2.625 and optimum one is 1.875).
Strength percentage average increases from 120.43 kg/cm^2 to 136.87 kg/cm^2. It means optimum combination can increase 16.24 kg/cm^2 for strength.

CONCLUSION

1. Factors that influence the temple miniature are resin composition (A), cobalt composition (B), catalyst composition (C), talk composition (D), and mixing duration (E).
2. The optimal factor level combination is $A_1B_2C_2D_1E_2$ (55% resin composition, 0.3 % cobalt composition, 0.4 % catalyst composition, 44% talk composition and 10 minutes mixing duration). It can successfully improve quality and reduce cost.
3. Optimum parameter setting can reduce shrinkage to be 1.875 % and strength average can be improved to 136.875 kg/cm^2. This combination also reduces cost to Rp. 30.53/ product.

ABSTRACT

The aim of this research is to obtain the optimal gas product's route distribution so that the distance can be reduced and the total distribution cost at the gas company can also be optimized efficiently. Routes optimization were achieved using Differential Evolution Algorithm. Differential Evolution is a population based and direct stochastic seacrh algorithm (minimizer or maximazer) with simple, yet powerful, and straightforward. The result from this research is the optimal product's route distribution based on the distance analysis, vehicle utilization, and delivery cost. The distance reduction of 351.96 km or 17.3% in a week is successfully obtained.

Keywords

Optimization, Vehicle Routing Problem, Differential Evolution Algorithm

1. INTRODUCTION

The companies all over the world are starting to realize that logistics had a significant impact to the total cost, and the decision of logistics is resulting to a different level of service to the customers. The definition of logistics itself, according to D.Lambert (1998), is a process of planning, implementing, and controlling the flow and the storage of goods, service and related information, effective and efficiently, from the starting location to the final destination in order to fill the customer needs. Moreover, the main objective of logistics management is to obtain a package of product or service at the right time, right place, and at the desired condition, by giving the largest contribution to the company. By achieving the proper logistics management, the work performance might be improved, and the effectiveness and the efficiency of the cost can also be obtained.

In order to reach the effectiveness and the efficiency in logistics cost, the optimization should be done in every aspects. One of them is by optimizing the distribution or the transportation. Transportation is a very important factor in distribution system because it has a big influence to customer satisfaction and the distribution cost. Transportation itself contributes 1/3 to 2/3 of the total distribution cost. The large sum of transportation cost contribution encouraged the companies to pay a special attention to this area. One of the major problems in distribution transportation is *Vehicle Routing Problem* (VRP). VRP is a design or a determination of a number of vehicle routes with a number of constraints faced, such as the vehicle must be started and ended in the depot, every customer is widespread geographically and only be served once by a vehicle, and the total demand brought will not surpass the vehicle capacity.

The distribution of gas is conducted based on the form, size of gas packaging and the amount of gas need of customers. Therefore, in distributing the product, the gas company is using two types of delivery, i.e. tank truck and cylinder gas transporter. In the cylinder gas product distribution, the company sends a number of cylinder gas to the destination as ordered, and picks up the empty cylinder gas to the depot to be refilled. This type of distribution is known as *delivery and pick-up service*, which is basically a vehicle serving a customer to send him a new product while at the same time taking the old product from that customer.

Therefore, in determining of when the delivery should be done best, and how to make a certain vehicle routing to reach a certain destination, the company has to make a delivery routing determination in daily basis. Those routes have been arranged based on the experience of the transportation division to the customer's location area and the tracks that have been passed through.

Therefore, an improvement in those problems is extremely necessary to be conducted in order to get fuel saving which is closely related to the distance taken by the vehicles, and the best way to do that is by doing the optimization.

There are various techniques applied for the routing optimization, and one of them is *Evolutionary Algorithms* (EA). EA is a optimization technique that using a strategy to move the variation of the parameters' vectors. In the application itself, EA is using the biological principles analogy such as selection, mutation, and combination. There are few algorithms that are categorized in this EA type, which are Genetic Algorithm, *Ant Colony*, *Particel Swarm*, and *Differential Evolution*. *Differential Evolution* (DE) algorithm is a new type of algorithm that is tough enough to be used in facing the problems with many constraints. Compared with the other EA algorithm in solving this case, DE is better in its simple type of structures, easy implementation, fast in reaching the objective, and quite tough. Therefore, the use of DE here is expected to be able to optimize the distribution problem, and in the other hand, still able to defend the service level to the customers.

2. VRP PICK-UP AND DELIVERY

2.1 Definition and Characteristics

VRP with Pick-up and Delivery (VRPPD) is one of the classic type of VRP in which a customer needs both delivery and pick-up service of the goods. In general, the purpose of VRPPD is to minimize cost of the system. Each service in a location covers delivery point and pick-up point, and a number of requests that must be met, at the same time, for any route, the vehicle cannot ignore the obstacles, such as vehicle capacity and distance. In short, there are some limitations that must be fulfilled:

- For each customer, delivery and pick-up can only be done once
- Not exceed vehicle capacity
- Delivery and pick-up in the same vehicle routes

VRPPD can be developed according to the problems faced by the case, when there are constraints such as time windows, then VRPPD developed into VRPPDTW (VRPPD with Time Windows), namely the form of the development of VRPPD and VRP with Time Windows (VRPTW).

Example of VRPPD case is in the soft drink industry. In this case, empty bottles must be returned to the factory to be used again, or at the grocery stores, pallet / container, where reusable pallets/containers are used for the transportation of merchandise. By using VRPPD, then there will be only one route, the route of delivery and pick-up simultaneously.

2.2 Mathematical Formulation

There are k vehicles in the depot 0, and stands for the set of customers to be visited, where n=V is the number of customers. The location of depot and customers are known. Each customer has a known delivery demand level and a known pick-up demand level, j=1,2,…,n. Delivery routes for vehicles are required to start and finish at the depot, so that all customer demands are satisfied and each customer is visited just by one vehicle.

Suppose there are k vehicles in the depot 0, dan V stands for the set of customers to be visited, where $n=|V|$ is the number of customers. Each customer has a known delivery demand level d_j pickup demand level p_j, where j = 1, 2, …, n. Delivery routes for vehicles are required to start and finish at the depot, so that all customer demands are satisfied and each customer is visited just by one vehicle. $V_0 = V \cup \{0\}$ is the set of clients plus depot (client 0); c_{ij} is the distance between i and j; and the capacity of each vehicle is Q. Decision variable is x_{ijk} = 1, if arc (i, j) belongs to the route operated by vehicle k, otherwise is 0. y_{ij} is the demand picked-up in clients routed up to node i and transported in arc (i, j); z_{ij} is the demand to be delivered to clients routed after node i and transported in arc (i, j).

The mathematical formulation of VRPPD is given by:

$$\min \sum_{k=1}^{k}\sum_{i=0}^{n}\sum_{j=0}^{n} c_{ij}x_{ij} \quad (1)$$

$$s.t. \sum_{i=0}^{n}\sum_{k=1}^{k} x_{ijk} = 1,\ j = 1,2,...,n \quad (2)$$

$$\sum_{i=0}^{n} x_{ijk} - \sum_{i=0}^{n} x_{jik} = 0, \quad j = 0,1,....n; k = 0,1,...,k \quad (3)$$

$$\sum_{j=1}^{n} x_{0jk} \le 1, k = 1,2,...,k \quad (4)$$

$$\sum_{i=0}^{n} y_{ji} + \sum_{i=0}^{n} y_{ij}, = p_j, \forall j \ne 0 \quad (5)$$

$$\sum_{i=0}^{n} z_{ij} - \sum_{i=0}^{n} z_{ji} = d_j, \forall \ne 0 \quad (6)$$

$$yij + zij \le Q\sum_{k=1}^{k} xijk, i, j = 0,1,...., n \quad (7)$$

$$\sum_{i=0}^{n}\sum_{j=0}^{n} d_{ij}x_{ijk} \le Lk = 0,1,2,...,k \quad (8)$$

$$x_{ijk} \in \{0,1\}, y_{ij} \ge 0, z_{ij} \ge 0, i, j = 0,1,...,n; \quad k = 0,1,...,k \quad (9)$$

The objective function seeks to minimize total distance traveled is shown in equation (1). Equation (2) to (9) is the limitations that should be noticed. Constraint (2) ensures that each customer will be only visited by exactly one vehicle, constraint (3) guarantees that the same vehicle arrives and departs from each client it serves. Restriction (4) defines that at most k vehicles are used. Restrictions (5) and (6) are flow equations for pick-up and delivery demands, respectively. Constraint (7) establishes that pick-up and delivery demands will only be transported using arcs included in the solution. Restriction (8) is the maximum distance limit, L is the upper limit on the total load transported by a vehicle in any given section of the route. Finally, constraint (9) is the decision variable.

3. DIFFERENTIAL EVOLUTION ALGORITHM

DE works by copying the theory of the evolution of biology. DE had several superiority compared with the optimization classic method, i.e. :

- Having population which is the solution candidates
- The method non-deterministic that produced solutions that were different although the model initially was not changed, because of working with used random sampling.
- Using elements from available solutions to create the new solution with the characteristics that were bequeathed from elements of its mother.

Similar to with other EA, DE used vectors that represent resolution candidates where its search technique was carried out at the same time on several solutions that were mentioned as the population.

In each generation, each individual of the resolution candidates will pass the process of the evaluation where these individuals will form the target vector and were counted by the function of its objective (or often was mentioned as fitness function). Moreover, these individuals will be done by the mutation process and crossover in order to be able to form the vector trial that was used to form the child population (the next generation's population). The next generation's population will be formed by comparing the objective of parent and child vectors (trial vectors) where the individual values with the best objective function will pass to the next generation. This process will be repeated until the termination's criteria fulfilled. In the process of finding the solution, DE will through the initialization (the determination of the control parameter, the initial population, and the evaluation of the function of the objective), mutation, crossover, selection, and termination.

3.1 Initialization

The initialization is the determination of the control parameter and the initial population (the 0 generation). The aim of the control parameter determination is to find the solution that could be accepted through several evaluations of the function and will have an impact on the performance of DE. The DE control parameter is the population size, mutation control parameter, and crossover control parameter.

The population size (Np) is the number of the population's channels in one generation (took form in the matrix column) that has the same value during solution searching process. The mutation control parameter (F) is the valuable control parameter of the positive original number that has functioned in controlling the population evolution level. The common effective F value is between 0,4 and 1. The crossover control parameter (Cr) is used to determine inheritance gene that is owned by the target and mutation vectors in order to form trial vector by comparing it with random numbers which are generated in the crossover process. This Cr value is between 0 and 1.

In this problem, the decisive variable or the number of dimensions was the number of visited customers, but especially for the outlet customers' case, it could be several outlet customers but in the same location, so it only visits one place. Therefore, for the outlet customers' case, the dimension size is the location of the delivery points. The number of delivery points is 63, so the outlet customer's population size is 126. In the meantime, for the industrial and the hospital customer, the number of delivery point is the same as the number of customers. So when the number of dimensions is 33, the population size is 66. The best mutation parameter (F) value is 0,4 and best crossover parameter (Cr) value is 0,5. Termination criteria are determined based on the number of maximum iteration which is 1000.

When determining the VRP initial population, each initial individual will represent the number of routes to serve all customers and the delivery points in each route. The initial population is appointed randomly. Every initial individual is elaborated by function:

Initial individual = lower limit + (upper limit – lower limit) x random number

In this process, the random numbers that was used is between 0 and 1. The lower and upper limit is -1 and 1. In this case, the parameter of the population size is twice the number of customers. It means if there are 33 customers, then the number of initial individuals is 66. Because the population consisted of 66 individuals and each individual consisted of 33 dimensions, then the initial population in this date is a 66 x 33 matrix.

The initial population was a random number between -1 to 1, so this initial population did not represent the

sequence of delivery points to each customer. Therefore, the random number must be translated into integer number so we can read the sequence of delivery points to each customer.

The objective function is to minimize the serving distance of the entire customer through determining the route and delivery sequences in this route with some constraints that have been mentioned at mathematical VRPPD model in the sub-chapter 2.2.

Each initial individual is evaluated by using the objective function above or by determining initial solution. The initial solution has a role as the target vector or parents' vector (the A Vector).

3.2 Mutation

The mutation process is intended to make a new individual called the mutant individual. Therefore, in order to create it, 3 random individuals should be picked from the starting population. Here is the equation to form the mutant individuals:

$$\text{Mutant Individual} = a + (b-c)* 0.4 \quad (10)$$

The number 0.4 is a mutation parameter (F) that has been determined at the earlier stage.

3.3 Crossover

The cross-over process is intended to create a new individual called the trial individual, so it will enrich the diversity of genes in a population that will enter the next generation. Parameter value or the individual dimensions of this part of the trial comes from the individual parameter target and some come from individual mutant, by considering the cross-operator move (Cr) and a random number. Cr value is set at initialization stage.

If the random number r (from 0 to 1) that is obtained is smaller or at least at the same value of CR, then the one who has the opportunity to be the i-th dimension value of the trial individual is the i-th dimension value of the mutant individual. Otherwise, then the i-th dimension value of the individual trial is the i-th dimension value of the starting individual. The visual representation is shown below:

$$u_{j,g} = u_{j,j,g} = \begin{cases} v_{j,j,g} & \text{if } (\text{rand}_j(0,1) \leq Cr \text{ or } j = j_{\text{rand}}) \\ x_{j,j,g} & \text{if } (\text{rand}_j(0,1) > Cr \text{ or } j = j_{\text{rand}}) \end{cases} \quad (11)$$

Each individual in trial population will be evaluated just as in the starting population. The individual with the least distance will enter the selection process next.

3.4 Selection

This process is the stage of determining the proper individual that deserves to be the member of the next generation, which is by comparing the target individual's objective function with that of the trial individual. In this case, the individual with the least distance will be chosen.

3.5 Termination

Termination occured when the process of searching optimal solution has been reached termination criteria. However, if the termination criteria has not been fulfilled, it will be established again with the new generation to repeat the previous steps from the beginning. Termination criterions are as follows:

- Maximum computation time
- Maximum iteration
- Reach the convergence (the value of the optimal objective function does not change)

In this research, maximum iteration is used as termination criterion. Stage 2 to stage 7 is a process for one time iteration. This process will keep repeating until the iteration number reaching 1000. The next program will select the individual with the least distance from the 1000 iteration that has been done.

4. VRPPD PROBLEM SOLVING FOR THE GAS PROVIDER COMPANY USING DIFFERENTIAL EVOLUTION

To write the DE algorithm along with the optimal solution searching, a programming language using *Visual Basic for Application* (VBA) Microsoft Excel 2007 is used. Through this program, the desired result is not only at the form of the solution of distance calculation using the DE algorithm, but it is also complied with the ability to integrate the customer database with the necessary data to do an optimization, such as the in-between customer distance matrix, amount of demand, vehicle capacity, vehicle velocity, and the time windows, in order to simplify the use of this application in scheduling and determining the optimal delivery routes in a shorter range of time. It is also supported by the situation in the company with the recent change in demand every day, whether it is from the demand or from the customer who asked for the delivery.

The creation of the this optimal distribution route using DE algorithm written in VBA Excel is based on the objective function which is to minimize the route distance, so that the desired output from this program will be in a form of a delivery routes sequence for each operating vehicles and the total distance of those routes.

This research is conducted in two distribution cases in the gas provider company, whereas the company has two types of customers which are outlet customers and industry & hospital customers. The transportation fleet that the company owned is around 5 vehicles, i.e. 2 pick-up cars to do delivery to the outlet customers, and 3 trucks to do delivery to the industry and hospital customers, to be more specific. The vehicle specification

can be seen on Table 1. The numbers of outlet customers that are served are 227 customers, widely spread

Table 1: Type and Number of Vehicles

No	Type of vehicles	Capacity (cylinders)	Number of vehicles
1	*Pick-Up*	40	2
2	Single Truck	60	2
3	Double Truck	90	1

throughout 63 locations, while the industry and hospital customers were spread out to 33 locations. The DE parameter used here is Np = 126 for the distribution route optimization for the outlet customers and Np = 66 for the distribution route optimization for the industry and hospital customers, F = 0.4 and CR = 0.5, with maximum number of iteration = 1000. The running of the program is conducted for the 5-days data request, which is from Monday, April 20th 2009 to Friday, April 24th 2009. Examples of outlet and industry & hospital customer data request are shown on Table 2 and 3.

The totals distance comparison before and after the optimization done is shown on Table 6 and 7.

From the table 6 and 7, we can see that the optimization using the DE algorithm resulted a shorter distance compared to the current methods used by the company. It means that this algorithm has been successfully used to optimize the routes in order to minimize the total distance. The distance reduction is aligned with the distribution operational cost reduction or the fuel cost. With a fuel cost of IDR 900 per liter and fuel usage ratio of 1:5 for all the vehicles, then the distribution cost comparisons before and after the optimization are shown on Table 8 and 9, also in figure 1 and 2.

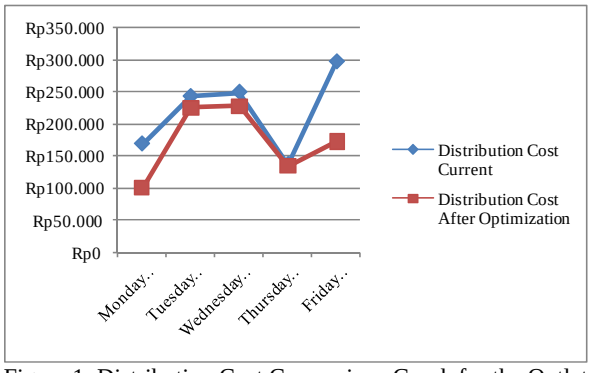

Figure 1: Distribution Cost Comparison Graph for the Outlet Customers

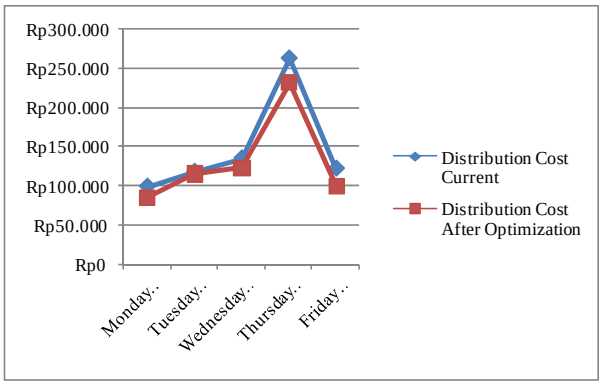

Figure 2: Distribution Cost Comparison Graph for the Industry and Hospital Customers

5. CONCLUSION

Based on the case study of the distribution route determination of the cylinder gas delivery in the gas provider company using the *Differential Evolution algorithm* and with the help of the VBA Excel programming, such conclusions may be reached as follow.

The daily route distribution determination using *Differential Evolution* algorithm has provided a new and better distribution route compared with the current methods used by the company. In the distribution of the outlet customers, the total distance reached for 5 days is 817.51 km with a distance reduction for 89.18 km or 10.9 % in percentage. Meanwhile, at the distribution for the industry and hospital customers, the distance reached for 5 days is 953.73 km with distance reduction by 262.79 km or 21.6% in percentage.

The distance reduction will directly affect the distribution cost spent. For the distribution to the outlet customers, the new distribution cost after it has been accumulated for one year is Rp.31.464.000,-, or in the other word the cost reduction in a year is Rp. 3.852.432,- or 10.9%. Meanwhile, the distribution cost for the industry and hospital customers is Rp. 41.201.350,-, or in other word, the cost reduction here is Rp.11.352.314,- or 21.6%. The total distribution cost that could be saved by the company for a year is Rp. 15.204.746,- or 20.92%.

ABSTRACT

Software engineering is urgently required by *Bank X to make its important business process faster and easier. In the other hand, Bank X's software engineering process sometimes gets some troubles. Those troubles are over budget, overtime, and inappropriate quality with the requirement. Therefore, process improvement effort is tried to be done through Capability Maturity Model (CMM) implementation as a software engineering standard process.CMM is implemented by measuring the maturity level of software engineering based on key process area of CMM repeatable level, then identifying the gap between CMM and Bank X's software engineering process, and formulizing the gap treatment to achieve repeatable level of maturity.*
From the measument process, we can know that the maturity level of its software engineering is 87% in CMM repeatable level. Meanwhile, from gap analysis, it is showed that 25% of CMM key practices in repeatable level have been partially implemented and 3% have not been impelemented. In order to handle those gaps and to improve software engineering process, some recommendations are formulated. The recommendations are training and orientation about key process areas CMM, measurement standard of developing activity status, configuration library procedure, SCM plan, automation testing tools implementation, and automation of software engineering procedure.

Keywords:

Capability, maturity model, maturity level, gap analysis, software engineering

1. Introduction

Nowadays, software engineering is urgently required by Bank X to make its important business process faster and easier. In the other hand, Bank X's software engineering process sometimes gets some troubles. Those troubles are over budget, overtime, and inappropriate quality with the requirement. The troubles can be caused by non transparency and consistency project management, inconsistency human resource management with the plan, inappropriate user requirement and documentation management.

To fix those problems is required improvement effort. One of the improvement efforts that can be establish is software process improvement through Capability Maturity Model (CMM) implementation. CMM was released by Software Engineering Institute. CMM is a set of best practices of software engineering process that divided into several Key Process Areas (KPAs). It will improve process maturity of Bank X's software engineering. If the maturity of software engineering increase, the system productivity and software quality will be better.

Based on this background, we can found that the main problem of this research is CMM implementation in Bank X's software engineering. This can be established through maturity level identification and quality improvement plan of software engineering based on gap analysis.

CMM is devided into 22 KPAs and take a long time to implement all of KPAs. Therefore, this reserch is tried to be done only in repeatable level that have 6 KPA, those are Software

Requirement Management, Software Project Planning, Software Project Tracking and Oversight, Software Subcontract Management, Software Quality Assurance, and Software Configuration Management.

Overall, this journal is about CMM implementation through maturity level measurement and gap analysis process in Bank X's software engineering in order to improve software process quality.

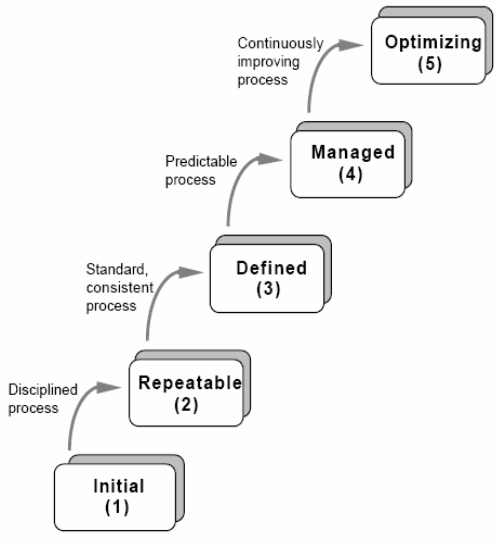
2. CAPABILITY MATURITY MODEL

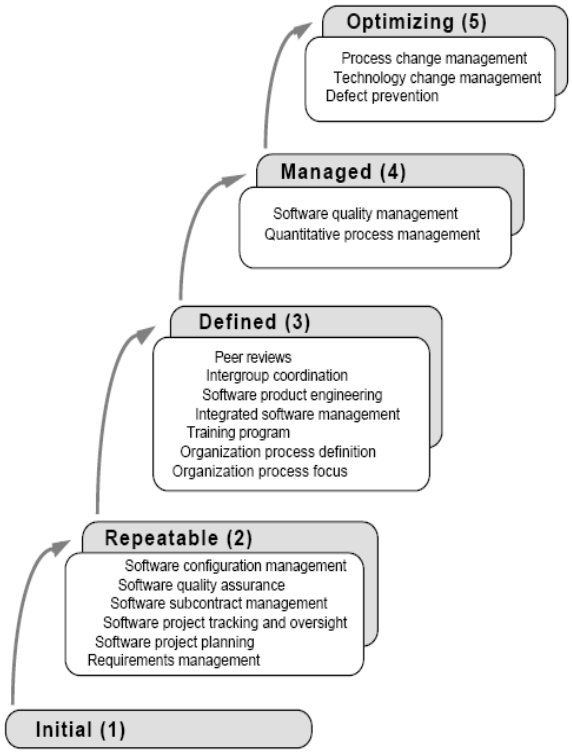
In initial, Capability Maturity Model was developed to fulfill USA Defense Department need in selecting software vendor / supplier. Therefore, the Defense Department collaborates with Carnegie Mellon University establish Software Engineering Institute (SEI) for developing new model / standard in software process quality improvement.

Then the model was known as Capability Maturity Model, a model consist best practices of software engineering process that divided into several Key Process Areas (KPAs). Those KPAs can be looked at picture 1.

Picture 1. CMM *Key Process Areas* [2]

CMM is tried to be implemented step by step based on CMM level, start with initial level until optimizing level. The five levels in CMM cab be looked in the picture below.





Picture 2. CMM Levels [5]

The key practices / best practices in CMM are activities that must be done and several procedures that must be had in software engineering process. These key practices in each KPA are divided into several group activities.

a. Commitment to perform, the activities to ensure stability and continuity process

b. Ability to perform, the activities group or requirement that must be had to implement good software engineering process

c. Activities performed, the procedures that needed to implement CMM key process area

d. Measurement & analysis, the needs to measure the process and analyze the result

e. Verifying Implementation, the steps to ensure activities run based on the process

3. METHOD

There are two steps that must be established to implement CMM. The first step is maturity level measurement and the second is gap analysis process to get gap treatment and

process improvement planning. Maturity level measurement process needs a good tool that gives a valid result.

To measure maturity level, Software Engineering Institute have published maturity questionnaire. In order to make easy the implementation, maturity questionnaire is developed and divided into 2 parts, process compliance interview and document review.

Process compliance interview was chosen and developed because through this process, the software engineering process in Bank X can be easily explored and confirmed.

The data that be gathered through this process are:

i. Applicability data each CMM key practice (6 KPAs CMM)

ii. Process compliance measurement of key practice (6 KPAs CMM)

The interview has closed questions and each question has 4 options: Yes, Partially, No, and Not Applicable with each weight: 1, 0.5, 0, and no weight. The amount of question is

Table 1. Question Competition of Interview

KPA	Amount of Question
SRM	12
SPP	25
SPTO	24
SSM	22
SQA	17
SCM	21
Total	**121**

To calculate the CMM compliance use the equation below

$$Q_n = \frac{(Fn+0.5Pn)}{(Fn+Pn+Nn)} \times 100\ \%$$

Legend:

Q : key practice mark

n : Number of Question

F : Total of "Yes" answer

P : Total of "Partially" answer

N : Total of " No" answer

Document review is the second step to get maturity level. The data that be gathered through this process are:

i. Document compliance measurement

ii. Documents gap based on CMM

The document review questionnaire has closed questions and each question has 4 options:

Table 2. The Answer Options for Document Review

Answer	weight	Document Status
E	1	*Evidence:* 1. Decided 2. Have a legal format 3. Implemented in all projects
F	0.8	*Formalized:* 1. Decided 2. Have a legal format 3. Implemented not in all projects
U	0.5	*Usable:* 1. Decided 2. Not have a legal format 3. Implemented not in all projects
N	0	*Not Available*

The amount of question is in the table 3.

Table 3. Question Competition of Interview

KPA	Amount of Question
SRM	9
SPP	20
SPTO	20
SSM	27
SQA	13
SCM	15
Total	**94**

To calculate the CMM document review use the equation below

$$Q_n = \frac{(En+0.8Fn+0.5Un)}{(En+Fn+Un+Nn)} \text{ X } 100\%$$

Legend:

Q : Key practice mark

n : Number of Question

E : Total of "E" answer

F : Total of "F" answer

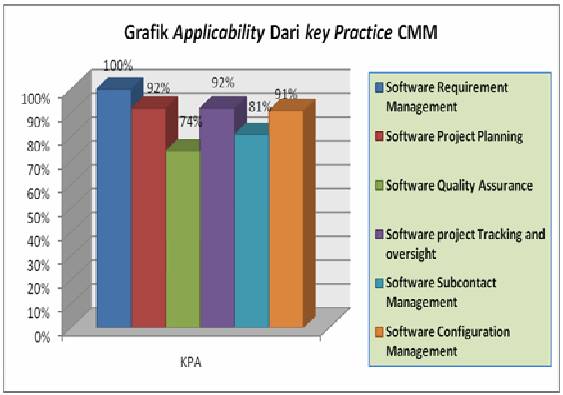
U : Total of "U" answer

N : Total of "N" answer

4. RESULT AND ANALYSIS

From the interview process that explore 121 key practices applicability, there are 17 key practices that not applicable to be implemented in Bank X. It means only 86% key practices CMM from repeatable level can be implemented. Although the applicability is 86 %, the CMM implementation can not be troubled.

It means that the software engineering process in Bank X has good processes and compliance with almost key practice in CMM repeatable level. From data calculation and consolidation from interview and document review process, Bank X's maturity level is 87 % at repeatable level.



engineering that has 87 % of maturity level:

a. Bank X has software engineering policy that arrange development and maintenance of software

b. Have a good documentation in software development process

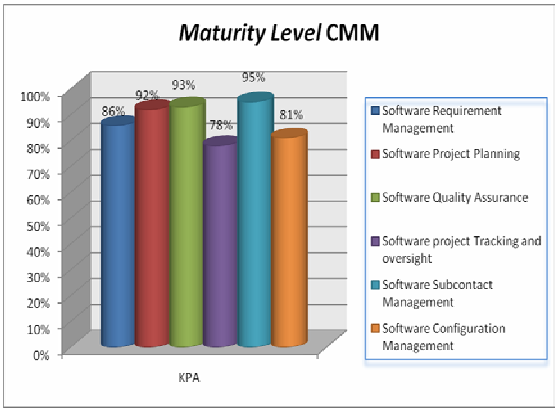
c. Good change management

d. Job of segregation has been defined very well

e. Risk in software development process always be identified

All those strengthen will keep software quality good and appropriate with the requirement standard. Good software quality is needed by Bank X because almost softwares that produced are used with national scope and critical in banking process. The maturity level for each KPA can be looked at picture 4.

In order to get CMM license in repeatable level, Bank X have to complete the CMM implementation, that is 13 % implementation. The highest priority to fulfill the implementation is Software Project Tracking and Oversight because have the lowest compliance with the CMM.



Picture 0. Calculation Result of Maturity Level

The result of maturity level measurement is also input for gap analysis process. Gap analysis process shows that 78 key practices have been implemented, 27 key practices partially have been implemented and 3 key practices not yet.

To find out root of problems why there are some key practice have partially and not been implemented, the fish bond diagram is used. The causes of problem are grouped into 3 categories. Those are human, method, and equipment. The root causes of problem are explained below:

a. Personnel Knowledge about technical aspect and management is less

b. Less of control in development policy implementation

c. Less of standard and procedure about KPA CMM

d. No measurement status from development activities

After get the causes root from the fishbod diagram, the next step is gap treatment formulation. The gap treatments are developed by analysing each gap and try to cover it.

These below are agp treatment plan to improve maturity level in Bank X's software development process

a. Training and orientation about CMM

- Requirement management

Give knowledge to make and arrange software engineering that needed to fulfill user's / customer's requirement.

- *Project management*

Give knowledge to personnel about creating a good planning in software project

- *Configuration management*

Give knowledge to personnel about goals, methods, and procedures in software configuration.

b. Measurement Standard

- Comparison between existing SQA activity and SQA planning

c. Status Measurement of software configuration management

d. Configuration library procedure

It needs a procedure for manage software configuration that cover configuration saving, using, and documenting.

e. Automation testing tool for software quality assurance

One of CMM implementation requirement is automation. The automation priority is in the software quality assurance activity, testing process.

f. Automation in software development procedure

With automation in software development procedure, documatation in developmenet process will be better managed and arranged

5. CONCLUTION

In overall, Bank X's software engineering almost complies with CMM. Based on maturity level measurement for CMM implementation in KPA: SRM, SPTO, SPP, SCM, SSM, & SQA, the maturity level is 87 %. To improve the maturity level, gap treatment planning are formulated, those are:

a. Training and orientation about CMM

a. Measurement Standard

b. Configuration library procedure

c. Automation testing tool for software quality assurance

d. Automation in software development procedure

ABSTRACT

Cole & Illum (2005) have researched about relationship among performance quality, experience quality, tourist's satisfaction, and behavioral intention. At the end, it was known that tourist's satisfaction became mediating variable between experience quality and behavioral intention, while performance quality affected behavioral intention indirectly through experience quality. This model was applied in festival research as the object. In service sector, service qualities play vital roles. A good service quality can emerge customer's behavioral intention.

This research will use Cole & Illum's model in different scope, which is applied in Bandung tourism destination. Bandung is chosen as the object research because it has diversity in tourism destination place such as artificial places, nature places, and historical building. Service quality is needed to enhance and preserve amount of the visitor for tourism's sustainability.

The research's objective is to study the relationship between behavioral intention and service quality in tourism destination place with mix tourism objects. Data is collected through questionnaire that will be distributed to several respondents. Structural equation modeling is used in confirming relationship between related variables in model measurement. The result is to confirm the continuity of tourism activity as implication of quality management in tourism destination place. Further practical implication will be discussed and be recommended to Bandung tourism stakeholders, especially local government and business' proprietor.

Keywords:
Service quality, Behavioral intention, Tourist's satisfaction, Tourism.

1. INTRODUCTION

In almost every country, tourism sector gives big contribution in increasing country's income and insensitive to economic crisis. There are several reasons which can be mentioned in order to improve management of tourism sector in Indonesia: 1)Indonesia has diversity of tourism destinations which are spreaded in every province; 2) prospect of tourism in Indonesia shows tendency which always increases every year; 3) contribution of oil and gas to country's income is become smaller; 4) tourism can enhance prosperity of community in Indonesia since they are involved in managing this sector. Tourism sector provides dominant job opportunity (take 10% of all job opportunity areas). In 2004, it was stated that 7.3 millions Indonesian worked as direct labors in this sector. While 5 millions Indonesian participated as indirect labors in similar sector (Santosa, 2004).

Although there were researches which proved that tourism sector could be superior sector in enhancing country's income, management of this sector was still low. Indonesia tourism hasn't grown significantly as tourism in

other country, such as Thailand, Malaysia, and Thailand (Rachbini, 2008). But the government always attempts to promote Indonesia tourism, both inside and abroad. Provinces which have superior tourism destination are Bali, West Java, East Java, Yogyakarta, and North Sumatra (BAPPEDA, 2005).

This study takes Bandung as the object. Nowadays, Bandung becomes show window for tourism sector in West Java since many tourists chose Bandung as their destination. Bandung has diversity in its tourism destinations, such as heritage, nature, artificial, and education destination. Base on statistic, number of tourists that visit Bandung shows significant incremental every year (BAPPEDA, 2005). Number of tourists' visit can be enhanced in two manners: 1) attracting tourist that has visited the tourism destination to revisit; 2) attracting potential tourist that hasn't visited the tourism destination. Tourist's intention to visit some destinations is affected by many factors. One factor that influences this intention is performance or service quality which is given by management team of tourism destination.

Hence, there should be an integrative cooperation among all tourism stakeholders in Bandung in developing and caring tourism destination. Through development of tourism destination, Bandung tourism sector is expected to give prosperity for local community and contributes externally in affecting development in other areas.

Objectives

The main objective in this study is to confirm Cole&Illum's model in selected tourism destination. It will be proven whether experience quality of the visitor affects behavioral intention directly or precise indirectly through tourist's satisfaction. Besides, this study is also intended to probe factors which conduct performance quality of management team in order to enhance behavioral intention of the visitor. Several reccomendations will be mentioned and can be used by tourism stakeholders, such as local government, management team of selected tourism destination, and business' proprietor.

2. CONCEPTUAL FRAMEWORK

Baker and Crompton (2000, p.788) defined tourists as 'an integral part of the service process, which is one of the characteristics that distinguishes services from products.' Because of this unique consumer, tourism has a different way to classify service quality and satisfaction. Cole & Illum (2005) classified service qualities and satisfaction at two levels, i.e. transaction level and global level. In this level, they divided in terms of performance quality and experience quality.

Many researchers studied performance quality in tourism service. Performance quality defined as a measurement of attribute level that can be controlled by the service's provider or tourism management (Cole & Illum 2005) According to this definition, performance quality can be measured by evaluating tourist's perception. (Baker & Crompton 2000). The service providers can control the attribute level such as the employee, the services or facilities that are provided by the tourism management.

On the other hand, experience quality is defined as 'those benefits or outcomes that people experience as a result of a trip or visit to a tourist attraction'. (Cole & Illum 2005, p.81). The other opinion said that experience quality shows the satisfaction of the tourists those refer to their emotional (Baker & Crompton 2000).

Performance quality can influence the experience quality of the tourist. Cole and Scott (2004, p.81) explain the 'relationship between performance quality and experience quality is intuitively straightforward'. The differences between performance quality and experience quality have been identified by Otto & Ritchie (1995, in Chen 2007, p.1131) by comparing them. The experience quality is more 'subjective to measure, evaluate tend to be holistic and focus evaluation for self (internal) and the scope is more general.' The psychological is more important than cognitive affecting to the tourist's opinion. Rather than experience quality, performance quality 'refers to service quality at attribute level, more objective to measure and the scope more specific because of the attribute.' (Otto & Ritchie, 1995, in Chen 2007, p.1131)

Lee et al (2007, p.404) said that visitor's satisfaction or tourist's satisfaction can 'increased through enhancing quality experiences by improving the quality of facilities and services.' And according to Chen (2007), between the satisfaction and service quality have a relationship on the variable that interchangeably. Previous study had indicated that service quality could influence the satisfaction of the tourists and also their behavior to intent some tourism's object (Baker & Crompton 2000, Cole et al 2002, Cole & Crompton 2003, Cole & Scott 2004, Cole & Illum 2006, Chen 2007).

Behavior intention refers to 'plans to visit the site again in the future' (Cole & Scott 2004). This behavior is an important key to the company or the service providers in tourism for a long term (Chen 2007). Behavior intention had been examined in many researches such as in wildlife refuge (Cole et al 2002), festival (Bake & Crompton 2000, Cole & Illum 2006, and Lee et al 2007), and zoo (Cole & Scott 2004, Tomas et al 2002). Model Cole and Illum (2006) is used in this research.

This research different with Cole and Scott (2004). They found that there were direct and indirect influence among the experience quality and overall satisfaction and behavior intention. But this research tries to examine direct relationship of experience quality to behavioral intention, then to see indirect relationship between experience quality to behavioral intention through overall satisfaction (Figure 1).

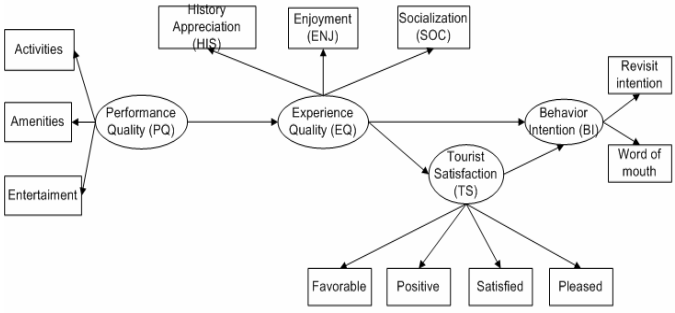

Figure 1
Model from Cole and Illum, 2006

3. RESEARCH METHODOLOGY

3.1. Study Area

Tourism destinations, which were selected to be research's objects, were decided after interviewing local government, tracing from BAPPEDA (2005) and related documents. Selected tourism destination must meet these requirements:

1. Taking location in Bandung.
2. Potential tourism destination to be developed. In other words, it must be tourism destination which hasn't been superior one.

Finally, two tourism destinations were chosen: THR. Ir. Djuanda (as representative of natural tourism object) and Asia Africa Museum (as representative of heritage object). These objects were potential ones to be developed in future.

3.2. Data Collection

Target population was visitors which fit these requirements:

1. Minimum age was 15 years. This minimum age was assumed to have adequate income or pocket money to visit researched tourism destination.
2. The visitor had ever come to selected tourism destination, maximum 5 years ago (2004).
3. The visitor must be Indonesian (domestic visitor).

This research used judgment sampling since respondent's profile was emerged.

Questionnaires were used to collect primary data. Initial questionnaires were first constructed in order to eliminate variables that would be used in main questionnaire. Thirty questionnaires for each selected tourism destination were distributed. By using SPSS 12.0, validity test and reliability test were done. From these tests, several variables were deleted. Chosen variables were kept to be used in main questionnaire. Finally, there were 54 main questions and 62 main questions respectively in questionnaire of Asia Africa Museum and THR. Ir. Djuanda.

Minimum sample size was decided by considering:

1. Amount of respondents in target population.
2. Amount of questions in questionnaire.

Since amount of respondents in target population couldn't be stated clearly, number of sample was decided by considering number of question in questionnaire. Greater number of respondents was better. Simamora (2004) stated that minimum sample size to be used in factor analysis was three to five times of number of questions. Thus, 343 questionnaires and 314 questionnaires, respectively, were distributed. For Asia Africa Museum, 221 questionnaires (rate of 64.43%) could be drawn back and be extracted. Whereas for THR. Ir. Djuanda, 257 questionnaires (rate of 81.84%) were gathered.

3.3. Operationalization of Constructs

Questions in main questionnaire were constructed by combining several items from other similar researches.

Initial questionnaire comprised of:

1. Part One Respondent's profile: age, gender, marital status, kind of work, living location, income per month, arrival frequency, and last arrival to selected tourism destination. Nominal scale was used in this part. Type of questions were closed questions. Output of this part was used in descriptive analysis of tourist's demography.
2. Part Two Variables identification, which consisted of 64 questions. In main questionnaire, there were only several questions used. Likert scale (from 1 to 5, strongly disagree to strongly agree) was used in this part. Output of this part will be used in confirmatory analysis.

3.4. Construct Measurement

Primary data from questionnaire's part two were classified in several factors by using factor analysis. After emerging those factors, overall model was constructed.

There are three constructed models:

1. Structural model, which stated relationship between latent variables (performance quality (PQ), experience quality (EQ), tourist's satisfaction (TS), and behavioral intention (BI)).
2. Measurement model, which stated relationship between latent variable and its factors.
3. Overall model, which showed all emerged relationships.

Testing of those models was done by using Lisrel 8.7. Yielded output will be analyzed in next step.

4. RESULTS

4.1. THR. Ir. Djuanda

From respondent's demography of THR Ir.Djuanda, it was showed that dominant respondent had these characteristic: interval age between 21-30 years old (42.02%), woman (57.20%), unmarried (71.21%), work as officer of private sector (41.25%), residing in North Bandung (41.25%), last arrival time is less than 6 months (37.74%), and arrival frequency is 1-2 times (54.86%). Data related to respondent's demography can be seen at Table 1.

Table 1. Respondent's demography of THR Ir. Djuanda

Gender

31-40 years old	29	11.28%
40 years old and above	39	15.18%

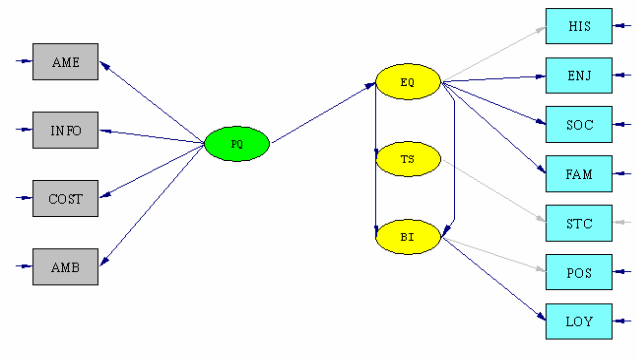

Figure 2. Conceptual Model for THR. Ir. Djuanda

From questionnaire part II, it was yielded that Alpha Cronbach of data was 0.992. Then, by using Spearman Correlation, it was showed that all data were valid in significance level = 0.01. SPSS 12.0 was used in completing these tests.

Figure 2 shows processed conceptual model by using LISREL 8.70. The result for the goodness-of-fit of model refers to Table 2. Commonly, the structure model is assessed by the χ^2 of the goodness-of-fit (Lee, 2009). The χ^2 goodness-of-fit has a function to compare between the 'adequacy of the theorized model's creation of a covariance matrix and estimated coefficients with the observed covariance matrix.' (Lee, 2009, p.228). McDonald and Ho (2002, in Lee, 2009, p.228) said that 'many researchers have divided the value of $\chi 2$ by degrees of freedom to accommodate large samples size.' But the ratio of the model could not determine the goodness-of-fit of the model (Anderson and Gerbing, 1982 in Lee,2009,p.228). Other indicators that can be used to assess model's goodness-of-fit are fit and alternate indices as showed in Table 2.

Table 2. GOF of structural model (THR Ir. Djuanda)

	Criteria	Initial	Revised

RMR	<0.05	0.2	0.08

The relationship among latent variable and its manifest is showed in Table 3. This data explain both initial and revised model. Improvement of standardized loading factor happened after model revised. Most of relationships among the latent variable with the manifest variables are significant except relationship between performance quality & amenities (0.02), and experience quality & socialization (0.1).

Table 3. Standardized Loading Factor and t-value

Construct & Indicators	Initial		Revised	
	SLF	t-value	SLF	t-value

Experience Quality->Behavior Intention	0.55		-0.14	0.41
Tourist Satisfaction->Behavior Intention	0.17			0.17

4.2. Asia AfricaMuseum

From tourists' profile that have been visited Asia Africa Museum in Bandung, it was dominated by youth, students and colleges, living in East Bandung, and income less than IDR 1 million. Probably, this result was affected by distribution sampling that was centered to young respondent. According to visit frequency, most respondents have been visited 1-2 times and the last visit was 6 months and below. This result indicated their intention to revisit. Unfortunately, there was still no conclusion because there was no segregation between once and twice visit. Hence, it couldn't be concluded whether they had high intention to revisit or not. Completely, respondent's demography of Asia Africa Museum is showed in Table 5.

From questionnaire part II, it was yielded that Alpha Cronbach of data was 0.884. Then, by using Spearman Correlation, it was showed that all data were valid in significance level = 0.01. SPSS 12.0 was used in completing these tests.

Not mentioned	1	0.45%

Factor analysis was done in order to probe number of factors that were used in confirmatory analysis by using LISREL 8.70. Results of rotated component matrix showed that there were 15 extracted factors which categorized each item as showed in Figure 3. Therefore, there were 15 manifest variables and 4 latent variables used as the inputs of LISREL. Factors of performance quality (PQ) are: facilities, activities, staffs, amenities, information, ambience, and emotional response. While factors for experience quality (EQ) are history appreciation, socialization, enjoyment, and cost. Tourist' satisfaction (TS) is constructed by two factors: pleased and satisfied. Behavioral intention is also constructed by two factors: say positive things and loyalty. Complete conceptual diagram for Asia Africa Museum is showed in Figure 3.

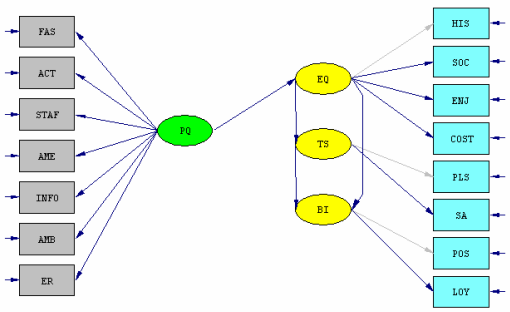

Figure 3. Conceptual Model for Asia Africa Museum

Revised model differed from initial one since there was alteration in setting error covariance of FAS (facilities) and

ACT (activities). Statistic data which was conducted by LISREL are showed below.

Table 6. GOF of structural model

	Criteria	Initial	Revised
Chi-square			
$\chi 2$	p>0.05	608.78 (p<0.00)	210.71 (p<0.00)
d.f	-	86	85
$\chi 2$/d.f	<5	7.07	2.48
Fit indicate			
GFI	>0.9	0.73	0.89
AGFI	>0.9	0.62	0.84
RFI	>0.9	0.70	0.88
NFI	>0.9	0.75	0.90
NNFI	>0.9	0.73	0.92
Alternative indicates:			
CFI	>0.95	0.78	0.94
RMSEA	<0.05	0.17	0.082
RMR	<0.05	0.18	0.11

From Table 6, it was showed that revised model met better fit than initial one.

Table 7. Standardized Loading Factor and t-value

Construct & Indicators	Initial		Revised	
	SLF	t-value	SLF	t-value
Performance Quality (PQ)				
Facilities	0.91	14.84	0.25	3.52
Activities	0.92	15.05	0.25	3.43
Staff	0.29	4.27	0.40	5.77
Amenities	0.23	3.26	0.46	6.77

Behavior Intention (BI)				
Say positive things	0.72	-*	0.72	-*
Loyalty	0.70	7.99	0.70	8.03

*) very significant,

From Table 7, it was showed that there were several differences in SLF and t-value between two models. Significant differences were among factors which constructed PQ and EQ. All factors which gave stronger effect to PQ in initial model became factors with weaker effect in revised model, and vice versa. Constructed factors in revised model for EQ showed weaker effect than initial one, although in insignificant value.

Table 8 showed SLF and t-value of latent variables. From this table, it was known that the greatest effect was showed in path from PQ to EQ. Besides, it was also known that effect from EQ to BI was better through TS.

Table 8. Direct and Indirect effect Among Variables

Effect among variable	Effects			
	Direct	Indirect		TOTAL
		EQ	TS	
Performance Quality->Experience Quality	0.85			0.85
Performance Quality->Tourist Satisfaction		0.56		0.56
Performance Quality->Behavior Intention			0.58	0.58
Experience Quality -> Tourist Satisfaction	0.66			0.66
Experience Quality->Behavior Intention	0.32		0.36	0.68
Tourist Satisfaction->Behavior Intention	0.55			0.55

5. DISCUSSION

5.1. THR. Ir. Djuanda

From the result, it is founded that performance quality has strong relation with ambience as the manifest variable. 'Ambience' refers to authenticity of place, individuality of place, and there is no similar tourism destination in Bandung. Result indicates that ambience has become superior factor of tourism and require to be preserved. Weak relation in performance quality is happened at amenities. 'Amenities' refer to supporting facilities that give visitor's freshness, such as availability of parking area, restroom, souvenir shop, staff which dress nattily and also friendly, variation of activities, and feel secure. This finding is enough occasions because amenities support visitor's freshness when reside in the tourism destination. Tourist's freshness will affect behavioral intention positively, shown with revisit behavior of the visitor. Base on respondent's demography, it is known that 58.76% visitors come from outside of North Bandung. Therefore, visitor's freshness becomes important factor to be notice. This factor will attract them to revisit although the duration journey, which usually becomes visitor's internal consideration, takes long time.

For experience quality, strong relation is happened at history as the manifest variable. 'History' refers to history's atmosphere which felt during at the tourism destination. While weak relation is happened at socialization. 'Socialization' refers to interaction between visitor and friend, family, and other visitors. THR Ir.Djuanda has a vast area which is useful for social activities like family vacation, school vacation or others social groups such as student group which explors the tunnels. Some respondents say that they choose THR Ir.Djuanda to do activity group because of the location is vast and the air is balmy. Respondent's demography shows that dominant respondent are in the age of 21-30 years old (42.02%) and unmarried (71.21%). This finding shows why THR Ir.Djuanda used for social activity. But the data showed that socialization gave weak relation. In fact, this tourism destination is usually used for social activity. Previous explanation, which describes about

amenities factor, states that freshness in tourism destination can also influence the visitor social interaction. Thus, both amenities and socialization need to be improved.

Pursuant to the last arrival of respondent, most respondents express that they just visit the tourism destination in the last 6 months. If last arrival data is related to the frequency of arrival, the result shows that most of them are new visitors who visit THR Ir.Djuanda once or twice. This finding needs to analyzed carefully since the result indicates that loyalty influences intention behavioral weakly. It means that arrival frequency (once or twice visit) may become indicator of low tourist's revisit to the tourism destination. Thus, developer has to notice and control performance quality because it is able to influence the tourist's behavioral intention.

From the relationship among latent variables, it can be seen that performance quality can affect the behavioral intention both directly and indirectly (Table 4). Indirect relationship between performance quality and behavioral intention doesn't show strong relationship. Although the relationship is not strong enough, but the influence of performance quality to behavioral intention needs to be considered. According to Cole and Illum (2005), performance quality is the factor that can be controlled by tourism management team. Significant relationship is happened between experience quality and tourist's satisfaction. Cole and Illum (2005) have already explained that in experience quality, mood of tourist has an important role to increase the tourist's satisfaction. Although experience quality could not be controlled by the tourism management team, but experience quality can be influenced by good performance quality.

Implication for THR. Ir. Djuanda management team is to keep the ambience of THR. Ir. Djuanda in order to preserve the authenticity of tourism destination. Besides , it is also recommended to improve the amenities by providing good facilities, such as restroom, parking area, variation of activities, etc. Other thing that should be noticed by management team is interaction of people which has been obtained in explanation about socialization variable. It means that improvement in amenities and socialization can influence the tourist's behavioral intention. especially to revisit to THR. Ir. Djuanda.

5.2. Asia Africa Museum

Acoording to statistic data which is showed in Table 8, it is founded that experience quality has greater effect to behavioral intention through tourist's satisfaction. In other words, for Asia Africa Museum, it can be concluded that indirect model is more suitable than direct model. It is because museum's visitor usually has high expectation to be served well when visit the museum. Performance quality has vital role in emerging tourist's satisfaction, especially in service from tour guide or staff. It will yield different emotional response when visitor is accompanied by tour guide. By receiving direct explanation from tour guide or museum's staff, it is possible to emerge higher visitor's sense of belonging to the history.

Besides, from Table 7 it is showed that variable 'positive' and 'loyalty' are similar in giving strong effect to behavioral-intention's construct. While for tourist's satisfaction, variable 'satisfied' gives stronger effect than variable 'pleased'. It can be interpreted that to enhance Behavioral Intention, satisfaction of the visitor should be increased.

For experience quality, variable 'history appreciation' and 'socialization' give stronger effect than other variables which construct similar latent variable. Variable 'cost' also gives positive effect, but weaker than other two variables. Whereas, variable 'enjoyment' gives negative effect to experience quality. If this finding is related with respondent's demography, it can be explained by respondent's age. Most of respondents are youth whose ages are under 20 years old. They usually come to Museum for academic task and their arrival isn't for get enjoyment or refreshing. There are also several respondents whose ages more than 40 years old. This type of respondents has tendency to visit museum with family. Their motive tends to introduce history of Indonesia to their children and not for enjoyment purpose.

For performance quality, variable 'emotional response' and 'ambience' give stronger effect than other variables. It can be interpreted that management team of Asia Africa Museum has given good performance quality which relates with these variables. Whereas, variable 'facilities' and 'activities' give similar effect which are the weakest of all. Other variables such as 'staff', 'amenities', and 'information' also show weak effect. According to data simulation, behavioral intention and its manifest variables will be higher if all factors which construct performance quality are also high.

Thus, there are several implications managerial for management team of Asia Africa Museum. Strong suggestion is preserving the authenticity of the place. If there will be some rehabilitations, it is not suggested to change the place significantly so that visitor still feel historic atmosphere.

Besides, other suggestion is availability of comfort facilities, include facility for handicapped person. Other facilities to be noticed are availability of parking area, restrooms, and restaurants which take place around the museum. For restaurant availability, management team of Asia Africa Museum can cooperate with business' proprietor around the museum. While, suggestions which relate with Museum's activities are availability of variation activities for visitor and promotion of museum.

It is also suggested to enhance performance quality which relates with amenities, staff, and information. Amenity refers to visitor's pleasure, such as cleanliness and layout arrangement. Staff refers to knowledge, hospitality, and availability of tour guide which also can speak other languages, especially English. Information refers to availability of information display, information centre, map, and catalogues.

6. CONCLUSION

It can be concluded that Cole&Illum's model can be applied in both heritage and nature tourism destination. Direct relationship from experience quality to behavioral intention is founded stronger in nature tourism destination. It implies higher visitor's behavioral intention can be achieved through higher experience quality. It isn't needed to notice tourist's satisfaction significantly.

Whereas, indirect relationship from experience to behavioral intention of the visitor is founded stronger in heritage tourism destination. It implies higher behavioral intention can be reached by enhancing experience quality through tourist's satisfaction.

Similar conclusion for nature and heritage tourism destination is higher performance quality can affect visitor's behavioral intention positively. It means that management team of those tourism destinations should notice their performance quality.

7. SUGGESTION

Several suggestions for further research are: 1) setting larger number of sample in order to get model comparation of behavioral intention for similar tourism destination. Besides, it has a purpose to state whether each museum and nature tourism destination has similar model. Therefore, model generalization of behavioral intention for each tourism destination can be yielded; 2) exploring respondent's demography and make segment categorization so that type of behavioral intention for each segment can be identified; 3) deeper analysis in profile segmentation can increase performance quality of management team at each tourism destination; 4) applying similar model for different tourism destination which haven't been discussed in this study. Therefore, there will be a complete model of Bandung tourism object which obtains about behavioral intention of the tourist.

ACKNOWLEDGMENT

Authors thank to management team of Asia Africa Museum, THR Ir. Djuanda, and Departement of Tourism for West Java.

ABSTRACT

Minor defect is a defect category that made to anticipate the types of potential defect. These preventive actions generate the increasing type and number of defect (there are more than 34 types of defect for minor defect and will continue to grow). Therefore, it's required a number of efforts to reduce the number of defect and to eliminate the types of defect.

MEDIC method is used to reduce the number of defect with high frequency of occurrence. We get 17 types of defect to be done, and then we identify the root causes that result 51 proposed solutions. From 51 solutions, 10 of them are implemented. As the result, the defect proportion of 11 from 17 defects are significantly reduced with α=5%.

The Deming Cycle (PDSA) method is used to eliminate the types of the defect with low frequency of occurrence from defect list. We get 14 types of defect to be eliminated. And then, for the trial period (11 days), we get 13 from 14 types of defect that will be proposed to be eliminated, because they have not emerged for the last 3 months and have passed the trial period.

Keywords

Preventive action, Minor defect, Occurrence's frequency, MEDIC, PDSA.

1. INTRODUCTION

"Quality is fitness for use" is a definition of quality by Joseph M. Juran. Quality must be maintained by a company in order to improve company's competitive advantage. Each company has to improve its product quality and process quality continually. There is no limitation for continuous quality improvement.

A company often focuses their quality improvement by doing a final inspection at the end of the production process. It seems too late, because the defective product will be detected at the end of the process, where all of the production's input has been used. This research focuses on the quality effort all along the production process, in order to prevent the defective product attain the end production process.

A lamp manufacturer, which produce VTL lamp, has four categories for their defect. They are as follow:

a. Critical safety defect, defect which is related to lamp user's safety.
b. Inoperative defect, defect which is related to the lamp reliability
c. Major defect, defect which influence customer's purchase interest.
d. Minor defect, defect which is tolerable but the company focuses on it, in order to maintain its product quality.

The focus of this research is on the minor defect because the number of minor defect is tending to increase. The objective of this research is to minimize several high frequency defect types and to eliminate several low frequency defect types from the minor defect list, at the end process quality control.

2. RESEARCH METHOD

This research follows MEDIC steps. The step can be seen at Figure 1. In the exploration and evaluation phase, the Deming Cycle is used to eliminate defect types with low frequency of occurrence. The application of Deming Cycle can be seen at Figure 2.

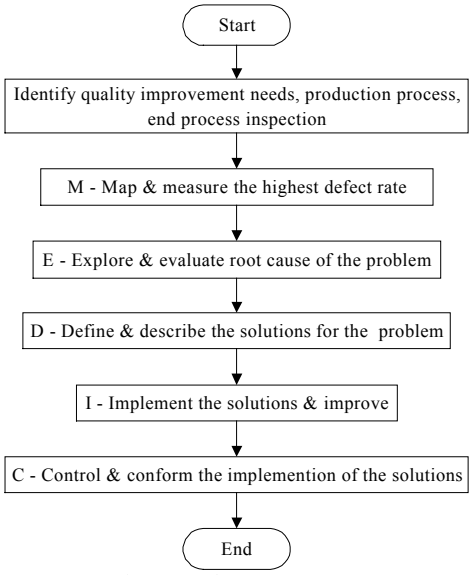

Figure 1: The MEDIC steps

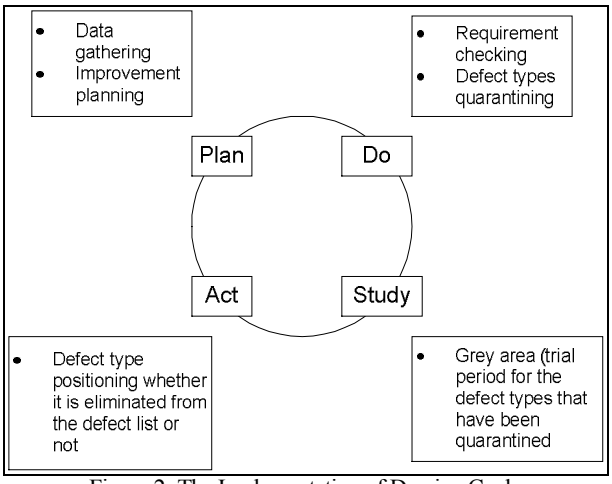

Figure 2: The Implementation of Deming Cycle

3. DATA ANALYSIS

3.1 Mapping and Measurement

The production division of the lamp manufacturer has eleven production processes to produce a VTL Lamp. They are as follow:

a. Washing and drying
b. Coating and drying
c. Oven sintering
d. Wiping and marking
e. Stem and mounting
f. Sealing
g. Pumping
h. Capping
i. Soldering
j. Flushing and testing
k. Packing

End process quality control is a quality control activity that is done at the end of production process (before packing). The objective is to inspect whether there is any defective VTL lamp or not, before the lamp is delivered to customer. The latest six month historical data from the end process quality control is used to find the highest minor defect rate. The data can be seen at Table 1.

Table 1: Historical data

Defect Type	Frequency
Foreign object	4
Mercury fleck	140
Swirling	108
Aslant cap	207
Cement waste	342
Knot 1	161
Dented cap	310
Unclear outer box's stamp	1
Unsticky tape	206
Loosen sleeve	113
Wrong packing date	5
Window	859
Powder off < 1 mm	65
Powder off 1-2 mm	63
Powder off > 2 mm	123
Dirty coating < 1 mm	90
Dirty coating 1-2 mm	30
Dirty coating > 2 mm	48
Pin hole	106
Rough coating	110
Stripe coating	98
Overflow 1/4 lamp's length	105
Air line glass	62
Defective glass	171
Fish eye > 10 mm	687
Fish eye < 10 mm	598
Blistered	230
Printed tape is sticky with the lamp	368
Long sleeve	72
Short sleeve	99
Clamp mark	58
Light stain	880
Motley	95
Glue stain	389
Wringkle	19
Aslant stel	59
No friction tape	11
Collide stel	16
Damaged sleeve	50
Damaged stel	2
High cap	31
Dirty tube	0
Blown	16
Bad sleeve	24
Folded seal	3
No coating	2
Thin coating	1
Glass stain	1
Sit high cap	1
Mire cap	4
Glass chips	1
Double sleeve	1
Flat lamp	1

Pareto Chart is built based on the data (see Figure 3). According to 80-20 rule, it can be seen from the chart that 80% defect types with high occurrence contains of 17 defect types. They are light stain, window, fish eye > 10 mm, fish eye < 10 mm, glue stain, printed tape is sticky with the lamp, cement waste, dented cap, blistered, aslant cap, unsticky tape, defective glass, knot 1, Mercury fleck, powder off > 2mm, loosen sleeve and rough coating. In the next step, these defect types will be analyzed, so they can be minimized in quantity.

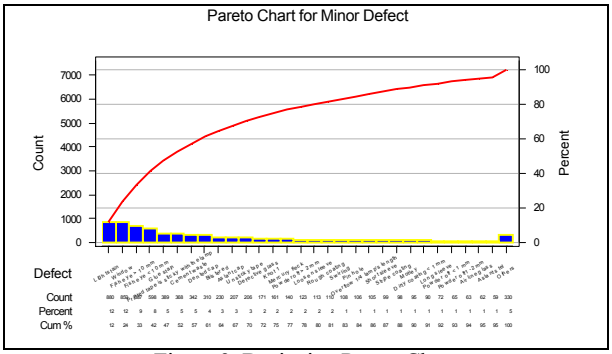

Figure 3: Beginning Pareto Chart

3.2 Exploration and Evaluation

3.2.1 Defect types with high frequency of occurrence

There are 17 defect types with high frequency of occurrence as mentioned before. In this phase, the root causes of all this defect types are explored using 5 WHY and Fault Tree Analysis (FTA). The objective of 5 Why is only to find the root causes of the problem, but the objective of FTA is not only to find the root causes of the problem, but also to find the relationship between the root causes. The example of 5 WHY and FTA for light stain can be seen at Table 2 and Figure 4.

Table 2: 5 WHY for light stain

No.	Problem	Why 1	Why 2	Why 3	Why 4	Why 5
1	Light Stain	Polluted suspension	Spray from cylinder air's oil	No cover at cylinder air's filter		
			Dew from cylinder air's oil			
		Unstable blast from drying blower	One or several butterflies are blocked	Saturated butterfly's filter at ducting		
			Unstable blast from segment 1-7	One or several butterflies are blocked by waste		
				Return pressure from segment 8-19		

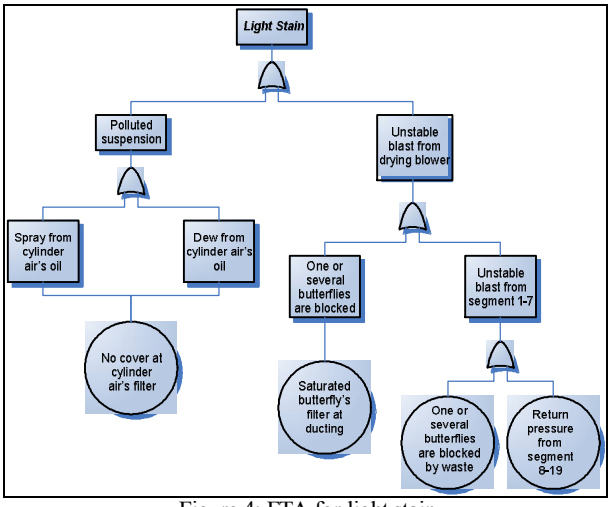

Figure 4: FTA for light stain

Totally, there are 49 root causes for the 17 defect types. The amount of root causes for each defect type can bee seen at Table 3.

Table 3: Number of root causes for each defect types

Defect Type	Number of Root Causes
Light stain	4
Window	5
Fish eye > 10 mm	2
Fish eye < 10 mm	
Glue stain	6
Printed tape is sticky with the lamp	7
Cement waste	3
Dented cap	4
Blistered	3
Aslant cap	2
Unsticky tape	2
Defective glass	1
Knot 1	1
Mercury fleck	1
Powder off > 2 mm	2
Loosen sleeve	5
Rough coating	1

3.2.2 Defect types with low frequency of occurrence

As mentioned before, Deming cycle is used to analyze defect type with low frequency of occurrence.

"Plan" phase has been done when the Pareto Chart was built. Some defect types with low frequency of occurrence can be seen from the chart.

In the "Do" phase, all of defect types are screened using four categories. They are as follow:

a. Process stability
   This requirement use Time Line Chart as a tool to examine the defect fluctuation and trend in the last three month, for defect types which have total number not more than 1 for the latest six month.
b. Customer requirement
   This requirement examine whether a defect type is included in the voice of customer or not.
c. Company requirement
   This requirement examine whether a defect type is included in company standard or not
d. IEC standard requirement
   This requirement examine whether a defect type is included in international lamp requirement or not.

As a result, there are 14 defect types that pass the screening. They are foreign object, unclear outer box's stamp, collide stel, damaged stel, dirty tube, folded seal, no coating, thin coating, glass stain, sit high cap, mire cap, glass chips, double sleeve, and flat lamp.

In the "Study" phase, 14 defect types enter the eleven days trial period, which is call grey area. If they can pass the trial period, which mean no defective item related with the defect types, then the defect types can be eliminated from the minor defect list. But if there is a defectives item related with them, they can not be eliminated from the defect list.

In the "Act" phase, the defect types' statue is determined, whether they can be eliminated from the minor defect list or not. The trial period result can be seen at Table 4. There are 13 defect types that pass the trial period, so they can be eliminated from the minor defect list. But there is only one defect type that fails to pass the trial period, which is unclear outer box's stamp. It can be seen that there are two unclear outer box's stamp in day 7.

Table 4: Trial period result

Defect Type	Day 1	Day 2	Day 3	Day 4	Day 5	Day 6	Day 7	Day 8	Day 9	Day 10	Day 11
Foreign object	0	0	0	0	0	0	0	0	0	0	0
Unclear outer box's stamp	0	0	0	0	0	0	2	0	0	0	0
Collide stel	0	0	0	0	0	0	0	0	0	0	0
Damaged stel	0	0	0	0	0	0	0	0	0	0	0
Dirty tube	0	0	0	0	0	0	0	0	0	0	0
Folded seal	0	0	0	0	0	0	0	0	0	0	0
No coating	0	0	0	0	0	0	0	0	0	0	0
Thin coating	0	0	0	0	0	0	0	0	0	0	0
Glass stain	0	0	0	0	0	0	0	0	0	0	0
Sit high cap	0	0	0	0	0	0	0	0	0	0	0
Mire cap	0	0	0	0	0	0	0	0	0	0	0
Glass chips	0	0	0	0	0	0	0	0	0	0	0
Double sleeve	0	0	0	0	0	0	0	0	0	0	0
Flat lamp	0	0	0	0	0	0	0	0	0	0	0

3.3 Definition and Description

As mentioned before, there are 49 root causes of 17 defect types. Through brainstorming, there are 51 proposed solutions; 10 of them will be implemented. They are as follow:

a. Modification of air cylinder sprayer filter.
   This solution prevents light stain, which is caused by suspension which is polluted by oil.
b. Additional cooling blower for tube which is come from oven sintering.
   This solution prevents window that is caused by tube which is not cool enough.
c. Additional automatic tool for suspension filling from offline to online,
   This solution prevents fish eye that is caused by bubble in the suspension which is flown from water base to production line.
d. Modification of glue needle.
   This solution prevent glue stain, that is caused by he position of the glue needle is change.
e. Modification of printed tape holding device.
   This solution prevent printed tape is sticky with the lamp, that is caused by the twisting position of printed tape.
f. Nozzle point modification by installing rubber seal.
   This solution prevents cement waste that come from turret cap filler.
g. Modification of cover tray.
   This solution prevents cement waste that is caused by dirty pin cap on the tray.
h. Additional upper holding device on the skater cap and turret meeting point.
   This solution prevents dented cap, which is caused by wide distance between skater cap and turret.
i. Glue viscosity study.
   This solution prevents unsticky tape that is caused by unfit dryness rate when the tape is assembled with the sleeve.
j. Socialization the new standard of suspension making process.
   This solution prevent powder off that is caused by less composition of material and prevent rough coating that is caused by less homogeneity of suspension.

3.4 Implementation and Improvement

The implementation has been done for a month at all line production. The result can be seen at Table 5. There is one defect type that the percentage after implementation is increased. It is loosening sleeve. After analyzing, it is known that supplier interface is needed to prevent this defect type. So it will become long term quality improvement for the company.

Pareto Chart after implementation can be seen at Figure 5. From the chart, it can be known that the defect types order is not the same with the beginning Pareto Chart. The highest defect type not light stains anymore, but window. Light stain is in the second order. In the third, the defect type not fish eye > 10 mm anymore, but change to cement waste, and so on.

Table 5: Implementation result

Defect Type	Before Implementation		After Implementation		Decreasing
	Number of cases	Percentage	Number of cases	Percentage	
Fleck merkuri	140	0.0201%	25	0.0134%	0.0067%
Aslant cap	207	0.0298%	19	0.0102%	0.0196%
Cement waste	342	0.0492%	70	0.0376%	0.0116%
Knot 1	161	0.0232%	12	0.0065%	0.0167%
Dented cap	310	0.0446%	49	0.0263%	0.0183%
Unsticky tape	206	0.0296%	45	0.0242%	0.0054%
Loosen sleeve	113	0.0163%	68	0.0366%	-0.0203%
Window	859	0.1236%	121	0.0651%	0.0585%
Powder off > 2 mm	123	0.0177%	21	0.0113%	0.0064%
Rough coating	110	0.0158%	24	0.0129%	0.0029%
Defective glass	171	0.0246%	10	0.0054%	0.0192%
Fish eye > 10 mm	687	0.0988%	66	0.0355%	0.0634%
Fish eye < 10 mm	598	0.0860%	68	0.0366%	0.0495%
Blistered	230	0.0331%	15	0.0081%	0.0250%
Printed tape is sticky with the lamp	368	0.0529%	40	0.0215%	0.0314%
Light stain	880	0.1266%	120	0.0645%	0.0621%
Glue stain	389	0.0560%	61	0.0328%	0.0232%
Total sample	695040		186000		

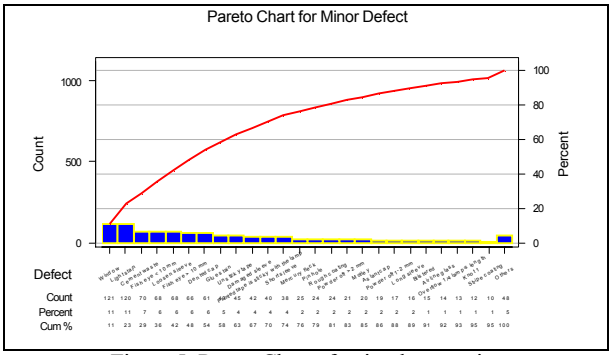

Figure 5: Pareto Chart after implementation

There is possibility that it is only order changing. A further analysis is needed. Two proportions test is done to find whether the percentage decreasing is significant or not ($\alpha = 0.05$). The result can be seen at Table 6. Among 17 defect types with high frequency of occurrence, there are 11 defect types which the percentage decreasing is significant. But the rest still not significant, include loosen sleeves which has a rising defect percentage after implementation. So, a continuous improvement is needed.

Table 6: Two proportions test

Defect Type	*P-Value*	Result
Light stain	0	Significant
Window	0	Significant
Fish eye > 10 mm	0	Significant
Fish eye < 10 mm	0	Significant
Glue stain	0	Significant
Printed tape is sticky with the lamp	0	Significant
Cement waste	0.096	Not significant
Dented cap	0.001	Significant
Blistered	0	Significant
Aslant cap	0	Significant
Unsticky tape	0.27	Not significant
Defective glass	0	Significant
Knot 1	0	Significant
Mercury fleck	0.065	Not significant
Powder off > 2 mm	0.052	Not significant
Loosen sleeve	1	Not significant
Rough coating	0.325	Not significant

4. CONCLUSION

There are 13 defect types with low frequency of occurrence that can be eliminated from the minor defect list, after the trial period. They are foreign object, collide stel, damaged stel, dirty tube, folded seal, no coating, thin coating, glass stain, sit high cap, mire cap, glass chips, double sleeve, and flat lamp.

There are 17 defect types with high frequency of occurrence that can be minimized. They are light stain, window, fish eye > 10 mm, fish eye < 10 mm, glue stain, printed tape is sticky with the lamp, cement waste, dented cap, blistered, aslant cap, unsticky tape, defective glass, knot 1, Mercury fleck, powder off > 2mm, loosen sleeve and rough coating. There are 51 proposed solutions, 10 of them are implemented. After implementation the defect types order at Pareto Chart is changed. Beside that, there are 11 defect types that decrease significantly.

In a cluster, enterprises colaborate by means of information exchange and integrated into similar activities in order to achieve competitive advantage among its members and regional economic improvement (Bititci, 2004). Information exchanges and integrated activities can be conducted through interaction among the members (Boedisetio, 2004). Interaction can be described by modeling (Abdullah et. al; 2000). Modeling can map resource of knowledge, input-output, and flow of knowledge (Davenport and Prusak, 2000).

Enterprise engineering modeling framework is used as an alternative because of its better representative overview againts the whole organization (multi view) and representative tools (Presley, 1997). Presley has developed Holonic Enterprise Modelling Ontology (HEMO). This model/new schema is a schema for collaboration model in knowledge-based inter and intra-enterprise in industry cluster, process and configuration partner enterprise, followed by business rules, activity, resources, business process and organization.

This research will result as follows: 1) integrated of modeling framework and knowledge modeling, consisting of modelling method and tools which can be captured and created the knowledge, through modelling of cluster activities. 2) The cluster as holon and enterprise group consists of sub-holon in which makes interaction through the activities. 3) Process of capture and create conducted by mediator which facilitates tacit and explicit knowledge into domain knowledge.

Keyword: *HEMO methodology, knowledge, collaboration, industrial*

Introduction

The importance of an industry to grow make the selection process happens in that industry. Improvements in research and development (R&D) resources, product and service have to be done to make an industry able to follow the selection process in the enterprise. Impacts of the R&D are global innovations in that industry. Small and middle size industry cannot conduct R&D activities by them self as they have limited resources and technology. These limitations can be minimized by collaborating in industry cluster.

The collaboration process can be defined as a horizontal integration of supply chain characteristic, group planning and technology sharing between enterprises. The aim of this collaboration is to enable each enterprise to respond to the rapid change of product demand in the market as quickly as possible. Quick respond are a combination of each activities, knowledge and enterprise capability, so they can grow and develop rapidly. This idea should be transformed through knowledge and available capacities.

Presley, 1997, developed a model schema for integration multi-view model of an enterprise. This model/schema focuses on analysis of processes and configuration partner enterprise; include business rules, activity, resources, business process, and organization. This model schema known as the Holonic Enterprise Modeling Ontology (HEMO). The Process and configuration issues of this

enterprise are temporary and fixed nature of relationship and law to protect intellectual rights and core competency of each participant [10]. These issues have close relationship with the collaboration process characteristic in industry cluster.

This research follows systematically the HEMO methodology, where model developed is a new schema for model collaboration from interaction knowledge base inter and intra-enterprise on one industry cluster, through information flow development product (this research focused on metal product), and all that related to the working process. Model collaboration in this research includes exchange mechanism and knowledge web, relevant actor types, and collective learning in innovation.

The aim of this research is to make a new model schema based on the HEMO methodology for collaboration inters and intra enterprise in industry cluster.

1. Problem Solving Approach

Problem Solving approach in this research consists of two-step that identify basic activities in industry cluster and explorative study with collaboration mapping with HEMO approach, as illustrated in Figure 1

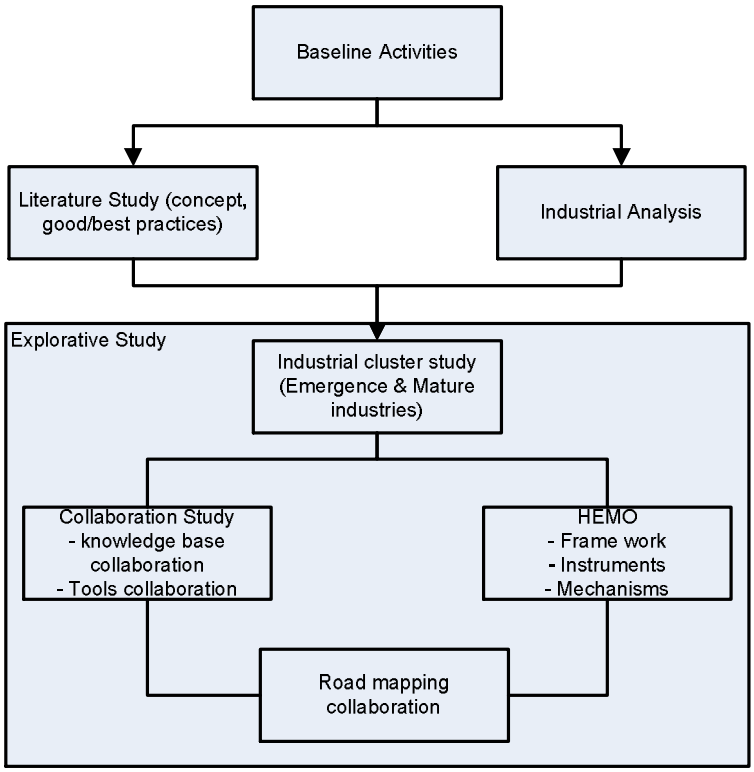

Figure 1. Problem Solving Frame work

Enterprise Modelling

Nowadays, enterprise modelling used in organization for predicting and estimating changes because of external factors.

Based on literature study [15] enterprise modelling is used:

- To facilitate understanding and communication
- To support management and to develop process
- To facilitate benchmarking
- To enable to communicate in enterprise engineering context (Bernus, 1995)
- For a mechanism at planning implementation level, namely strategic, tactics and operational.
- To fasten competition process (Wood, 1994)

Modelling Method

Recently, there are number of methods developed and implemented including IDEF-*Family* and mapping process that are always used in enterprise modelling. This section

explains the relationship between all methods used in this research, which are IDEF0, IDEF3 and IDEF5.

IDEF-*Family*

IDEF0 models is able to capture business activities but it is still not comfortable to be applied for one data base relation and IDEF1X which can accommodate that. Similarly, IDEF0 captures temporal information and limitation that can represent temporal relation between business activities (i.e. object in internal structure of those activities). In addition, that differentiation made strongest in IDEF0 [2].

InterDEF3 represents process, time interval and temporal relation, ideally illustration information about time and position; including capacity to illustration free information about participant in specified process [3].

Relationship between IDEF3 and IDEF5 is very clear. Schematic language IDEF5 is similar to IDEF1 and IDEF1X. The relationship between IDEF1/1X and IDEF5 analogically like IDEF0 and IDEF3. Information in model IDEF1/1X principally can be illustrated in elaboration language IDEF5. As it does not have better designs, the IDEF5 becomes impractical for planning database relational [4].

HEMO Methodology

Presley (1997) introduced holonic Enterprise Modelling Ontology (HEMO). This approach focuses on elements input, constraints, outputs and mechanism in business roles model, started with divinized existing model and information use for input on planning and business model using IDEF5, then it can be decomposed for each organization by available resources as an emphasis on model. Then output of activities in IDEF5 is applied as input for IDEF0 with output process template remodeling using IEF5. HEMO methodology is illustrated in Figure 2.

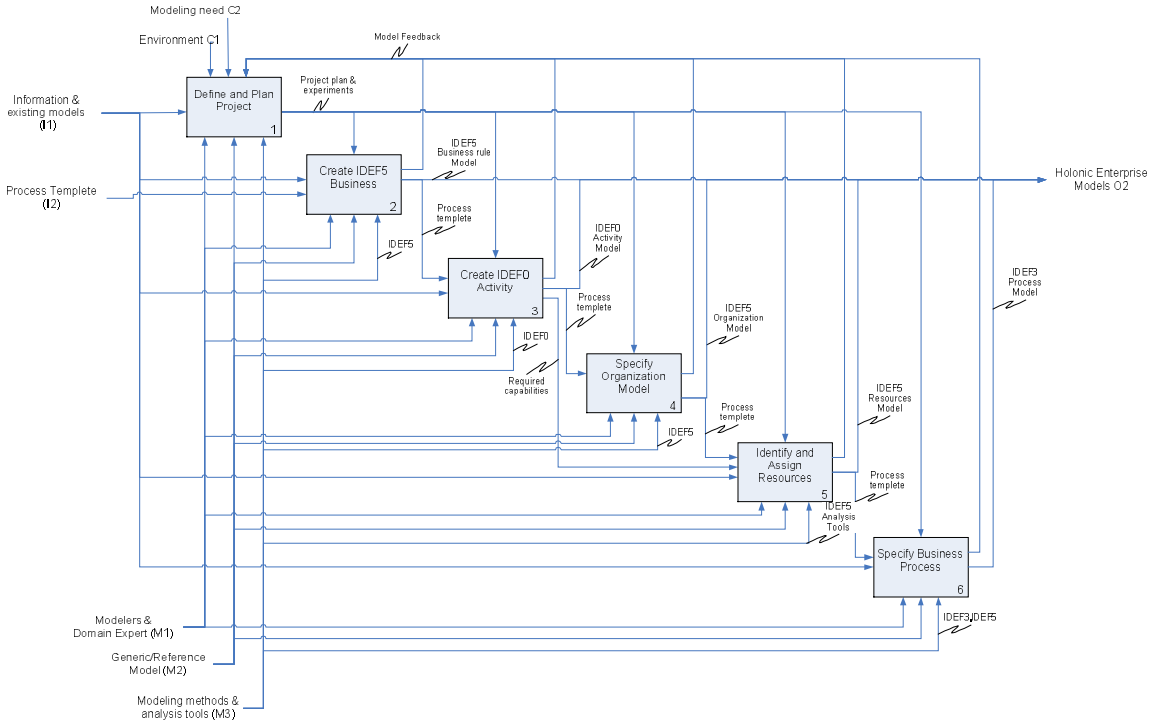

Figure 2. HEMO Methodology

From that model, HEMO methodology uses integration view from business rule model (IDEF5), activity model (IDEF0), organization model (IDEF5), resources model (IDEF5) and process model (IDEF3), as it can be seen on Figure 3.

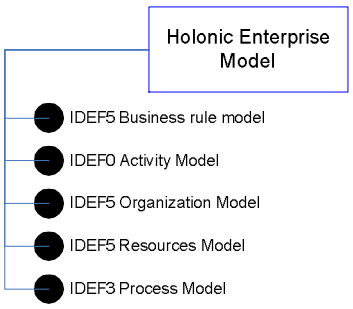

Figure 3. Elements of HEMO

Ontology (IICE,1994)

Word "ontology" has made a lot of contravention in discussion about AI. It has long history in philosophy, where it refers as a subject but it is still epistemology confusing, about knowledge and knowing.

In the contexts of knowledge sharing, ontology means as specification from a conceptualisation. Therefore, ontology means a description (like a formal specification of a program) of concepts and relationships that exist for one or community of agents. This definition consistent with the use of ontology as a set of definition concept but it is more general. Moreover, this definition has different sense of using word in philosophy.

Ontology usually resemblance with hierarchies of classes on taxonomy class, class definitions, and group of relations, but it cannot be limited with that kind of form. Ontology also cannot be limited by conservative definition where definition on traditional logic sense just to introduce terminology and not to add up knowledge in real world [5]. To elaborate a concept, it is important to mention axioms which have limited possibility interpretations on particular terms.

Ontology is a domain catalogue inside a set of details definitions or axioms, which limitation meaning from terms on catalogue completely which possible consistent interpretation from statements used on catalogue.

To make ontology minimum, three products should be made:

1. Catalogue of the terms
2. Capture the constraints that lead how those terms can be used to make descriptive statement about the domain.
3. Build a model that supported by a specific descriptive statement.

Motivation on using ontology:

1. Standardisation
2. Reusability

HOLON

Holon was introduced by Arthur Koestler (1989), as a basic unit for biology modeling and social system on his book, *The Ghost in the Machine*. This term, according to Koestler means, explaining every entity which definition as "a whole unto itself, and a part of other whole(s)." Holons as structure contains particular units, which is used independently but depends on other units. This structure is called as a Holarchy, which is temporal, combined from holons, which has a specified set of goals and temporal objectives. Strangest from a Holarchy is the ability to build multifarious, efficient resources system which fragile to internal and external disturbances and can be adapted with environment [10].

Holon and holarchy concepts can be applied to social structure like a company. A manufacture company can be considered as a Holon that concise of several set of Holon which represented several functions or engineering or organization of a company. For examples, consider manufacturing and engineering. Using control architecture, Automated Manufacturing Research Facility (AMRF), manufacture can be divided into five levels: facility, shop, cell, workstation equipment. The highest holon level determines the goal of the lowest level and coordinates the whole control. At the same time, the lowest level has specified autonomy on action and controlling. On virtual enterprise case, the virtual enterprise is the highest holon level, where every partner has beginning holon level.

Industry Cluster

Industry cluster consists of core industry element, unite industry, support industry, supplier, customer and supporting department, are skeleton of adaptation process in every industry in order to work together to make innovations and achieve competitive advantage [12].

Dynamic cluster is a model, which grows based on the combination of a company population and several companies, which grow faster. It constitutes a chain feedback effect that adds up on technology diversity from specified location. Dynamic cluster model is a cycle of the following components:

1. Cluster (enterprise specialization)

   Cluster connected with resources from productivity, value chain [10] refers to specialization for company supply and feedback such as the production factor. Specialisation build on cluster related to the process with objectives have a unique capability and competitive advantage.

2. Development enterprise (technology spin-off)

   This component generates a unique productive capability, raises technology differentiation, makes opportunities to develop a new product, and helps develop opportunities for other companies in specific location a special potential. Technology spin-off is defined on productive capabilities and interaction with market opportunities under urgent situations.

3. Technological Variation (industrial speciation)

   Represented new companies are needed to exploit of new product opportunities. In this process, they company made opportunities to have different specialization compared to other company.

4. Horizontal integration and re-integration (open system)

   Horizontal integration and reintegration are possible from different technology, which build collective knowledge or an "invisible college". In horizontal integration, speed and tough process build by combination from companies, or relationship explored from new opportunities.

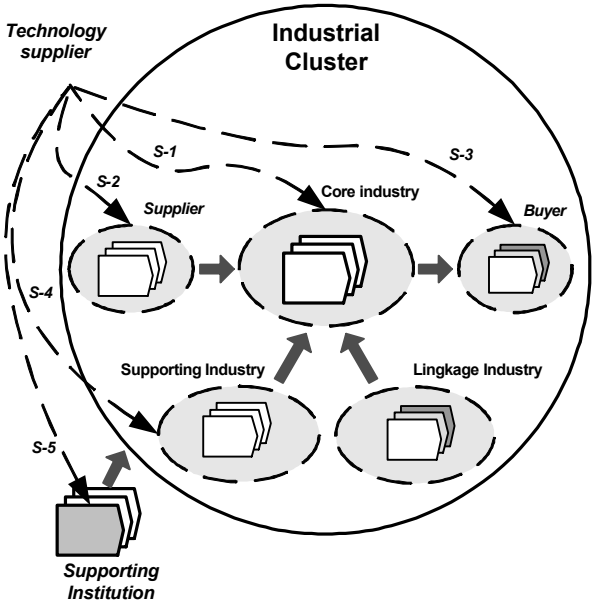

Figure 4. Interaction of Technology Supplier and Industrial Cluster
(Source: BBPT: 2004)

Collaboration Model

Collaboration is a process under knowledge, has the meaning that collaboration is process guided by knowledge (Simon, 1997). As process under knowledge, collaboration needs participants with knowledge on processing skill. Participants can be human, computer or hybrid of both human and computer (Holsapple and Joshi, 2002).

In the first stage, often need identification and analysis industry cluster as location that has coordination. Several quantitative tools often use to identify industry cluster based on detailed data (several digits) under SIC (*Standard Industrial Classification*), such as location-quotients, analysis input-output, growth-share matrix who develop by Boston Consulting Group, etc. [1]

This research will conduct collaboration process using HEMO methodology, which adds up on dynamic cluster concept as a formal media from cluster industry. HEMO methodology

[1] *Another source was discuss about this, ex http://www.hhh.umn.edu/centers/slp/ edweb/cluster.htm*

phase consists of conceptual stage and interaction inter and intra company.

Process Centred Enterprise Models as a basic HEMO modelling can be relevant to be used on cluster because activities which is explained on the process is the activities from company units, or units on group of companies on strategic alliance or virtual enterprise [10].

Data and Analysis

Cluster industry does not only reflect that product is important, but also explicitly reflect about the importance between subsystem elements process created value with subsystem element process other creation as one unity. If the attentions is just concentrated on products (usually dynamic and fragmented), it is difficult to expect to raise competitiveness significantly and able to assist effort (often sector and partial) [12].

Explorative study objectives are to find information from source actors (company, government and university) especially about potential support and obstacles on collaboration formation. This study consists of a comparison of multiple view architecture, which will be adopted to build new schema cluster (Table 1). The new schema adopts multiple views from HEMO (ARR [1]).

Table 1. Multiple View of Architecture [10]

Architecture	CIMOSA	Zahcman Framework (IDEF)	Stecher	Curtis	ARRI (HEMO)
Views	Function	Data	Entity	Functional	Activity
	Information	Process	Function or process	Behaviour	Process
	Resource	Network	Organization	Organizational (resource)	Organizational
	Organization	People	Location	Informational	Business Rule
		Time			Resource.
		Purpose			

Basic study is conducted based on the case study of metal industry cluster in Bandung. This study concentrates on automotives components. Collaboration area concise of business model on handling order process with area study as illustrated on Figure 5.

Based on requirement gathering, therefore building system can be suitable with that need; collaboration industry cluster expectantly can produce system, which is able to:

- Swiftly handling customer order process
- Swiftly capacity respond and production process ability on cluster
- Swiftly technology information flow on cluster

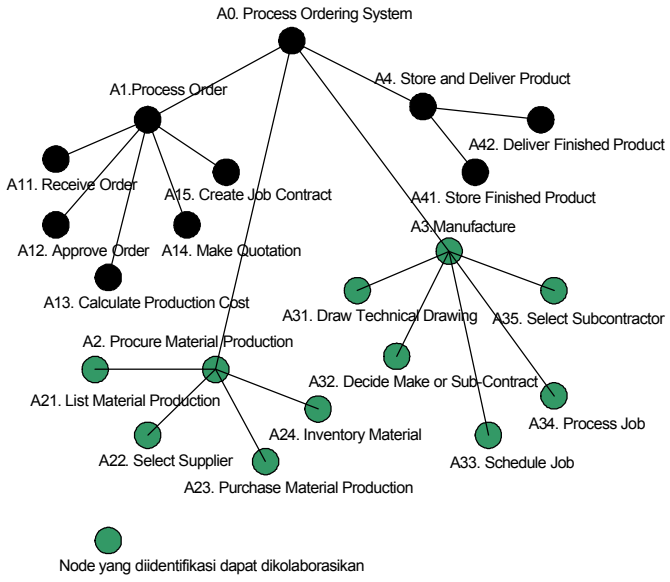

Figure 5. Process Order Diagram

ISSN 114-1284

With assumptions:

- Production is an external system and only gives information about production capacity and technology.
- Material purchase outer concern this system, therefore only give recommendation about supplier who has to be contact for complete production material basic from order and job specification, and also for job sub-contract.

Data Collection Methodologies

Killing (1993) explained that collaboration success based on complexity, which can be managed by actors. Three main factors that influence complexity are activities area, uncertainty of that activities, and collaboration skill.

Explorative studies focus on quarry of those factors from actors in each industry. Study will be done by interview (field survey) and restricted discussions. Sources of information are individual who has capacity as strategy decision making in organization and expert in their field.

Explorative Study

The goal of the explorative study is to make collaboration model by using interaction knowledge base inter and intra-enterprise on industry cluster, through information flow on develop product (in this research we focus on metal product), and related to its work process. Focus on developing activities, organization and resources on industry cluster. Collaboration models concise of exchange mechanism and knowledge networks, types of relevant actors, and collective learning in innovation.

The stages of this study are as follow:

- Identification of important elements for collaboration knowledge base formation, in particular area potential collaboration formation and collaboration mode.
- Find out sources of policies, in particular outline (issue and structure), instrument and mechanism.

Focus industry based on explorative study and input potential strategy complementary capability and need between actors, and indication good will to collaboration.

Business Model

Now companies on cluster have limited technology and production capacity, therefore if pull order happen, company executes subcontract process with similar company which has similar specification order. This has been already identified as collaboration process between those companies but only on going framework. Therefore, this research will modify collaboration process to become collaboration flow as seen on Figure 6. Focus on this problem is business process made by enterprise when they handle an order.

From two issues often appear problems like production process delay and shipping delay because of limited material source on warehouse and supplier. In this matter, will be changed on customer order handling by process adjustment on every activity selection process (companies that has ability basic on product on capacity and technology).

Then insert condition activities that involve cluster member on handling order because of limited technology and capacity on companies who receive order. This condition motorizes by companies, which receive order, and distributed to cluster member.

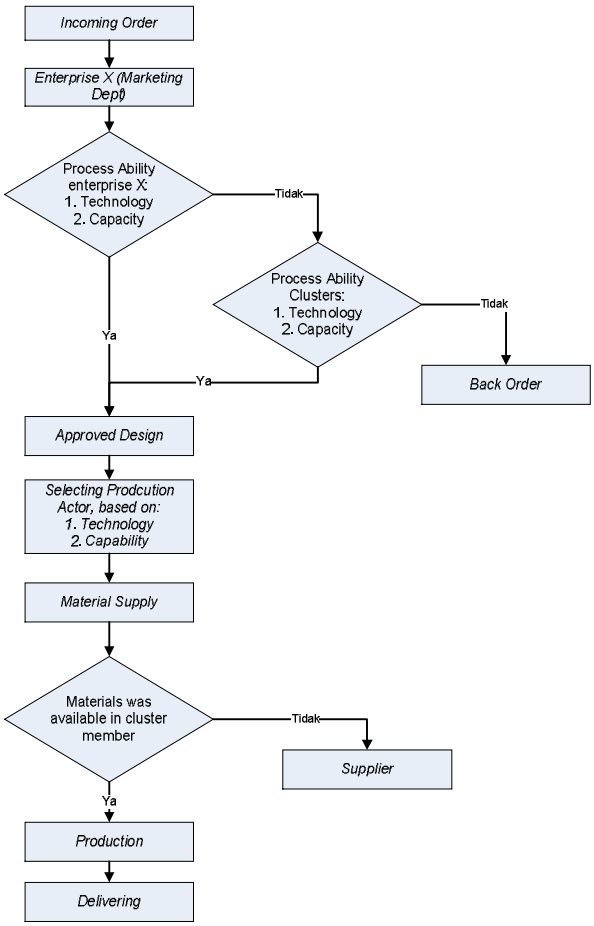

Figure 6. Order Handling Process Modelling

HEMO Multiple View adopted from ARRI with phase view as seen on figure 3. On new schema will be develop with basic consideration system order process on figure 4, which identification which area can be collaboration are manufacture and production, therefore this preliminary research can be made the new schema, therefore it needs verification and validation, as seen on figure 7.

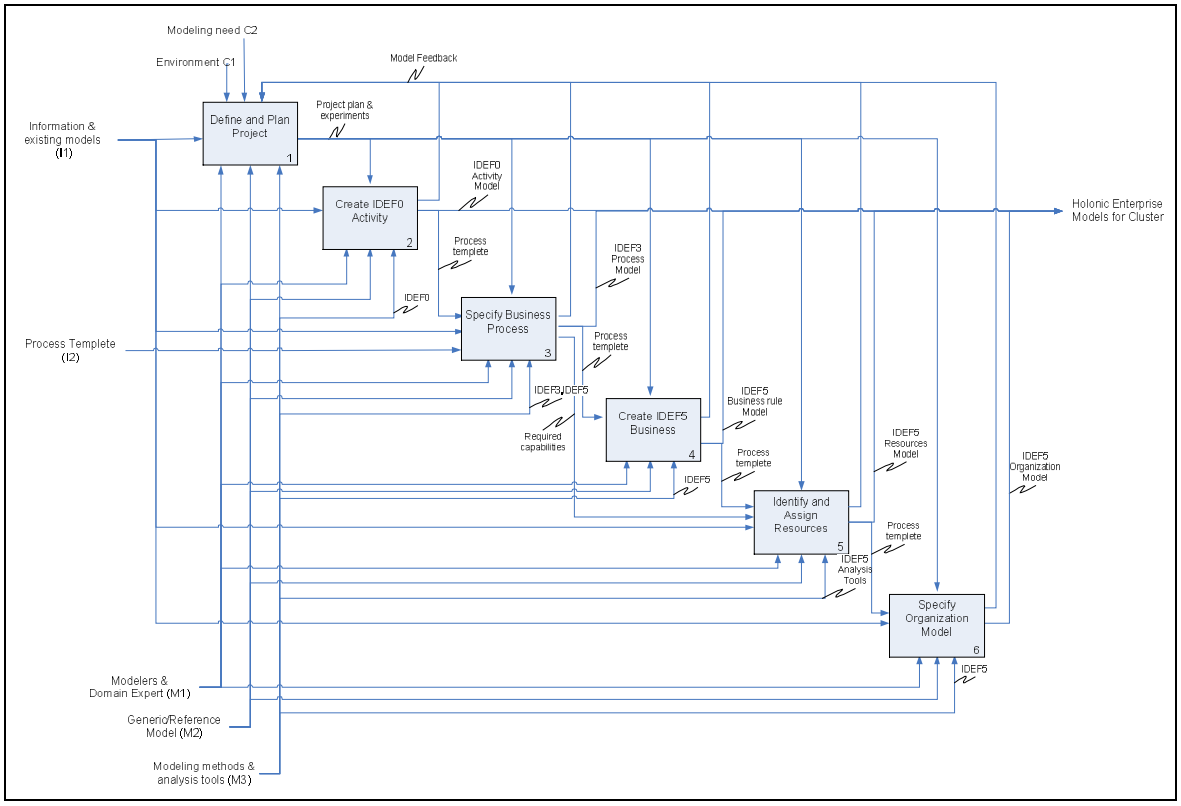

Figure 7. HEMO-Cluster Methodology

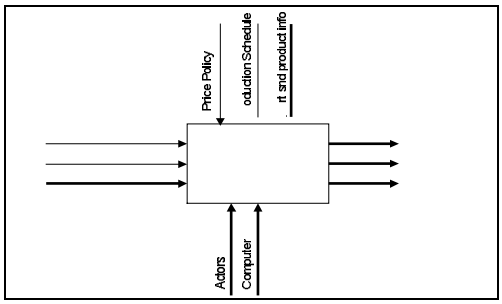

Figure 8. IDEF0 Model (A0-Order Handling)

This model using method from IDEF family such as IDEF0, IDEF3, to mapping order process handling as can be seen on the Figure 9

.

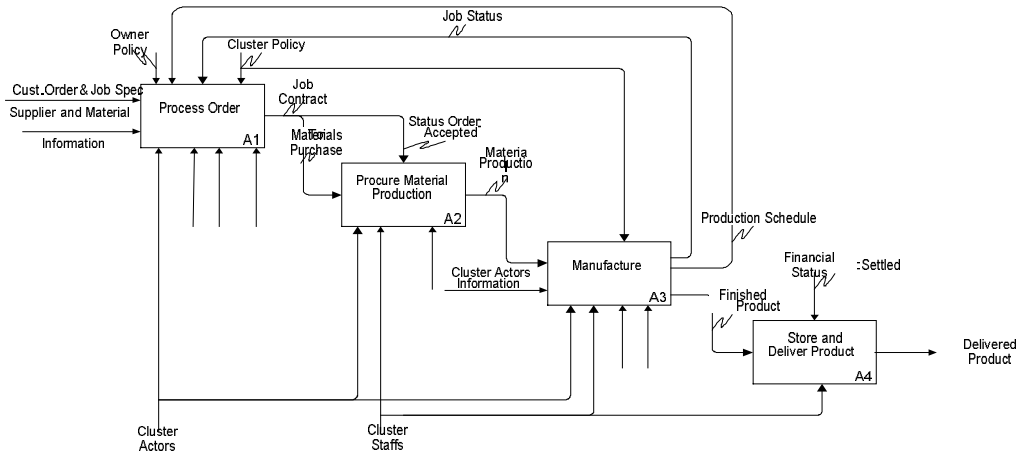

Figure 9. IDEF0 Model (A1-order Handling)

After concluding the modelling and decomposition process, output of the IDEF0 is reference as model on IDEF5, about process that becomes issue. Issue on this case is order process evaluated based on technology and capacity ability that reference for mapping organization on collaboration like the available resource. See Figure 10 and 11.

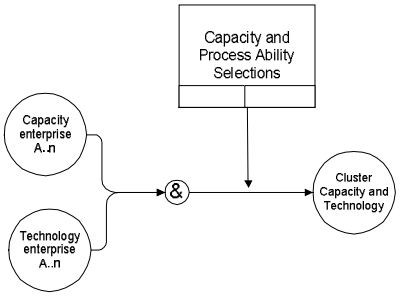

Figure 11. Resources Model IDEF5

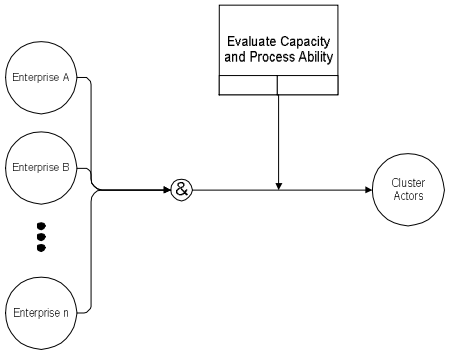

Figure 10. Organization Model IDEF5

IDEF5 model is used only until diagrammatic model, but not as elaborate language model. After organization model and available resource process, then decompositions based on capacity object and technology on IDEF5 model on IDEF3, with IDEF3 as Figure 12:

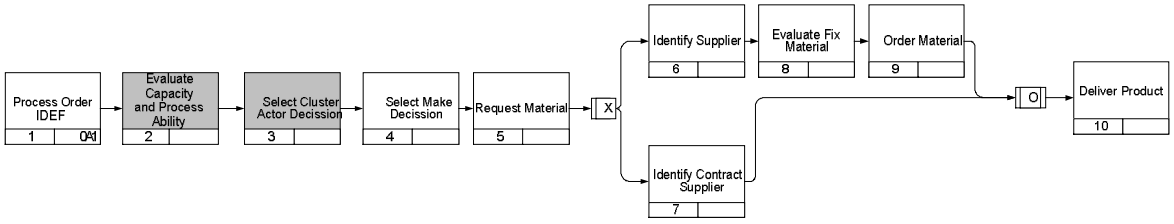

Figure 12. IDEF3 Order Process in Cluster

Analysis

On this paper, the schema is just on conceptual phase and it needs specific descriptions, but in overall, it can be compared as follow;

Table 2. HEMO and HEMO (Cluster)

	HEMO	HEMO (Cluster)
Focus	Process Centered	Process Centered
Design object	Activity	Activity
Model Scope	Business Rule	Activity
	Activity	Business Rule
	Organizational	Organizational
	Resource	Resource
	Process	Process

Based on characteristic of the industry cluster, several basic factors can be essential factors on the schema developed on collaboration process such as:

1. Activities area that has similar object, like metal industry cluster.
2. Unbalanced order in this case specification, involve ability of capacity and technology owned by companies on cluster.

On business model (Figure 6), input order handle by cluster actor has objectives as media on evaluated actor on cluster, which is able to fulfil order. Evaluation form and selection cluster actor based on:

1. Ability to fulfil specification (technology)
2. Production capacity

In this case, knowledge flow is accommodated by each actor on cluster by media information such as catalogue process, product and resources. This research decomposition have not particular complete about knowledge transformation process, as about media neither forms.

From this factor emerges value to collaboration through knowledge transformation on handling order process. Activities and process, through business process can be collaborated. They have several characteristic as follow:

1. Products that need expert skill and high precession.
2. Mass component products or specific product.
3. Products, which are made on small numbers and not fixed.
4. Products influenced by location and transportation cost.
5. Product, which has special design or the one, which has high innovation.
6. Operation flexibility and indirect low cost.

Conclusion and Suggestion

1. In particular, this schema concludes approach that possible for potential companies on cluster and scope can have significant result on process collaboration intra and inter companies especially involve:
   a. Captures process through activities model, process and limited resources on area cluster.
   b. Use of comparative advantages (particularly on flexible ability on handing order).
2. Using holon in this framework facilitate how people drawing knowledge, grouping and abridging knowledge transfer.
3. IDEF0 and IDEF3 is the tool for capturing knowledge from the actors, particularly on growing/nurturing technopreneurship on industry cluster.

ABSTRACT

A Passenger Terminal is a transportation facility as a station to controlling and managing the transportation mode, and moving the passenger between transportation modes. Integrated passenger terminal, a solution to provide travel efficiency, integrates all transportation modes such as train, bus, and/or connecting bus or train to airport.

Bandung city council has a plan to build an Integrated Passenger Terminal in Gedebage. The terminal will connect rail, road transportation modes, and commercial centers. A concept of the Integrated Terminal is to use the space effectively and efficiently as society activity centers. Space efficiency should consider the terminal planning by identifying the facility society needs to provide maximum services to the society.

Cost planning is an important aspect in building the infrastructure to provide space and the construction project. Therefore, the economy of the project should be analyzed in order to show feasibility of the project. It can be decided by analyzing the project feasibility indicators.

The feasibility analysis shows that the Gedebage Integrated Terminal is feasible to be built by the investors with investment 10% -70% of the total cost when the capital return is around 8-11 years with the concession for 30 years.

Keywords
Integrated Terminal, Feasibility Study.

.

1. INTRODUCTION

Nowadays intercity transportations are served by various transportation companies for variuos lines of transportation such as air, train and bus. Especially for busses, there are several large bus companies operate from Leuwipanjang Terminal to the west part of and Cicaheum Terminal to east part of. Both terminals are not convenient any longer for passengers. Those terminals create pollution, traffic jams, and cause travel time much longer. Because of these, ilegal terminals emerges as an alternative, for passengers and operators. Therefore, Bandung council planning to built an integrated terminal in devoloping of Gedebage areas.

2. METHODOLOGY

The analysis model for that being used are the Pre-design model analysis and financial analysis for Integrated Terminal Gedebage. Pre-design analysis model for Integrated Terminal Gedebage consider several parameters; forecast for growth of passengers, room space and capability of terminal facilities required.

To predict the size of activities in terminal and room space availability is very crucial (*Makridakis, Spyros, Steven C. Wheelwright, dan Victor E. Mc Gee,*. There are three steps in forecasting; determine model formulation, decide appropriate parameters, and model validation. These steps are needed to obtain the performance indicators of the terminal,

Room space required based on terminal activities and room facilities level needed, entry data based on peak-hours and other standard published by Dinas Lalu Lintas Angkutan dan Jalan (DLLAJ) and other references from Studi Kelayakan Terminal Regional Kotamadya Bandung, 1996 (PT. Citra Karya Utama) and *Apple, J.M. (1990)*

Room facilities needed depends on activities during the peak-hours, room requirement and length of time for every person on the facilities. Standard room space requirement per person on each facilities reference to a book published by architect Ernst Neufert as follows:

a. Rest room size =1,10 m^2.
b. First Aid room size =4,50 m^2.
c. Information room size =1,00 m^2.

d. Guard room size =1,05 m^2.
e. Prayer room size =2,0 m^2.
f. Restourant size =1,05 m2.
g. Waiting room size =1,50 m^2.
h. Departure Room size =1,00 m^2.
i. Arrival Room size =1,00 m^2.

Pre-design Financial analysis for Integrated Terminal Gedebage measured by the following feasibilities indicators level (*Newnan, Donald G)*:

(1) *Net Present Value* (NPV), is feasible if NPV for the project positive (NPV>0)
(2) *Internal Rate of Return* (IRR), if feasible if IRR for the project > *social opportunity cost* or *social interest rate*.
(3) *Benefit Cost Ratio* (BCR), is feasible if BCR for the project > one (BCR > 1,0).
(4) *Payback Period* (PP), is time required for Break Event Point (BEP).

3. DATA COLLECTION AND CUMPUTATION

Secondary datas used as input in research questionnaire arrange which it outputs are primary datas.
Secondary datas are collected interrelated with finance evaluation through pre-design integrated terminal Gedebage among other Bandung city general situation, Bandung Citizen and terminal as infrastructure.

The arise number of buses and passengers every month in Cicaheum and Leuwipanjang Terminals as shown in Table I and II:

Table I. Number of Buses and passenger in Cicaheum Terminal

Source: Terminal – official transportation Bandung city 2006

The secondary datas are from passenger Cicaheum and Luwipanjang Terminal. Its is used to forcast the maximum passengger in several time.
The forcasting model is Box-Jenkins thats mix model simple ARIMA(1,0,1)(0,0,1)^{12} with seasional factor. The result is constant (μ') = 5,6933526,autoregresif parameter AR1(Φ) = 0,95759947 moving average, parameter MA1 (θ) = 0,3284120 and seasonal moving average parameter SMA1 (Θ) = -0,5405997.

The calculation result of bus pessange growth is taken from the most number of passengger.in the length of forcasting time.
From spending time forecast 2007 – 2039, which is December 2031 with total passengers 493.574. Total Passengers per day 16.227

4. RESULT AND DISCUSION

Sample sizes by Slovin. Daily population taken based on the sum of average passengers per day at both Terminals (Leuwi Panjang and Cicaheum) plus safety factors 30% produce 23.025 samples with 10% error, so minimum sample has to be taken is 100 samples. To avoid data error, questioners spread out to 200 respondens. Returned questioners are 173.

The Terminal facilities for passengers is devided into main and minor facilities and from the primary entry from the questioners about their most preffered facilities. According to database and analysis, preffered facilties is similar to all facilities which are included inKEPMEN. Facilities are planned to be built in Terminal Terpadu Gedebage as shown in Table III.

Table III. Terminal Facilities

Main Facilities	Minor Facilities
o Embarkation Line for Public Transportation o Arrival Line for Public Transportation o Main Parking space, include rest area before departure o Main Building Office o Waiting room for passengers and relatives o Surveillance Tower o Tickets Box o Signs, Informations, Directions, Time-Schedule, Price-List,etc o Parking Area for Public, Family and Taxis	o Rest Room / toilets o Musholla o Kiosk / Canteen o Medical Room o Information o Public Phone o Luuggage Storage o Public Park

The size of integrated terminal gedebage is design according to the result of data calculation, which are primary and secondary datas. The component of primary datas are public faciliteis which must provided arround terminal. The size of room falilities in terminal are based on proximity of calculation number of maximum bus terminal user.
Pre-design of integrated terminal area are consist following things:

1. Arrival and departure terminal for passenggers
2. Commercial buildings
3. Train Station building
4. Work Shop building dan paper building
5. Parking areas

The design of commercial buildings have five floors, with total area 40.000 m2. The inside of facilities must accommodate customer needs which suitable with questionnaire distribution, so Commercial buildings will be usefull for people. The terminal integrated building for passenger design in two floors, which the first floor is arrival terminal and the second one is for departure.
The deferent of movement carakteristic between feeder, public transportation, also intercity transportation, so the three kind of vehicle movement must be separately.
The parking areas for intercity buses, interstate buses, east and west destination, also public transportation parking area must be separately.
Demand of room facilities in terminal based on calculation result whith assumption the shape of room is square, as shown in Table IV and V.

Table IV. Size (Square) of Departure Facilities Building

No	Facilities	Size (m^2)	Dimention (m)
1	Meeting Room / Wave Room	406	20,1 x 20,1
2	Passenger Waiting Room	236	15,4 x 15,4
3	Counter	150	12,2 x 12,3

Result from observation above: Intergrated Terminal Gedebage is feasible observed from the financial analysis.

4. CONCLUSION

Based on the result, obtained in this research we have conclutions as follows:

1. Pre-design terminal, calculating project budget by public approach not by jobs, etc. Only focus on feasibility study of the investment
2. Forecasting high numbers of passengers movement create possibility to higher capacity so it need to be planned carefully in order to gain efficiency and effectively in operation.
3. Investment is not feasible if the selling price of commercial space Rp. 15.000.000/m^2.
4. Investment is feasible if the Municiple of Bandung funds the investment on land with interest rate at 12% / year, increase revenue 5%/year and increase operational and maintenance costs 5% / year with criteria as follows:
   a) Revenue on selling commersial buildings at Rp.20.000.000/m^2 plus annual revenue from retribution and other revenue such as display room, advertising boards, project budget based on price per unit published by P.U. Kota Bandung year 2006, investment is feasible if loan factors 10% - 70%. if project budget based on market price Kota Bandung year 2006, investment is feasible with maximun loan factors 10%.
   b) Loan factors impact toward NPV (Net Present Value) and payback Period, bigger loan factor longer payback period.
   Investment is still feasible altough revenue from retribution is excluded from the investment, if so price based on price per unit published by Pekerjaan Umum Kota Bandung at the price Rp. 20.000.000/m^2. for Commercial building.

Performance Measurement Supply Chain By Using Method SCOR (*Supply Chain Operations Reference*) and AHP (*Analytical Hierarchy Process*) Case study in Furniture Industry Dheling Asri, Yogyakarta

Elisa Kusrini[1] Heri Furqon Sabana[2]

1) Majors Instructor Staff Industrial Engineering in University Islam Indonesia, Yogyakarta

2) Majors Student Industrial Engineering in University Islam Indonesia, Yogyakarta

ABSTRAK

Performance measurement can assist target of performance improvement to reach SCM excellence. Although some of empirical studies have done to measure performance SCM but there are no agreement of certain measurement method that used yet. Up to now, the currents performance measurement method which applied in SCM has significant difference in scopes and focuses. And it has different way to determine performance target. This research focused on design and measurement of performance in small industry. Supply chain performance measurement schemes use SCOR and AHP approach can used for knowing the performance of achievement company level in managing the supply chain. SCOR schemes gives common reference in assessment of factor and criteria, but the application adapted to supply chain field which will be evaluated.

Keywords *: Supply Chain Management, Performance Measurement, SCOR, AHP*

1. Introduction

Conventionally, measurement of performance defined as quantification process efficiency and effectiveness level of an activity into measurable value (Neely(1995),Lebas (1995)). At management of modern business, measurement of performance has broader and deeper meaning than to quantification and calculation. From management perspective, measurement of performance can provide feedback of information that very valuable for manager in monitoring performance of company improvement, to increase motivation, communications and diagnose of a problem (Rolstandas ,1995 ,Waggoner,1999 in Chan,2002). Performance measurement also applied to assess level of strategy effectiveness used in SCM and identified successfulness and opportunity in the future. Measurement of performance gives a real important contribution in decision making process in SCM especially in re- planning process purposes and corporate strategy then at re-engineering process.

Some of models to measure SCM performance have built by some researchers (Beamon,1999, Gunasekaran,2001,Bulinger,et all,2002,Chan,2002,Chan,2003). But measurement of performance conventionally

ISSN 114-1284

which only focused at financial aspect has weakness because focused at short term and profit orientation that in the end tends to reach local optimization, failed to support continous improvement and use one measurement dimensions only (Holmberg,2000,Kaplan and Norton,1992). Furthermore, measurement of performance in SCM also has many weaknesses that are inexistence of the relation of with corporate strategy, doesn't have any approach which balancing between financial and non financial, lack of system approach in SCM understanding where SCM must be viewed as unity of entity from overall member, loss or imprecisely measurement in SCM context. From mentioned above, measurement method of SCM performance is not able to use assist in SCM expansion yet. Effectiveness in Measurement Method of performance still in debate and requires exploration of research farther (Beamon,1999, Holmberg,2000,Ho and Newton,2002,Beamon,1998,Chan,2003,Chen and Labarni,2005).

Although some of empirical studies have done to measure SCM performance but there are no any agreement for using measurement method. Up to now, measurement methods of performance applied in SCM have significant difference in scope and focus. And there are have different way in determining the target of performance. Therefore require to make a framework measurement of performance merging performance scale to every member of supply chain. This research will focused at making of framework measurement of supply chain performance at small industry by taking case study at furniture company Dheling Asri Jogjakarta.

2. Purpose Of Research

Purpose this research is design and measures SCM performance at small industry and know action refinement.

3. Literature review

Research about performance measurement SCM has scope and different focus in significant (Ho and Newton, 2002). Beamon (1998) classification of performance measurement bases on qualitative based measures and quantitative based measures and emphasizes purpose of supply chain to reach level of high efficiency, level of customer service which is high and prosperity for effective response to environmental transformation in simultan. Further, Beamon (1999) submits measurement system focus at 3 purpose of strategic of the organization and proposes performance measurement from resources, output and flexibility for indicate level attainment in purpose organization.

Gunasekaran(2001) submits performance measurement method with emphasizing at balanced approach and categorizes performance measurement financial and non financial at level management strategic, tactical and operational and integrates this measurement with four activities interacting from a net-work supply chain (plan, source, production, delivery) with a purpose to service and satisfaction of consumer. Method balanced score card is measurement method internal performance of company that indicator financial integration and non financial. This approach aim to evaluate internal business out of four perspective that is financial perspective, customer perspective, internal business process perspective and learning and growth perspective (Kaplan and Norton,1992).

Supply chain council (2001) develops model to mention the supply chain operational reference (SCOR) for measure performance at all of business process involving in net-work supply chain. This model integrates three principal elements in management that is business process reengineering, benchmarking, and process measurement in passed function skeleton supply chain. Third the element has function as follow:

Business process reengineering in essence catch's complex process happened this

moment (as is) and definition desirous process (to be).

Benchmarking is activity to get operational performance data from Congener Company. Internal target then is appointment based on performance best in class obtained.

Measurement process functions to measure, controls, and repairs process supply chain

Business process in SCOR covers:

a. PLAN, that is process related to equilibrium between actual requests by what has been planned.

b. SOURCE, that is process related to purchasing of feedstock material to fulfill the request.

c. MAKE, that is process related to transformation process of feedstock becomes semi finished product and also product thus to fulfill the request.

d. DELIVER, that is process related to finished goods inventory, including in it about management of transportation, warehouse, all to fulfill consumer request.

e. RETURN, that is process related to return process of product because certain reason, for example because product unmatched to consumer request, and others.

From some things upper to be knowable that improvement of company performance through SCM has drawn interest from practitioner and researcher. Although some empirical studies has been done to measure performance SCM but has not there is an agreement for use measurement method. Till now measurement method of performance applied in SCM to have scope and different focus in significant. And also there is different way in determining target of performance. Therefore require to make a framework performance measurement of supply chain. In this research will be made framework measurement of supply chain applies approach of SCOR with load applies method Analytic Hierarchy Process (AHP).

3.2. Method Load and Normalization

To get performance value, a performance measurement must be able to show individual values every metric and also aggregate values at every level gauging hierarchy. Load at each factor is done with method Analytic Hierarchy Process (Saaty,1994), where every performance objective paired and done comparison of level of the importance.

Because every business process (factor) in method SCOR contains different weight with different parameter, therefore required equation process of parameter, that is way normalization. Here normalization plays a part enough important for the shake of reaching of finally value from performance gauging. At this measurement, every indicator weight converted to in certain value interval that is 0 to 100. Zero (0) interpreted bad, and one hundred (100) interpreted best. Trienekens and Hvolby (in I Nyoman Pujawan et al., 2002) applies model to do interpolation of performance measurement value as follows:

$$\frac{(S_i - S_{min})}{(S_{max} - S_{min})} x100$$

Where:

Si = Indicator value actual which successfully is reached

Smax = Attainment value of best performance from performance indicator

Smin = Attainment value of bad performance from performance indicator

4. Methodology Research

4.1 Research Object and Location of Research

Research Object is industry Mabel Bamboo Dheling Asri, which is goods producer from crafting of bamboo especially furniture having location in orchard Mlati, Sleman, yogjakarta.

4.2 Problem solving

Problem solving steps as follows:

Step 1.Research early stage is compile skeleton supply chain consisted of by party involving in levying, making and delivery of product so that product up to consumer hand.

Step 2.Second step is compile hierarchy in measurement of supply chain adapted for by company state of Dheling Asri.

Step 3.This phase is phase calculation performance value Supply chain based on measurement hierarchy of supply chain.

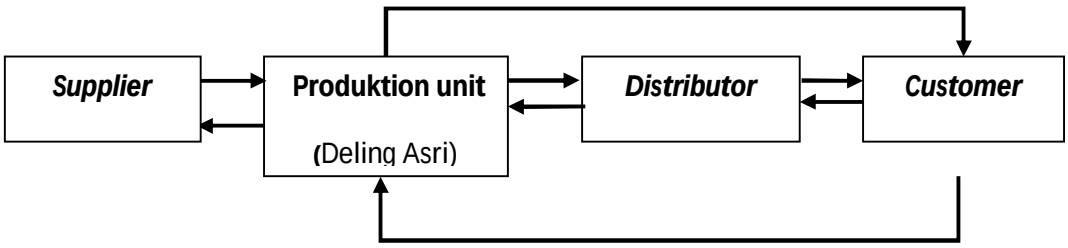
Step 4.This step is analyzing data and discussion.

Step 5.This step is conclusion and action of refinement.

5. Result Of Research and Discussion

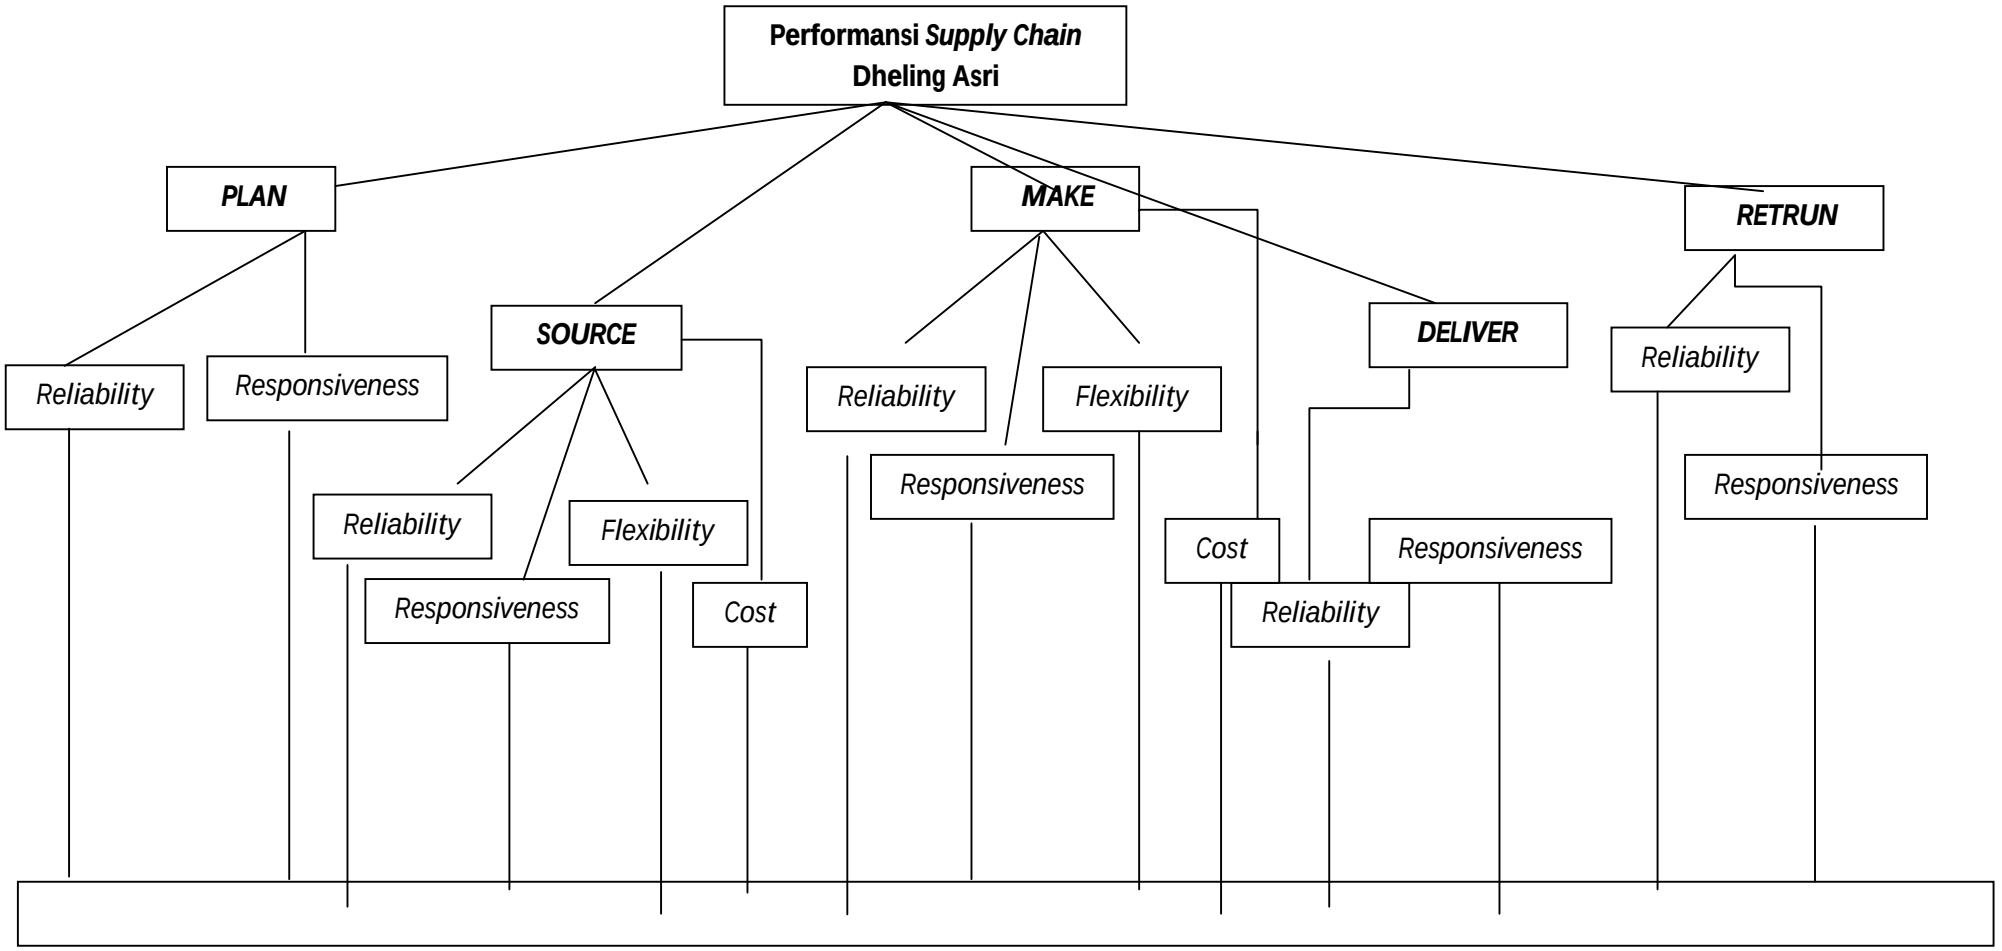
Research is done in furniture company Dheling Asri Jogjakarta which active in bamboo industry, one of the product is table and chair. Bamboo furniture industry Dheling Asri has some distributors and also supplier which spread over in some regions in Yogyakarta, Surabaya, Magelang, Semarang and some other places. To get performance value supply chain to do through phases as follows.

Phase 1. Research early stage is compile skeleton supply chain consisted of by party involving in levying, making and delivery of product so that product up to consumer hand. Activity diagram of supply chain given in drawing 1.



Drawing 1 . Activity Diagram Supply Chain

ISSN 114-1284



Drawing 2. Performance measurement Hierarchy supply chain Dheling Asri

Phase 2. Second phase is compile hierarchy in measurement of supply chain adapted for by company state of Dheling Asri. Hierarchy consisted of 3 level. Level 0 is performance value supply chain. Level 1 consisted of factors assessed in performance measurement supply chain. Factor entangled consisted of 5 factor that is plan, source, make, deliver, return (Levi,2000) Level 2 consisted of criterion criteria from each factor. There are four criteria applied that is: Reliability (relates to Reliability), Responsiveness (related to speed of response time all changes), Flexibility (relates to flexible in facing all changes) and Cost (relates to costs in supply chain). Level 3 consisted of is metric each criteria. Form of performance hierarchy supply chain in Dheling Asri given in drawing 2.

Phase 3. This phase is phase calculation performance value Supply chain based on measurement hierarchy of supply chain at drawing 2. Performance measurement value supply chain will be calculated based on formula (2)

Performance SC = $\sum$ (weight factor level1 x value factor level 1) ……(2)

Factor weight level 1 is calculated to apply method AHP. Whereas value factor level 1 is calculated based on formula (3).

Value factor level 1 = $\sum$ (load criteria at level 2 x value criteria at level 2)……..(3)

Load criteria at level 2 is calculated to applies method AHP. While assessing criteria at level 2 is calculated based on Formula (4)

Value criteria at level 2 = $\sum$ (load metrics x metric value)……(4)

Load each metrics is calculated based on proportion metrics to amounts metrics in every criteria. Value metrics got from direct measurement in company Dheling asri, where this value then is normalization applies formula (1).

Metric measurement at each criterion and factor in Dheling Asri, applies formula and measurement period as follows.

- . ***Plan***

Scope plan covers aspects and metrics-metrics like following:

1. *Forecast inaccuracy*

   - Definition : Percentage deviation of actual request with request result of forecasting.
   - Formula : $\frac{|\text{forecast of request - actual request}|}{\text{actual request}} \text{x1}$ 00% ……(5)
   - Measurement period: Once a month

2. *Inventory inaccuracy for finish product*

   - Definition: Percentage deviation from amount stocks product in warehouse (physical) with stock noted (documentation).
   - Formula: $\frac{|\text{amount of physical units - number of units is note}|}{\text{amount of units is note}}$ x100% ...(6)
   - Measurement period: Once a month

3. *Inventory level for finish product*

   - Definition : Average of stowage long in warehouse
   - Formula: $\frac{|\text{Average of inventory monthly}|}{\text{amount of average monthly request amounts}}$ x100% …….(7)
   - Measurement period: Once a month

4. *Number of trainee in PPC*

   - Definition : Average of employee amounts part of PPC which got

ISSN 114-1284

training about production planning in each time training.
- Measurement period: Once a year

B. *Responsiveness*

1. *Time to identify new product specifications*

- Definition : Time required to do new research and product development
- Measurement period: Every happened identification of new product

2. *Planning cycle time*

- Definition : Time required to compile production schedule
- Measurement period: Once a month

- ***Source***

Scope source include aspects and metrics like following:

A. *Reliability*

1. *Defect rate*

- Definition : Percentage of defect material unit amounts returned to by supplier
- Formula:

$$\frac{|\text{amount of defect units}|}{\text{amount of units sent}} x100\%$$

…….……. (8)
- Measurement period: Once a month

2. *Source fill rate*

- Definition : percentage of request amounts which able to be fulfilled supplier
- Measurement period: Once a month

3. *Incorrect quantity deliveries*

- Definition : Percentage of lacking of unit sent by supplier (imprecise of quantity) divided with entirety delivery total
- Formula :

$$\frac{|\text{amount of bambooes that is less}|}{\text{amount of bambooes order}} x100\%$$

…… (9)
- Measurement period: Once a month

4. *Fluctuation price frequency*

- Definition : How much happened increase price of bamboo material from supplier in one years
- Measurement period: Once a month

5. *Number of meeting with suppliers*

- Definition : Number of meetings with supplier to do evaluation
- Measurement period: Once a month

6. *Deviation wheat arrival schedule*

- Definition : Average deviation date of arrival bamboo cargo
- Measurement period: Once a month

B. *Responsiveness*

1. *Source lead time*

- Definition : Time from material order company to supplier up to company receives goods for the things first time
- Measurement period: Once a month

2. *Source Responsiveness*

- Definition : Time required by company to look for supplier substitution if first supplier cannot fulfill company request
- Measurement period: Each time happened seeking of supplier substitution

ISSN 114-1284

C. *Flexibility*

1. *Source Flexibility*

- Definition : Amount of supplier which able to be made as supplier substitution if first supplier cannot fulfill company request
- Measurement period: Each time happened seeking of supplier substitution

2. *Minimum Order Quantity*

- Definition: Amount of minimum quantities each time order which able to be fulfilled by supplier
- Measurement period: Once a month

D. *Cost*

1. *Cost For Order to Supplier*

- Definition : Amount of costs applied to order feedstock to supplier
- Measurement period: Each time happened ordering of feedstock supplier

- ***Make***

Scope make include aspects and metrics like following:

A. *Reliability*

1. *Yield*

- Definition : Comparison ratio between output is divided input (for chair)
- Formula : $\frac{|\text{Output chair}|}{\text{Input bamboo}} x100\%$ …….. (10)
- Measurement period: Once a month

2. *Packing failure rates*

- Definition : Amount of products failing process is divided with product total which ought to be yielded.
- Formula: $\frac{|\text{Amount of failing products}|}{\text{Amount of products which ought to be yielded}} x100\%$ (11)
- Measurement period: Once a month

3. *Sampling out of specification*

- Definition : Percentage of product unit amounts sampling, secretory from heavy specification limit
- Formula: $\frac{|\text{Amount of failing products}|}{\text{Amount of products which ought to be yielded}} x100\%$ …(12)
- Measurement period: Once a month

B. *Responsiveness*

1. *Make Item Responsiveness*

- Definition : Time required by company to fulfill request consumer in the event of order
- Measurement period: Each time happened ordering

C. *Flexibility*

1. *Make Item Flexibility*

- Definition : Amount of additions variation product item which able to be fulfilled company
- Measurement period: Each time happened addition variation item

D. *Cost*

1. *Cost for finish product*

ISSN 114-1284

- Definition: Amount of costs released for production process
- Measurement period: Once a month

- ***Deliver***

Scope deliver include aspects and metrics like following:

A. *Reliability*

1. *Fill rate*

- Definition : Percentage of goods unit which able to cover market request
- Measurement period: Once a month

2. *Stock out Probability*

- Definition: Probability the happening running out of stock
- Measurement period: Once a month

3. *Orders ready to pick by customer*

- Definition : Percentage of order frequency ready taken consumer is divided with entirety order frequency total
- Measurement period: Once a month

4. *Number of visit to customer*

- Definition : How many times company pays a visit to end customer to perform visit directly
- Measurement period: Once a month

B. *Responsiveness*

1. *Delivery deadline (in yogyakarta)*

- Definition: grace period given by company to consumer in Java to take goods in Deling Asri since Delivery Order is published.
- Measurement period: Once a month

2. *Delivery deadline (*outside *yogyakarta)*

- Definition: grace period given by company to consumer outside Java to take goods in Deling Asri since Delivery Order is published.
- Measurement period: Once a month

- ***Return***

Scope return includes aspects and metrics like following:

A. *Reliability*

1. *Customer complaint*

- Definition : Number of consumer complains to the side of company
- Measurement period: Once a month

2. *Return rate from Costumer*

- Definition : Percentage of return defect unit to company
- Formula : $\frac{\left|\text{Amount of units returned}\right|}{\text{Amount of units received}} x100\%$ ……(13)
- Measurement period: Once a month

B. *Responsiveness*

1. *Product replacement time*

- Definition : Time which can be fulfilled company to change product returned by consumer
- Measurement period: Once a month

From result of gauging and normalization is got metric value like presented in Table 1 until Table 14.

Table 1. Calculation of Terminal Value Plan-reliability

Deliver	*Reliability*	100	0,875	87,5	100
	Responsiveness	100	0,125	12,5	
Return	*Reliability*	100	0,875	87,5	100
	Responsiveness	100	0,125	12,5	

By Using Tables 15, countable assessed performance supply chain in company Deling Asri like given in Table 16.

Table 16. Calculation of Value Performance Supply Chain Dheling Asri

	Total Aspect	weight	Performance
Plan	61,501	0,136	8,36
Source	74,03	0,065	4,81
Make	70,79	0,26	18,41
Deliver	100	0,502	50,2
Return	100	0,0349	3,49
		Total	85,27

From calculation performance value supply chain it is known that company performance value Dheling Asri enough heights. Factor make and deliver has a real contribution significant to performance supply chain. From measurement of direct it is got that factor deliver and return has highest score, where this thing shows till now delivery of goods and the relation of company with very good consumer. Action of refinement can be done by paying attention to some metric having low relative score like presented in Table 17.

Tables. 17. Metric-metric with Low Score

Aspect	No	Metric	Score
Plan	1	*Forecast inaccuracy*	45,88
	2	*Inventory level for finish product*	49,2
	3	*Number of trainee in PPC*	40
Source	4	*Fluctuation price frequency*	33,33
Make	5	*Yield*	32
	6	*Make Item Responsiveness*	40

Some alternative refinement for example with repairing forecasting method applied, refinement quotation or better documentation for product and or product which have been sent by will to consider easy in doing gauging which will come, refinement planning of production schedule and inventory, improvement of skill employee, construction of the relation with supplier, controller quality of feedstock and employee productivity and cuts short manufacturing lead time.

6. Conclusion

Supply chain performance measurement schemes using SCOR and AHP approach can use to knowing attainment level of company performance in managing the supply chain. SCOR scheme gives common reference in assessment of factor and criterion, but for the application of adapted to supply chain area which will be evaluated. Refinement of supply chain can be start from metric with low score value by maintains performance metric with high score. Measurement of performance periodically will assist the company in performance evaluation.

ABSTRACT

Single point turning tool is an important mechanical component that is prone to premature failure. Hence it is mandatory to continuously monitor the status of the tool tip during continuous machining. In this research work an attempt is made to compare the performance of back propagation algorithm (BPA) and the Radial Basis Function (RBF) in tool wear detection. The vibration signals acquired using microphone of a new tool and worn out tool are used for this comparison study. The results show Radial Basis Function identifies the fault more accurately than the BPA.

Keywords: *Radial Basis Function, back propagation training algorithm, microphone, tool wear, fault identification, vibration.*

1. INTRODUCTION

Vibration monitoring of the machine during the machining operation is one of the important signal measuring procedure for detecting the status of the tool wear [1]. Vibration signals of good and damaged tool are used for analysis. The need for detection of status of the tool wear has warranted research and development of efficient fault diagnosis and prognosis. Many analysis include fuzzy logic, multivariate statistical analysis artificial neural network etc. Since neural network is a non-linear dynamic system and capable of mapping non-linear functions, it is widely applied in the field of pattern recognition and classification [2]. There are many types of neural networks, among them, the back propagation network, which is a kind of feed forward multilayer networks, is the most popular network used in engineering applications. Although many improved versions for BPA have been developed to increase the speed of training and to avoid trapping into local minima, their effectiveness of solving problems are not promising [3]. The determination of a suitable architecture for the BPA such as the number of neurons in the hidden layer, is difficult. The radial basis function (RBF) network offers a new and more effective method for training [4]. Since it can avoid complicated calculations, the time required for training can be much faster than that of the BPA. It has the ability of fast convergence and is able to fix centres in the hidden layer during training [5]. An optimized architecture for the RBF network can be obtained. In this paper both, RBF and BPA are used to detect the status of the tool wear from the vibration data. From the results it is clear that, RBF network is more suitable for tool wear detection from vibration data when compared to that of BPA.

2. ARTIFICIAL NEURAL NETWORK

An artificial neural network (ANN) is an abstract simulation of a real nervous system that contains a collection of neuron units, communicating with each other via axon connections. Such a model bears a strong resemblance to axons and dendrites in a nervous system. Due to this self-organizing and adaptive nature, the model offers potentially a new parallel processing paradigm [6]. This model could be more robust and user-friendly than the traditional approaches.

ANN can be viewed as computing elements, simulating the structure and function of the biological neural network. These networks are expected to solve the problems, in a manner which is different from conventional mapping [7]. Neural networks are used to mimic the operational details of the human brain in a computer. Neural networks are made of artificial 'neurons', which are actually simplified versions of the natural neurons that occur in the human brain. It is hoped, that it would be possible to replicate some of the desirable features of the human brain by constructing networks that consist of a large number of neurons. A neural architecture comprises massively parallel adaptive elements with interconnection networks, which are structured hierarchically.

Artificial neural networks are computing elements which are based on the structure and function of the biological neurons. These networks have nodes or neurons which are described by difference or differential equations. The nodes are interconnected layer-wise or intra-connected among themselves. Each node in the successive layer receives the inner product of synaptic weights with the outputs of the nodes in the previous layer. The inner product is called the activation value. The activation value is passed through a non-linear function. When the vectors are binary or bipolar, hard-limiting non-linearity is used. When the vectors are analog, a squashed function is used. Some of the squashed functions are sigmoid (0 to 1), tanh (-1 to +1), Gaussian, logarithmic and exponential. The BPA is a supervised training method which uses the error in the output layer of the network. The error is used to update the weights of the network so as to reach the minimum of the objective function which is defined to be the summation of averaged mean squared errors between the desired outputs and the network outputs [8, 9]. The convergence rate of BPA is much slower when compared to other neural network algorithm [10].

3. RADIAL BASIS FUNCTION

The concept of distance measure is used to associate the input and output pattern values. Radial Basis Functions (RBFs) are capable of producing approximations to an unknown function 'f' from a set of input data. The approximation is produced by passing an input point through a set of basis functions, each of which contains one of the RBF centres, multiplying the result of each function by a coefficient and then summing them linearly [11]. The data have been trained using radial basis functions. The RBF learns 27 patterns during training and testing. Table 1 gives training and testing steps by RBF.

4. PREPARING THE TEST DATA

Cepstrum analysis is an important sound processing algorithm that separates high frequency noise from low frequency information.

Steps involved in converting vibration data into training input for RBF and BPA are given below:

1. Acquire vibration data using PCB 130 series microphone
2. Remove zeros which does not give any information.
3. Apply linear predictive analysis.
4. Apply fast fourier transform.
5. Apply log for the output in step 4.
6. Apply inverse fast fast fourier transform.
7. Apply levinson Durban equation.
8. Repeat step 3 to step 7 for every 10 samples of the data and average all values to finally get only 10 values.
9. Label the averaged patterns using the corresponding vb values.
10. Repeat step 9 for 27 different turning conditions.

Table 1: Radial Basis function

Training RBF
Step 1: Apply Radial Basis Function.for the cepstrum values obtained from the collected vibration data No. of Input = 10 No. of Patterns = 27 No. of Centre = 4 Calculate RBF as RBF = exp (-X) Calculate Matrix as G = RBF $A = G^T * G$ Calculate $B = A^{-1}$ Calculate $E = B * G^T$ Step 2: Calculate the Final Weight F = E * D Step 3: Store the Final Weights in a File.
Testing
Step 1: Obtain cepstrum values from the vibrational data Step 2: Calculate RBF as. RBF = exp (-X) Step 3: Calculate. Value = F * RBF Step 4: Classify the value based on the stipulated threshold to decide the status of the tool wear.

5. EXPERIMENTAL SETUP FOR COLLECTING TOOL WEAR DATA

The experimental setup includes collection of sound from the turning machine in different turning conditions. The sound were collected using PCB 130 series of Array Microphones coupled with ICP sensor powered preamps and are thus referred to as ICP microphones. The 130 series provide an extremely cost effective method for large channel count sound pressure measurements. Figure 1 to 9 shows some of the sound files associated with different turning conditions. Table 2 shows the cepstrum values for the Figures 1 to 9. Out of 27 sound wave files only 9 wave files are shown as sample. Steps given in section 4 have been used to create the data in Table 2.

6. RESULTS AND DISCUSSIONS.

The effects of number of centre (Table 3) in identifying normal and abnormal tool wear are shown in Figures 10 to 13.Table 3 gives the comparison performance of RBF and BPA.

7. CONCLUSIONS

Microphone has been used to record vibration sound during turning operation with normal condition and completely worn out tool. Sampling was done at 44khz. The data have been converted into cepstrum values to be used as inputs for RBF and BPA. The RBF with 3 centers is able to correctly identify tool which is about to reach

the non acceptable wear limit. However BPA does not show improvements in fault identification more than 70%. The future work can be focused on vibration data for many turning machines. and the suitability of RBF can be further analyzed.

Table 3: Performance of radial basis function centres

S.No	No. of centres	Percentage identification for averaged patterns in each category
1	1	0 %
2	2	25%
3	3	75%
4	4	100 %

ABSTRACT

The increasing number of cellular provider companies causes customer disloyalty phenomena. This phenomena is a challenge for the cellular provider companies to defend and also to increase the number of their customers. The purpose of this paper is to identify factors that can influence customer loyalty and develop conceptual model of customer loyalty. This paper will focus on the loyalty of customers that have changed their number to other providers.

Based on literature studies, interviews and observations, loyalty model is influenced by the changing risk, product quality, promotional program, and environmental factors. Data is collected using a non probability sampling method, questionnaires and interviews. The concept of Structural Equation Modeling (SEM) is used as a basic model. Software LISREL 8.70 is used for the data processing. The results of the research are all of the factors can influence customer loyalty, with promotions and environmental factors being more dominant than the others.

Keywords:
Celullar provider, customer loyalty, SEM, LISREL.

1. INTRODUCTION

The rapid progress of communication technology today makes globalization (politics, social, economy and culture) spread all over the world. Indonesia as the biggest archipelago cannot resist this effect. Thousands of islands that spread from Sabang to Merauke are united because the residents can do the synergy works, this is possible because of the development of communication technology on cellular phone [10]. This technology development is very important because one percent progress in one area will increase economic development by three percent [14].

The appearance of so many cellular phone provider in Indonesia such as PT. Telekomunikasi Indonesia with the trade name Flexi, PT. Excelcomindo Pratama (XL) with trade name Bebas and Jempol, PT. Telkomsel with the trade name Hallo (postpaid), Simpati (prepaid) and AS (prepaid), PT. Indosat with the trade name Mentari and IM3, PT. Mobile-8 Telecom with the trade name Mobile-8, PT. Bakrie Telecom with the trade name Esia, Hutchison Charoen Pokphand Telecom with the trade name Three (3), makes the Indonesian communication business are very crowded.

In this tight competition, the companies need strong customer loyalty for survive, even if today many customers are only loyal to the price [9]. The Vice President of PT. Telkomsel of Java and Bali area. Agus Witjaksana said, "*Today, the cheap starter pack sales may increase the 13% growth rate on cellular phone industry. But the irony is the growth rate is threatened by the increase of churn rate that could reach 5%*". The same phenomena also happen on Indosat. According to the Indosat vice president cellular for east region Herry Moelyanto, one time use of the starter pack user occurs in about 11 % of their customer. He said, "*Churn rate percentage is never more than 6%, but since the Indosat customer number are increase, so does the churn rate*" [1].

The customer will be loyal as long as they gain financial benefit [7]. Besides that, about more than 100 million cellular phone users have more than one card [6]. This matter will definitely affect customer loyalty to the cellular provider, because the number of loyal customer will bring a significant effect to the company.

Base on the phenomenon, the paper is written to discover the factors that may affect customer loyalty and then create its conceptual model. Whole description on the paper is focused on customer who has changed their prepaid card from provider X in Bandung.

2. CUSTOMER LOYALTY

In the business context, customer loyalty as customer willingness to patron on one company for a long time and recommend their products to friend or other [3]. Customer loyalty is a deep commitment to repurchase a certain product or service consistently in the future, hard to accept other influence and difficult to change [8]. In this case, it is concluded that the loyal consumer cannot be defined from their purchase quantity, but from how often they repurchase and recommend other people to buy the product [5]. As Grifin (2003) in [3] said, that the loyal customers have these characteristics: repurchase regularly, buy from other variants of product or services from the same line, recommends product and shows consistency to the opponent products.

The final objective on successful companies is to create a relation with their customer and build strong loyalties [15]. To have loyal customers, the companies should understand at least four loyalty principles. They are customer value, customer characteristics, switching barrier, and customer satisfaction (Budi in [4]).

a. Customer value is about the customer perception from cost and benefit calculation result which will they obtain. If the customer perception of one provider has a bigger benefit than its cost, so it is called customer value.
b. Customer characteristics are regarded to the cultural background and customer experience that affect consumer characteristics.
c. Switching barrier is a barrier to prevent customer which move to other products.
d. Customer satisfaction explained that a satisfied customer is not really loyal but a loyal consumer is definitely satisfied.

According to the survey on Indonesian Customer Loyalty Index which was held by MARS and SWA [13], the five factors that create customer loyalty are:

a. Customer value is the customer perception which compares between the cost that they should take and the benefit.
b. Switching barrier are the difficulties or effort or cost that customer should take if they switch to other products.
c. Customer characteristics are the consumer character when using a product.
d. Customer satisfaction is the customer experience when using a contact with the product that they use.
e. Competitive environment is about the competition of different brands on one product.

The customer loyalty measurement is influenced by the four dimensions: word of mouth communication, purchase intention, price sensitivity and complaining behavior [15].

The factor that influence on customer loyalties, they are: the expense needed to switch to other products or services, the similar quality, quantity or services from the alternative products or services, the difference price risk from the switch of products or services and the changes of satisfaction level that can be obtained from a new brand compared to their old brand [2].

Based on the explanation above, the paper are uses: changing risk, product quality, promotional programs, and environmental factors for the research.

3. METHOD

This research is using secondary data (by interviews the provider X supervisor) and primary data (by questioner distribution, including the introduction and fixed questioners). From interviews and the introduction questioner distributions, we have found the dimensional identifications that can be used on customer loyalty measurement. The introduction questioners are distributed to 36 samples and the repaid results are used as construct variables on the fixed questioner. The Fix questioner is using Likert scale (1 to 5; where 1 = very disagree and 5 = very agree). This questioner is used to observe which factors that may affect customer loyalty, so the results can be applied to make the conceptual model.

Data is collected using a non probability sampling method (by accidental sampling). The samples are people who are on the survey location, and represent the sample criteria. The sample size is determined from the number of variance and covariance on observed variables [11]. Based on the explanation, so the sample size for the research is:

1. Required Data :
   - Observed variable: p = 18 item.
   - Variance and covariance on observed variables: p (p+1)/2 = 18 (18+1)/2 = 171.
     So, the numbers of data are 171.
2. Estimated parameters :
   - Regression coefficient (lambda = L): 18-4 = 14. Minus 4 because on the indicator standard, there is one L which set as 1 for standardization
   - Error variance (delta = d) = 18
   - Latent variable = 4
   - Variance and covariance : 4 (4+1) = 10
     So, the parameters are 14 + 18+ 10 = 42

From the calculation above, the minimal sample size for the research is:

Sample size = number of data – number of parameters
= 171-42 = 129

On data distribution, the research is using 273 samples. The populations are respondents who live in rural and city area in Bandung. They have used products from provider X, and are not using them anymore. The respondent consists of 131 males and 142 females with the distribution shows on Table 1 below.

Table 1: Sample distribution.

Segmentation	Frequency
Age	
<15 years old	2.93%
15-29 years old	79.12%
30-44 years old	16.21%
45-59 years old	1.83%
> 60 years old	0 .00 %
Level of education	
junior Hig sch	1.83%
Senior High Sch	60.07%
Diploma	12.09%
Bachelor	21.25%
Master	1.83%
others	2.93%
Income per month	
< Rp 500.000	27.63%
Rp 500.000 - Rp 999.999	26.85%
Rp 1.000.000 - Rp1.999.999	29.96%
Rp2.000.000 - Rp2.999.999	9.73%
>Rp 3.000.000	5.84%
Job	
Civil servant (PNS)	5.56%
Public Sector	0.74%
Private Sector	31.11%
Entrepreneur	12.59%
Collage Student	32.22%
others	17.78%
Term of Using	
< 1 year	3.30%
1-1.9 years	25.27%
2-2.9 years	26.47%
3-3.9 years	35.90%
>4 years	8.79%

4. IDENTIFICATION OF LOYALTY MEASUREMENT MODEL

Based on literature studies, interviews provider X and observations, it can be concluded that the customer loyalty measurement dimension (y) that will be used on the research are:

1. Changing risk.
   The dimension is a joint from two lovelock factors, they are: the amount of changing cost and changing risk. The factor are joint, because both of them are latent variable that can be explained by one observed variable, which is a variable that can be defined from several items, like: starter pack, cost to change phone number, phone tariff and SMS tariff. All of the item will create the different cost as a risk by changing providers. F1 dimension are measured by four observed variable:
   - Starter pack price (p1).
   - Expenses to confirm a new phone number (p2).
   - Phone tariff (p3).
   - SMS tariff (p4).

   H1: Changing risk has significant positive effects on customer loyalty at provider X.
2. The same quality with alternative products.
   The dimension is a provider quality measurement, and it can be divided into two groups, they are: network or signal quality and service quality. On the paper, services are means the customer service and operator assistances. Observed variables are:
   - Signal quality (p5).
   - Frequency of network trouble (p6).
   - Effort to contact the call centre (p7).
   - Customer service office location (p8).
   - Operator or customer service hospitality (p9).
   - Operator or customer service understanding to the customer problem (p10).
   - Understandable information which is given by the operator or customer service to solve customer problem (p11).
   - Operator or customer service speed, when solving the customer problem (p12).
   - Understandable instruction for user which written on starter pack (p13).

   Variable p7 to p13 are used to measure the quality of operator and customer service assistance. The variable can be determined, only from the customer who had contact operator or customer service. Therefore, the research is using two loyalty measurement models. One model involves operator and customer services assistance quality, and the other one is not.
   H2: The same quality with alternative products has significant positive effects on customer loyalty at provider X.
3. Promotional program.
   The dimension is used to measure the affect of promotional program to customers. The dimension is added because many providers offer the different kind of promotion to rises their sales rate. The dimension consists of several variables:
   - Media promotion (magazine, newspaper, radio, television, etc) (p14).
   - Program promotion (p15).
   - Condition and term applied (p16).
   - Promotional program frequency (p17).

   H3: Promotional program has significant positive effects on customer loyalty at provider X.
4. Environmental condition.
   Environmental condition is added on the research, since there is the different tariff when customers contact their family or friends at the same provider or the different one. This is can affect their tendency to choose the same provider with their family and friends.
   H4: Environmental condition has significant positive effects on customer loyalty at provider X.

Figure 1 and 2 below shows the measurement model on customer loyalty at provider X.

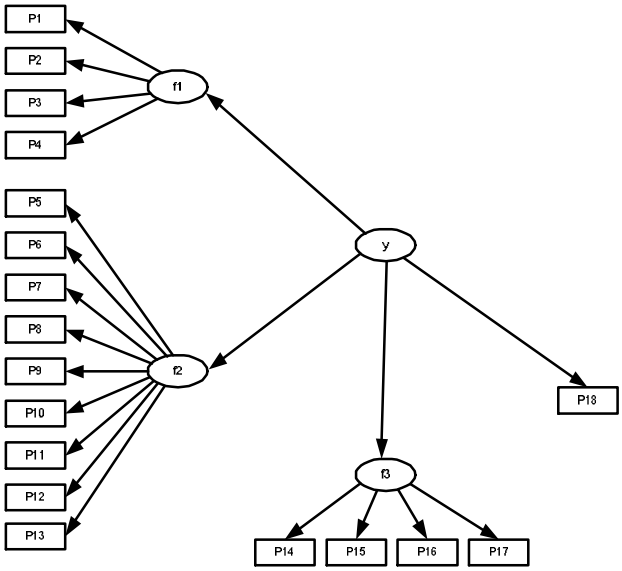

Figure 1: Measurement model on customer loyalty at provider X, by paying attention to the customer satisfaction factor on customer service and operator assistance.

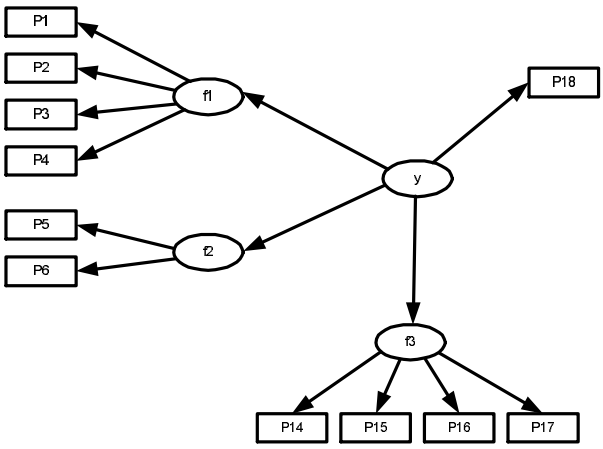

Figure 2: Measurement model on customer loyalty at provider X, without paying attention to the customer satisfaction factor on customer service and operator assistance.

5. RESULTS AND ANALYSIS

Data processing is done by using LISREL 8.70, and the analysis includes:

- Data fit test for the measurement models.
- Validity and reliability test for the measurement models.
- Hypothetical test analysis
- Customer segmentation analysis which includes: the influence of age, education, income and type of work to the dominant factors that may affect on customer loyalty.

5.1. Data Fit Test

Data fit measure for the measurement model are consists of three measures, they are: absolute-fit measures, incremental-fit measures, and parsimonious-fit measures also CN which represents the data fit size. Normal , p-value, GFI and RMSEA represents absolute-fit measures, NNFI represent incremental-fit measures and CFI represent parsimonious-fit measures. Table 2 shows the fit value size for model 1 and 2. Table 2 above indicates that the data has a good fit to the model.

Table 2: Parameter fit test for Model 1 and 2.

	absolute-fit measures				incremental -fit measures	parsimonious -fit measures	
	Normal	p-value	GFI	RMSEA	NNFI	CFI	CN
MODEL 1							
y	2.39	0.302	0.99	0.034	0.99	1	680.5
f1	1.67	0.43	1	0	1.01	1	954.72
f2	11.94	0.61	0.99	0	1	1	423.43
f3	1.14	0.57	1	0	1.02	1	1408.92
MODEL 2							
y	6.8	0.34	0.99	0.022	0.99	1	642.36
f1	1.39	0.24	1	0.038	0.99	1	1295.38
f3	3	0.22	0.99	0.043	0.99	1	863.27

5.2. Validity and Reliability Test

Model validity can be measured from the size of t-value and standard loading factor (SLF). Observed variable has a significant effect to the factor if t-value is greater than 1.96 [12]. Table 3 and 4 shows t-value and CR from the model 1 and 2. Construct reliability (CR) value indicates the reliability level from measurement model.

In Table 3 and 4 below can be shown that there is only one observed variable which not valid, it is P2. CR values for both model, are between 0.6 until 0.99. It means that the model has a good reliability level.

Table 3: Reliability and validity test for Model 1.

	t-value	SLF	residual	CR
Measurement model (f1)				
p1	3.36	0.25	0.94

f2	5.92	0.35	0.48	
f3	6.02	0.35	0.88	
p18	3.76	0.23	0.95	0.62

5.3. Hypothetical Test Analysis

Based on the test above, it can be concluded that hypothetical H1, H2, H3 and H4 are proven. It indicates that t-value for the all latent variables are >1.96, which means that changing risk, product quality, promotional program, and environmental factors have significant positive effects on customer loyalty at provider X.

5.4. Customer Segmentation Analysis

One thing that can be used for making a product marketing strategy is to give more attention to the dominant factors which affects on the customer loyalty. By the data processing results, we may obtain the latent variable values from f1, f2, f3, and p18. Based on the latent score, it can be known that the most dominant factors which influence on customer loyalty are the environmental factor (54.6%) and promotional program (37.93%) (They are shown on figure 3).

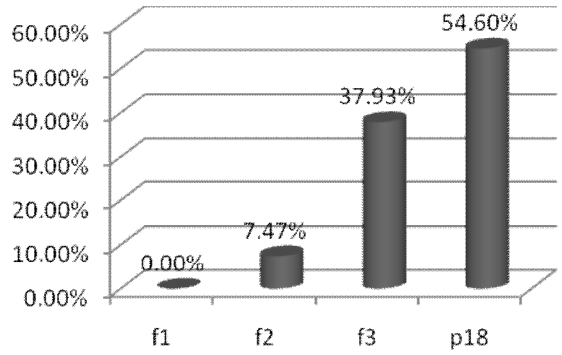

Figure 3: The influence of each factor on customer loyalty.

Environmental factor are affecting customer loyalty, because of the customer needs to contact their family or close relatives has a higher frequency compared to others. When the phone or SMS tariff across provider tends to be more expensive, this is of course raises the tendency of mobile phone users to select the same provider with their family or close relatives. The company also should give more attention to the promotional program. To increase the competitiveness, a provider must continue to innovate with their programs that offer promotion to attract more customers. For example, give cheap tariff promotions to customers who contact the phone numbers from other providers, of course with the terms and conditions that do not charge customers.

In this paper, the respondent is segmented into several groups based on the age, education, income and the type of their work, to see their influences to the dominant factors that may affect on customer loyalty. The segmentation result is shown in Figure 4.

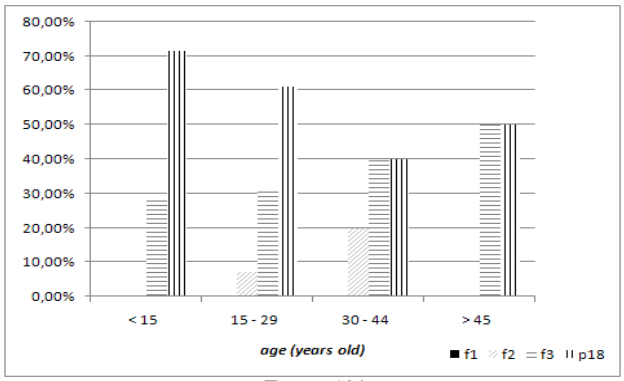

Figure 4(a)

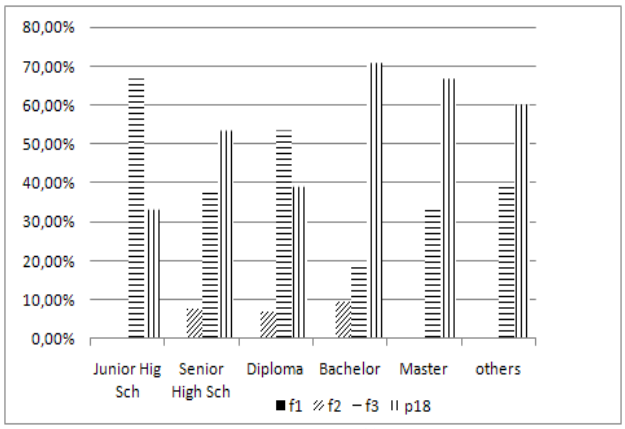

Figure 4(b)

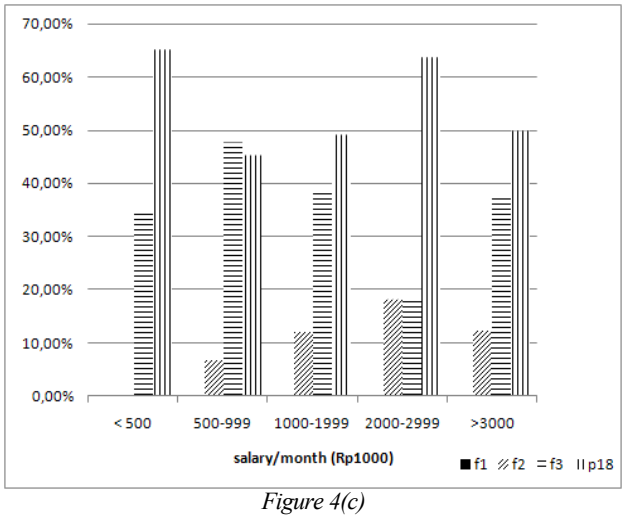

Figure 4(c)

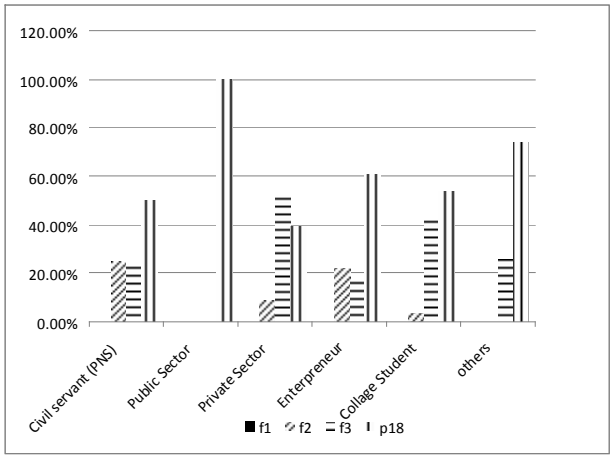

Figure 4(d)

Figure 4: The influence of each factor on customer loyalty, based on the segmentation of: (a) the age (b) level of education (c) income and (d) the type of work.

Figure 4 above shows that the most dominant factor which affect on customer loyalty for:

1. The age segment is environmental factor.
2. Level of education segment (for Junior High School and Diploma Program) is promotional program.
3. Income segment is environmental factor. But for the Rp2.000.000-Rp2.999.000 group, product quality and promotional program factors have the same influence on customer loyalty.
4. The type of work segment for work civil servants are product quality and promotional programs factors. Whereas for the private sector employee, promotional programs are more influence than the environmental factor.

From the segmentation results, it can be seen that the customer who 30-44 years old, working with civil servants or self-employed and have earnings above Rp2.000.000 give more attention to the product quality factor. So, it can be concluded that the customer whose profession involves associating with many people, also gives more attention to the signal and service quality factors to ensure reliable communication. Basically, quality is one of the key on customer loyalty towards the product.

6. CONCLUSION

Based on the previous discussion, it can be concluded that the customer loyalty are influenced by the changing risk, product quality, promotional program, and environmental factors. Overall, the factor provides a positive influence on customer loyalty for prepaid card products from provider X. The most dominant factor is environment by the 54.6%. It means that the customer tends to be more loyal if their close relatives or family using the same provider with them. So, the company may arrange the right marketing strategy by combine promotional program and environmental factors. For example: using the cheap tariff promotions to the customer who call to the different numbers even on different providers. For the next research is suggested to focus on marketing strategy for every customer segment based on their characteristic.

ACKNOWLEDGMENT

The author would like give acknowledge to Dr. Ir. Kadarsah Suryadi and the staff on Management and Industrial Engineering at Bandung Institute of Technology (ITB) for the suggestion that are useful for the improvement and progress of the research. Also to the provider X supervisor who had been interviewed, thank you for provide very useful information about customer loyalty of the prepaid card products.

ABSTRACT

Due to the increasing pressure to enhance production and reduce cost, asset management has become a top priority in the mining company. Equipment replacement problem become an important issue and should be optimized especially for fleet of dump trucks and excavators. Until now, a systematic approach for making replacement decision has not been applied to the industry so that the company does not know the most economical age of their equipments. Minimum life cycle cost namely optimal replacement age determination is crucial. In this study, the determination of optimal replacement age of the fleets is conducted based on optimal replacement interval method. The method uses costs per hour to determine the optimal replacement. From this study, a simple guideline to develop replacement strategy is obtained.

Keywords : *optimal replacement age, life cycle cost, cost per hour, optimal replacement interval methodology*

1. INTRODUCTION

Fierce competition coupled by the global economical crisis has forced every company to have a more competitive advantage than its competitors. Every company has to optimize their operational activities in order to reach the best operational performance level. A right decision making is also crucial in the investment decision because it involves a large sum of money. A decision that a company mostly facing is whether to replace the current asset, to continue using it after overhauling, or to replace the asset with the new ones.

Every asset used, whether to manufacture the goods, to transport them, or to provide services, should be replaced after a certain period of time. Replacement occurs when an asset fails and cannot be repaired, when the cost of keeping an asset operational is prohibitive, or when technology changes makes the asset inferior or obsolete [1]. The point on a replacement decision is to determine when the best time for an asset or equipment to better be replaced. The approach used for this replacement decision is usually depends on the economical optimization perspective that is an asset should be replaced at the minimal point of its life cycle cost [2].

In mining industry, asset management is crucial to determine whether the company will have more profit or the opposite. However, managing and maintaining of mining machinery, especially in underground applications, are a difficult task. In addition, the costs associated with running and maintaining a trackless fleet are significant. The costs increased resulting from older machines are not well understood or quantified, and hence accumulate a large proportion of hidden as well as direct costs. A number of reasons causes the problems, namely:

- The complex nature of the machines where numerous and various components exist and are interrelated
- The way and the type of information are recorded
- The nature of the mining cycle does not easily allow one to determine the impact of an unreliable machine.

2 THEORITICAL BASIS

2.1 Replacement Concepts

One of the biggest decisions in a company is deciding when an asset or equipment has to be replaced. As an optimization problem, the decision depends on expectations regarding how the existing and new equipment operating costs change over time and on expectations regarding future capital cost and salvages value [2]. The replacement itself is affected by few certain factors such as the decreasing performance of the equipment, the change in working environment, technology, and financial condition.

As the equipment aging, the operational costs (spare part cost, maintenance cost, and fuel cost) increases while at the same time its resale value decreases. At some moments, the operational cost will become extremely high that it will be profitable to replace that old equipment with the new one. In basic model of capital replacement, the economical age can be determined using the minimal equivalent cost flow of the equipment. The implicit assumption of this model is a machine will be replaced at the end of its economic life by a perpetual sequence of identical machines [5].

Basically, equipment's age can be divided into three, which are [6]:

- Physical life is the interval of time, typically measured in years or hours, between the purchase and the moment when the equipment ceases to operate.
- Useful life is the total time in which the equipment operates, continuously or intermittently.
- Economic life is the interval of time between the purchase and the point at which the equipment's total equivalent annual cost (EAC) curve reaches minimum.

Modern replacement theory is based on discounted cash flow. Discounting future transactions means that the value of money is changing with time. Based on this simple concept, all the costs and profit flows occur in different times should be converted into value at a time and then summed [7]. Replacement problem can be solved in a profit-maximizing or cost-minimizing framework. In a cost minimizing framework, minimum cost can be found with net present value method or the annual equivalent cost [5].

The EAC method is commonly applied to solve the replacement problem when the equipment economical age is determined based on the smallest EAC value [3]. Basically EAC comprises of two components; the capital cost (investment cost and the salvage value) and the operational cost of the equipment. In mining industry, there are some other components of cost that should also be considered. For instance cost that caused by the decreasing availability of the equipment [4]. This cost is also known as the availability cost.

2.2 Theory of Vehicle Replacement

Theory of vehicle replacement says that vehicles should be replaced when the sum of ownership and operating costs is at its lowest historical [8]. The total cost curve is different for every type of vehicles. This variability is caused by differences in the design and engineering of the vehicles, differences in operating environments, the quality of care the vehicle receives, and other factors. As a result, most organizations develop recommended replacement cycles for a class or type of vehicles, which will approximate the optimal replacement cycle for most of the units in that particular class. This is most often accomplished in an informal manner such as based on discussions with mechanics and drivers or a comparison of replacement cycles with peer organizations.

Some organizations, however, employ an empirical approach. This approach, known as life-cycle cost analysis (LCA), involves modeling the stream of costs associated with acquiring, maintaining, and disposing of vehicles over various replacement cycles, and then determining the cycle with the lowest cost [8]. To determine the minimum cost cycle, EAC of each cycle is calculated and compared. The EAC of a vehicle is a uniform dollar amount expressed in today's dollars that someone could pay to produce the net present value of a stream of future costs associated with owning and operating the asset.

2.3 Optimal Replacement Interval Method

The optimal replacement interval method uses cost per hour to determine the optimal replacement age. The method incorporates the fundamentals from the theory of vehicle replacement that uses the lifecycle costs analysis; meaning that the analysis is driven by the capital and the running cost parameters. On this method, moreover, the discounting factors multiplication and the future cash flow concept are applied just like in the equivalent annuity method. The steps to use the optimal replacement interval method are as followed (see Figure 1):

- Determine, by summing, the input parameters such as the operational cost, availability cost, and the capital cost for a certain period of time, for instance: each 1000 hour interval.
- Apply discounting factor in order to account for the risk and cost of money for future cash. Discounting factor is applied based on the annual utilization.
- Cumulate the costs to adjust fluctuating data. This cumulative cost represents the lifecycle cost of the equipment until that stage in its life.
- Divide the cumulative costs by the number of hours accumulated (1000, 2000, 3000, ...). The results are cost per hour, which represents the average cost over the life of the equipment.
- Compare with the alternate life options. The lowest cost per hour is the optimal replacement interval.

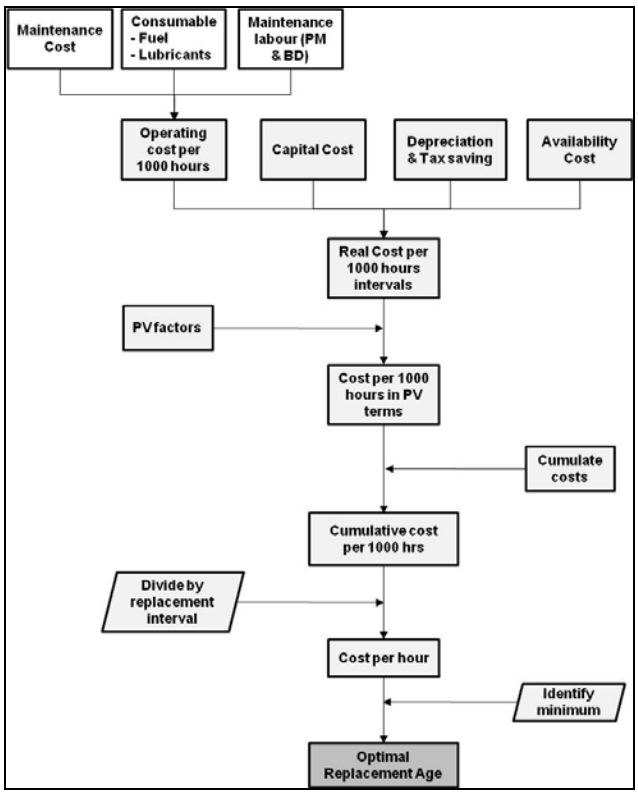

Figure 1: Optimal Replacement Interval Method

3. CASE STUDY

PT P is one of the biggest mining contractor companies in Indonesia that mines coal and gold. This company is often facing some complex replacement problems. Alas, no systematical approach applied there. The company just simply applies depreciation method. This raises doubts to the validity of the replacement strategy applied there. A more comprehensive and thorough method have to be implemented.

In this study case, the replacement age is calculated using the optimal replacement interval method developed by Sandvik Mining [4]. The method uses the cost per hour basis and it is developed based on the life cycle cost analysis concept, theory of vehicle replacement, cost per ton trends, and equivalent annuity. The input parameters are classed in the interval of 1000 hours. The availability cost is counted using two types of approaches, namely the productivity approach and the rental rate approach. Then, the replacement age obtained from these two approaches is compared.

This case is focused on Dump Truck type HD 7855 and the Excavator type PC 3000; both are the main production equipments for the company. The replacement age calculation is done to 8 units of dump truck and 2 units of excavator. The counting example can be seen in Table 2.

4. RESULTS and ANALYSIS

Of those 8 units of dump truck and 2 excavators, various results have been obtained. For each unit, two different replacement ages have been successfully obtained. The results are differentiated by availability cost value. The first age is obtained from the availability cost with the productivity approach, while the second age is obtained from the availability cost with rental rate approach. The best results are displayed on the table 1.

Table 1: Optimal Replacement Age (in hours)

Jenis Peralatan	Unit	Productivity	Rental Rate
Dump Truck	DT738	33000	33000
	DT741	30000	30000
	DT742	38000	38000
	DT746	38000	38000
	DT749	34000	38000
	DT750	39000	39000
	DT751	39000	39000
	DT752	34000	34000
Excavator	EX 705	30000	40000
	EX 707	27000	40000

The average replacement age for the dump truck is 35.625 hours using the productivity approach and 36.125 hours using rental rate approach. From the table above, it can be seen that the replacement age obtained with either productivity or rental rate approach are the same, except for unit DT 749.

For the excavator, the replacement age using the productivity and the rental rate approaches are different. The gap are due to the significant difference in availability cost value, after everything has been counted using the productivity and the rental rate approach. As seen from Figure 2, with the same downtime hours, the availability cost value obtained will be so much bigger if it is multiplied with the productivity. Using productivity approach, the value of availability cost has a large percentage at the cost per hour so that changes occur on the downtime hours will have a large impact on the replacement age.

To show how changing in cost per hour influences the age of the equipment, see the example followed. Figure 3 shows the moving of cost per hour of one the dump trucks. It shows clearly that at the interval of 1000 - 7000 hours, the cost per hour is still very high since at that time the capital cost is still highly dominated in a large number. After 15.000 hours, the cost per hour will get flatter that make it difficult to differentiate the value if it is seen only from the graph. This circumstance is due to decreasing in capital cost per hour traded off with the increasing in operational cost (the increment in cost per hour is extremely small). The availability cost percentage is started to show up and getting up, but the impact on the cost per hour is still very small. For the excavator, the availability cost percentage in cost per hour is bigger compared with that of the dump truck. The availability cost percentage also increases along with the increasing age. At the interval of 37.000 - 40.000 hours, the contribution of availability cost to cost per hour increases until it reaches the same level as the contribution of operational cost.

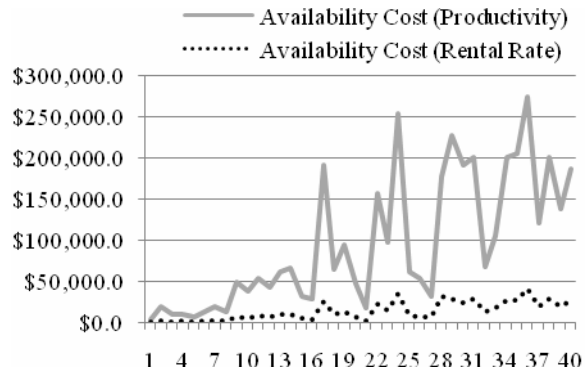

Figure 2: Excavator Availability Cost Comparison

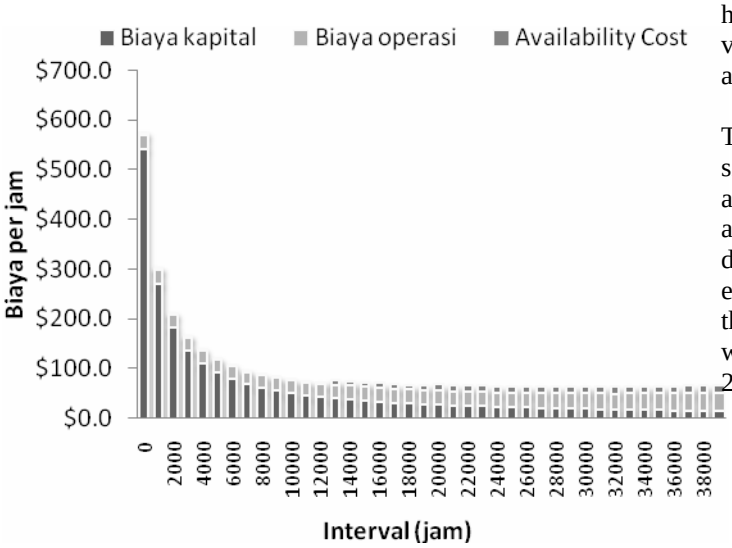

Figure 3: Cost per Hour

Next is to know the profit gained by applying the new strategy and the company's old replacement strategy. The comparison between the old replacement strategy and the new one, DT 752 is taken as example, is 40.000 hours to 34.000 hours. Figure 4 shows the cumulative cost for each replacement strategy. That cumulative cost is the total cost spent if the equipment is replaced every 40.000 hours and every 34.000 hours. This cumulative cost is simulated for long term, which is after the company has replaced the dump truck for few times. The total saving obtained by the company in a 40-year period is $894.225,9.

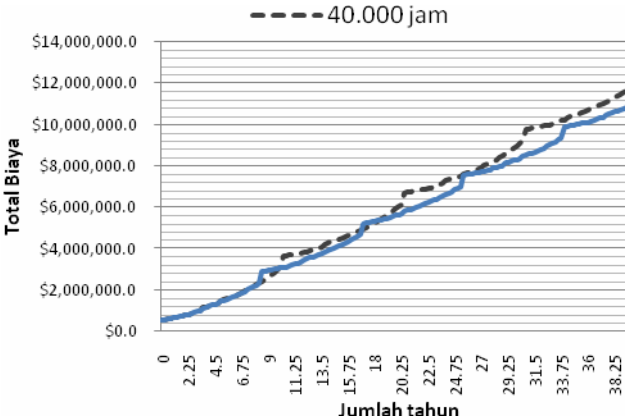

Figure 4: Cumulative Cost for Each Replacement Strategy

5. CONCLUSION

Based on the calculation, the optimal replacement age is 35.875 hours for the dump truck and 34.250 hours for the excavator. The availability cost that counted using two approaches namely the productivity and the rental rate gives different replacement age for the excavator. This happens because the excavator has a higher productivity value than the dump truck so that the availability cost affects the cost per hour.

The cost per hour of dump truck is affected so much by the size of the capital cost and the operational cost. The availability cost is around 40-50% for the operational cost and 20-45% for the capital cost. The replacement age depends so much on the changing of these two cost elements. While for the excavator, the availability cost and the operational cost is more dominating than the capital cost with a percentage of 38-40% for the operational cost and 27-36% for the availability cost.

Tabel 2 : Cost per Hour Calculation

Interval (Hours)	Operating Cost	Capital Cost	Availibility Cost		Depreciation	Tax	After-Tax		NPC		Cumulative		Cost Per Hour

Abstract

Employees are valuable investment in a company. However, they are somewhat assumed as expenses of the company. As part of the company resources, employees might be the biggest asset of a company, which is sometime neglected. This study attempts to determine the benefit produced by each employee based on human capital competency of a major electrical company in Indonesia. This is done by comparing the Return of Investment (ROI) for current condition and after using the human capital model. Sales, expenses and investment per month as employee's salary are used as factor or criteria to calculate the current ROI values. To modeling the human capital investment, pair wise comparison method is used to get the weight of each criteria of the human capital competency. The criteria were determined by doing benchmark with top management of the company. There are eleven criteria that may affect employee's performance. Afterward, the current ROI values are compared with that of the human capital model. Based on the human capital model, this study shows that almost 70% of the employees should receive higher benefit, while 30% should receive lower benefit compared with that of the current condition.

Keywords: *Human Capital, Competency, ROI*

1. INRODUCTION

Human Capital is one of new concept that has gained a tremendous amount of attention from both academic and practitioner communities. Human Capital is professional tool on Human Resources System which is used for strategy development in reporting, tracking, and organizational performance impact. Human Capital Concept considers anything that is done by employees will have effect to the company. Human Capital concept will give a significant effect if the company treat the employees not as a cost but as an investment. This study attempts to determine the benefit produced by each employee based on human capital competency of a major electrical company in Indonesia.

2. METHODS

Human Resources Management is a systems design in a formal organization to ensure that human is used as tools to achieve organization goal effectively and efficiently. Beforehand, human resources is defined as a process of recruitment and selection of prospectus employee. Once they become employees, then they will be trained and organized in accordance with the goals and the needs of the company. In its development, human resources were influenced by factors including: Law and Politics, Economic, and Cultural.

In some companies, human capital is used to find out talent, skills and knowledge of workers. Human capital is also concentrating on how the ability or capability can be developed and used to create productivity business performance goals and long-term strategy. Therefore, the measurement of human capital focused on the analysis development to measure and report the human capital management strategy with intervence whether the progress was in line with employee ability.

Human capital defined as "an approach to people management that treats it as a high-level strategic issue and seeks systematically to analyze, measure and evaluate how people policies and practices create value" [1]. Besides the knowledge and experience, this definition also includes dimensions of motivation and social interaction [1]. Qualitative and quantitative approaches can provide indications for the evaluation, assessment/evaluation, and control aspects of the human capital company.

Human Capital Management (HCM) focus on the acquisition, analysis, and reporting of data that directly inform strategy and value of the investment on the corporate level and Frontline Management [2]. HCM always focused on the purpose and objective measurement, not only measurement itself. Definition or other characteristics of HCM is they use metric approach, where employees seen as the asset and the emphasis on competitive advantage through strategy of investment of these assets, (i.e., with the retention and employee engagement, talent management, and learning and development programs).

There are four basic human capital management goals [2]:

1. The influence of human for the business and their contribution to shareholder value.
2. Shows that Human Resources practices can create added value in a period of time, such as Return on Investment (ROI).
3. Provide guidance for the future of human resource and business strategy.
4. Provide estimation and data that can used for planning and making strategy to improve effectiveness of a human organization.

The four fundamental objective of HCM are to [2]:

- Determine the impact of people on business and their contribution to shareholder value.
- Demonstrate that HR practice produce value for money in terms.
- Provide guidance for future HR and business strategy
- Provide diagnostic and predictive data that will inform strategies and practices designed to improve the effectiveness of people management in organization.

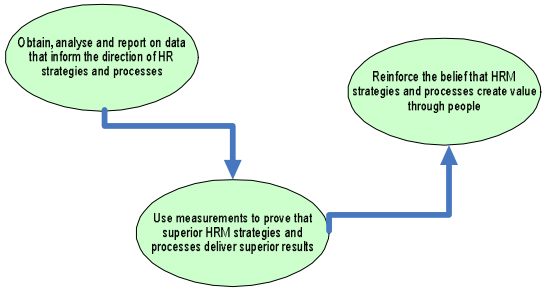

Figure 1: Specific Aims of HCM

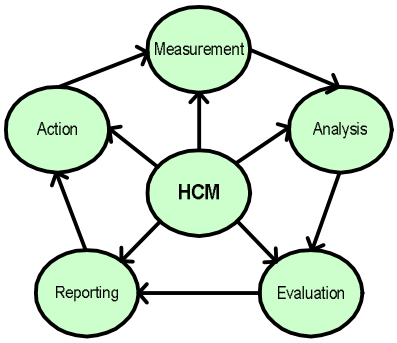

Figure 2: The Process of HCM (1)

Figure 3 and 4 below illustrate the HCM journey in which the key stages are measurement, reporting, drawing conclusion from data and action [1].

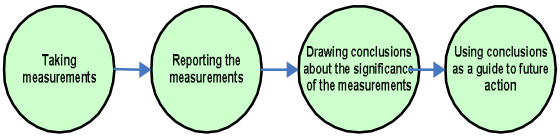

Figure 3: The Process of HCM (2)

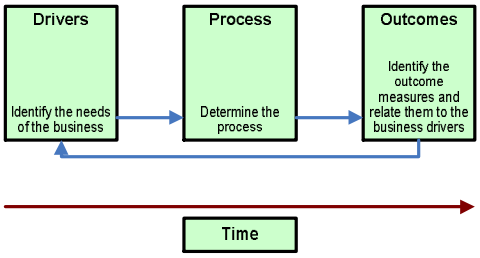

Picture 4: The Focus of HCM

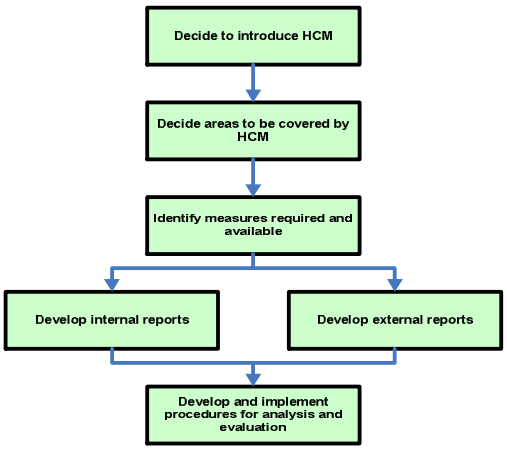

Figure 5: The Steps to Develop HCM

Pair wise comparison is a kind of divide-and-conquer relative order (ranking) of a group of items. This is often used as part of a process of assigning weights to criteria in design concept development. Using AHP in solving a decision problem involves four step [3] :

Step 1: Setting up the decision hierarchy by breaking down the decision problem into hierarchy of interrelated decision elements

Step 2: Colleting input data by paiwise comparisons of decision elements

Step 3: Using "Eigenvalue" Method to estimate the relative weights of decision elements

Step 4: Aggregating the relative weights of decision elements to arrive at a set of ratings for the decision alternative

Table 1: Pairwise Comparison Scale

Intensity of Importance	Definition
1	Equal importance of both elements
3	Weak importance of one element over another
5	Essential or strong importance of one element over another
7	Demonstrated importance of one element over another
9	Absolute importance of one element over another
2, 4, 6, 8	Intermediate values between two adjacent judgements

Results of pairwise comparison will processed to determine weight of each criteria.

$$MG = \sqrt[n]{\sum_{1=1}^{n} x_i} \quad (1)$$

where:
MG = *Geometric Mean*
X_i = Atribut i
n = total atribut

Normalization process is done by making the proportion Geometric mean. Formulation used in the process of normalization is

$$P_i = \frac{MGi}{\sum_{i=1}^{n} MGi} \quad (2)$$

where:
P_i = Proportion atribut– i.
MG_i = Geometric mean atribut - i.
N = Total atribut.

The weight of each alternative against the criteria specified with the formulation as follows:

$$V_i = \sum_{i=1}^{n} P_i x W_i \quad (3)$$

where:
P_i = Proportion atribut – i.
V_i = Weight atribut – i.
W_i = Wheight of Criteria – i.

In pairwise comparison, we have to check the consistency. For example, when in comparison A> B and B> C, then logically it should be A> C. Formula to measure the consistency in AHP can be written as follow:

$$CI = \frac{\lambda_{max}(n-1)}{n} \quad (4)$$

where:
λ_{max} = max eigen value
n = Matriks size.

$$CR = \frac{CI}{RI} \quad (5)$$

where:
CI = Consistency Index
RI = Ratio Index

Table 2: Index Ratio

N	1	2	3	4	5	6	7	8	9	10
RI	0	0	0.58	0.9	1.12	1.24	1.32	1.41	1.45	1.49

3. RESULT AND DISCUSSIONS

This analysis is done to one of Multinational Company in Electrical Solution for Utillity & Insdustry in Indonesia. Most of their employees were work as sales for their product. They have target to be as market leader in future.

Table 3: Turn Over 2007

Emp. Nr	Termination Date	Reason of Leaving	Year of Service
D0240	31-Jan-07	Move to another company	0.84
T0280	31-Jan-07	Terminated	17.93
T0333	31-Jan-07	Resigns based on personal reason	0.17

D0235	31-Dec-07	Terminated	1.87
D0269	31-Dec-07	Terminated	0.08

As a trading company they depend on their employees to achieve their target. However, in 2007, the company faced the problem of high turn over. This problem has caused difficulty for the company in reaching the target.

In this case, the reason of employee resignation can be classified into 3 groups:

- Group 1 : *terminated (contract is expired)*
- Group 2 : *based on personal reason*
- Group 3 : *move to another company*

The ratio of employees to retirement can be calculated as below:

$$\overline{Ri} = \frac{\sum Xi}{N} \qquad (6)$$

where:

R = Ratio of retirement for Group i
Xi = Number of employees who submit a resignation group i
N = Number of employees who submit a resignation

R group 1 = $\frac{\sum Xi}{N}$
= 7/26
= 26,9%

R group 2 = $\frac{\sum Xi}{N}$
= 7/26
= 26,9%

R group 3 = $\frac{\sum Xi}{N}$
= 12/26
= 46.2%

From the analysis, it found that the reasons for employee to resign because most of them get a job other company. In other words, they are moving to other company hoping to get better reward. From twelve employees who moved to other company, six people or 50% of them clearly stated that they get a higher salary.

Below is salary data in 2007 for eleven employees who are salesperson.

1. A : USD 29,200 / year
2. B : USD 28,000 / year
3. C : USD 12,600 / year
4. D : USD 8,500 / year
5. E : USD 8,600 / year
6. F : USD 17,700 / year
7. G : USD 11,700 / year
8. H : USD 29,900 / year
9. I : USD 11,000 / year
10. J : USD 5,800 / year
11. K : USD 12,500 / year

Table 4 shows sales target of the eleven employees for 2007.

Table 4: Sales Target for 2007

Employee	Target 2007 (USD)	Achievement 2007
A	800,000	50%
B	20,000,000	80%
C	665,000	80%
D	1,000,000	80%
E	2,750,000	93,8%
F	15,000,000	74.0%
G	3,000,000	93.8%
H	3,000,000	93.8%
I	3,500,000	82.0%
J	Not assign yet	73.1%
K	2,750,000	73.1%

While the cost of the company issued in the form of facilities to the employees can be seen in Table 5.

Table 5: Facilites Obtained

Facilities	Manager	Staf
Jamsostek	4.89% x *gross salary*	4.89% x *gross salary*
Outpatient	Rp. 7,000,000 / year	Rp. 5,000,000year
Health Insurance	Rp. 4,100,000 / year	Rp. 2,580,000 / year
Car	Rp. 5,000,000 / month	Rp. 3,000,000 / month
THR	1 x *gross salary*	1 x *gross salary*

With the assumption of average gross margin of 20%, then the ROI can be calculated as:

$$ROI = \frac{Margin - Investment - Cost}{Investment - Cost} \qquad (7)$$

From data, 90% of employees get ROI > 1. It means that the employees give added value to the Company. However, the ROI is not absolute value; we still have to consider other factors of their performance. In this case, there are 10 other factors which affect sales performances, which are:

1. Education
2. Work Experience
3. Communication Skill
4. Product Knowledge
5. Initiative
6. Administrative Skill
7. Human relationship skill
8. Job description
9. Leadership
10. Thinking challence

By doing pairwise comparison, the weight of each criterion was found as follow:

Education = 1.59%
Work Experience = 10.99%
Communication Skill = 9.47%
Product Knowledge = 15.15%

Initiative = 6.37 %
Administrative Skill = 2.6%
Human relationship skill = 9.77%
Job description = 3.04%
Leadership = 7.17%
Thinking challenge = 10.7%
% Target Achievement = 23.16%

Therefore, the Human Capital Model can be written as follow:

$$Y = 1.59\% X_1 + 10.99\% X_2 + 9.47\% X_3 + 15.15\% X_4 + 6.37\% X_5 + 2.6\% X_6 + 9.77\% X_7 + 3.04\% X_8 + 7.17\% X_9 + 10.7\% X_{10} + 23.16\% X_{11}$$

4. CONCLUSIONS

From paiwise comparison result, it can be found the Human Capital Model. From the model, we can recalculate new ROI with assumption that maximum total cost and investment for each employee is 7.3% from total sales of each employee. By comparing the current ROI and the new ROI, we can see that 70% of the employees should have better benefit, and 30% of the employee have lower ROI compared with the model. Keep in mind that the investment which is calculated in the model is based on the maximum amount of investment, means that employees can get benefit and other costs but will not exceed that maximum amount, because the company has a policy that maximum amount of benefits for the employees is 7.3% of value sales.

ABSTRACT

Wafer Stick Department of a company located in Bekasi, Indonesia, produces 18 kinds of cookies daily to serve both domestic and foreign markets. All these products had the same production processes, namely warehousing of raw materials, mixing, drying, and packing. This department had its own production plan and would like to know whether the existing plan was a good plan or not. The purpose of this paper is to propose linear programming as a technique that can be used to formulate daily production plan for the Wafer Stick Department. In this paper, we compare the maximum profit obtained by the linear programming to that of the existing plan. The comparison was based on a five week schedule.
Observations to the plant, especially at the Wafer Stick Department, interviews with the production planner of the Wafer Stick Department as well as the Marketing Department, and the collection of the required data were used to characterize parameters of the linear programming, namely profit contribution of each product, machine capacity, technological coefficients representing resource usage for producing each type of product in each machine, and other necessary requirements. We used WinQSB to solve our linear programming model which resulted in a feasible and optimal solution with a total profit for the five weeks 2.47 billion rupiahs and this is 0.73 billion rupiahs higher than the use of the existing production schedule.

Keywords: *production planning, linear programming, wafer stick*

1. INTRODUCTION

A cookie or biscuit producing company located in Bekasi, Indonesia, produces various kinds of cookies to meet both domestic and foreign markets. One of the departments responsible for the production was the Wafer Stick Department which produced 18 kinds of cookies. All products or cookies had the same production process, starting from warehousing of raw materials, mixing, drying, and packing. The drying process by oven was the major process in that production. The existing method used to schedule forecasted demands was based on historical production schedules. The Production Planner in the Wafer Stick Department would like to have an alternative schedule that could be used as comparison to the existing practice. Therefore, the objective of this paper is to propose the use of linear programming for scheduling in that department.
The production planning as shown in figure 1 began with demand forecasting by the Marketing Department. The forecasted demand would be given to production planner responsible for production planning and control (PPC). In this regard, the production planner would coordinate with warehousing concerning the available stock or inventory in the warehouse. The implementation of the production and material plan would be done by the production department. The finished goods would be kept in the warehouse.

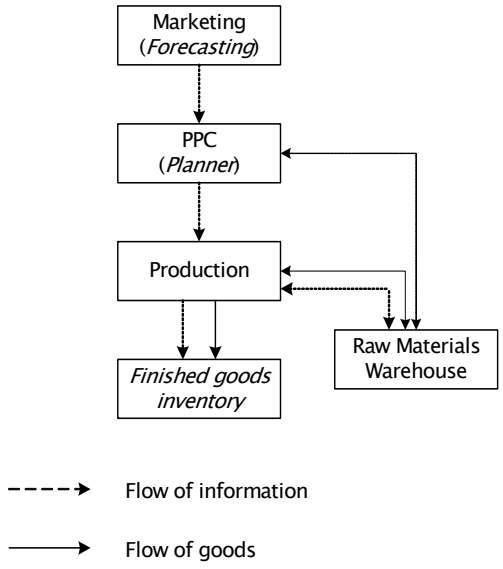

Figure 1. Production planning process

ISSN 114-1284

2. METHODOLOGY

We propose a linear programming model [2], consisting of decision variables, objective function, and constraints. We conducted direct observations to the plant, interviews with the Production Planner, and collected the required data from the Wafer Stick Department to characterize the linear programming model. In this paper, we only make the model for five weeks as agreed with the Production Planner.
The general form of the linear programming model would use the following notations: Z for total profit, X_{ij} for the number of product i to be produced in week j, d_i for demand of product i in one month, r_j for machine capacity in week j, a_j for maximum work-in-process (WIP) in week j, and b_{ij} for time required to make product i at week j (in minutes).

a. Objective function

The objective function was to maximize total profit (Z) by producing product i at week j (X_{ij}) with each product had its profit contribution of C_{ij}. In this regard, we consider 18 products (i = 1, 2, …, 18) being produced in five weeks (j = 1, 2, 3, 4, 5).

$$Z = \sum_{i=1}^{n}\sum_{j=1}^{m} C_{ij} X_{ij} \quad (1)$$

b. Constraints

* Machine capacity

$$\sum_{i=1}^{n} b_{ij} \sum_{i=1}^{n} X_{ij} \le r_j \quad (2)$$

* Forecasted demand from Marketing

$$\sum_{j=1}^{m} X_{ij} \le d_i \quad (3)$$

* *Secondary process*

$$\sum_{j=1}^{m} X_{ij} \le a_{ij} \quad (4)$$

* Non-negativity

$$X_{ij} \ge 0 \quad (5)$$

3. RESULTS

Based on our agreement with the Production Planner, we would use initials for all products. Table 1 shows profit per cart for each product.

Table 1. Profit for each product

Product initial	Size	Profit/cart (rupiahs)
X1	36 x 60 grams	6,340
X2	120 x 33 grams	8,500
X3	36 x 60 grams	6,500
X4	24 x 60 grams	6,340
X5	24 x 120 grams	4,500
X6	24 x 60 grams	6,000
X7	24 x 120 grams	6,200
X8	6 x 750 grams	15,500
X9	12 x 350 grams	10,800
X10	12 x 350 grams	5,800
X11	12 x 350 grams	16,800
X12	6 x 750 grams	16,800
X13	24 x 150 grams	11,200
X14	24 x 150 grams	9,200
X15	12 x 400 grams	4,100
X16	12 x 400 grams	1,100
X17	12 x 400 grams	12,900
X18	12 x 400 grams	20,500

Total forecasted demands for the overall five weeks provided by the Marketing Department are shown in Table 2. Times required to produce each cart of each product is shown in Table 3. Effective machine capacity for the five weeks is shown in Table 4.

Table 2. Forecasted demands

Product initial	Forecasted demand (carts)

Using WinQSB [1] we solve the linear programming (LP) model and the solution is summarized in Table 6. As shown in Table 7, this schedule is able to generate a total profit of 2.474 billion rupiahs. The company's production schedule is shown in Table 8 which generated a total profit of 1.737 billion rupiahs as shown in Table 9. Therefore, the company's schedule had 736.8 million rupiahs less than the proposed schedule using linear programming. This shows that linear programming could be used by the company to optimize its schedules in the future, provided that they would be willing to learn and use it.

X18	1,192	20,500	24,436,000
Total			1,737,264,200

The use of the existing capacity through the existing production schedule is shown in Table 10 which shows total minutes used in each week. The use of the existing capacity through the use of LP production schedule is shown in Table 11.

The comparison of idle or unused capacity for each week by the company's production schedule to LP's schedule is shown in Table 10. It indicates that LP's schedule resulted in greater efficiency of machine capacity use.

Table 10. Comparison of idle machine capacity

Week	Company's schedule	LP's schedule
1	29,561	0
2	9,645	5
3	24,376	1
4	9,912	0
5	7,318	0
Total	80,632	6

4. DISCUSSION

The use of linear programming (LP) resulted in different product mix compared to the product mix of the schedule used by the company. The production planner could see and check that this alternative production schedule provided a higher total profit with less idle machine capacity. He/ she should be interested in using this model for future production scheduling in his/her department.

We were also interested in looking at the sensitivity analysis of the LP solution to see possible changes of certain parameters which do not change the optimal solution that had been obtained. In this regard, we took a look at the values of the decision variables or right-hand-side and machine capacity. From the WinQSB output, we can show the sensitivity of the decision variables indicating minimum and maximum values for each product. This is summarized in Table 11. The notation "M" indicates a very big number. Table 12 shows sensitivity of total machine capacity in each week.

Table 11. Sensitivity of values of decision variables (units)

Product	Minimum	Maximum
X1	29,744	36,032
X2	18,983	30,254

2	237,787	345,250
3	305,912	331,250
4	239,846	294,736
5	146,348	202,407

5. CONCLUSIONS

We conclude that linear programming (LP) could actually be used by the Production Planner to solve his/her scheduling task since it can help him/her to find the optimal schedule which would generate the maximum profit with respect to constraints. In addition, the optimal schedule would use existing resources, such as machine capacity, efficiently in which idle capacity would be minimized. We believe that through learning and exercises in mathematical formulation and the use of an optimization software, production planner would eventually get used to it. For large problem involving larger variables and constraints, we thought that a more powerful software than WinQSB would be needed.

Managing Soft Innovation Process under Uncertainty

Gembong Baskoro

Universitas Widya Kartika
Surabaya, Indonesia
email: gembong_baskoro@yahoo.com, gbaskoro@widyakartika.ac.id

ABSTRACT

It is not surprisingly for manufacturers to survive in the business they usually increase the market share of new products. This means manufacturers must increase the speed of innovation. Ideally, the innovation in the new products is done by manufacturers to compensate the previous product weaknesses related to classical business pressures. The classical business pressures are (1) Time, (2) Profitability, (3) Functionality, and (4) Quality/Reliability. In contrast, Baskoro indicated that new products delivered to the market may contain immature (1) Technology and/or (2) Production process [1]. Consequently, if a product is developed in immature Technology and/or Production process then the product potential of having hard reliability problems. Hard reliability problems or specification violation is a situation where a product is not able to meet the explicit technical product specifications. This paper argues that hard reliability problems closely related to hard innovation concept. However, Brombacher et al. indicated that these type of products, high-end consumer electronics, instead of having hard reliability problems they also suffer soft reliability problems [2]. Soft reliability problems or customer expectation deficiencies is a situation where, instead of meeting with the explicit product specifications, a customer explicitly complains about the lack of functionality of the product. This paper also argues that soft reliability problems closely related to soft innovation concept. If soft reliability problems appear in the product, customer will always dissatisfy with the product. Therefore, Baskoro argue that a strategy to secure customer satisfaction is to deliver a new product that having less (or free) soft reliability problems [1]. This can be done by managing the innovation process. For this reason the objective of this paper is to explore a method of soft innovation process that ensure a new product having less, if not free, soft reliability problems.

Keywords
Innovation, Hard Innovation, Soft Innovation, Hard reliability problems, Soft Reliability Problems

1. INTRODUCTION

It is not surprisingly that in today global market, in highly competitive business environment, only some companies can survive while others must leave from the playground because their products simply cannot compete. Among other reasons that make a product fails to survive in the market is due to "Product Reliability". Therefore, in order to survive in the business, companies must consider a number of potentially conflicting issues including but not limited to "Product Reliability" in their product development strategy [2]. It is familiar as the business pressures that contain the issues of Time, Profitability, Functionality, and Quality and Reliability.

- Time: does the product reach the market at the required moment in time?
- Profitability: is the difference between product cost and product sales price adequate?
- Functionality: is the product able to fulfill its intended function(s)?
- Quality and Reliability: does the product fulfill customer requirements at 'all' customers, not only at the moment of purchasing but also during operational life of the product?

However, Baskoro shows that although companies have understood the business pressure they are not secured yet in the business [1]. For example: to shorten Time-to-Market of their product in order to arrive in the market earlier. The expectation is that by arriving in the market earlier they have the privilege to dominate the market and dictate the market price. For this reason, companies can sometimes take risks to deliver a product to the market with less mature technology. Consequently, it is not surprise if this product may contain (reliability) problems and the problems can show up after real testing (use) by customers. In practice, there is reported an increasing number of complaints by customer, suspected by reliability problems, on specifically product performance. Sometimes the problems are unknown; there is no specific root causes related to the problems. On this situation, it is possible that the problems are caused either/both by (1) the product, and/or (2) the user. Many researches have tried to elaborate research on the product, and seldom on the

user. Therefore, this paper interests on dealing with (soft) reliability problems especially where problems are caused by extreme users.

2. RELIABILITY PROBLEM

Recently, manufacturers and/or customers should aware on product reliability instead of only product quality. For customers, on the one hand, reliability indicates that customers will get their right to at least replacement of the product when the product has problem during the warranty time. For manufacturers, on the other hand, reliability associates to the company reputation e.g. brand image especially if the problem on the product can cause injury and or damage. Therefore, problems occur in a product during warranty period are problems that related to product reliability. This is also known as "reliability problems".

Reliability problems can be categorized into (1) Hard reliability problems, and (2) Soft reliability problems [2].

1. Hard Reliability Problems (Specification Violation)
A situation when a product is not able to meet the explicit written technical product specifications.

2. Soft Reliability Problems (Customer Expectation Deficiencies)
A situation where, in spite of meeting with the written explicit product specifications, a customer will explicitly complains about the lack of functionality on the product.

The above classification of reliability problems is covered in the class of "non-inventive" reliability problems. However, there are also known the "inventive" reliability problems that are new both for manufacturers and users [1].

A problem in a product is recognized as an "inventive" problem if this problem is new and never seen before by the manufacturer. On the contrary, "non-inventive" problem is a problem that has been experienced before.

3. FACTS-FIGURES OF (SOFT) RELIABILITY PROBLEMS

Although reliability problems are identified during the use of the product, reasonably they are initiated during product development process. When the reliability problems occur and slip through the production process but do not reach the customer, the manufacturer has a chance to recall the products with reasonable cost consequences. However, if reliability problems occur after customers use the product, then the manufacturer will face several consequences. The consequences can be that the manufacturer risks customer dissatisfaction, legal warranty claims, and/or lawsuits. Usually, especially in Europe, if the reliability problems have potential consequences for customer safety, the manufacturer is urged by law to recall the product from the market (Directive 1999/34/EC). In real cases, if the problems can potentially create a bad reputation and damage the company image, then the company will take extreme actions by voluntarily recalling the product from the market and/or applying a product replacement program. In practice, this situation can happen to any company including but not limited to the established companies in the field. Baskoro showed several cases related to this situation that took place in Europe [1]. For example as reported by local news paper on August 2007 that a France branded car withdrew 80,000 cars from Germany and 10,500 cars from Denmark. In Indonesia several related cases have been publicly reported by customer in news paper related to reliability problems especially for consumer electronic products. For example on July 2007, a local news paper publishes a complaint from customer regarding reliability problems shortly after purchase of a Netherlands branded Hand Phone. On October 2007, the same news paper reported reliability problems (short product life) experienced by customer on a Finland branded Hand Phone.

These facts show that companies are willing to take extreme actions by voluntarily recalling the product from the market to protect the customer from being dissatisfied with the product and to secure potential business in the future. Mainly, the cost to settle the problems can be extremely high if manufacturers fail to prevent the problems earlier.

4. INNOVATION CONCEPT

There are many ways to distinguish the innovation concept. In general, Chesbrough classified innovation into a. Close Innovation and, b. Open Innovation [3]. This classification is based point of view on the influence of other to the innovation process. This method of classification enables to accelerate the process of innovation without spending too much cost. However, in practice this method especially open innovation requires open culture from the actors because they need to adapt and adopt something new from outside their organization. It simply not easy for organizations that still maintain a traditional culture and way of thinking on everything must be invented here.

4.1. Closed Innovation

It is a traditional concept of innovation where all (re)sources for the innovation process come within the organization. The close innovation, figure 1, is considered as old paradigm and tends to be ineffective for today business environment [3]. It is indicated by high investment spending to setup internal research and development division. However, in the past the concept of close

innovation has proved to deliver innovative products to customer. It was possible because time to market was not the main concern and the competition tends to be relatively small.

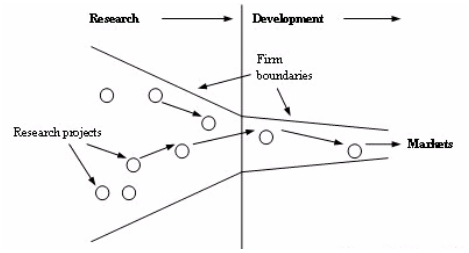

Figure 1. Close Innovation [Chesbrough 2003]

4.2. Open Innovation

The open innovation is a way of thinking that the process of innovation can be done not just by the company itself. There are two important things to be considered i.e. 1. Idea, and 2. Market. In this concept, the source and target of both idea and market is not limited to internal and or external sources. Open innovation, figure 2, can combine both internal and external ideas to advance the innovation [3]. Similarly, the result of innovation can be marketed to existing or new market opportunity even from outside company business channels. The main consideration is to efficiently and effectively generate value.

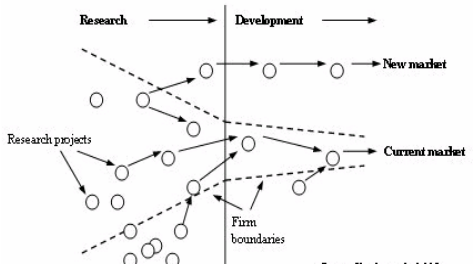

Figure 2. Open Innovation [Chesbrough 2003]

4.3. Hard Innovation

Hard innovation is an innovation process that focuses on the technology and functionality of a product. Hard innovation can be distinguished easily by the improvement or betterment made in a product. Hard innovation can be categorized into 1. Radical, and 2. Incremental Innovation. It is called radical if the innovation is totally changed the technology and or total replacement of the concept. Therefore it requires capability to do exploration of new technology. On the other hand, it is called incremental innovation if the innovation made is only partial. It is simply as step by step improvement on the product. Therefore, it is more or less the exploitation of the existing technology.

Hard innovation requires strong technology and resources capability. The sources can be within the organization (Close) or outside organization (open). Therefore, the capability to build up internal competence is a key success factor on hard innovation.

4.4. Soft Innovation

Soft innovation is an innovation focusing on the concept, system, procedure, etc. other than the hard factors. Therefore, investment requires in soft innovation is considered affordable. It can be done by any organizations so long they want to do it. The source of soft innovation may be come form outside organization (open) or within the organization (close).

5. DISCUSSION

The concept of Innovation therefore can be simplified into a matrix that consists of four quadrants as in Figure 3.

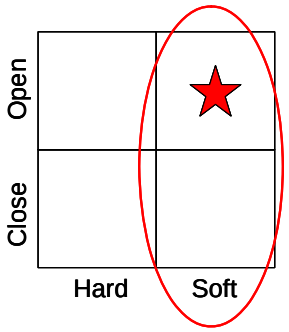

Figure 3. Matrix of Innovation

This diagram is a matrix that connects Open/Close Innovation versus Hard/Soft Innovation. It is shown from the matrix that a company can have innovation concept in between the quadrants. The star in figure 3 indicates that the innovation concept is soft and open innovation. This indicates that the innovation will be focused on the soft aspect and the idea can come within or from other organization. The matrix is considered acceptable for a company that has medium financial and resource strength but it has an ambition to go forward.

The reasoning of becoming a star is that an organization must keep moving regardless their capability to explore knowledge, either by performing radical or incremental innovation. Therefore, rather than making a lot of investment for building up the knowledge and its resources, the company can still go

forward with the innovation process on the soft side with limited resources.

This paper considers that in today uncertain economic downturn. Organization should consider seriously adopting the concept of soft and open innovation. The reason is that in the difficult situation, rather than seizing hard innovation process that will impact to the morale of organization, it is a better to keep the activity of the organization going on. One choice is that organization can focus to soft innovation process. However, to ensure the efficiency and effectiveness it is good to adopt idea and disseminate results outside organization by adopting open innovation concept.

ANALYSIS ON AUTOMOTIVE COMPONENTS INDUSTRY CAPABILITIES BY USING *SHINDAN SHI* MODEL AS AN EFFORT TO INCREASE THE SME_S PRODUCTIVITY

H a f i d[1]

[1]*Metal Industrial Industies Development Centre (MIDC), Ministry of Industry Indonesia*
Jl. Sangkuriang No. 12 Bandung 40135, Tel : (022) 2503171, Fax : (022) 2503978
Email : hafidochan@yahoo.com

ABSTRACT

This research is an analysis on automotive components industry capabilities by using Shindan Shi model as an effort to increase the SME_S productivity. The Shindan model adopted from Japan is a model which can be used to diagnose industries by using comprehensive management analysis to improve company performance. The variables of capabilities to be observed are : (1) 5S/5R/5K, (2) production quality, (3) accounting and book keeping, (4) human resource, and (5) organization management. The results of this research are expected to be able to contributed to the efforts of improving quality, productivity and competitiveness in global market of automotive industrial business. The results of this research carried out in Bandung area, in which involved 9 (nine) automotive components of SMEs, can define the following capability classifications : 1 company on class I (growth level), 5 companies on class II (potential level), and 3 companies on class III (autonomous level). By using the same method, the case study may also be implemented for other SMEs in other areas. For example of diagnosis in PT. W, with covers : (1) SWOT analysis, (2) increased CNC machine efficiency was more than 80%, (3) has decreased the average reject ratio of BCM KF 150 T Deluxe to be 5%, (3) 5S activities in machining center to be better. The results of this research are expected to be able to contributed to the efforts of improving quality, productivity and competitiveness in global market of automotive industrial business.

Keywords : *Shindan shi, automotive components, capabilities, SMEs, productivity*

1. INTRODUCTION

SMEs has an important and strategic role in national economy system, due to: (1) a very large number of business units (record about 3.4 millions), (2) absorbing many labors (in 2006 for 8.7 million people), (3) a relatively submissive creditor in cash return, (4) quite high SMEs endurance in confronting many fluctuations (monetary crisis in 1997). Thus, we may say that SMEs is economy spine with continuously proven contribution for more than 50% PDB.

Based on the SMEs study result in Indonesia conducted by Prof. Urata from Japan in 2000, he found 4 (four) SMEs's primary weaknesses, they are : (1) lack of production technology knowledge and quality control, (2) limited capability on marketing, (3) limited human resources for enhancing the quality of human resources, (4) lack of knowledge on financial accounting administration.

Now, in West Java there are approximately 200 automotive components industry needing supports in improving Quality (Q), Cost (C), Delivery time (D), Engineering (E), Management (M) and Technology (T). As efforts to strengthen Automotive Supporting Industries (ASI) in order to have competitiveness in global market, it is necessary to implement Shindan Shi system through "Accompaniment" and direct consulting in form of analysis and diagnosis of issues that SMEs confronts with.

This research methodology by using the method case study the implementation of model Shindan Shi system on selected automotive components industry in Bandung with identification purpose of : (1) SMEs's automotive component conditions and (2) gradual analysis of automotive components industry capability using Shindan Shi as efforts to increase SMEs productivity.

Whereas, expected benefits from this research are that it may be model program for development of automotive components industry in Bandung in particular and in general for SMEs in Indonesia to improve quality, productivity and companies' competitive excellence in global market.

2. METHODOLOGIES RESEARCH

The sequence of this research steps can be seen in Figure 1. And then do this : (1) the steps of solving problems in automotive components industry capabilities, (2) the steps of solving problems for the test of validity, reliabilities and sufficiency of data and (3) the steps of solving problems Shindan Shi model. For example the implementation of Shindan Shi model does at PT. W-21 that the representing one of the automotive component producer in Bandung.

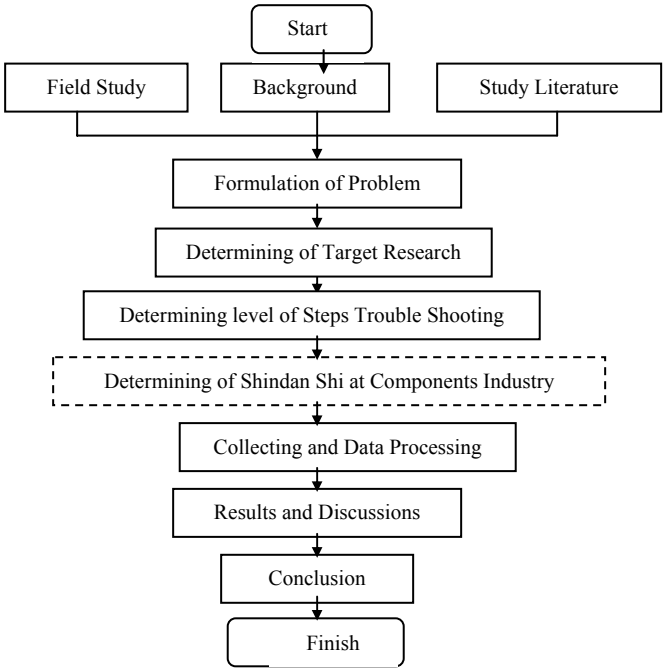

Figure 1. Flow chart of methodologies research

The methodologies research steps of automotive components industry capabilities shall be as follows :

1. Capabilities level :

   Which one to be criterion or parameter assessment of automotive components capabilities industry is show more clear at Table 1. For analysis quantitatively in this research is used by scale of Likert.

Table 1. Automotive components industry of SMEs parameter

No	Variable	Variable sub
1	5S/5R/5K	- Clearing up (X_1) - Tidying up (X_2) - Cleaning (X_3) - Standardizing (X_4) - Training and Discipline (X_5)
2	Production quality	- Reject ratio/NG (X_6)
3	Accounting and book keeping	- Book keeping (X_7) - Jurnal and ledger (X_8) - Balance Sheet and Income Statement (X_9) - NPWP (X_{10})
4	Human resources	- Total of labour (X_{11}) - Labour qualification (X_{12})
5	Organization Management	- Organization chart (X_{13}) - Vision and mission (X_{14}) - Vision mission implementation (X_{15}) - Corporate planning (X_{16})

2. The Parameter value

   a. 5S/5K/5R

      The Assessment 5S/5K/5R is classified to be 5 level with score that is as follows :

      5 = Very good, 4 = Good, 3 = Enough, 2 = Less, 1 = Very Less.

   b. Production quality

      For the assessment of production quality (Q) is used a reference based on rejection rate level that accepted by customer. Rejected level is calculated by calculate the average of total product (unit) that reject in specified period compared to the amount of product which is made in connection period. For the reject level (% NG) is divided to be 2 fields, that is : casting and machining/pressing. The Assessment of Production quality (Q) is classified to be 5 reject level (% NG) that is with the following score :

      - Level of reject casting : 5 = Very good (NG≤1), 4 = Good (1<NG≤3), 3 = Enough (3<NG≤5), 2 = Less(5<NG≤10), 1 = Very less (NG>10).
      - Reject machining/pressing Level : 5 = Very good (NG≤5), 4 = Good (5<NG≤10), 3 = Enough (10<NG≤20), 2 = Less (20<NG≤30), 1 = Very less (NG> 0).

   c. Accounting and book keeping

      The Assessment of Accounting and Bookkeeping (C) is relied on equipment from book keeping company of pertinent. Each equipment of book keeping get the following score :

      - Book keeping (cash, sale, etc.) score = 40
      - Journal and ledger score = 20
      - Financial statement score = 20
      - NPWP score = 20

      Based on the score, is arranged the furthermore assessment :

      5 = Very good (C ≥ 90), 4 = Good (75 ≤ C < 90), 3 = Enough (60 ≤ C < 75), 2 = Less (40 ≤ C < 60), 1 = Very less (C < 40).

   d. Human Resources

      The Labor which is concerned in business that calculated by average per month. From the result of the average conducted assessment base on to 2 (two) condition, that is : (a) Total of labor and (b) labor qualification. The Assessment of human resources to be 5 group level, that is with the following score :

      a. Total of labor :
         - 100 s/d 199 peoples score = 25
         - 50 s/d 99 peoples score = 20
         - 20 s/d 49 peoples score = 15
         - 10 s/d 19 peoples score = 10
         - 1 s/d 9 peoples score = 5

      b. Labor qualification (taken away from by highest value) :
         - Man power (S1) score = 25
         - Man power (So) score = 20
         - Man power experience score = 10
         - Man power not experience score = 5

      Based on the score, performed by furthermore

assessment as follows :
5 = Very good (D ≥ 150), 4 = Good (100 ≤ D < 150), 3 = Enough (50 ≤ D < 100), 2 = Less (10 ≤ D < 50), 1 = Very less (< 10).

e. Organization Management
The assessment of management organization is classified to be 5 levels that are as follows :
5 = Very good, 4 = Good, 3 = Enough, 2 = Less, 1 = Very less.

3. The Assessment of capabilities
The multiplication result weight with the parameter value is point per parameter. As quite high of point obtained to be high will also level of technical capabilities of components industry. More clear level of capabilities calculated by like shown at Table 2

Table 2. Parameter/Criterion Assessment

No	Parameter/ Criterion Assessment	Weight (%)	Value	Weight x Value
1	P1	B1	N1	B1 x N1
2	P2	B2	N2	B2 x N2
3	P3	B3	N3	B3 x N3
4	P4	B4	N4	B4 x N4
5	P5	B5	N5	B5 x N5
		ΣnB = 100%	ΣnN =	ΣPn =
		Final Value		

Notes : P = Point from at every criterion or parameter, B = Specified weight (%),
ΣnB = 100 %, N = Value every parameter, ΣPn = Showing level of capabilities technical from automotive components industry of pertinent

4. The Final Value
The Final value is multiplication between the score that to be got multiplied with each weight. Based on the final value, is known by level of automotive components capabilities pertinent, with the following rules : (a) Class I (Growth Level) : if the final value point (NA) obtained 20 – 40, (b) Class II (Potential Level) : if the final value point (NA) obtained 40 – 60, (c) Class III (Autonomous Level) : if the final value point (NA) obtained > 60 %.

3. RESULTS AND DISCUSSIONS

Based on address list data in Office on DINAS Industry and Commerce West Java Province in Bandung there are around 15 automotive components SMEs. And then, after checked direct through field visit survey to the companies, with rule of the following conditions : (a) Had business legality (SIUP/TDI/IUI/TDP and NPWP), (b) Had run at least 2 years, (c) Still performed production activity, (d) Had business organizations, (e) Had financial reports, (f) Were available to share necessary information and data proven by written statement.

From the result of observation and interview with the companies, 9 (nine) "selected" companies were determined with review criteria including : (a) high interest from their Owners/Directors to be Shindan Shi models and (b) good improvement (kaizen) themes to be followed up by Shindan.

Every companies with Shindan Shi programs will be decided which quantitative targets should be achieved in 6 months. In the end period the guidance and consulting for diagnosing achievement will be evaluated in a workshop attended by managements from companies with the programs.

3.1 Determining Level of SMEs Automotive Components

On the basis of evaluation from check list of questioner identify potency business and automotive components industry capabilities, then writer determine level classification of SMEs automotive components like shown at Table 7 (appendix 1).

3.2 Level of Automotive Components Capabilities of SMEs in Bandung

Based on primary data to obtained from result of field survey to 9 SMEs automotive components in Bandung. And then by using rules as elaborated at Determination level of SMEs automotive components (Table 7), finally will be obtained by SMEs automotive components capabilities to the each companies, like shown at Table 3.

Table 3. The Level Automotive Components Capabilities of SMEs in Bandung

Companies	Classification Value					Final Value	Level		
	5S/5R/5K	Production Quality	Accounting and Book Keeping	Human Resources	Organization Management		I (Growth)	II (Potential)	III (Autonomous)
W-21	3	3	5	3	3	66	-	-	III
W-22	3	2	5	3	3	61	-	-	III
W-23	2	2	5	3	3	53	-	II	-
W-24	2	1	5	3	3	48	-	II	-
W-25	1	1	2	2	1	25	I	-	-
W-26	1	3	2	3	3	41	-	II	-
W-27	2	1	5	3	3	48	-	II	-
W-28	2	2	5	3	3	53	-	II	-
W-29	3	3	5	3	3	66	-	-	III
Total results of classified companies capabilities							1	5	3

3.3 Analysis on Automotive Components Capabilities of SMEs In Bandung

3.3.1 Analysis of 5S Capabilities

1. Clearing up
   To dispose unnecessary materials from workplace, to create more work scope and more space to move, without blocked materials that not used.
2. Tidying up
   To manage matter storage, with purpose to : (a) identify if any violations, (b) facilitate to easily take matters, and (c) to accelerate restore matters.
3. Cleaning
   To keep everything clean in workplace, with purpose to : (a) create work place to keep clean and quite, (b) create work place to comfortable, (c) prevent work completeness so that do not quickly broken.
4. Standardizing
   To keep workplace clearing up, tidying up, and clening with purpose to: (a) prevent decreased environment conditions from 3S, (b) Maintain habit of 3S.
5. Training and Dicipline
   To accustom to following procedures properly and precisely, with purpose to : (a) Control "visual control" in workplace, (b) maintain care in workplace, (c) to prevent decreased condition 5S.

5S method is used to minimize waste in workplace. If employees do not follow 5S, it means that their ways are not good.

Writer have done activity identify companies to see the existing condition of work environment on SMEs automotive components in Bandung by using 5S check form. And then based on Table 4 we can know the value of capabilities 5S to the each companies shall be as follows : (a) 3 companies have value = 3 or Enough, (b) 4 companies have value = 2 or Less, (c) 2 companies have value = 1 or Very Less. From the result can be concluded that applying 5S is not applied in an optimal fashion yet by SMEs automotive components in Bandung.

3.3.2 Analysis On Capabilities Of Production Quality.

By seeing at the result of assessment capabilities of production quality from 9 SMEs automotive components, like shown at Table 4 we can know that value capabilities of production quality to the each companies shall be as follows : (a) 3 companies have value = 3 or Enough, (b) 3 companies have value = 2 or Less, and (c) 3 companies have value = 1 Very Less.

From the result we can conclude that produce of quality product by SMEs automotive components still lower or less. The mentioned can be caused for example by :

1. The technology process that is applied not exactly yet, because the equipments and machine that used is still limited. It's cause for example because limitation of capital owned.
2. The quality of human resources is less because of less education bases and is low ethos work so it causes to lower discipline activities.
3. The quality of raw material often do not standard, because raw material and assistant still depended by import. Other side of price often fluctuation. Nowadays, the selection of raw material becomes difficult to execute.

From low product quality, brings the impact to :

1. The product specification that is produced in limited variation, so that makes the limited marketing
2. The high reject ratio is affected to reworking or minimize repair so that cause the efficiency to be low because the expense to be increase, delivery time become late and the profit become decrease or even lose.

Because of that, SMEs automotive components earn more to development is needed steps, for example as follows :

1. Restructuring machine and production equipments : to support the increase of technology ability produce so the settlement and completion of factory by increment and replacement existing conventional to standard production equipments.
2. Implementation of Shindan Shi System from "Adjacently" and direct consultancy in the form of analysis and diagnosed problem that is faced by SMEs by Shindan Shi.

3.3.3 Analysis on Capabilities of Accounting and Book keeping

Based on Table 4 we can know that the value of accounting and book keeping capabilities from 9 SMEs automotive components shall be as follows : (a) 7 companies have value = 5 or Very Good, and (b) 2 companies have value = 2 or Less.

To both company that have the less value, so the effort that be able to be conducted is to improve the book keeping and financial report system. With applying of bookkeeping system, so the applying of logical advantage plan, sale plan, management plan etc can be executed. Besides also can control CGS (cost of goods sold) and budget control. With existence of production plan, can minimize change of production amount, so that can stabilize everyday production amount.

3.3.4 Analysis of Human Resource Capabilities

Based on Table 4 we can know the value of human resources capabilities from 9 SMEs automotive components shall be as follows : (a) 8 companies have value = 3 or Enough, and (b) 1 company have value = 2 or Less.

By seeing at Table 3, generally each every companies involved labor between 10 up to 99, labor qualification most have skills and not have back ground academic and expert labor.

Meanly the to labor in place have well-balanced skill

and way of activity which much the same to between company one with other company.

There is two labor faction running activity of the production in place, that is :

1. Class owning skill of production technique, for example : turner, worker of stamping, welder, molding worker
2. Class representing assistant in doing production process, for example : assistant of turner, ministrant worker of casting, ministrant welder and assistant of worker in other area.

Besides the mentioned above transfer of skill (to junior workers) can walk naturally, where more contagious skillful worker indirectly its skill to other labor which still not skillful yet and also which still have less job experience.

The Labor that exist in Class I (Growth Level) use the employees from the around company, both for blood is still a relation with owner of company and also with no blood relation.

Still lower labor productivity labor that exist in SMEs automotive component in Bandung, this matter can know from to the number of time which is castaway because the preparation of unfavorable job (time of dandori), but awareness about problem is very low. So that its high work productivity need the existence of increased skilled and knowledge of employees.

3.3.5 Analysis of Organization Management Capabilities

Based on the Table 4 can know the value of organization management capabilities from 9 SMEs automotive components shall be as follows : (a) 8 companies have to have value = 3 or Enough, (b) 1 company have value = 1 or Very Less.

From the result can be concluded that organizational management not yet goodness.

Therefore SMEs automotive components have good organizational management capabilities, so needed by the following the steps is : (a) company have to have organization chart complete with breakdown of task, authority and responsibility from each its shares, (b) company have to have mission and vision and also earn its it field, (c) company have to have planning, good that short term, middle term and long term.

3.4 The Implementation of Shindan System

PT. W-21 established in 1993, has been producing automotive components industry. produced product type of all kinds but product the core important is: (1) bracket compressor mounting (BCM), (2) exhaust manifold, and (3) spring bracket. The company in this time have labor about 140 peoples with earnings about Rp 4.5 billion/year (USD 500,000).

To know the condition of internal and external situation environment company of W-21 to analyse SWOT, like shown in Table 4.

Table 4. SWOT analysis of PT. W-21

Strength : 1. Has ISO 9001:2000 Certificate 2. Had financial statement 3. Having good relation with partnership 4. Average employees have productive age, active, energy and skilled.	Weakness : 1. It fails to enforce 5S activities to the fullest extent. 2. Low of CNC machine Efficiency for Mori Seiki and Topper 920 about 60% 3. BCM as the excellent product have the percentage of rejected the high was approximately 26%.
Opportunity : There is a good prospect for demand growth relating to domestic after markets and automotive OEM parts	Threaten : 1. Consumer claim of product quality which to high 2. Influenced by condition and situation of automotive industry 3. Company of a kind has more equipments and machine go forward.

3.4.1 Increased Of CNC Machine Efficiency

The problem arises on the decreased of CNC machine efficiency for Mori Seiki and Topper 920 in the line machining center was approximately 60 %. While expense of investment for the purchasing of the machine require big fund. Therefore company management and Shindan Shi target to increased efficiency 2007 becoming above 80 %. To decreased cost production carried out improvement : (1) decreased of machine stop time, (2) improving cycle time.

To improving it, hence factors causing of machine down time have to be immediately known in detail. From result of research in September 2007 known that trouble types (disturbance) at machine of Mori Seiki and of Topper 920 can be classified to become 6 (six) especial trouble type, that is like at Table 5. Then factors becoming cause of down time in October 2007 to December 2007 monitored and overcome.

Table 5. Down time machine of CNC in PT W

No	Disturbance	Mori Seiki		Topper 920	
		Per month (hour)	Presentation (%)	Per month (hour)	Presentation (%)
1	*M/C Trouble*	77	55	25	22
2	*Trial*	15	11	12	10
3	*Jig change*	*)11	8	**)40	34
4	*Tool change*	12	9	12	10
5	Material	-	-	4	3
6	Others	24	17	25	21
Total		139	100	118	100

Notes : *) 4 times only, **) 9 times only

Efforts to troubleshoot different down time troubles can be seen in Table 5, including : (1) jig changes include jig changing system, distributing lift-bolt to plat jig, jig compounding system, pallet address to jig drift, etc. (2) machine troubles include machine repair with agents, clamping system, etc. (3) others include chamfering process changes. The results of increased machine efficiency of Mori Seiki and of Topper 920 before and after repair can be seen in Table 6.

Table 6. The result of increased machine efficiency Mori Seiki and Topper 920

Type of Improvement	Mori Seiki		Topper 920	
	Before Improvement (hours)	After Improvement (hours)	Before Improvement (hours)	After Improvement (hours)
1. Jig change	38	23	50	37
2. M/C Trouble	40	18	18	0
3. Trial	19	15	14	15
4. Other	7	5	8	8
Total	104	61	90	60

By repairing jig change, machining center troubles, trial etc., as shown in Table 4. On January 2007 stop-machine time reduction in Mori Seiki machine and Topper 920 would be produced (from 104 hour become 61 hour) and Topper 920 (from 90 hour become 60 hour). Similarly in 1 time of jig change, the time may be decreased from 45 minutes to 30 minutes.

Based on increasing graph of efficiency result of Mori Seiki and Topper as shown in Figure 2, it is found that on September 2007 the bench mark is machine efficiency of Mori Seiki about 66% and Topper 920 about 74%. But after improvement by shindan team, the increasing result of efficiency of Mori Seiki machine was 81% and Topper 920 was 83%.

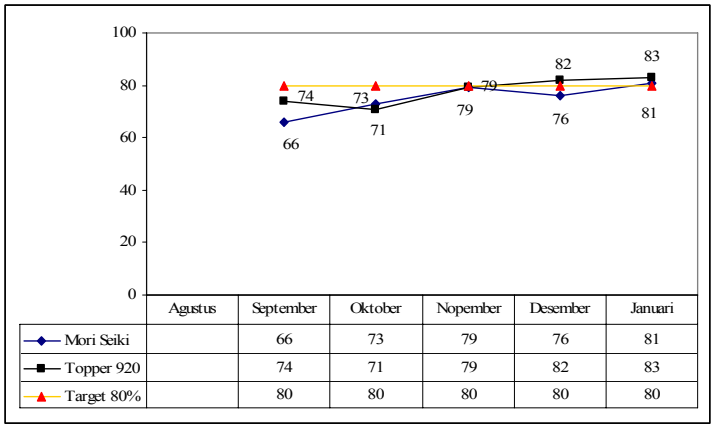

Figure 2. The result of machine efficiency of CNC : Mori Seki and of Topper 920

3.4.2 Increased of Product Quality

In Table 6, it is found that BCM KF 510 T deluxe products have highest reject ratio of 0.26% and damaged product size amounts 70 units. Therefore, top priority of quality control is directed to the product.

Target in 2007 was reject ratio not more than 0.10%. Repairing the quality of BCM KF 510 T deluxe product needs 5 recommendations, they are: (a) repairing documentation system, (b) identifying in-field process, (c) separation part NG from pallet, (d) counter measuring BCM KF 510 T deluxe products, and (e) repairing 50 items of work documents. The result of improved BCMKF 510 T deluxe product quality *deluxe* after improving becomes 5%.

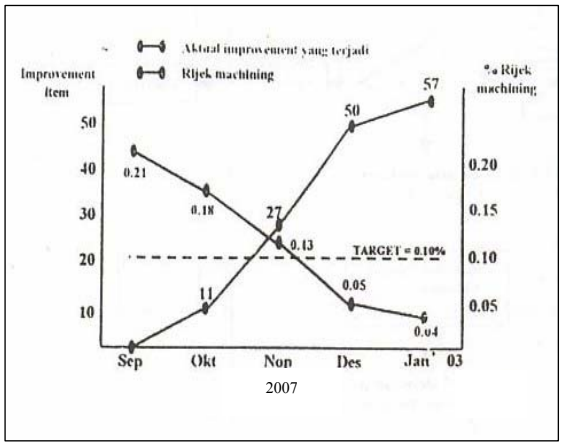
Table 6. The results of production PT. W-21 (period of January to August 2007)

No	Components	Total of Production (Unit)	Total of Reject (Unit)	Reject (%)
1	BCM KF 510 T 2L	8.139	19	0,23
2	BCM KZ 2000	3.688	12	0,33
3	BCM KF 510 Deluxe	26.492	70	0,26
4	BCM KF Standard	4.124	8	0,19
5	Wagon R	3.683	42	1,14
6	BCM Baleno	3.105	16	0,52
7	BCM Tercel	4.500	9	0,20
8	BCM Expass X-479	1.629	7	0,43
9	BCM KZ 2D00	1.358	26	1,91
10	BCM Futura	6.580	21	0,32
11	Attachment	3.939	8	0,08
12	Proton Saga	1.624	4	0,25
13	Exh. Man 4JAI	10.450	24	0,23
14	Bracket ASM Powe	12.433	38	0,31
Total		91.744	Average reject	0,46

Based on the result graph of increased quality of BCM KF 510 T deluxe product (Figure 3), on September 2007 the bench mark is reject machining about 0.21%, after improvement 50 items of work documents (September 2007) and 57 items of work documents (January 2008). Reject machining results in 0.05% (December 2007) and 0.04% (January 2008).

To overcome of BCM KF 510 T deluxe products needs to find the causes. Figure 4 shows that the cause of highest damage is “slotting no good”. It is true because of : (1) used materials, (2) used equipments and machines, (3) employed methods, (4) operators, and (5) work place

environment. Therefore, in analyzing the cause and effect on to activity "slotting no good", factors above reruire to be paid attention. From analysis the cause and effect then we may find the ways to overcome it, so that it should eliminate or lower damages or improving activities from the occurring "slotting no good".



Fiqure 3. The result of increased quality of BCM KF 510 T Deluxe.

4. CONCLUSIONS

1. Based on the results of case study on 9 automotive components of SMEs selected in Bandung, can define the following capability classifications : (a) 1 company have value 25 to be classifications on class I (growth level), (b) 5 companies have value 53, 48, 41, 48, 53 to be classifications on class II (potential level), (c) 3 companies have value 66, 61, 66 to be classifications on class III (autonomous level).
2. Variables influencing automotive components SMEs capabilities posed at Table 1, known that its value capabilities is : (a) X_1, X_2, X_3, X_{10}, X_{11}, X_{12}, X_{14}, X_{15}, X_{16} have value = 3 (Enough), (b) X_4, X_5, X_6 have value = 2 (Less), (c) X_7, X_8, X_9 have value = 5 (Very Good), (d) X_{13} have value = 4 (Good).
3. The results of implemented Shindan System in PT. W-21, with cover : (a) SWOT Analysis, (b) increased CNC machine efficiency for Mori Seiki (from 66% to be 83%) and Topper 920 (from 74% to be 83%), (c) had decreased the average reject ratio of BCM 510 T deluxe from 26% to be 5%, (d) 5S in machining center workshop to be better.
4. By using the same method, the case study may also be implemented for other automotive components SMEs in other areas, like: Jakarta, Bogor, Sukabumi, Bekasi, Depok and Tangerang West Java and also for SMEs in Indonesia to increasing competitiveness in global market.

ACKNOWLEDGEMENT

The author would like to thank Mr. Korenori Takahashi, Mr. Yoshio Hirono and Mr. Fukaya as experts from Toyota Motor Cooperation Japan for her advice and suggestion during the research.

ABSTRACT

This article analyses some important factors that significantly contribute to the success of mobile phone, an example of a short life cycle product. Some variables are performed to represent the factors. Technical superiority is used to represent product quality, meanwhile, launching time, brand, and price represent marketing strategy factor. The analysis is classified based on its product segment.. The result shows that (1) there are different significant factors for each product segment. Brand is the only variable that positively significant correlates to product performance in all segments (2) price negatively correlates to product performance in low and medium end segments but it positively correlates to product performance for high-end product (3)technical superiority has significantly negative correlation to product performance for low end product. In medium and high end segment, technical superiority indirectly correlates to product performance. Technical superiority indirectly correlates to product performance through brand in medium end and through innovation in high end (4) launching timing has different effect to product performance for different segment. In low-end segment, time has significantly negative correlation to product performance. This is different to medium and high end products that tend to neutral. These indicate that life cycle of low-end product tends to be shorter than life cycle medium and high end product. (5) Innovation correlates to product performance for high-end product segment. It cannot be measured in low and medium end segment because of the same innovation value.

Keywords: *quality, brand, price, innovation, launching*

1. INTRODUCTION

In a review paper, Hart observed 'Recognition of the importance of new product development to corporate and economic prosperity, coupled with the high risk of failure in such endeavors, has triggered considerable research interest in the dynamics of new product development'[1]. NPD remains an important field of research since many companies were still not achieving the success rates that they and their governments desire [2]. Crawford identified that 35 % to 45 % of new products failed to compete in market [3]. Stevens and Burley even identified that the failure rate of new products was somewhere between 40 % and 75% [4]. Given the high costs associated with new product development, minimization of the high failure rate is a topic of considerable theoretical and managerial interest. Some significant causes of the failures were identified [5]. They were inadequate market analysis (24 %), product defect (16 %), lack of effective marketing effort, (14 %), and high cost (10%).

In contrast, there were also some researchers who tried to identify factors that influence new product success. Three most important factors were identified, they were: (1). Product advantage (2) Proficiency of pre-development activities. (3) Protocol [6]. Cooper identified 11 dimensions (from 77 observed independent variables) of product success [7]. They were product uniqueness/superiority, market knowledge and marketing proficiency, technical synergy/proficiency, market dynamics, market need (growth and size), price, marketing and managerial synergy, marketing competitiveness and customer satisfaction, newest to firm, strength of marketing communication and launch effort and source of idea/investment magnitude. Eight factors of two categories were the most frequently included factors in the studies reviewed and they were the ones for which integratable statistics were most consistently reported: (1) strategic factors-- product advantage, technological synergy, and marketing synergy, and (2) development process factors

proficiency of technological activities, proficiency of marketing activities, protocol, top management support/ skill, and proficiency of predevelopment activities [8].

Henard & Szymanski develop taxonomy of product success factors that consist of 4 main factors. They were product characteristics, firm strategies, firm process characteristics, and market characteristics [9]. By using meta analysis of 60 empirical studies, It also showed 8 important variables of product performance. They are product advantage, product innovativeness, marketing strategy, technological strategy, structured effort, market orientation, cross functional integration and competitive response intensity. Cooper & Kleinschimidt based on effect on profitability and impact, identified some critical factors which drived product success. Top four of them were high quality product process, new product strategy, adequate resources, R & D spending [10].

Based on the facts, a very important factor of product success/failure is customer knowledge though there are many factors influence product success or failure. Thus, this article will focus on analyzing some important factors that significantly contribute to the success of mobile phone, an example of a short life cycle product. Three important factors, namely product quality, marketing strategy and product innovation, are analyzed and compared.

2. PRODUCT DEVELOPMENT CONCEPT

Product design is a synthesis of technology and human needs into manufacturable products. Asimow defines engineering design as a purposeful activity directed toward the goal of fulfilling human needs, particularly those which can be met by the technological factors of our culture [11]. In practice, design means many things, ranging from styling to ergonomics to setting final product specifications. Product design and development has some variant of product development process. Ulrich and Eppinger claim there are fives variants [12]. Two of them are market-pull (affirm begin product development with market opportunity and then seek out whatever technologies are required to satisfy the market need), and technology push (begin with a new technology then find an appropriate market). Otto and Wood classify a design into original, adaptive, and variant design [13].

New product development projects comprise two main phases: pre-launch and post-launch. Learning about customer preferences (i.e., customer knowledge development) occurs in both phases but entails lower costs and lower strategic risk in the pre-launch phase. Ulrich and Eppinger also formulated pre-launch product phase in 5 phases: concept development, system level design, detailed design, testing & refinement and production ramp-up [12].

The term product performance is closely linked to product properties. Different definitions of performance are found in literature. According to the Oxford English Dictionary, performance is: “The accomplishment, execution, carrying out, working out of anything ordered or undertaken; the doing of any action or work; working, action (personal or mechanical); specification. The capabilities of a machine or device, now esp. those of a motor vehicle or aircraft measured under test and expressed in a specification also used attribute to designate a motor vehicle with very good performance”. Ulrich and Eppinger define product performance as: How well a product implements its intended functions. Typical product performance characteristics are speed, efficiency, life, accuracy, and noise [12]. Many of these given definitions imply that product performance is a measure of functional aspects of the product. When one talks about product performance he must also bring in properties such as form, durability, and so on. In the opinion of Hubka and Eder, the performance variables are related to three categories: *design properties* (e.g. function, form, tolerance, surface, materials, and dimensions), *internal properties* (e.g. strength, stiffness, hardness, elasticity, corrosion, resistance, etc.), and *external properties* (e.g. ergonomic, aesthetic, economy of operation, reliability, maintainability, and safety) [14]. The manufacturer is concerned with all three, but the customers are mainly concerned with the external product properties.

Stauffer and Kirby suggest that engineering design research should be increased in: (a) the connection between market, consumer and design information, (b) support launching products into the marketplace, and (c) equating product features with customer value to ensure a sustainable rate of return to small companies [15]. Launching timing is very important variable to product success [16, 17].

Brand value is very an important variable of company superiority. Brand equity is important variable for customers to buy a product [18, 19]. How product design (conceptualized as product aesthetics and function) interacts with brand strength to influence consumers’ product liking and quality evaluation is also important point to be discussed. Page and Herr stated that design and brand strength differentially impact liking and quality judgments [19]. In addition, judgments of liking and quality are found to be different in the way they are formed. Specifically, product *liking* appears to be readily formed through a process that integrates design information only; brand strength exhibits no significant influence. *Quality* judgments appear to take longer to process, and involve the integration of design and brand information.

3. METHODOLOGY

The mobile phones are classified into three class namely low-end, medium-end and high–end product based on their price. This research uses 38 samples (mobile phones models/types) that have very good sales performance report, consist of 17 low-end products, 10 medium-end products and 11 high-end products. . The product is classified as low end

ISSN 114-1284

product if its price is less than $ 150, meanwhile the high product has price more than $ 300. The medium product price is in between of the two classes. The data are collected from more than 200 mobile phone shops in Yogyakarta Indonesia in the period of January until September 2008.

Three factors, namely product quality, marketing strategy and product innovation, are analyzed. Some variables are involved in this analysis, they are launching date, technical specification, price, and brand value. Technical superiority is used to represent product quality, meanwhile, launching time, brand, and price represent marketing strategy factor. For each segment, some successful mobile phone series are analyzed to identify the important variables. Launching dates are used to determine both launching duration and innovation (with technical specification). Technical superiority values are determined by calculating the average of some technical specification such as screen resolution, data transfer speed, and features. Likert scoring is used to quantify the features rate. As same as technical superiority, innovation variable is generated based on modification of Booz-Allen & Hamilton [2]. The norm is presented in Table 1.

Table 1: Innovation Norm

Value	Description
5	New to the World Product
4	New Product line to the firm
3	Add to existing line
2	Improvement
1	Reposition

This research uses mobile phone brand value analysis done by SWA and MARS 2008 and % sales were taken from Yogyakarta Nokia Representative. Brand values were determined based on brand share, brand awareness, advertisement awareness, customer satisfaction, and gain index. They were analyzed from survey that involved 2648 respondents collected from 7 big cities of Indonesia [20]. In low and medium segment, innovation is not involved because of the similarity for all products.. Brand is not involved in high segment either.

4. RESULT AND DISCUSSION

Some variables are performed to represent the factors. Technical superiority is used to represent product quality, meanwhile, launching time, brand, and price represent marketing strategy factor. To identify the factors for product each segment, some successful mobile phone series of each product segment are analyzed. The correlation among variables is presented in Table 2.

The result shows that there are different significant factors for each product segment. Brand is the only variable that positively significant correlates to product performance in all segments. In high end segment, brand becomes an important variable because only one brand dominates market although the correlation value cannot be calculated. Besides, brand also correlates to other variables. In low end segment, brand negatively correlates with time from launching and technical superiority, though they are not significant. Brand has different effect to technical superiority in medium end segment. It significantly positively correlates with technical superiority. This is in line to Page and Herr finding that *Quality* judgments appear to take longer to process, and involve the integration of design and brand information [19].

Price negatively correlates to product performance in low and medium end segments but it positively correlates to product performance for high-end product. In low and medium segment, price is sensitive variable. In low end, it becomes variable that influence % sales through technical superiority that significantly negative correlation to product performance.

Technical superiority indirectly correlates to product performance through brand in medium end and through innovation in high end.

Launching timing has different effect to product performance for different segment. In low-end segment, time has significantly negative correlation to product performance. This is different to medium and high end product that tend to neutral (correlation coefficient is close to 0). These indicate that life cycle of low-end product tends to be shorter than life cycle medium and high end product.

Innovation correlates to product performance for high-end product segment. It cannot be measured in low and medium end segment because of the same innovation value.

Table 2: The performance comparative study among forecasting methods

	Price	Time From Launching	Tech. Superiority	Brand	Innovation	% Sales
Low-end Product(n=17)						
Price	1.000	.068	.840(**)	.001		-.289
Time From Launching	.068	1.000	.136	-.239		-.509(*)
Tech. Superiority	.840(**)	.136	1.000	-.393		-.599(*)
Brand	.001	-.239	-.393	1.000		.849(**)
% Sales	-.289	-.509(*)	-.599(*)	.849(**)		1.000
Medium-End (n=10)						
Price	1.000	-.445	.327	-.017		-.418
Time From Launching	-.445	1.000	-.142	-.065		-.055
Tech. Superiority	.327	-.142	1.000	.728(*)		.208
Brand	-.017	-.065	.728(*)	1.000		.701(*)
% Sales	-.418	-.055	.208	.701(*)		1.000
High-End(n=9)						
Price	1.000	.222	.561		.810(**)	.683(*)
Time From Launching	.222	1.000	.085		-.054	.053
Tech. Superiority	.561	.085	1.000		.794(*)	.036
Innovation	.810(**)	-.054	.794(*)		1.000	.574
% Sales	.683(*)	.053	.036		.574	1.000

Conclusion

1. There are different significant factors for each product segment. Brand is the only variable that positively significant correlates to product performance in all segments

2. For low end product, product performance correlates to time from launching, technical superiority and brand

3. Brand is the only significant variable to product performance for medium end product. Brand also significantly correlates to technical superiority.

4. In high end segment, product performance only correlated to price. Innovation correlates to price and technical superiority.

ABSTRACT

Unlimited shelf in online store on internet allows much more variety of products to be offered to the customers than those can be offered by brick-and-mortar stores. This leads to the concept of Long Tail which argues that unlimited choice to customers can create unlimited demand and thus increases sales. However, as a consequence to the abundant choice available online, customer search-time to find the specific products they want definitely increases. Thus filtering mechanism is deemed to be increasingly important. In this paper, the value of pre-filter and post-filter process will be analyzed. In doing so, the long tail theory and case studies of some commercial and non-commercial websites are reviewed and analyzed. Each filtering mechanism appears to have a distinctive characteristic in the traditional brick-and-mortar and the Long Tail (online) business. We conclude that the pre-filter is indispensable for the success of the commercial online store because it provides the minimal quality control for the offered products. The post-filter that provides personalized offering, can be added as an additional commercial service.

Keywords
Long Tail, Pre-filtering, Post-filtering, Retailer, Commercial Value

1. INTRODUCTION

Ever since the emergence of the industrial revolution, consumers become more and more familiar with the existence of retailers. In Indonesia alone, there are various categories of retailers, starting from general retailers (e.g: Hypermart, Carrefour, Giant), electronic and appliances retailers (e.g: Electronic city, ACE Hardware) to hobby, books and music stores (e.g: Gramedia, Disc Tara). The word retailer itself refers to "a business that sells products and / or services to consumers for their personal or family use" [1]. It distributes products and creates values to consumers by [1]:

- Providing an assortment of products and services
- Breaking bulk
- Holding inventory
- Providing services

Providing a wide range of product assortments is costly to retailers because that means they need to provide more space for inventory while the main concern of the traditional retail stores is the space or capacity constraint. Shelf capacity constraint forces the retailers to only sell "popular products" that generate most sales and are favored by the mass market. Thus retailers limit the number of assortments and varieties of products sold on the shelf. They forego niche and obscure products that are not popular to the mass market but are still demanded by a very small number of customers. Prior to deciding on what to be displayed on the shelf, these retailers make predictions on which products are going to be popular, which brands to sell, what price range is acceptable to the customer, what level of quality of goods to be sold, local customer preferences and so on. These are some of the criteria used by the merchandisers to select and discriminate products to sell in order to maximize their sales.

Current innovation in technology has changed the way business is conducted. Internet has provided an alternative to the traditional retail product distribution. The minimum cost of adding the list of inventory on the internet attracts many retailers to branch out to the e-tailer or what is known as online retailer. Products ranging from highly demanded to obscure products, from the premium quality to the poor quality, from all over the world are available in the online market. Although much more variety and assortments of goods can now be found, consumers may find it harder to find the right product among the sea of junks. The customer search-time increases as the number of choice increases. Therefore, a filter is needed to screen the products available online.

This paper aims to analyze and evaluate the prospect and commercial value of the filtering process. That is, whether the filtering process has a distinctive selling point to make it saleable or whether it is something that can only be provided freely to the customers. To achieve this objective, first, the long tail theory will be reviewed. Then the value of filtering process, both pre-filter and post-filter, in brick-and-mortar and online retailers will be analyzed and discussed. Case studies of Amazon, Wikipedia, YouTube, Rhapsody and IEEE publications are also presented to point out the value of their filtering applications. Then conclusions will be drawn.

2. BRICK-AND-MORTAR VS. LONG TAIL

The Long Tail concept was coined by Chris Anderson in 2006 [2]. He built on the work by Brynjolfsson et. al, who observed that limited shelf space in conventional retail outlets constrains the type of products that can be discovered, evaluated, and easily purchased by consumers; while Internet customers have easy access to millions of products that they could not easily locate or purchase through brick-and-mortar retailers [3]. Brynjolfsson also provides empirical data for the Long Tail phenomenon. He claimed that the Internet purchases are more skewed toward obscure products, thus going further down the Long Tail online [4], [5].

The basic argument of the Long Tail phenomenon is depicted in Fig. 1. In Figure 1, the Short Head is the area prior to the first threshold line. The Short Head represents popular products that are mainly seen and displayed on the brick-and-mortar shelves. This Short Head is then followed by the Long Tail which underlines the fact that as retailers move to online market, more and more products can be offered to the customers. Anderson summarized the Long Tail phenomenon in these claims [2]:

In virtually all markets, there are far more niche goods than hits. The cost of reaching those niches is now falling dramatically due to digital distribution, powerful search technologies and critical mass of broadband penetration. Thus, in many markets, it is now possible to offer a massively expanded variety of products. Although none of the niche products sell in huge numbers, there are so many of them that collectively they can comprise a market rivaling the hits.

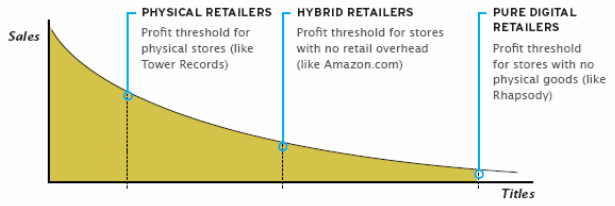

Figure 1: The Long Tail and its relation to the retailers [2]

Anderson argues that the Long Tail phenomenon is the new trend. However he is also confident that the brick-and-mortar retailers will remain to exist [2]. He writes *"Long tail markets tend to be a bit flatter than traditional markets, but they still have their share of blockbusters. For each way that we differ from one another, there are more ways that we're alike"*.

Therefore it is safe to assume that we will see the brick-and-mortar retailers to coexist with the Long Tail world of online distributors. The winners will be companies who know how to navigate through both worlds.

3. THE LONG TAIL DEBATE

In 2008, Anita Elberse wrote a seemingly refutation of the Long Tail theory [6]. She claimed that digital channels (online distributors) do not actually amplify the Long Tail phenomenon as is shown in Figure 2. On the contrary, it is still very much a Short Head world and the digital channel would only strengthen and amplify the hit products.

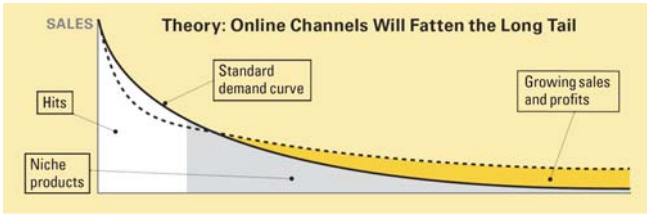

Figure 2: The Flattening of the Long Tail [6]

Elberse quoted the data from Rhapsody and Quickflix to back-up her claims. The data from Rhapsody (in 2006) showed the top 10% of titles accounted for 78% of all plays, and the top 1% of titles for 32% of all plays. "One percent of a million is still 10,000, when translated into album terms, equal to the entire music inventory of a typical Wal-Mart store" [6]. Elberse claimed that these data showed a clear high level of concentration. The same goes for the data from Quickflix. The top 10% of DVDs accounted for 48% of all rentals, and the top 1% for 18% of all rentals. In other words, some 150 titles (roughly the number of movies released annually to theaters by major Hollywood studios) accounted for nearly a fifth of all rentals. Elberse further argued that although the concentration of sales of Quickflix is not as strong as Rhapsody, it is still deemed substantial [6].

Elberse also observed the shopping carts of Quickflix video customers. She found that on average, 61% of these customers' rentals came from the highest decile, and another 13% from the second highest. Less than 1% of their choices came from the lowest decile – the most obscure titles [6]. For Elberse, these data are clear signs of concentration and there is no observable shift towards obscure products in online distributors.

There are interesting exchanges between Anderson and Elberse in the Harvard Business Blog [7], [8]. Anderson argues that the problem lies in the definition of the Head and the Tail. He pointed out that in Rhapsody, the 1% Head only represents 32% of all the plays. It means that the Tail represents 68%, thus the Tail is still showing its dominance. Likewise in Quickflix data, the top 10% only accounts for 48% of all rentals and the top 1% accounts for 18%. Therefore, Anderson argues that the different definitions of the Head and Tail will generate very different results [7].

Anderson also pointed out that the Long Tail has a fractal character [2]. It means that, if we zoom into the Long Tail curve, we always find another Long Tail structure. The Long Tail is made of many mini-tails, thus the big power-law curve of, say, "music", is really a superposition of all the little powerlaw curves formed by each musical genre. Therefore, the Short Head and the Long Tail are actually quite inseparable. The debate between Anderson and Elberse accentuates this fact. The Long-Tail-like curve can even be found in a typical supermarket, not necessarily an online distributor [9]. No wonder it becomes difficult to strictly define the exact boundary between the Head and the Tail.

Nevertheless, Anderson seems to be aware of the necessity of having the Short Head (popular products) in the Long Tail (obscure products) market. As many customers are not familiar to the long tail products and its quality, Short Head seems to be a must for an online distribution. The Short head becomes an entry point for customers to start their search of the products and to further explore down to the Long Tail. Here, post-filtering starts to play its role to screen the products and to give recommendation to customers who buy popular products. From this recommendation, customers are introduced to more obscure products and this eventually increases the sales of the e-tailer. The next section will discuss more about pre-filter and post-filter for brick-and-mortar and online market.

4. PRE-FILTER & POST-FILTER

Filtering denotes the process of making people find quality products. In the brick-and-mortar retails, filters come naturally because of the shelf space limitation. In the existing Short Head markets, where distribution is expensive and shelf space is at a premium, the supply side of the market has to be exceedingly discriminating in what it allows through [2]. Anderson calls this process pre-filtering, in which products are selected based on the prediction of their future popularity. The pre-filtering is performed by record label scouts, book editors, studio executives or department store buyers.

The Long Tail market is enabled by another kind of filtering. In the Long Tail paradigm, the maxim is to make everything available online, so pre-filtering seems, at the first sight, to be unnecessary. The function of the filter is shifting from being a gatekeeper to become an advisor [2]. Anderson uses the term post-filter. The post-filter amplifies, rather than predicts. It supplies demand to the goods which are already available, thus driving demand down the Tail. It functions in the form of peer or collaborative recommendations. This distinction of pre-filter and post-filter is summarized in Table 1. "Without the post-filter, the Long Tail risks just being noise", said Anderson [2].

Table 1: Pre-filters & post-filters differences [2]

Pre-Filters	Post-filters
Editors	Blogs
Record label scouts	Playlists
Studio executives	Reviews
Department store buyers	Customers
Marketers	Recommendations
Advertisers	Consumers

The post filtering itself takes form in various sophistication levels although they serve the same purpose as a guide or a screen to what to purchase. The simple form is the customer feedbacks written in words on blogs and reviews or simply customer ratings. By relying on customer rating, instead of having overflowing options of items with a very wide range of quality, the potential buyer or consumer can screen out their options to the best quality items only.

The more sophisticated post-filtering uses certain algorithms to provide recommendations to the potential buyers and consumers. Using a more advanced technology, these recommendation algorithms are commonly used on e-commerce websites such as Amazon [10]. Some of the commonly used techniques are traditional collaborative filtering and cluster method which provide a screening to the options based on similarity of a customer to another [10], [11]. Another post-filtering method is search based method, a search engine which filters the products based on keywords and certain criteria such as price, degree of quality and category. The latest one that is being used by Amazon is the Item-to-Item Collaborative filtering which allows customers to "filter their recommendations by product line and subject area, rate the recommended products, rate their previous purchases and see why items are recommended" [10].

The post-filtering mechanism, on the contrary, is not so dominant in the brick-and-mortar retailers. Many retailers do not display the popular and recommended products, although some have already done that. Gramedia book stores, for example, have a special section to display the best seller books, which provides a convenience to

customers who walk in to the store without knowing what to buy. The lack of post-filtering process in brick-and-mortar retailer may be due to the manual effort required to continually update the statistics and recommendations. Investment on technology to provide an access point for post-filtering mechanism can be done but needs further cost / benefit analysis.

5. THE PROSPECT OF FILTERING

As mentioned in Section 4, at the first sight, the pre-filter is not needed in the Long Tail market. Because the two maxims in the Long Tail market is: (1) Make everything available and (2) Help me find it [2]. However, when Amazon for example, delivers best seller books, the pre-filtering already exists as a part of the process. This goes also for blockbuster movies or top hits music, where the pre-filtering has been done by the record companies or the film studios.

Furthermore, from the discussion in the previous sections, it is also clear that the Short Head and the Long Tail will coexist and will be quite inseparable. Although the pre-filter is closely associated with the brick-and-mortar market and the post-filter is usually related to the Long Tail distributor; in reality, all cases involve a mix of the two types of filters. A predominantly Long Tail service will show a strong reliance on the post-filter strategy. This is displayed, for example, by YouTube and Wikipedia. However, common commercial online distributors will have a balanced mix of pre-filter and post-filter approach, for example, Amazon and Rhapsody. A peculiar example of online distribution, which shows more characteristics of a Short Head market is the IEEE journal publication.

5.1 YouTube and Wikipedia

YouTube and Wikipedia have different filtering mechanism from Amazon and Blockbuster movie online seller. YouTube, a Google subsidiary company, allows users to upload unlimited number of videos to the website which can be accessed by users for free. Pre-filtering process is impossible to be done as 20 hours of videos are uploaded every minute on website [12]. However, the post-filtering is very dominant. Users can rate the quality of the video and leave comments. The popular movies can be identified by looking at the number of viewers for each video.

Wikipedia, the collaborative online encyclopedia which aims to make all information available, is rather unique. It allows users with an account to log on and post anything on the website without pre-filtering. However, the post-filtering mechanism is also unique that other users can revise and update the previous post. Thus, the post-filtering mechanism enhances the quality of the posted information.

The similarity between the two groups is they make every thing, ranging from the popular products to obscure products, available online. The pre-filtering mechanism seems to be almost absent on these non-commercial websites. The enormous number of items being uploaded to the websites, such as in the Wikipedia case, make pre-filtering not cost justified. Therefore, such websites rely on customers to do the work "voluntarily" without a cost. A simple post-filtering mechanism, a search engine, is also provided to ease the work of finding a particular item among the huge amount of data. However, due to the absence of strong pre-filtering, the quality can diverse greatly.

Now, it is also misleading to think that Wikipedia performs absolutely no pre-filtering. One of the principle for posting in Wikipedia is "verifiability" [13]. Contributors should not submit original research. All materials must have been published by a reputable source. So, the focus is on verifiability, not truth. Editors are not responsible to determine the truthfulness of the quoted information, as long as the source is a reliable, peer-reviewed source. Thus this is a very weak version of pre-filtering. In YouTube, we can also find parts of commercial movies, which are mostly pre-filtered products. Therefore, although the pre-filters are very weak in YouTube and Wikipedia, they will not entirely disappear.

5.2 Amazon and Rhapsody

Amazon, online bookstore, music and video online stores, are for commercial purpose while Wikipedia and YouTube are for non-commercial purpose. The pre-filtering mechanism still exists on the e-commerce websites because that becomes one of their competitive advantages. When the potential buyers log on to the website, they already have the assurance to the quality of items sold on the website which later on increases the customer loyalty to continue the purchase from the websites.

Rhapsody, offering more than 5 million songs and thousands of artists, ensures that only master copy of songs are distributed in the site. In addition, Rhapsody also has editors which review new artists whose songs are uploaded to the site. Here, pre-filtering mechanism takes place to maintain the quality of songs distributed online. Amazon, which sells books online, ensures the quality of books sold by relying on the publishers.

Anderson also stressed the importance of pre-filtering for the commercial online distributors. The pre-filter delivers popular products (the Short Head), which serve as a point of entry for the customers. Anderson put it as follows [2]:
If you just have the products at the Head, you find that very quickly your customers want more and you cannot offer it. If you just have the products at the Tail, you find that

customers have no idea where to start. They are unable to get traction in the marketplace because everything you are offering is unfamiliar to them. The importance of offering the stuff at both the Head and the Tail is that you can start in the world that customers already know.

The post-filtering is clearly needed in the case of Amazon and Rhapsody. Reviews, collaborative recommendations and personalized offerings can really aid in navigating the Long Tail, thus enhancing the chance of finding the desired products.

5.3 IEEE Journal Papers

More peer-reviewed scientific journal papers are moving online, for example the IEEE publications. Online distribution makes accessing and searching for journal papers highly convenient. The IEEE conference and journal papers can be obtained fully online through http://ieeexplore.ieee.org.

However, despite the online nature of the distribution, the products in the IEEE site resemble the Short Head market more than the Long Tail characteristic of, for example, Wikipedia. The IEEE published papers are strongly peer-reviewed, maintaining the high quality of the papers. This represents a strong pre-filtering process. Post-filtering, on the other hand, is almost absent despite the easiness to deploy it in the online setting.

Although there are no collaborative recommendations in the IEEE journal site, the post-filtering is also not entirely absent. In this case, the post-filtering is embedded in the citations or references of the published papers. The IEEE Journal papers represent an online distribution which relies strongly on pre-filtering, with a weak post-filtering process.

5.4 The Commercial Value of Filters

From the discussed examples, it seems quite clear that the pre-filter is directly related to the commerciality of the products. Although the filtering process itself cannot be sold commercially, the cost is already included in the total cost of the products. The pre-filtering delivers popular products, hits music, blockbuster movies, or high quality journal papers. Therefore, the less commercial sites such as YouTube and Wikipedia do not rely on the pre-filtering as much as their commercial counterparts: Amazon and Rhapsody.

The post-filtering process arises because of the Long Tail phenomenon. It provides the ability to efficiently identify the desired product, while having everything available online. Whether the post-filtering process can be sold is debatable. Most of the current post-filtering process is provided freely, even in commercial sites such as Amazon. However, sophisticated and more effective post-filtering algorithms may provide added-value services that might be saleable.

6. CONCLUSIONS

The Long Tail theory and debate confirm that the Short Head and the Long Tail are actually inseparable. The pre-filter has already been an indispensable part of the brick-and-mortar retailers. It stays an important component of the distribution services, which aim at delivering quality products. In this sense, the pre-filter is closely related to the commercial value of the quality products distribution. It is understandable, for example that we pay quite a lot for the access to scientific peer-reviewed journal papers, while documents on Wikipedia are completely free. In Amazon and Rhapsody, pre-filtering is performed by editors and music editors. We pay for the high quality of products achieved through the pre-filtering.

The post-filtering is a new phenomenon triggered by the rise of the Long Tail market and the ease of digital technology. Because the Long Tail market makes all things virtually available, post-filtering in the form of product reviews, collaborative recommendations or personalized offerings must be provided for customers to efficiently find the desired products. Up to date, post-filtering is still a free-service. However, commercial value of post-filtering can perhaps be created if personalization according to customer taste is provided. It is also imaginable to have professionals, who review products, thus providing premium post-filtering services.

One interesting question regarding the Long Tail phenomenon is the effect of post-filtering to the movement of products between the Tail and the Head. Further research can be directed to measure the effectiveness of post-filtering mechanism in the long tail area, i.e., how fast can the quality products in the Tail be identified and move to the Head area. In addition, further study on a more advanced post-filtering algorithm for product offering personalization can also be conducted.

ABSTRACT

In order to get outrival in the corporate world, company management should be oriented to market dynamics that is interaction between producer, consumer, and competitor. In order to make a reliable and high competitiveness product, the strategy is made an attempt on product development. Great number of cellular phone supply requires producer for meeting the consumer desires. One of the ways for the company to meet the consumer requirement is using Kansei Engineering methodology for esthetic aspect. Kansei Engineering is developed to involve a human's sense into a product development.

This research used questioner as the research instrument that is put down consumer expectation and perception toward cellular phone design through the Kansei's words. The research held in two kinds of treatments those are with and without touch of the cellular phone as the research object. After that, qualitative data collection was used to determine consumer's importance degree and significance difference test by use of software.

Resulting from the research has been done the analysis about consumer's importance degree and difference treatment that is significantly having an effect on Kansei's words. From the test result calculation, has been find out that consumer priority in cellular phone design's image in a row are easy to operate, durable, exclusive, modern, elegant, charming, impressive, interesting, strong, easy to keep, neat, masculine, striking, and dark. Research also found out that touch and no touch treatment of cellular phone produced two Kansei words having significantly difference on consumer appraisal. Those Kansei words are easy to operate and easy to keep.

1. INTRODUCTION

Along with the development in the world of science and technology, industry is also experiencing a fairly rapid progress. Competition in the industry is also increasingly strict where each company makes a variety of design strategies in the planning, design manufacturing, and selling products in the market. Creating products that match the desired specifications of the consumers is very important. This is highly influential on the level of sales especially if the product is not the only one circulating in the market. In this case consumers have many opportunities to compare and select products that fit with their desire. With this market condition, strategy to win the competition is to provide products that can satisfy the needs and desires of consumers. To produce products that match market needs and desires, it is necessary to have knowledge about consumer behavior.

In order to get outrival in the corporate world, company management should be oriented to market dynamics that is interaction between producer, consumer, and competitor. In order to make a reliable and high competitiveness product, the strategy is made an attempt on product development. Product development process is a unity of activity needed to create a new concept to the market [Otto & Wood, 2001]. Product development is basically the company's efforts to create new products, improve, or modify old products, in order to meet market demands and consumer tastes [Yamit, 2000]. The criteria of product development process have a great opportunity because the companies are required to take advantage of opportunities in the development of products.

This study focuses on the cellular phone object. Great numbers of cellular phone supply require producers to satisfy the desire of consumer with a reliable and high competitiveness product. Consumer tastes for cellular phones that circulate in the market continue to shift. A sale of mobile devices is increasing rapidly over the cellular phone technology that increasingly sophisticated while the selling price decrease. IDC Indonesia's data indicate that the volume of sales of cellular phone in Indonesia during the quarter II/2008 increased very sharply, amounting to 74.9% compared with the quarter II/2007. This indicates the need for a cellular phone is getting higher. The cellular phone has also become a lifestyle and quite important in life at this time.

Design is also an important consideration in the consumer to purchase a cellular phone. Therefore, companies should also be able to respond the taste of the market cellular phone design. Design mobile phone is not only seen in terms of the design specifications but also involves the aspect of aesthetics.

One of the ways that companies can meet the needs of consumers in terms of aesthetics is to use a Kansei engineering method that was developed to involve feelings into product design. Kansei Engineering method was developed by Dr. Mitsuo Nagamishi in Japan and proven success in the design of Mazda cars in 1986 [Guerin, 2004]. Kansei can be defined as emotional or total effect obtained by someone's property, the environment, or situation by using the senses such as vision, hearing, or feeling [Nagamichi 2001, quoted from Schütte, 2005]. Kansei Engineering method can translate the feeling and impression of the product design process parameters. The most common way is through the measurement of Kansei

words. By using Kansei words as an indicator is ascertainable the desire and the perception of consumers towards the cellular phone design.
Based on the descriptions above is conducted research to determine consumer perceptions and willingness to design a cellular phone according to the feelings of consumer using Kansei Engineering.
Based on the background that has been described, the problems raised in this research is how consumers' desires and perceptions of mobile phone design is in accordance with the feelings and image using the method of Kansei Engineering.

2. RESEARCH METHODOLOGY

Research methodology chart is appeared in this following picture:

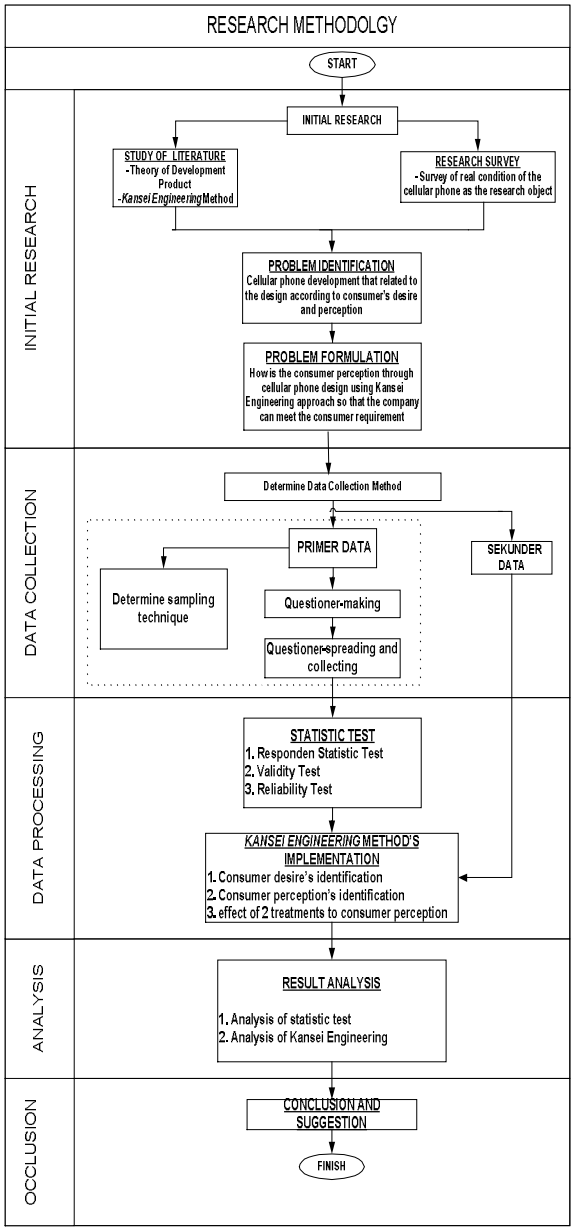

Figure 1: Research Methodology Chart

3. DATA COLLECTING AND PROCESSING

Kansei words used:

Table 1: Kansei words that is used in this research

No	Kansei words
1	Traditional

the mobile phone as the objects of research is selected as many as five species. Election of five this mobile phones be done with the consideration of physical aspects of the mobile phone with a candybar type and size (dimensions and weight) is relatively the same.

Table 2: Cellular phone's specification

NO	JENIS HP	GENERAL		MEASUREMENT		DISPLAY		RING TONE	
		TYPE	NETWORK	DIMENSION	WEIGHT	TYPE	MEASUREMENT	TYPE	VIBRATION
1	NOKIA 1650	Candybar	GSM	104.2 x 43.8 x 17.8 mm	80 g	Color	65k	Polyphonic	Yes
2	NOKIA 1209	Candybar	GSM	102 x 44.1 x 17.5 mm	79 g	Color	65k	Polyphonic	Yes
3	SE J110i	Candybar	GSM	99 x 44x 17 mm	75 g	Color	65k	Polyphonic	Yes
4	SE R300	Candybar	GSM	101 x 46 x 12 mm	75 g	Color	65k	Polyphonic	Yes
5	SAMSUNG E200	Candybar	GSM	103 x 44.5 x 15.5 mm	79 g	Color	65k	Polyphonic	Yes

Furthermore, structured questionnaire that consists of two parts. The first section contains questions concerning consumer expectations of mobile phone design based on the kansei words. Whereas in the second section, containing questions about respondents' perceptions of several types of mobile phones. This category consists of 2 trials, which involve no touch and touch to engage the object of research.

1. Determine consumer's importance degree based on kansei words.
   Consumer's importance degree is the average value of the total value of respondents' answers to the points concerned.
   Total answers for grains 2 = 271
   Total respondents = 60
   consumer's importance degree = 271/60 = 4.52

Table 3: Recapitulation of consumer's importance degree

Kansei words	Consumer's Importance Degree
2 (Exclusive)	4,52
3 (Elegant)	4,20
4 (Modern)	4,35
5 (Strong)	4,08
6 (Easy to keep)	3,95
7 (Masculin)	3,85
9 (Interesting)	4,10
10 (Dark)	2,72
11 (Easy to operate)	4,67
13 (Durable)	4,67
14 (Impressive)	4,13
16 (Neat)	3,92
17 (Charming)	4,18
19 (Striking)	3,02

2. Determining influence of difference treatment that is significantly having an effect on consumer perception's value based on Kansei words. To know the significance of the different perceptions of kansei words through 2 treatments, with and without touch, is made a pair sample T test with significance milestone 0.05. T test is done for each kansei words and the type of cellular phone as the object of research.

   Example of calculation:
   Kansei word :exclusive
   Type :Nokia1650
   Hypothetical :
   H_0 = no difference in consumer perception of kansei words 2 through with and without touch treatment
   H_1 = there is a difference in consumer perception of kansei words 2 through with and without touch treatment

Calculation with the SPSS output:

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	tanpa sentuhan	2,97	60	,780	,101
	dengan sentuhan	2,63	60	,663	,086

Paired Samples Test

		Paired Differences					t	df	ig. (2-tailed
		Mean	td. Deviatio	Std. Erro Mean	95% Confidence Interval of the Difference Lower	Upper			
Pair 1	tanpa sentuha dengan sentul	,333	,857	,111	,112	,555	3,013	59	,004

Decision : Because the value of P = 0004 < α then Ho is declined.
Conclusion : there are differences in consumer perception of the kansei word 2 through with and without touch treatment

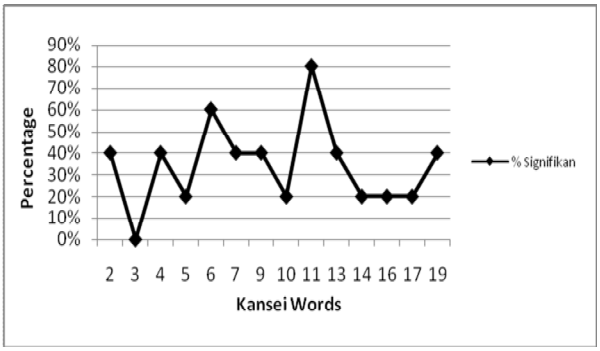

Figure 2: graphs of % Significant average from a pair Sample T Test through cellular phone design

4. RESULTS ANALYSIS

1. Analysis of consumer's importance degree Based on Kansei Words
   Based on the data processing that has done, it can be seen the most influential kansei words in determining the image of cellular phone design.

Table 4: Consumer's importance degree based on the Kansei Words

Kansei Words	Consumer's Importance Degree
11 (Easy to operate)	4,67
13 (durable)	4,67
2 (Exclusive)	4,52
4 (Modern)	4,35
3 (Elegant)	4,20
17 (Charming)	4,18
14 (Impressive)	4,13
9 (Interesting)	4,10
5 (Strong)	4,08
6 (Easy to keep)	3,95
16 (Neat)	3,92
7 (Masculin)	3,85
19 (Striking)	3,02
10 (Dark)	2,72

Based on the kansei words, product developers can provide best performance of the design of a cellular phone from the esthetic function. This design will make consumers like a product more from emotional aspect.

2. Analysis of 2 treatments of cellular phone that having significantly difference on consumer appraisal based on kansei words.
   Recapitulation shown that are 2 kansei words, which is easy to operate and easy to keep, that having % significantly more than 50%. This indicates that there is a difference of the consumer perception wirh different treatment for two of the kansei words. Two of the kansei of words that have a significant, that is easy to operate and easy to keep note that the assessment will change if given a two different treatment done in this research. This is because those words may not be considered to visualization only. While other Kansei-words are not to significantly alter the assessment because those are only need the senses of vision only. A large number of kansei words that tend to make significant influence in the treatment given, demanding the manufacturer of the cellular phone to make the design more eye-catching so that the resulting product has a reliability and high competitiveness.

5. CONCLUSION

1. From experiments carried out on the respondents with and without touch on the cellular phone, the two kansei words that have a significant difference in the results of the assessment that is easy to operate and easy to keep. This means that the respondents' assessment of kansei words are not enough only with the visualization, but also determined by the touch of the user.
2. Fourteen of the kansei word processed on the research, has been find out the consumer's importance degree that will reflect the consumer's desire of cellular phone design. consumer priority in cellular phone design's image in a row are easy to operate, durable, exclusive, modern, elegant, charming, impressive, interesting, strong, easy to keep, neat, masculine, striking, and dark.

6. SUGGESTIONS

1. Evaluating consumer perceptions by using the method of Quality Function Deployment (QFD), this can find out the needs of consumers in terms of performance, function, and quality of the mobile phone.
2. Perform data collection category by adding the sample to be taken such as income level, education level, and age.

ABSTRACT

Competition in the corporate world now becomes tighter. Each company is doing many kinds of strategies in planning, design, production, and sale its product. With those strategies, the company expects that its product will be sold out in the market area.
Kansei Engineering is a method of product design from Japan. This method tries to bond between consumer desires to product specification design by translating consumer desires through Kansei words.
Research has been executed in Furniture Company, CV. "X" Padang. CV. "X" tried to develop the product market and Kansei Engineering was using to find the appropriate design. This research took lazy chair as the research object. Lazy chair should be set as people's ease because it is in direct correlation to the user.
Using of Kansei Engineering and combining it with ergonomic approach that is anthropometry in product design, will produce a design not only appropriate to consumer needs but also in an ergonomic manner.

Keywords: *Design, Lazy Chair, Kansei Engineering, and Anthropometry*

1. INTRODUCTION

Competition in the corporate world now becomes tighter. Each company is doing many kinds of strategies in planning, design, production, and sale its product. With those strategies, the company expects that its product will be sold out in the market area. Create a product that really appropriate to consumer's desire is very important. It will affect the number of product sold moreover if the product is not the only one circulating in the market. In this case consumers have many opportunities to compare and select products that fit with their desire.

Product development process is a unity of activity needed to create a new concept to the market (Otto & Wood, 2001). Ulrich and Eppinger (2001) explain that the development phase concept include identification of target market's needs, creation and evaluation of alternative product concept, and selection of the best product development concept. The criteria of product development process have a great opportunity because the companies are required to take advantage of opportunities in the development of products.
This study focuses on the lazy chair object. Lazy chair is a product that has been made by Furniture Company. This object has been chosen because lazy chair is directly correlated with the user. Consumers have different interest through a lazy chair. The company certainly has to pay an attention on the differences especially in production strategy. Market in concept strategy is a production based on consumer's suit.
In order to respond the changes of market's taste quickly was developed kansei engineering method to satisfy the desire of consumer. Kansei engineering method was developed by Dr. Mitsuo Nagamishi in Japan and proven success in the design of Mazda cars. The previous research that implements kansei engineering has done by Khoriyah and Nurwidiana (2006) with garden chair is the object. The purpose of their research predicted design element of garden chair that appropriate with the image of consumer. Now, in order to know the consumer's desire is also used kansei words as the indicator. In this research is also used an anthropometry data in design element to get save and comfort design.
Based on the descriptions above is conducted research to determine element design of lazy chair that properly with feeling and image by using kansei engineering, and an ergonomic design using anthropometry data.

2. RESEARCH METHODOLOGY

Research methodology chart is appeared in this following picture:

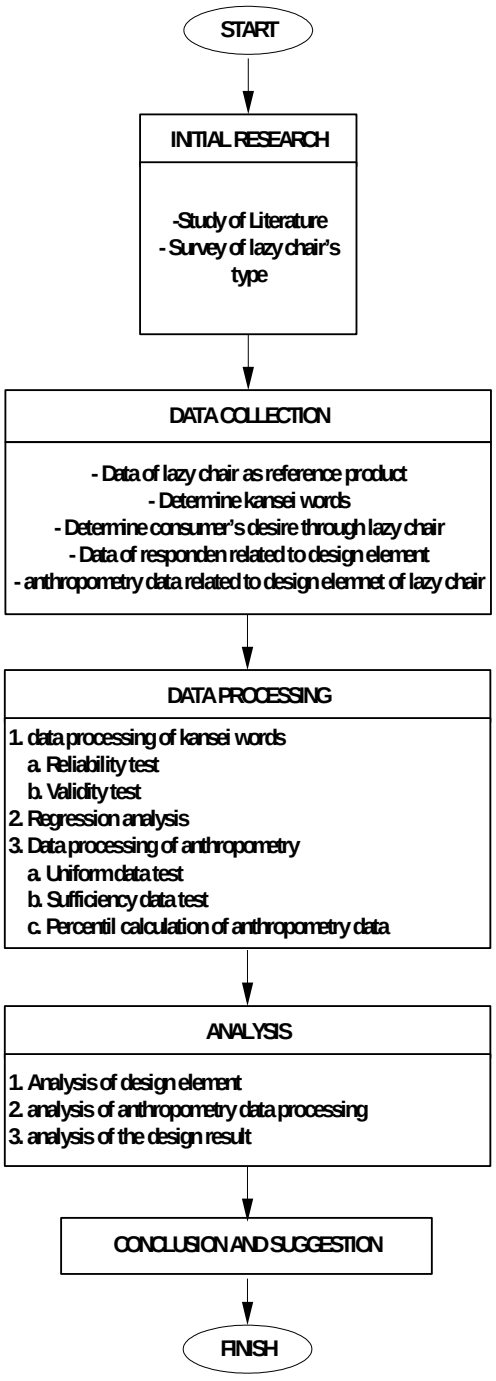

Figure 1: Research Methodology Chart

3. DATA COLLECTING AND PROCESSING

Table 1: Kansei words used in this research

No	Kansei words
1	Traditional
2	Modern
3	Antique
4	Strong
5	Rough
6	Soft
7	Clean
8	Durable

Data processing has been done by doing the regression linear calculation. Regression testing is used to predict a variable (dependent variable) based on a variable or some other variable (independent variable) in a linear equation. In the regression analysis of this research is comprised of 2 types. The first regression explore the relationship between design elements, with the kansei word, which is the dependent variable is respondents's appraisal (likert scale) while independent variables is the result of the selection of design elements. The second regression that explore the relationship between the two categories of design elements with the kansei word, the dependent variable is the value of the respondents (likert scale) and the independent variable is the result of the election category of the design elements. In this regression used α = 0.05 or 5% error level. Regression analysis was conducted using the SPSS 15 software assistance.

Those who become the variables in the first regression is:

dependent variable (Y) is the value of the respondents (likert scale).

independent variable (X) is the result of the selection of design elements.

Those who become the variables in this second regression is:

dependent variable (Y) is the value of the respondents (likert scale).

independent variable (X) is the result of the election category design elements.

Example of calculation:

1. First regression

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.853(a)	.727	.659	.70711	2,700

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	5.333	1	5.333	10.667	.031(a)
	Residual	2.000	4	.500		
	Total	7.333	5			

Linear regression equation for word "traditional":

$Y_{traditional} = 12 + 4\ X_1 - X_2 - X_3 - 1{,}52\ X_5$

2. Second regression

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.830(a)	.688	.221	1.069	1.777

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	5.048	3	1.683	17.472	.043(a)
	Residual	2.286	2	1.143		
	Total	7.333	5			

Linear regression equation for word "traditional":

$Y_{traditional} = 16{,}857 - 0{,}429X_3 - 1{,}143\ X_4 + 1.571\ X_8$

4. RESULTS ANALYSIS

1. Analysis of element design selection
   From data processing of kansei engineering using linear regression, is procurable element design that affect the chair's image. There are 18 words that affect the element design.

2. Analysis of the design result
   The selection of element design produced some variations of lazy chair's design. Comparison between each design has done by 3D sketch using AutoCad software.

Figure 3: 3D sketch of currently lasy chair

Figure 4: 3D sketch of lazy chair's 1st alternative

Figure 5: 3D sketch of lazy chair's 2nd alternative

Figure 6: 3D sketch of lazy chair's 3rd alternative

5. CONCLUSION

1. From 25 kansei words there are 18 words that are affected by element design of lazy chair.

2. Producer can get some alternatives of product design by implementing kansei engineering.

6. SUGGESTIONS

1. Perform production planning process and economic analysis through the design result of lazy chair.

ABSTRACT

Worker as human being have a limitation especially in work performance. This condition related to metabolism changing of body which is fatigue occurs in conducted working process. Fatigue can overcome by working time arrangement, which consist of work duration and resting time. Criterion that used in working time arrangement is working performance and energy expenditure. The objective of this study is to determine the extent of compliance with ergonomic principles in the relationship of working time arrangement in normal and fasting condition.

The working condition of unloading worker in cement bag factory is relocation each batch of sewing bag from belt conveyor to the destination place repetitively during 6 hour with standing position in normal and fast condition. Result of research is optimal productivity expressed by comparison of worker performance and consumption of energy. Optimal condition obtained if unloading worker do work activity with interval working duration every 4 hour totally 6 hour per day for normal condition, meanwhile in fasting condition every 2 hour totally 5 hour each day for optimal performance. While each interval working is given minimum resting time 30 minutes according to recommended interval working hour each condition.

Keywords
Working Condition, Working Performance, Energy Expenditure and Working Time

1. INTRODUCTION

Determining of company wisdom in scheme of work system has important influence to prosperity of operator. One of the aspect scheme of work system is relating to working time arrangement, for example; the duration someone can work in good productivity and healthy.

Arrangement in working time and resting time has contributed to organizational aspects which support company performance. Increasing in working time exceed ability, resulting degradation of productivity, incidence of fatigue, disease and also working accident. Research indicate that decreasing office hours from 8.75 hour/day become 8 office hours one day can improve work performance between 3% until 10 % [Tarwaka, 2004].

Base on result of interview with head and also human resources division of bag factory in PT. X, he said there is no research of in working time and resting time arrangement in normal and fasting condition. PT X is only use reference for working time and resting time arrangement based on company policy No.1120/ SED/ DESDM/ 07.2008. Working scheduling in this company pursuant to 2 division laboring working team by rotation during 7 day for shift A (08.00-15.00) and 6 day for shift B (15.00-22.00), commutation of each shift every one week. These policies also do in fasting condition (Ramadan Month) with tolerance reduction of resting time. It is based on company policy of No.113/PUM/ DESDM/ 08.2008.

The research is conducted by observation at unloading sewing bag operator work area. The working condition of unloading operator in cement bag factory is relocation each batch of sewing bag from belt conveyor to the destination place repetitively during 6 hour with standing position in normal and fast condition. this condition can be seen at Figure 1.1.

Figure 1. Work condition of *Unloading Operator*

2. LITERATURE STUDY

Quality human life base on (ILO) [Tarwaka, 2004] :

1. *work should respect the worker life's dan health.*
2. *work should leave the worker whit free time for rest and leisure.*

3. *work should enabel the worker to serve society and achive self-fulfillment by developing his personal capacities.*

3. RESEARCH METHODOLOGIES.

3.1. Phase Preparation.

Preparation step taken:

1. Introduction Research.
   Introduction Research is done for got information about condition of early from research object by interview and direct observation.

a. Interview
   Interview is done to know operator complaint when doing the job (unloading of sewing bag).

b. Observation.
   Observation is to know the condition of work activity at work station of unloading sewing bag operator in line 2 and characteristic work of fast and normal condition.

2. Literature Study.
   Literature study is reference research result and references related to in working time and resting time and also other related literature with this research.

3. Identify Problem.
   Observation with the working condition of unloading operator in cement bag factory is relocation each batch of sewing bag from belt conveyor to the destination place repetitively during 6 hour with standing position in normal and fast condition

4. Problem Formulation
   Strength of problem identifying result, hence becoming this research issue is How to arrange working and resting time base on work performance and energy expenditure for normal and fasting condition

5. Research boundary

- Object of research is unloading sewing bag workstation.
- Measurement criteria in this research are work performance and energy expenditure.
- Work performance is achievement measurement of unloading sewing bag process in certain time interval.
- Research is done in 1 shift each day (08.00 – 15.00) for normal and fasting condition every 30 minute interval of observing time.
- Time arrangement criteria are resting time and work duration for 1 shift.
- Research has been conducted at September 2008 for fasting condition and October 2008 for normal condition.
- Tools that use in this research is *Pulse Monitor* tipe PU-701 NSSG.
- This research just observing working time factor, another factor is assumed stabile and have no relationship.

6. Object of Research.

- Understanding relationship between work performance and energy expenditure for normal and fasting condition
- Analyze and arrange working time for normal and fasting condition.
- Analyze and arrange resting time for normal and fasting condition.

3.2. Collection and Processing Data

1. Data collecting
   Data required to this research shall be as follows:
   a. General Information about work system
   b. General Information about operator.
   c. Data about environment work
   d. Dimension physical data and method work station work now.
   e. Data of Anthropometry
   f. Heart pulse Measurement.
   g. Work Performance
2. Processing Data
   Data which have been collected was processed as according to requirement of research.
   a. Calculation of Anthropometry Data.
      Homogeneity test of Sample.
   b. Calculation of Energy expenditure.

3.3. Analysis.

3.3.1. Statistical Analysis.

Experiment 2 factor.
This experiment is used to investigate difference between energy expenditure and work performance in normal and fasting condition.

3.3.2. Result Analysis.

Result analysis will be studied result of data processing and also analyze obtained data curve. Pursuant to curve analysis will know optimize time of the working duration.

4. RESULT

4.1 Analysis Operator Election

Through homogeneous test to the operator, it is conclusion that there are no differences of ability (work performance) among operator.

Tables 1 *ANOVA for the operator election*

Source of Variation	SS	df	MS	F	F crit
Between Groups	1	3	0,333333333	0,012626	3,238872
Within Groups	316,8	16	26,4		
Total	317,8	19			

F_{table} :
Significance level 5 % ($\alpha = 0,05$)
$F_{(0,05;\ 5;\ 24)}$ in table = 3,238
F :
F = 0,012626

4.2 Analysis Experiment 2-Factor.

4.2.1 Experiment 2-Factor of Work Performance

This examination will be seen influence of some factor to work performance, the influences are:

- Operator and work performance relationship.
- Work condition and work performance relationship.
- Interaction between work condition and operator.

The conclusion of this examination:

1. There are not differences work performances among operator of unloading.
2. There is influence between work condition and work performance.
3. There is no influence of interaction between work condition and operator with work performance factor.

This strengthens the statement at the examination of ability for the election of operator. Equally, conclusions prove that ability of operator in work performance is same. The examination also obtained that working at normal condition give different work performance than in fasting condition.

Tables 2 *ANOVA experiment 2-Factor Work Performance.*

Source of Variation	JK	db	KT	F	F tabel
(A) Worker	4680,143	1	4680,143	0,233049	4,26
(B) Condition	250047	1	250047	12,45115	4,26

Galat	481974	24	20082,24		
Total	737072,4	27			

4.2.2 Experiment 2-Factor of Energy Expenditure.

Tables 3 *ANOVA experiment 2-factor of Energy Expenditure*.

Source of Variation	JK	db	KT	F	F table
(A) Worker	0,037216	1	0,037216	0,002984	4,26
(B) Condition	1,793149	1	1,793149	0,143791	4,26
Interaksi	15,96735	1	15,96735	1,280407	4,26
Galat	299	24	12,47053		
Total	317,0904	27			

This examination will be seen influence of some factor to energy expenditure, the influences are

1. There is not differences work performance among operator of unloading.
2. There is no influence between work condition and work performance.
3. There is no influence of interaction between work condition and operator with work performance factor

5. DISCUSSION

5.1 Analysis of Working Time

5.1.1 Analysis of Working Duration

Analysis of working duration is done base on curve of energy expenditure and work performance. The curve showed there is change of performance (work performance) and physiological condition of body during period of work. It will be able to be conducted in working time arrangement. Assessment criterion the used are comparison between wok performance and energy expenditure in certain work duration.

Steps in analysis of work duration:

1. Analysis Curve of Energy Expenditure.

Curve show pattern which is same relative to the each work condition and operator. Values energy expenditure is increasing until at 11.00 am. After at 11.00, in the reality assess energy expenditure tend to downhill which represent response of operator peak burden activity cause exhaustion after operator stop over.

Figure 2 Representing alliance curve energy expenditure of operator 2 in both condition, it is show that value energy expenditure of operator 2 is more excessively in fasting condition rather than normal condition. Whereas operator 2, he has energy expenditure same relative in both condition seen at Figure 2.

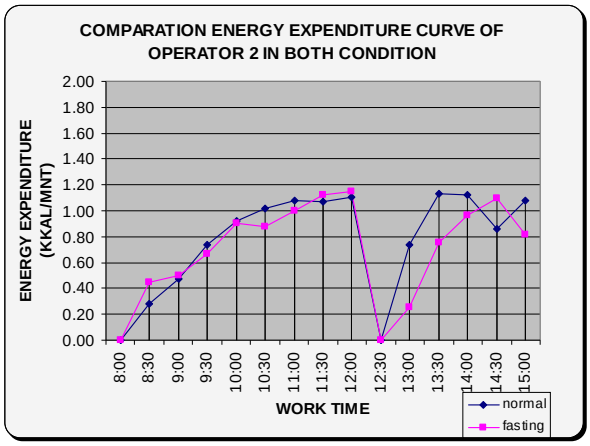

Figure 2. Curve energy expenditure of operator 1 in normal and fasting condition

2. Analysis Curve of Work Performance

Value work performance is found on curve represents work performance average value in time interval and same work condition. While statistically that is passing experiment 2-Factor work performances how there are no difference of work performance among operator and work condition.

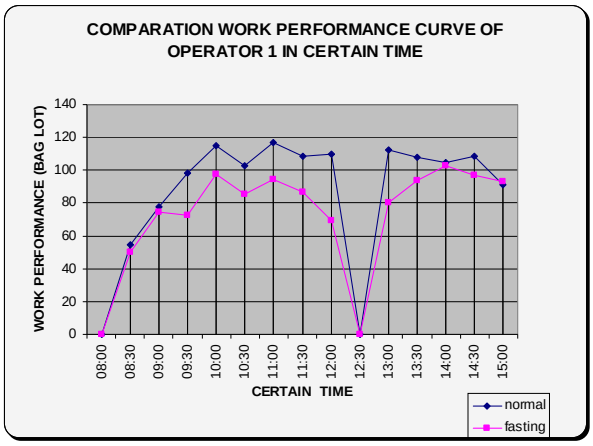

Figure 3. Curve work performance of operator 2 in both work condition.

Curve work performance show same fluctuation, but tend to happened degradation of work performance in fasting condition rather than in normal condition. Figure 3 is

representing work performance value of operator 2 in normal condition and fast. It is shown at curve that work performance value increasing until 10:30 am and have fluctuation during at 12:00 a.m. After at 11:00 operator work performance is tend to downhill until work activity rest. Similar after rest has experience of pattern which same to condition of working before rest.

3. Optimize work duration.

Seen at Figure 4 and 5 that is operator work performance early in working increasing till at 12:00 even there although there are work performance and energy expenditure fluctuations at 10:00 up to at 12:00 representing critical time or phase of operator. At time interval 10:00 - 12:00 many factor which possible influence operator, e.g others environmental factor and is psychological (it is not conducted measurement in this research).

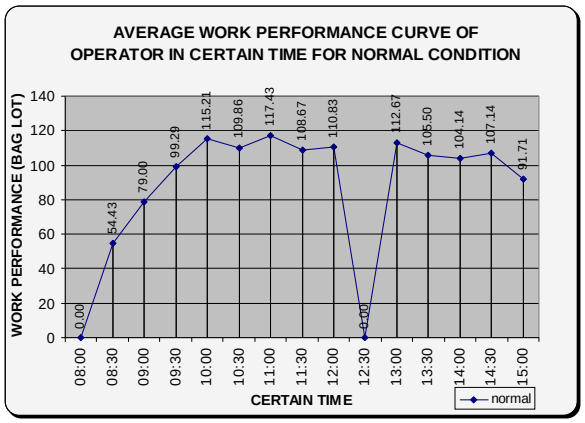

Figure 4 Curve of work performance in normal condition.

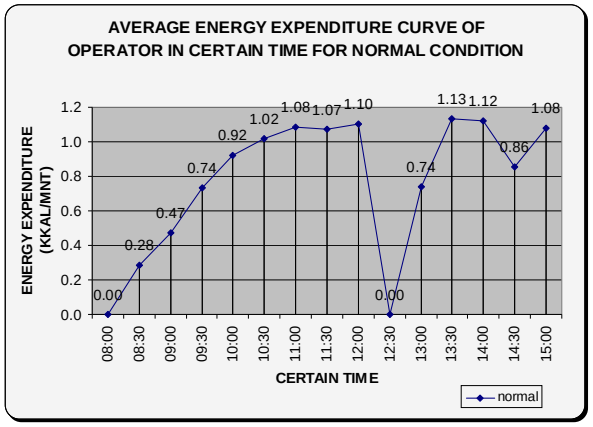

Figure 5. Curve of energy expenditure in normal condition.

Figure 6 is shown movement work performance operator of association of time. Therefore with Figure 6 seen clearly the condition of where natural operator fatigue is occur in time interval 10:00 up to 12:00, where curve tend to downhill. Degradation of curve at interval time of 10:00-12:00 supported also with make-up of value energy expenditure at the time (Figure 7). This matter indicate that at fasting condition after operator work average 2 hours represent critical time of operator to experience of fatigue marked with degradation of work performance and also the refreshing of energy expenditure. If this condition continue to take place will cause degradation of work productivity, degradation of quality work and also degradation of health of operator with the meaning loss of profit to company.

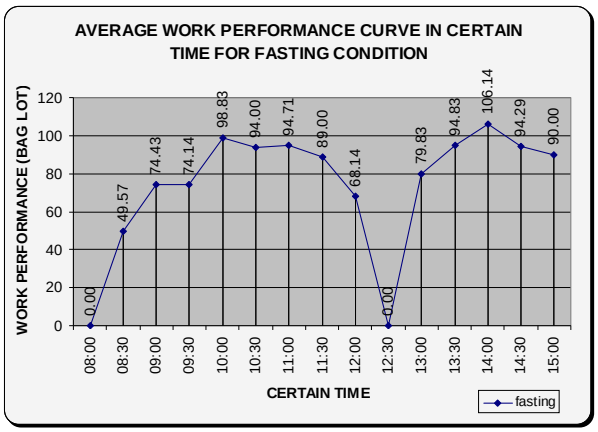

Figure 6 Work Performance curve in certain time in fasting condition

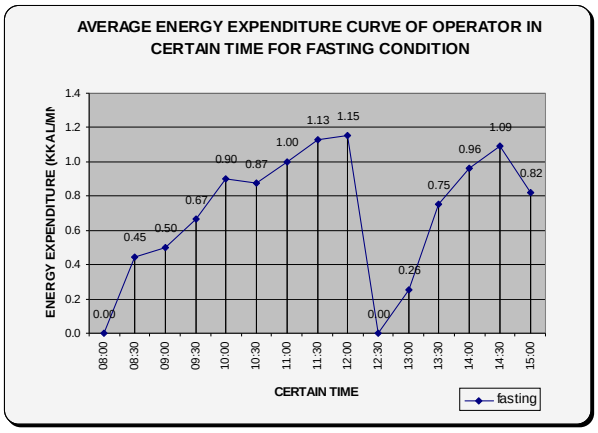

Figure 7 Energy expenditure curve operator in fasting condition

Figure 8 showing duration work during 4 hour give work performance per hour larger ones compared to work duration during 3 hour, 2 hour and 1 hour to both operators in normal condition. While in fasting condition working duration during 2 hour give best work performance compare energy expenditure per hour compared than work duration 1, 3 and 4 hours.

Furthermore, the comparison of work performance value and energy expenditure is show ability of operator to work performance 1 kkal. For example, the comparison of work performance versus energy expenditure of operator 1 for normal condition in work duration 2 hours is 102.655 lot /kkal. It is meaning with work duration 2 hour, operator 1 can produce 102.655 bag lot in 1 kkal.

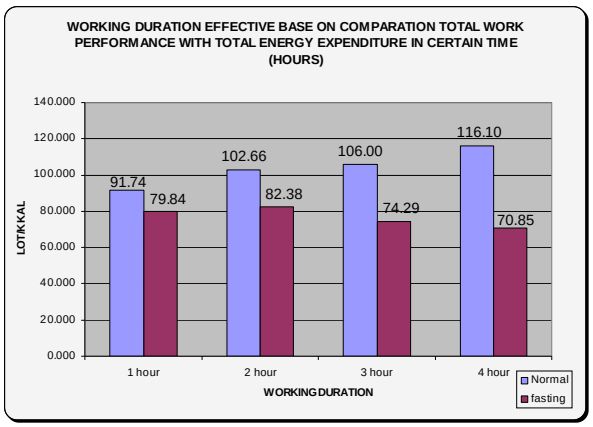

Figure 8 Curve determination of work duration

Pursuant to Figure 8 total comparison of work performance with energy expenditure obtained conclusion that optimal work duration in normal condition is 4 hours while at fasting condition is 2 hours.

5.2 Analysis Resting Time.

Result of research show, duration time for take a rest in 30 minute. This conclusion is obtained by seen the condition of pulse culminate at both the work condition which is same relative at heart rate 96.3 up to 96.4. So that equivalent required cure time both the work condition. Heart Pulse is recorded every 10 minute.

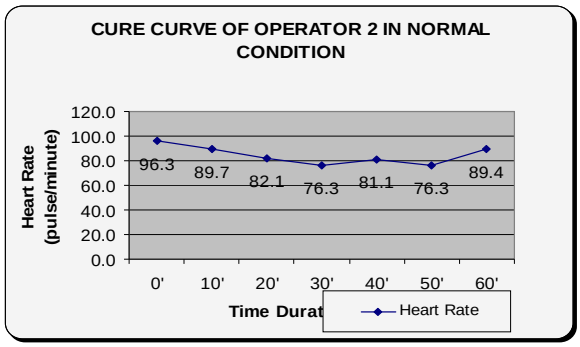

Figure 9 Curve cure of operator 2 in normal condition.

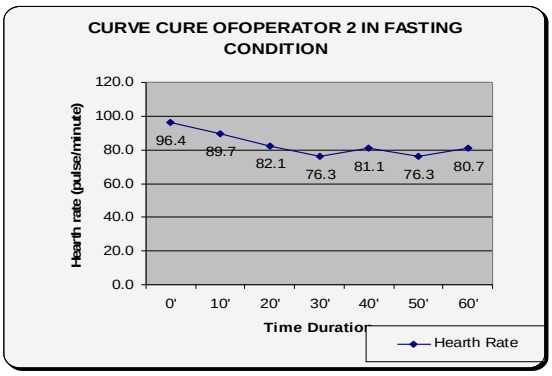

Figure 10 Curve cure of operator 2 in fasting condition.

While Figure 10 showing heart pulse operator 2 in fasting condition is 96.4 beat / minute. Heart pulse will return to refresh condition after 30 minute and relative constant until the operator starting his work.

All cure curves show that resting heart pulse of operator unloading sewing bag becoming to experience of degradation swiftly at first minute till the rest. The resting time duration of sewing bag operator normal in condition and fasting condition are same about 30 minute.

5.3 Working Time Arrangement

Hence in the working time suggestion got repetition each counted 3 times restating for the normal condition. Even more for the fasting condition is need be a change 5 times restating. Tables 4 and tables of 5 representing schedule work normal condition and fasting condition.

Tables 4 Schedule working time for normal condition.

Normal Condition		
Repetition	Work Duration	Note
1	08.00 - 12.00	Working Time
2	12.00 - 13.00	Resting Time
3	13.00 - 15.00	Working Time

Tables 5 Schedule working time for fasting condition

Fasting Condition		
Repetition	Work Duration	Note
1	08.00 - 10.00	Working Time
2	10.00 - 10.30	Resting Time
3	10.30 - 12.30	Working Time
4	12.30 - 13.30	Resting Time
5	13.30 - 15.00	Working Time

With existence of in working time arrangement pursuant to work performance criterion and energy expenditure, health and productivity level of operator will be more goodness.

5. CONCLUTION

Base on result of 2 factor experiment resulting about work performance and energy expenditure, there is a no different between operator, and also there is no influence work condition with energy expenditure .But it have different in influence of wok condition to work performance.

Optimal working and resting time duration;

Working Time Duration In Normal Condition: 4 hours

Working Time Duration In Fasting Condition: 2 hours

Resting Time Duration in Both Condition: 30 minutes.

ABSTRACT

Rapid growth of telecommunication sector shows that nowadays information becomes a basic need. In order to realize telecommunication service to general public in Indonesia, the government builds minimal one telephone line (SST) in every village. This kind of program is known as USO (Universal Service Obligation). However, undertaking telecommunication service in rural area (Universal Service Obligation) in 2003 and 2004 has not served 43.000 villages by basic telephone service on the whole. Therefore, establishment of BTIP - organizer of rural telecommunication service which is supervised by Directorate General of Post and Telecommunication - signifies that government reverts to get prepared in implementing USO in order to realize development spreading throughout rural areas entirely. Different condition of villages will definitely influence the amount of cost services offered by operators to government. Also, in continuation of this program, developing aspect of rural potency is needed which could push flow of information exchange. Thus, analyzing rural potency is required. This study attempts to get classification of villages according to their potency and discovering selected village characteristics as indirect indicators toward call traffic by using Multivariate Analysis. It shows that business aspect gives a big contribution to utilization of telephone. The more advance level of business development indicates a higher level of need of information exchange. The results of this study will give some information for them who are in charge in USO. So, realization of following program planning will be involving some considerations which are expectedly going to attain effective and efficient result.

Keywords: *Rural Potency, Factor Analysis, Cluster Analysis, Universal Service Obligation*

1. INTRODUCTION

Rapid growth of telecommunication sector shows that nowadays information becomes a basic need which is necessary to be fulfilled because it gives a big contribution to the development of other sectors. It is reinforced by the result of ITU's (International Telecommunication Union) research declaring that 1% increasing of teledensity will support economic growth by 3% [1].

By definition, teledensity is a measurement indicating utilization of telecommunication facility in a country [2]. Teledensity is a ratio of telecommunication facility number to population in a country. In Indonesia, this number is not proper to be categorized into ideal. It can be seen from reality that Indonesia has just reached 6.7 million telephone connection units (SST) with 220 million of population number which means that only 3 SST is available for 100 inhabitants. In other word, teledensity is only 3% and 0.2% in rural area [3]. The fulfillment of information need can be carried out by every Indonesian people without exception, in other word, being able to attain spreading evenly information access, if telecommunication facilities already reach out entire area up to outlying districts, so that they are not in position of digital divide anymore.

Referring to the declaration of ITU, in order to realize telecommunication service to general public in Indonesia, the government, (i.e., Ministry of Communication and Informatics, Directorate General of Post and Telecommunication) builds minimal one telephone line (SST) in every village. This kind of program is known as USO (Universal Service Obligation) or KPU (Kewajiban Pelayanan Universal) which is organized by BTIP (Balai Telekomunikasi dan Informatika Pedesaan).

Undertaking USO by Indonesian governments had been taken place in 2003 through installation 3.010 telephone connection units in 3.010 villages and in 2004 through installation 2.620 telephone connection units in 2.341 villages. This number shows that 43.000 targeted villages have not been served by basic telephone service on the whole. Therefore, in doing the establishment of BTIP, the organizer of rural telecommunication service, which is supervised by Directorate General of Post and

Telecommunication, signifies that government reverts to get prepared in implementing USO in order to realize development spreading throughout rural areas entirely.

In preparing the following USO, BTIP strives to straighten former concepts of service providing. One of them is village categorizing which is aimed to arrange priority of installation based on rural potency. The different condition of villages will definitely influence the amount of cost services offered by operators to government. It becomes such an important thing concerning that government is expected to allocate operational fund wisely appropriate with the requirement. Furthermore, it is better that undertaking telecommunication service in rural area to be followed by monitoring of telephone utilization. It can be realized by tracing the average of phone call duration. The greater the phone call duration the more the frequency of information exchange. Therefore, in continuation of this program, aspect of rural potency pushing flow of information exchange needs to be developed which yields a high utilization of telephone.

For the purposes of this study, analysis will be done based on village characteristics in Lampung during period 2003-2004 and the following. It is because of the availability of call traffic (historical data) overwhelms only Lampung area as telecommunication service area of Sampoerna Telekomunikasi Indonesia. It refers to the objective of this study which is wrapping up information of rural potency. Hence, service characteristics given by operators in exertion of USO implementation will not be covered in this study. Thus, the main problem discussed in this study is analyzing rural potency of Lampung in undertaking USO by BTIP using multivariate statistics. This paper aims to achieve two objectives. The first objective is getting classification of villages according to their potency. And the second one is discovering village characteristics as indirect indicators of telecommunication facility utilization.

2. METHODS

Collected data is in the form of secondary data as BTIP's archives that is Rural Potency according to survey of BPS in the year 2005. This kind of data consists of village characteristics informing rural potency, the potency or capacity/power which enables to be developed within village autonomy area [5]. Characteristics selection is done refers to study of BTIP and also based on information acquired from literatures. Addition of characteristics is expected more encouraging in discovering other fundamental aspects needed to be considered. Besides adding characteristics, variable substitution is also executed. It is conducted not significantly different in meaning. In particular, that is done for the purpose of getting a more precise result.

This study also occupies historical data such a kind of call traffic of USO villages period 2003-2004 in Lampung (report of Sampoerna Telekomunikasi Indonesia) during 6 months in period of July-December 2005. It is not likely to collect data in period latter than that because the report just accommodates it concerning the policy of monitoring telecommunication facility assigned to operators prevails 1 year after facility establishment (2004).

This study involves population of villages of USO located in Lampung during period 2003-2004 and the following. It is conducted in order to gain information reflecting truly condition of Lampung. In fact, villages as the following WPUT (Telecommunication Universal Service Area) located in Lampung numbers ± 805 in amount, nevertheless based on the availability of data, only 789 villages are available to be observed. While, among 314 vilages of previous USO served by STI, there are only 303 of them feasible to be discussed by the same reason.

Data is processed by performing multivariate analysis. Multivariate analysis refers to all statistical methods that simultaneously analyze multiple measurements on each individual or object under investigation [6]. Conducting multivariate analysis is related to the requirement of measuring, explaining and predicting the degree of relationship between variates. Variate is a linear combination of variables along with their weights which are determined empirically. Multivariate analysis used in this study consists of factor analysis, cluster analysis and multiple regression analysis.

In case of arranging concepts, object which is going to be observed comprises candidate villages of next USO. Required techniques are factor analysis and cluster analysis. Factor analysis is a kind of statistical method whose primary purpose is to find interrelationship between variables which are independent with one another so that a number of original variables can be condensed into one or some sets of new factors. According to this study, this technique is aimed to make it easy in recognizing and understanding village characteristics as basis of rural potency assessment. That is summarizing 33 evaluating variables into some factors or underlying dimensions.

To complete the first objective, data processing is continued by implementing cluster analysis. Cluster analysis is a statistical procedure to classify objects based on identical characteristic they possess. It is organized with the aim of forming some clusters with respect to some characteristics implied. The case is classifying 789 villages into 4 clusters. Afterward, grading village is held by involving weight factors in determining rank. The biggest weight is assigned to factor which assumed as the most supporting aspect either in installation or maintenance of telecommunication facility later on.

The second objective is discovering rural potency as indirect indicators of telecommunication facility utilization together with their contribution toward telephone utilization level. This discussion is a kind of evaluation so that the objects observed are villages of previous USO located in Lampung during period 2003-2004. Multiple regression analysis is used to organize it.

3. RESULT AND DISCUSSIONS

There are 33 variables involved as indicators in assessing rural potency which can be seen in Table 1. Among 33 selected variables, there is one variables has no variance (zero variance) which means that the data has no value at all (null value). So observation is performed to the remaining variables (32 independent variables).

All of data processing is supported by SPSS 15.0. In order to be able to arrange potency factors of village teledensity which summarize selected variables, it is necessary to do proper test to these candidate variables. They are agreed to be processed. It can be seen from correlation test showed by 0, 672 of KMO value, Bartlett's Test of Sphericity value indicated by 2847.851 of Chi-Square value and Sig-value (0,000) < α = 0,05 (level of confidence chosen).

In factor analysis, number of factors to be formed is executed related to scree plot test, as can be seen in Figure 1. Based on the scree plot, with the aim of obtaining the best combination of 32 variables into factors, trial and error is carried out from 3 up to 5 in number of factors along with some rotating methods which are *varimax*, *quartimax*, *equamax*, *oblimin*, and *promax*. This procedure gave best arrangement as result of implementing varimax rotating factor method by 4 factors.

Table 1: Village Characteristics in Assessing Potency of USO Villages

Rural Potency			
Accessibility Aspect		**Affordability Aspect**	
Social Culture	**Accessibility**	**Social Economy**	**Basic Business Parameters**
Number of family	Number of terminal for four-wheel public vehicle	Percentage of agricultural household	Number of big industry
Number of state elementary school	Existence of post office	Number of Indonesia migrant workers (TKI)	Number of medium industry
Number of private elementary school	Existence of mobile post office	Number of market with non-permanent building	Number of small industry
Number of hospital	Geographical site of the village	Number of stall (warung)	Number of supermarket/minimarket/store
Number of clinic	Easiness to reach the village	Number of mini shop (toko kelontong)	Number of commercial banks
Number of public health centre (puskesmas)			Number of small financial institution (Bank perkreditan rakyat)
Number of midwives (bidan)			Number of village cooperative unit (KUD)
Number of public health sub-centre (posyandu)			Number of handicraft and small cooperative
Number of maternity clinic (polindes)			Number of saving and loan cooperative (koperasi simpan pinjam)
Density			Number of non-village cooperative unit (non-KUD)
Existence of mutual cooperation (gotong royong) in public facility construction			
Existence of main street lighting			
Number of household electricity users			

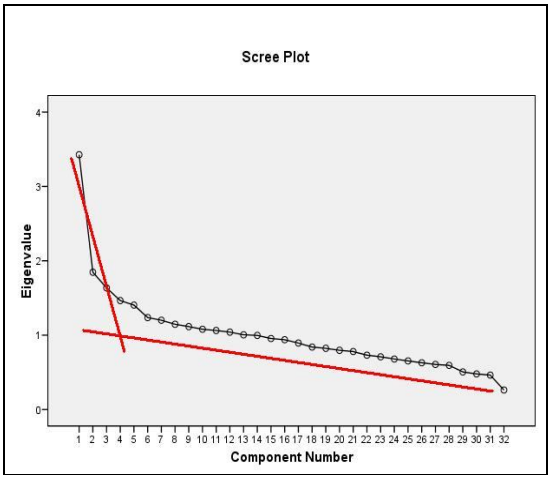

Figure 1: Scree Plot Factor Analysis

By applying rotating method, component rotated factor is produced which contains factor loading presenting correlation coefficients of variables in relation to factors. The highest loading identified membership for variables on any factors. Among 32 selected variables, 8 variables associate with factor 1, 11 variables associate with factor 2, 6 variables associate with factor 3 and 7 variables associate with factor 4. This allocating process developed 4 factors which are independent with one another. Subsequently, associating factors are labeled in accordance with information comprised. The arrangement of variables into factors accompanied by the name can be seen in Table 2.

Arrangement of rural characteristics (variables) into 4 factors is a little bit different from categorization generated by BTIP earlier. Rearrangement of variables is carried out with the aim of structuring factors statistically concerning with correlation among variables. Variables which grouped into one factor have a high correlation and they are influencing each other. Next, factor score is developed. Factor score, similar to original variables, is a value which blends grouped variables values (derived from factor analysis) consequently independent in nature as result (unrelated one another, no multicolinearity). Formulation of factor scores is useful as input in performing cluster analysis and multiple regression analysis.

By means of factors acquired, cluster analysis is executed. Number of cluster is four which is determined relates to treatment that would be held by BTIP and operators. Moreover, it allows comparing between output of research and study before. The result of cluster analysis can be seen in Table 3. The numbers show degree of rural potency of villages applied to factors acquired by description:

- Positive number indicates under average
- Negative number indicates above average

Table 2: Composition of Variables into 4 Factors

Factor	Factor Name	Variables
1	Characteristic and Facility of Basic Needs	Number of family, Number of state elementary school, Number of private elementary school, Number of public health sub-centre (posyandu), Number of stall (warung), Number of small shop (took kelontong), Existence of mutual cooperation (gotong royong) in public facility construction, Number of household electricity users
2	Economy and Health	Number of market with non-permanent building, Number of small financial institution (Bank Perkreditan Rakyat), Number of village cooperative unit, Number of handicraft and small cooperative, Number of saving and loan cooperative, Number of non-village cooperative unit, Number of Indonesian migrant workers (TKI), Number of hospital, Number of clinic, Number of public health centre (Puskesmas), Number of midwives.
3	Accessibility and Demography	Existence of mobile post office, Existence of main street lighting, Village geographical site, Easiness to reach the village, Density, Percentage of agricultural household
4	Business with its Supporting Facility	Existence of post office, Number of big industry, Number of medium industry, Number of small industry, Number of supermarket/minimarket/store, Number of maternity clinic, Number of terminal for four-wheel public vehicle

Table 3: Potency Value of Each Cluster Based on Factors Discovered

Factor	Cluster			
	1	2	3	4
Characteristic and Facility of Basic Need	0.1687550	-0.3654746	2.1639850	0.9351286
Economy and Health	2.3915211	-0.2118849	-1.1293309	-0.1807535
Accessibility and Demography	0.6416610	0.2191751	0.5324048	-0.8360114
Business with its Supporting facility	-0.3495429	0.0642848	9.5719679	-0.2155710

Clusters become references in accomplishing *grading* which is done by assigning weight in different number on each factor. Factor weight is settled refers to study of BTIP which can be seen in Table 4. Composition of villages resulted by cluster analysis is different with result of study before, which can be found out in Table 5. Afterward, cluster result in Table 4 might become some considerations in classifying villages; hence, on-hand fund would be allocated relevant to expenses required.

Table 4: Factor Weight

Factor	Factor Weight
Characteristic and Facility of Basic Need	10%
Economy and Health	45%
Accessibility and Demography	35%
Business with its Supporting Facility	10%
TOTAL	100%

Table 5: Comparison of Village Composition between BTIP's and This Study

Category of Village	Cluster based on BTIP	Cluster based on this study
Undeveloped village	155	190
Less developed village	490	533
Developed village	136	3
Highly developed village	8	63
TOTAL	789	789

Multiple regression analysis is constructed by involving all variables (33 village characteristics) along with call traffic. Backward is applied as approaching method in organizing this technique. Variables selection is made by eliminating variables that have less significant contribution. There are proposed variables which act as indirect indicators of villages toward telephone utilization, as can be seen in Table 6.

Table 6: Multiple Regression Result

Model	Unstandardized Coefficients (B)	P-Value
(constant)	-5.74429E-16	0.99999
Number of family	0.157617	0.00923
Number of maternity clinic	0.203566	0.00021
Density	-0.132288	0.01826
Percentage of agricultural household	0.101390	0.06436
Number of big industry	-0.136273	0.02023
Number of medium industry	0.178938	0.00095
Number of village cooperative unit	-0.153240	0.00475
Village geographical site	-0.150470	0.00617
Dependent variable: Zscore: Average of call traffic (6 months)		

By applying significance test toward each of regression coefficient at significance level of 5%, it is found that some variables influence telephone utilization significantly, they are: number of family, number of village giving birth house, density, number of big industry, number of medium industry, number of village unit cooperative and geographical site of village.

From this study, it is perceived that domination business aspect shows that it is so crucial to be considered in undertaking telecommunication infrastructure development. The advancement of business activity in a region indicates level of need of information exchange. According to this case, type of telecommunication service is definitely adjusted to the purpose of society's concern. Then, it concludes that region with a more advance business aspect is a more beneficial field to organizing business of telecommunication.

4. CONCLUSIONS

Based on the result, factors that summarize variables and become underlying aspect in assessing rural potency consist of: Characteristic and Facility of Basic Needs contains 8 variables, Economy and Health contains 11 variables, Accessibility and Civilization contains 6 variables and Business with Its Supporting Facility contains 7 variables. Afterward, according to these factors, villages are classified along with their grade, they are: immature village consists of 190 villages; semi mature village consists of 533 villages; mature village consists of 3 villages; and urbanized villages consists of 63 villages. In addition, there are 7 significant variables used as indirect indicator toward telephone utilization, they are: number of family, number of village giving birth house, density, number of big industry, number of medium industry, number of village unit cooperative and geographical site of village. It

concludes that business aspect gives a big contribution to utilization of telephone. The more advance level of business development indicates a higher level of need of information exchange. The results of this study will give some information for them who are in charge in USO. So, realization of following program planning will be involving some considerations which are expectedly going to attain effective and efficient result.

Improving Product Quality in Painting Production Line of Motorcyle Parts using Design of Experiments

Isti Surjandari[1] and Hanifa Dhina[2]

Industrial Engineering Department, Faculty of Engineering, University of ndonesia
Kampus Baru UI, Depok 16424, Indonesia
E-mail: [1] surjandari.2@osu.edu , [2] hanifa_dhina1@yahoo.com

ABSTRACT

Nowadays, quality is one of the key factors that have to be considered by a company to win a competition. Generally, quality is defined as meeting or exceeding customers' requirements. Quality is also become a major concern by PT Astra Otoparts Tbk, as one of the biggest producer of motorcycle parts in Indonesia. Data showed that defect rate is relatively high in some production lines, particularly in the painting process. The rejection number showed inefficiency in raw materials utilization because the rejected parts have to be replaced by producing new parts. In order to overcome this problem, an experiment is needed to analyze factors that affect the quality of painted parts in the painting production line. This study uses Design of Experiments (DOE), that is, the 2^k full factorial design method. DOE is a scientific method for identifying the critical parameters associated with a process and thereby determining the optimal settings for the process parameters for enhanced performance and quality. There are ten types of defect that are tested in this study, which are: orange peel, scratched, thin, dirt, oily, popping, dust, pervade, water dots, and painting melt. And there are four controllable factors used in the experiment, which are: conveyer speed, water spray pressure, hot water temperature, and degrease utilization. The results of this study show that controllable factors and their interactions are significantly affect the defect rate. There are five out of ten defect types which are statistically significant affected by the controllable factors in this experiment. Then, using response optimizer, this study finds the optimal setting for each of the controllable factors that might reduce the defect rate and improve the product quality.

***Keywords**: Design of Experiment, Full Factorial, Painting, Motorcycle Part*

1. INTRODUCTION

Recent economic condition in Indonesia indirectly affects transportation sector and its supporting industries. People now prefer to have transportation mode that support their mobility, such as a motorcycle. Motorcycle has more flexibility through the busy and crowded traffic conditions especially in the big cities such as Jakarta. It is also supported by its price, which is relatively achievable by most Indonesian people. This fact makes motorcycle sales in Indonesia increases every year.

Nowadays, PT Astra Otoparts Tbk (AOP) is the leading company in producing motorcycle parts in Indonesia. Its biggest customer is PT Astra Honda Motor (AHM), which is the leading company in producing motorcycles in Indonesia. In this case, AOP has to maintain and even increase its market share. In so doing, AOP has always give attention to quality improvement. Eventhough inspection and checking procedure take place in each production line, still defect may take place. Production lines which show relatively high rate in product defect are painting lines. In these lines, motorcycle parts, which were produced by the plastic injection section, are painted. Subsequently painted parts will be delivered to the assembling lines. There are three lines in this painting section, where the first two lines use hanging conveyor and the third line use manual conveyor. Figure 1 show parts which are painted in AOP.

Figure 1: Plastic Painted Parts in Motorcycle

Rejection rate in panting lines was 24.25% in Desember 2007, and increased to 30.20% in January 2008. It shows AOP has to bear high quality costs because the rejected parts have to be replaced by producing new parts. In this case, it becomes important for AOP to do quality improvements in the painting lines. The objective of this study is to investigate controllable factors that affect the defect product in painting lines using Design of

Experiments (DOE). Hence it can be determined the optimal setting of those factors in order to reduce rejection rate in the painting lines.

2. METHODS

For the purpose of this study, a 2^k *Full Factorial Design* will be used to improve product quality, which is plastic painted of motorcycle parts, in the second line of painting section. There are 10 types of defect that will be analyzed in this study, which are: orange peel, scratched, thin, dirt, oily, popping, dust, pervade, *water dots*, and paintings melt. Figure 1 shows percentage of each defect type in the second line.

Output of each experiments is the number of defect occurred for each of defect type, because there will be opportunity to have more than one type of defect occurred in the same part. The result will be converted into probability of success that is percentage of part without any defect type. Since the highest production rate in the painting lines is black colored parts (i.e., black is the preferred color by the consumen), but with the highest rejection rate, hence analysis will be focused on black color. Figure 3 shows rejection rate for each color.

Figure 4 shows flow process chart for painting in AOP. Basically, there 6 main processes in the painting line, which are: pre-treatment, air blow (1 and 2), dry and baking oven, setting room (1 and 2), under coat and top coat.

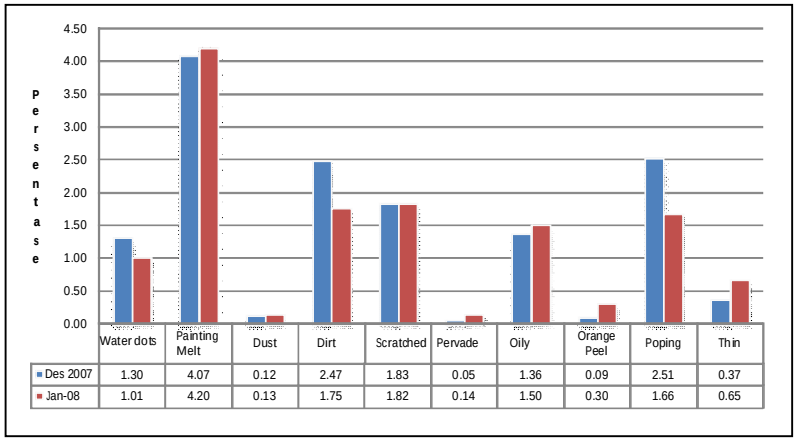

Figure 2: Percentage of each Defect Type in Line 2

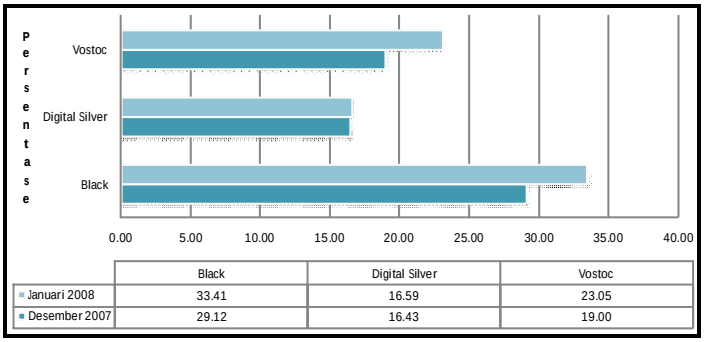

Figure 3: Rejection rate for each Color

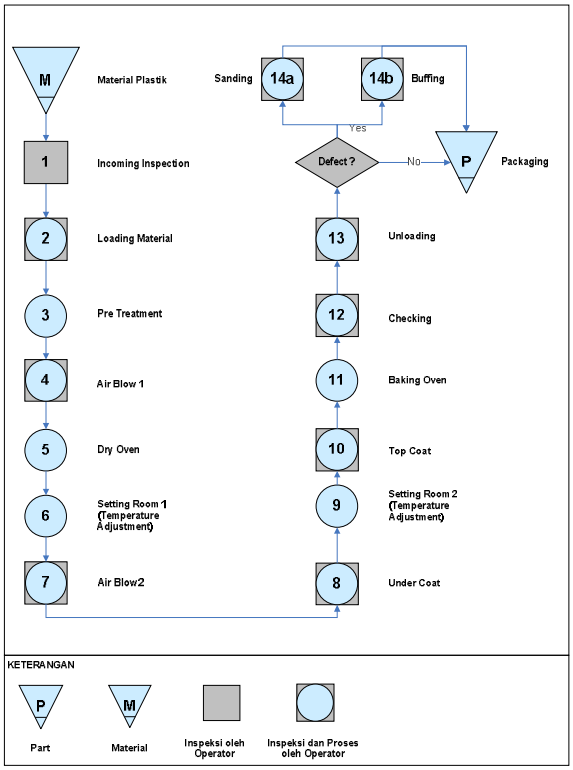

Figure 4: Flow process Chart of Painting Line

There are four controllable factors, each with two levels that will be analyzed in this experiment, which are:

1. *Conveyor speed:*
   A hanging conveyor is used in this line, where each plastic part will be loaded and hung on the conveyor. A hanger can load up to four big parts at once (e.g., rear wings and speedometer cover), and up to 12 small parts. There are 322 hangers in the second production line while 324 hangers remain in the first line. Cycle time for a material loaded until the final process is 1.5 hours. Each coloring process has different speed, depend on the color used. For the experiment, the speed for low level is 3.0 m/minute and for high level is 2.5 m/minute
2. *Water spray pressure:*
   Parts will be sprayed by water which comes out from nozzle surround the room. The range of water spray pressure is 0.6 psi to 0.8 psi. For the experiment, the water sprays pressure for low level is 0.6 psi and for the high level is 0.8 psi.
3. *Hot water temperature:*
   The hot water is required to demolish oil and grease left from the parts. The maximum temperature allowed to wash plastic materials is 60˚C. For the experiment, the hot water temperature for the low level is 52˚C and for the high level is 60˚C.
4. *Degrease utilization*
   Degrease is used in this process as detergent powder. It is used to demolish grease and oil left by compounding it with hot water in the first pump. For the experiment, the low level is not using degrease and the high level is using degrease.

The experiment will be run using two replications for each combination of the 2^k full factorial design, so the total number of experiments is 32 times. In order to minimize the effect of noise factors induced into the experiment, each trial condition was randomized. Randomization is aprocess of performing experimental trials in a random order, not that in which they are logically listed. The idea is to evenly distribute the effect of noise across the total number of experimental trials.The experimental design can be seen in Table 1, while Table 2 illustrate the results of the experimentfor scratched defect type. Since there are 5 defect types, each with its own experimental result, therefore, scratched type of defect will be used as an example for the discusion and analysis.

3. RESULT AND DISCUSSIONS

Table 3 shows the ANOVA result for scratched type of defect. It shows that no single factor in the experiment that affect scratched defect type. However, the two-way interaction between speed conveyor and degrease do have affect on the scratched defect type.

Table 4 shows ANOVA result for the controllable factors which are statistically significant affecting defects with significance level of 5%. There are 5 defect types which are affected by factors in the experiment, which are: dirt, oily, water dots, and painting melt.

The purpose of using degrease is to remove dirt attached, and it is significantly affect defect. Its interaction with right temperature is also affecting defect. Conveyor speed is also significantly affecting defect, because as the the conveyor gets slower the more time for degrease with the right temperature to wash the parts. Possible causes for orange peel, thin, and dust are operator skills which are not adequate. While for poping, it may caused by poorly dried part which comes from the dry oven in the pre-treatment process, hence it creates bubble in the painting process.

Scratched might be caused by parts wich rub against each other from the same or different hanger. Also, when parts enter the pre treatment process, there is a possibility for each part to get scratched because it will be sprayed by high pressure water, so it can make the hanger unsteady and the parts may rub against each other. This is why conveyer speed and water pressure becomes statistically significant affecting the defect rate.

Table 3: Summary of Defect Type Significant Values

	Term	T	P-Value
Dirt	Degrease	4.25	0.001
	Temp * Degrease	-5.39	0
	Speed * Temp * Degrease	2.49	0.024

Figure 5 shows the normal probability plot of the residual for scrathed type of defect. It shows that the data is normally distributed. The same results obtained from the other defect types.

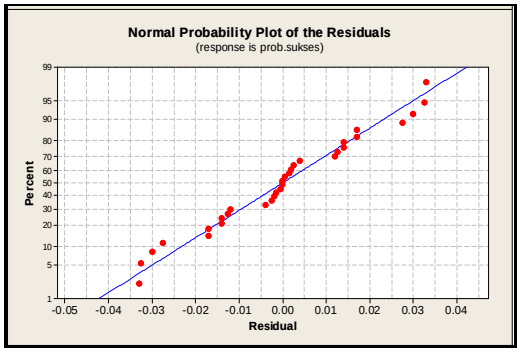

Figure 5: Normal Probability Plot for Scratched Type of Defect

After analyzing the defect causes, the next step is to find the optimal combination of factors in order to reduce the defect rate. Figure 6 sows the optimum combination for the controllable factors that is obtained using Response Optimizer. While Table 4 shows the interpretation of Responese Optimizer plot for scrathed type defect.

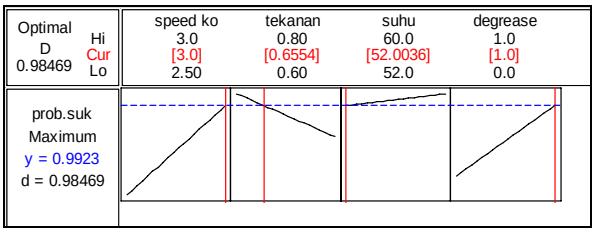

Figure 6: Response Optimizer for Scratched Type of Defect

Table 4: Response Optimizer Plot for Scratched Type of Defect

Setting	D-Value	conv. Speed	press	temp	degrease
Initial	0.98469	3	0.6554	52.0036	1
Optimal	0.98469	3	0.6554	52.0036	1

The response optimizer graph shows the best combination of controllable factors used to decrease the number of scratched part by using conveyor speed at high level (3 meter/minute), spray pressure at low level (0.6 psi), temperature at low level (52˚C), and using degrease.

Figure 7 shows the contour plot of interaction between Degrease and Speed Conveyor for the scratched type of defect.controllable factors used to reduce the other type of defect based on the Response Optimizer. It shows that the optimum setting of the controllable factors is generally the same to reduce all type of the defect types.

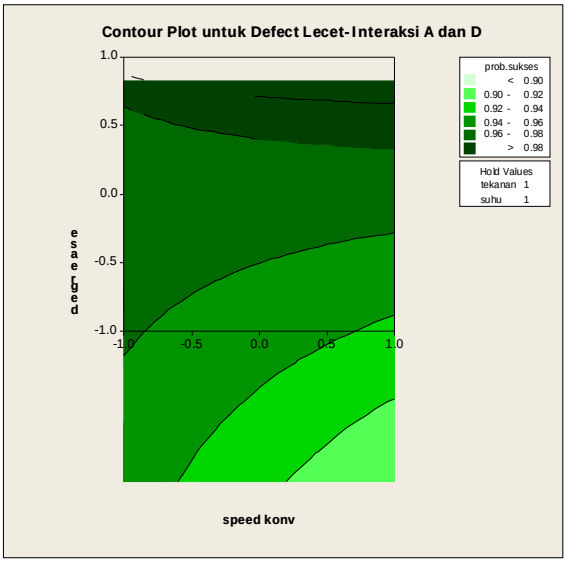

Figure 7: Contour Plot of Interaction between Degrease and Speed Coveyor for Scratched Type of Defect

Table 5 show the optimum combination of the

Table 5: Response Optimizer Combination

Defect Type	Conv. Speed		Pressure		Temperature		Degrease	
	2.5	3	0.6	0.8	52	60	Yes	No
Dirt		■		■	■		■	
Scratched		■	■		■		■	
Oily		■		■	■		■	
Water Dots		■		■		■	■	
Painting Melt		■		■	■		■	

CONCLUSIONS

The result of this study shows that there are 5 types of defect which are statistically significant affected by the controllable factors in the experiments. Those 5 defect types are scratched, dirt, oily, water dots, and painting melt. Each defect type is affected by different factors, and so they do for the interactions. Generally, the optimum combination of the controllable factors to decrease the defect rate is the almost same for each defect type.

ABSTRACT

This paper reports a design of experiments approach to optimize the injection moulding processes using recycled plastic materials. Observation on a plastic manufacturing company was performed to find the factors that have significant effect on the injection moulding process and product. Barrel temperature, injection pressure, and clamping pressure were determined as the factors and their effect to the process was investigated. The experimental design method using 3k factorial design technique was formulated for the experiments. The experiments were performed on the injection moulding machine. From the ANOVA, main effect plot and interaction plot produced by Minitab software, a combination of barrel temperature, injection pressure, and clamping pressure was determined to be the optimum setting for the process. This result was implemented as the combination of the machine setting to produce 12 batches of products and the number of defect product was decreased.

Keywords
Injection molding, plastics recycled material, 3k factorial design method, design of experiment

1. INTRODUCTION

The world's annual consumption of polymer materials has increased from around 5 million tonnes in the 1950s to nearly 100 million tonnes today [1]. According to Seung-Soo and Seungdo, continuous accumulation of plastic wastes leads to serious problems all over the world [2]. The disposal of these materials also represents a significant loss of a potentially valuable, reusable material estimated by PlasticsEurope for 2005 at 11.6 million tones for Europe alone [3].

Although the recycling capacity for plastics has been progressively increased, but the fraction of plastics that end up in a landfill is still very significant [4]. As its consequence, there is great interest in finding the new possibilities to use post-consumer plastics to produce new product. For example, Sahputra investigated the mechanical properties of recycled PET/HDPE that can be used for an alternative material of new consumer product [5].

Polypropylene is one of the most popular polymers used for household product. In 2000, Polypropylene represented 23% of the polymer consumed in Western Europe [6]. In the world, its sales in tonnage is the third most important amongst polymers [7]. Therefore the production process using recycled Polypropylene is a challenge to be considered.

Injection moulding is one of the most common processing methods for polymer [8]. The major advantages of injection moulding process includes its versatility in moulding a wide range of products, the ease with which automation can be introduced, the possibility of high production rates and the manufacture of articles with close tolerance [9].

In the injection moulding process, polymers in the form of granules or powders are put into the barrel through a hopper. In the barrel, polymers are heated until they are completely melted. They are then pushed through a nozzle into a cold mould which is clamped closed. After the polymers are cooled and solidified, the product is ejected and the process cycle is repeated.

Operating parameter optimization is considered the main challenge for injection moulding process to produce household product from recycled Polypropylene. Design of Experiments (DOE) is an efficient problem solving quality improvement technique that can be used for various experimental investigations. For example Lu and Khim implemented this technique in the injection moulding of plastic optical lenses [10]. Statistical methods were employed in the experimental studies in order to systematically analyze the effect of various process parameters on the lens contour errors.

Operating injection moulding parameter optimization for recycled polypropylene is reported in this paper using DOE methods. The injection moulding process was selected for production of basket in the manufacturing company partner. The objective of the experiment is to determine the optimal injection moulding process parameter setting that minimizes the product defect.

2. EXPERIMENTAL PROCEDURE

2.1 Materials and machines

The raw material to be used for the experiments was polypropylene from post-consumer household products such as bin, pot, bucket, and basin. These waste products were put into the plastics grinding machine to be cut to size of eight to ten millimeter square. After cutting process, these materials were washed by plastics washing machine for fifteen minutes. After washing process, the materials were put into the drying oven for eight hours. The raw material after being processed can be seen in figure 1.

The experiments were performed on an Elite Machinery Systems Injection Moulding Machine provided by a plastic manufacturing partner. The machine was used to produce household basket as the sample product.

2.2 The DOE implementation

After a thorough investigation of the existing process, the factors that affect the defect of the produced basket were identified as follows:

- Barrel temperature (X1)
- Injection pressure (X2)
- Clamping pressure (X3)

A current injection moulding process was investigated to determine the level for each factor. The machine setting was:

- Barrel temperature between 275°C - 255°C - 150°C and 320°C - 255°C - 190°C
- Injection pressure between 150 kg/cm^2 and 250 kg/cm^2
- Clamping pressure between 125 kg/cm^2 and 175 kg/cm^2

The initial experiment was conducted to produce 22.869 baskets and the product defect obtained was 6.63%.

Three levels for each factor were selected as shown in the table 1. Characteristic of the selected response was lower the better because of the expected number of product defect was the lowest possible. The replication was performed twice therefore the number of run was 54. Every replication was performed on the two machines for four hours and the product defect data was obtained.

Table 1: Selected levels for the factors.

Factor	Level		
	1	0	-1
X1	320°C - 255°C - 190°C	295°C - 255°C - 170°C	275°C - 255°C - 150°C
X2	250 kg/cm^2	200 kg/cm^2	150 kg/cm^2
X3	175 kg/cm^2	150 kg/cm^2	125 kg/cm^2

3. RESULTS AND DISCUSSION

The number of product defect data obtained from the experiment is shown in the table 2. Analysis of variance (ANOVA) was used to investigate and model the relationship between the response variable (defect) and the independent variables (barrel temperature, injection pressure, and clamping pressure). The ANOVA was performed using Minitab software. The results are shown in the figure 2.

In the figure 2, it can be seen that all p-values are printed as 0.000. This means that all the actual p-values are less than 0.0005. Since all p-values are less than the chosen α-level of 0.05, it means the effects of three factors and their combinations on response are significant.

From figure 3 we can see that all lines are not horizontal (parallel to the x-axis), therefore there are main effects present. The change in factor X1 (barrel temperature) shows the greatest magnitude of the difference on response as shown by its slope. This means that barrel temperature affect the product defect greater than injection pressure and clamping pressure.

Interaction plot was used to investigate the interaction between factors. An interaction occurs when the change in response from the one level of a factor to another level differs from the change in response at the same two levels of a second factor. That is, the effect of one factor is dependent upon a second factor. The plot is shown in the figure 3.

Figure 3 Interaction plot

From figure 3 it can be summarized as follows:

1. Row 1 panel shows level 1 (320°C - 255°C - 190°C) of factor X1 (barrel temperature) produced the least number of defect product
2. Row 2 panel shows level 0 (200 kg/cm^2) of factor X2 (injection pressure) produced the least number of defect product
3. Row 3 panel shows level 1 (175 kg/cm^2) of factor X3 (clamping pressure) produced the least number of defect product.

An experiment was conducted using the machine setting obtained from the DOE experiment result above. The machine setting was as follows:

- Barrel temperature : 320 ° C - 255 ° C - 190 ° C
- Injection pressure : 200 kg/cm^2
- Clamping pressure : 175 kg/cm^2

The experiment produced 12 batches of basket product. The total number product was 43.897 and the product defect was 1.2 %.

4. CONCLUSION

Experimental work using DOE method had been performed to find the optimum injection moulding process parameter setting. Three significant process parameters were investigated: barrel temperature, injection pressure and clamping pressure. An optimum setting for the three process parameters had been identified for producing basket products with minimum number of product defect.

ABSTRACT

As market mature and competition intensifies, firms are exploring ways to increase customer retention which has been shown to increase company profitability. One strategy to maintain customer retention is by improving determinant factors of service loyalty, that is service quality. This applied research in the marketing field is conducted to study determinant of customer loyalty using KA Parahyangan for Bandung-Jakarta trip. From 181 respondent, it is shown that service quality do have impacts on service loyalty with the pearson coefficient of 0.536 (p-value 0.000). Detailed refinement of correlation based on dimensionality perspective shown that every service quality dimension relate significantly to word-of-mouth communication dimension. Empathy dimension mainly determine the word-of-mouth communication, and this suggest the managerial of KA Parahyangan to improve the employee ability in treat customer as individual.

Keywords : *Service quality, service loyalty, railways services*

1. INTRODUCTION

Service quality has been the subject of considerable interest by both practitioners and researchers in recent years, spurred on by the original work of Parasuraman et. al. [10] An important reason for the interest in service quality by practitioners result from belief that this has a beneficial effect on bottom-line performance of the firm [3]. The concept of service quality and service loyalty are related to each other. Theoretically, the expectancy or disconfirmation paradigm can provide the grounding for this study, with service quality as an antecedent construct and service loyalty as an outcome variable. A better understanding of the effects of service quality and service loyalty can help academics in the development of a model of service marketing. It can also provide practitioners with indications as to where best devote marketing attention and scarce corporate resources [3]

This study seeks to contribute to the development of a conceptual framework that integrates service loyalty and service quality carried out among KA Parahyangan customer. As one of railway transportation, KA Parahyangan had ever been the first choice for Jakarta-Bandung roundtrip. After Cipularang freeway operated in 2005, significant number of railway customer are switch to other alternative because of the shorter travel time. In 2008, KA Parahyangan fare was reduce about 50% in order to maintain a large number of passenger. Based on that situation, it is needed to evaluate quality of transportation service provided by KA Parahyangan, and furthermore tested the hypothesis relationship of service quality and service loyalty.

2. LITERATURE REVIEW

2.1. Service Quality

Definition of service quality hold that this is the result of the comparison that customers make between their expectations about service and their perception of the way the service have been performed [10,11,12] According to Zeuthaml [14] service quality is often conceptualized as the comparison of service expectations with actual performance perceptions. On an operational level, research in service quality has been dominated by the SERVQUAL instrument, based on the so-called gap model. The central idea in this model is that service quality is a function of the difference scores or gaps between expectations and perceptions (P-E). It has been proposed that service quality is a multidimensional concept [10]. Five keys dimensions of service quality have been identified. *Reliability* is defined as the ability to deliver the promised service dependably and accurately. It is about keeping promises, furthermore, promises about delivery, pricing, complaint handling, etc. *Responsiveness* can be described as the willingness to help customers and provide prompt service. This dimension stresses service personel's attitude to be attentive to customer requests, questions and

complaints. *Assurance* is the dimension that focus on the ability to inspire trust and confidence. *Empathy* is the service aspect that stresses the treatment of customer as individuals. Finally, tangible is service dimension that focus on the elements that represent the service physically.

In spite of the widely use, SERVQUAL also been widely criticized. For instance, the validity and reliability of the difference between expectations and performance has been questioned and several authors have been suggested that perception scores alone offer a better indication of service quality [4]. An important advantage of SERVQUAL instrument is that it has been proven valid and reliable across a large range of service contexts. A considerably number of author have argued that service quality is an important determinant of service loyalty.

2.2 Service Loyalty

The conceptualization of service loyalty construct has evolved over the years. In the early days the focus of loyalty was brand loyalty with respect to tangible goods. Cunningham [6] defined brand loyalty simply as "the proportion of purchases of a household devoted to the brand it purchase more often". Loyalty was to broaden the spectrum of analysis by focusing on store as opposed to brand loyalty using the same measures he had use earlier for brands [7].

The behavioral and attitudinal aspects of loyalty are reflected in the conceptual definitions of brand loyalty offered by Jacoby and Chestnut [9] that brand loyalty was simply measured in term of outcome characteristics. Much of the work on loyalty in the 1970s and early 1980s has used this conceptualization. Dick and Basu [7] suggest an attitudinal theoretical framework that also envisages the loyalty construct as being composed of relative attitude and patronage behavior.

A further aspect of loyalty identified by other researchers in more recent years is cognitive loyalty. This is seen as a higher order dimension and involve the consumer's conscious decision-making process in the evaluation of alternative brands before a purchase is affected. Gremler and Brown [8] extend the concept of loyalty to intangible products, and their definition of service loyalty incorporates the three specific components of loyalty considered, namely : the purchase, attitude and cognition. Service loyalty is defined as the degree to which a customer exhibits repeat purchasing, behavior from a service provider, possesses a positive attitudinal disposition toward the provider, and considers using only this provider when a need for this service exists.

While loyalty is often included in service quality models as an outcome variable. Cronin & Taylor [4] measure service loyalty solely on repurchase intentions, while Boulding et al [2] operationalised repurchased intentions and willingness to recommend. As Zeithaml et al [14] argue, dimension of service loyalty, such as willingness to pay more and loyalty under increasing price. Singh [13] proposed customer evaluation following a negative service experience as a dimension of service loyalty also. Bloemer [2] studied the link between the individual dimensions of service quality and service loyalty.

3. RESEARCH METHODOLOGY

The questionnaire is used consisted of 37 items split between two instruments that 25 items measured service quality and 12 items measured service loyalty. Twenty five item measured service quality on the basis of perceived quality and consist of 6 items on Reliability, 4 items on Responsiveness, 5 items on Assurance, 5 items on Empathy and 5 items on Tangibles. Twelve items of service lotalty consists of 4 items for Word-of-Mouth-Communication, 2 items on Repurchase Intention, 3 items on Price sensitivity and 3 items on Complaining Behavior. Demographic variable were also collected. The research instrument consist of five-points scale. The questionnaire were pre-tested on a convenience sample of 30 passenger of KA Parahyangan. This pre-tested is aimed to verify the validity and reliability of questionnaire items. Tabel 1 and 2 shows the validity result and table 3 for reliability test

Table 1 : Validity Test for SQ Items

SQ Atribute	Item	Pearson Correlation	p-value	Description	
				Relationship	Validity
Reliability	V1	0.551	0.001	Moderate	VALID
	V2	0.664	0	Strong	VALID
	V3	0.607	0	Strong	VALID
	V4	0.444	0.007	Moderate	VALID
	V19	0.423	0.01	Moderate	VALID
	V25	0.58	0	Moderate	VALID
Responsiveness	V5	0.763	0	Strong	VALID
	V6	0.682	0	Strong	VALID
	V7	0.698	0	Strong	VALID
	V8	0.84	0	Very Strong	VALID
Assurance	V9	0.752	0	Strong	VALID
	V10	0.82	0	Very Strong	VALID
	V11	0.797	0	Strong	VALID
	V12	0.862	0	Very Strong	VALID
	V13	0.76	0	Strong	VALID
Empiaty	V14	0.745	0	Strong	VALID
	V15	0.413	0.012	Moderate	VALID
	V16	0.82	0	Very Strong	VALID
	V17	0.738	0	Strong	VALID
	V18	0.509	0.0002	Moderate	VALID
Tangible	V20	0.75	0	Strong	VALID
	V21	0.802	0	Very Strong	VALID
	V22	0.791	0	Strong	VALID
	V23	0.885	0	Very Strong	VALID
	V24	0.827	0	Very Strong	VALID

Based on the pilot sample, required number of sample is calculated. The highest standard deviation of 37 items was 0.817323, using 10% error and 90% confidence interval, expected number of sample is 180.76 ≈ 181.

Research data had been collected again aboard of KA Parahyangan until the number of sample requirement accomplished.

Table 2 : Validity Test for SL Items

SQ Atribute	Item	Pearson Correlation	p-value	Description	
				Relationship	Validity
WOM	A1	1	0	Very Strong	VALID
	A2	0.81	0	Very Strong	VALID

Atribute	Cronbach's Alpha
Reliability	0.710
Responsiveness	0.798
Assurance	0.806
Empathy	0.757
Tangibles	0.808
WOM	0.895
Repurchase Intention	0.780
Price Sensitivity	0.785
Complaining Behavior	0.746

4. RESULT

Respondent were almost equally split between males (46.67 %) and female, 62.22% of respondent were in the range of 20 until 40 years old, and 64.99 % had completed tertiary level of education. Only 25.55% of respondent were student and the rest is working people. The most interesting demographic finding is only 8% of respondent were first time customer using KA Parahyangan, 62.22 % admitted for over than 5 times using KA Parayhangan. The reason why they choose to take KA Parahyangan was 51.66 % because of the lowest fare.

The relationship between service quality and service loyalty then investigated using person correlation. Moderate correlation between two research constructs indicated by pearson correlation of 0.536 (see Figure 1). The positive correlation shows that high perceived service quality will lead to loyalty to service provider [1].

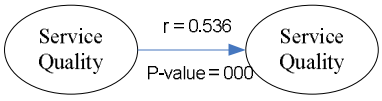

Figure 1 : Research finding of relationship between service quality and loyalty

Further testing of relationship between service quality and service loyalty construct in dimensional perspective is conducted. The valid relationship from all the five service quality dimensions only correlate to word-of-mouth communication dimension of service loyalty. No valid correlation coefficient that relate service quality dimension to the other service loyalty dimension (see Figure 2). Word-of-mouth communication is determined mainly by Empathy, service dimension aspect that stresses the treatment of customer as individuals. While high quality service had no effect on customer loyalty in using KA Parahyangan. Increasing fare, competitor lower price or negative experience may influence the customer to use the other alternative of Bandung-Jakarta transportation.

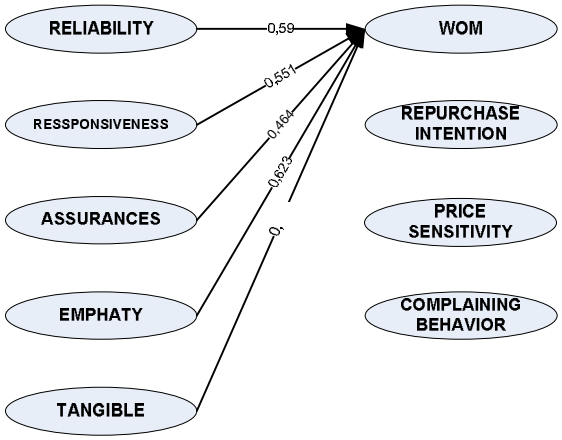

Figure 2 : Research finding of dimensional relationship between service quality and loyalty

The information on the service quality-service loyalty link on KA Parahyangan customer may provide actionable basis for improving performance through service quality. The managerial challenge of KA Parahyangan here is to train employees to give individualized attention to each customer and not treat them by the dozen [1]. Indices on service loyalty measured continuously over time may supplement measures of performance and signal changes in the value of customer assets.

Further research should be conducted to investigate determinant of the other service loyalty such as repurchase intention, price sensitivity and complaining behavior of KA Parahyangan customer.

ABSTRACT

Paradigm in Good Quality Management now becomes the soul in every enterprise which could be survived. In quality steps diagram, it's shown that towards good Total Quality Management should be start by 5S or 5 pillars culture as its basic. Many researches were done in applied 5S in an enterprises, nevertheless its sustainability always become the big questions. This research was done to get the data about involvement of each division in 5S application and its conjunction to Quality Management in large scope. Lack of involvement, understanding and awareness in Quality Management could affect on application of 5S itself. This research also using 5S checklist the capture how far the implementation of 5S in each enterprises, map its result to 5S radar and give recommendation needed. Main point in implementing 5S is how to keep it sustain. Each party should be realized their own role and responsibility.

Keywords: 5S sustainability, Quality Management, 5S radar

1. INTRODUCTION

Quality Management concept now becomes the main priority for each enterprise which needs to survive. One of the basic paradigms in creating good quality management is 5S. Applying 5S is not easy, because the succeed indicator is while 5 not only become a method, but it become company culture. Involvement of each part in the enterprise and good awareness of every personnel will be the key success of 5S implementation.
Practically, 5S is "behavior transformation" by doing neat arrangement and cleanliness of the workplace. Working place would reflect their employee treatment to the job, and this treatment would reflect their attitude and esteem to the job itself [1].
The purpose of this research is to find out what's the main cause of unsustainable 5S implementation and how to design the instrument to keep it sustain. Because sometime human factor who need/like to be controlled that make 5S hard to be a culture. Due to implementation of 5S, commonly nobody like to work in messy area, but he main problem is why 5S can not be sustain [1]. One of the case study is in garment industry which have applying 5S in the enterprise but can not be sustain because there's no control from the management. Messy workplace area, poor material coding, improper material stacking in the warehouse are some problems occur there. Furthermore 5S was applied in order to generate and maintain worker's spirit so that they can work more effective and efficient.

2. LITERATURE REVIEW

a. 5S method

5S is the name of a workplace organization methodology that uses a list of five Japanese words which, translated into English, start with the letter S. This list is a mnemonic for a methodology that is often incorrectly characterized as "standardized cleanup", however it is much more than cleanup. 5S is a philosophy and a way of organizing and managing the workspace and work flow with the intent to improve efficiency by eliminating waste, improving flow and reducing process unevenness.

5S is a method for organizing a workplace, especially a **shared** workplace (like a shop floor or an office space), and keeping it organized. It's sometimes referred to as a housekeeping methodology; however this characterization can be misleading, as workplace organization goes beyond housekeeping.

The key targets of 5S are workplace morale, safety and efficiency. The assertion of 5S is, by assigning everything a location, time is not wasted by looking for things. Additionally, it is quickly obvious when something is missing from its designated location. Advocates of 5S believe the benefits of this methodology come from deciding *what* should be kept, *where* it should be kept, and *how* it should be stored. This decision making process usually comes from a dialog about standardization which builds a clear understanding, between employees, of how

work should be done. It also instills ownership of the process in each employee.

In addition to the above, another key distinction between 5S and "standardized cleanup" is Seiton. Seiton is often misunderstood, perhaps due to efforts to translate into an English word beginning with "S" (such as "sort" or "straighten"). The key concept here is to order items or activities in a manner to promote work flow. For example, tools should be kept at the point of use, workers should not have to repetitively bend to access materials, flow paths can be altered to improve efficiency, etc.

The 5S's are :[2]

Phase 1 - **Seiri** (整理) Sorting: Going through all the tools, materials, etc., in the plant and work area and keeping only essential items. Everything else is stored or discarded.

Phase 2 - **Seiton** (整頓) Straighten or Set in Order: Focuses on efficiency. When we translate this to "Straighten or Set in Order", it sounds like more sorting or sweeping, but the intent is to arrange the tools, equipment and parts in a manner that promotes work flow. For example, tools and equipment should be kept where they will be used (i.e. straighten the flow path), and the process should be set in an order that maximizes efficiency. For every thing there should be place and every thing should be in its place. (Demarcation and labeling of place.)

Phase 3 - **Seisō** (清掃) Sweeping or Shining or Cleanliness: Systematic Cleaning or the need to keep the workplace clean as well as neat. At the end of each shift, the work area is cleaned up and everything is restored to its place. This makes it easy to know what goes where and have confidence that everything is where it should be. The key point is that maintaining cleanliness should be part of the daily work - not an occasional activity initiated when things get too messy.

Phase 4 - **Seiketsu** (清潔) Standardizing: Standardized work practices or operating in a consistent and standardized fashion. Everyone knows exactly what his or her responsibilities are to keep above 3S's.

Phase 5 - **Shitsuke** (躾) Sustaining the discipline: Refers to maintaining and reviewing standards. Once the previous 4S's have been established, they become the new way to operate. Maintain the focus on this new way of operating, and do not allow a gradual decline back to the old ways of operating. However, when an issue arises such as a suggested improvement, a new way of working, a new tool or a new output requirement, then a review of the first 4S's is appropriate.

A sixth phase, "Safety," is sometimes added. Purists, however, argue that adding it is unnecessary since following 5S correctly will result in a safe work environment. Often, however a poorly conceived and designed 5S process can result in increases in workplace hazard when employees attempt to maintain cleanliness at the expense of ensuring that safety standards are adequately followed.

There will have to be continuous education about maintaining standards. When there are changes that will affect the 5S program—such as new equipment, new products or new work rules—it is essential to make changes in the standards and provide training. Companies embracing 5S often use posters and signs as a way of educating employees and maintaining standards.

b. Eight Quality Management Principles:

Eight quality management principles come directly from TQM, there below are the definition [3]:

1. Customer focus - understanding customers' needs, striving to exceed their expectations. In term of ISO 9000:2000 [4], top management shall ensure that customer requirement are determined and are met with the aim of enhancing customer satisfaction. That definition note that customer complaints are common indicator to perceive.
2. Leadership - establishing direction, unity of purpose, and a supportive work environment. Top management should provide evidence of its commitment to the development and implementation of the quality management system and continually its effectiveness. Good leader will always concentrate in the employee, and act in democratic/autocratic depend on the situation.
3. Involvement of people - ensuring that all employees at all levels are able to fully use their abilities for the organization's benefit. Personnel performing work affecting product quality shall be competent on the basis appropriate education, training, skills and experience. As a core of the organization, employee should participate directly to support organization' advantage.
4. Process approach - recognizing that all work is done through processes, and managing them accordingly. This process contains with resources, asset, and all the supportive activities during the operational process.
5. System approach to management; expands on the previous principle in that achieving any objective requires a system of interrelated processes. In ISO terminology it called management review and management representative, that management have ensure the processes needed for the quality management system should be establish, implement and maintain.

6. Continual improvement; as a permanent organizational objective, recognizing and acting on the fact that no process is so good that further improvement is impossible. In Deming cycle, known by PDCA cycle (Plan, Do, Check, Action) [5]. One process that already taken being input to others process, and if does not meet the target then become feedback for further improvement.
7. Factual approach to decision making; acknowledging that sound decisions must be based on analysis of factual data and information, not on opinion or intuition. Management information system developed faster today, as it stand with information technology growing rapidly.
8. Mutually beneficial supplier relationships; to take advantage of the synergy that can be found in such relationships. Knowledge management that align with supply chain management give mutually benefit among the organization chain.

3. RESEARCH METHODOLOGY

Initial survey was done in some enterprises which have applied 5S. While implement the 5th S, usually it become stag. Because 5S not become a culture yet, looks like responsibility only for each worker. Literature review than was done to find out the effect of unsustainable 5S and how to improve it and the connection of 5S culture to Quality management. 5S audit by using checklist for each step than being design. This checklist being checked periodically to measure the improvement occurs. The pattern of these 5S audit (for each S) can be mapped in 5S radar. Each "S" axis from the 1st "S" to the 5th "S" than connected one another. The closer point to the tip of pentagon the better 5S implemented.

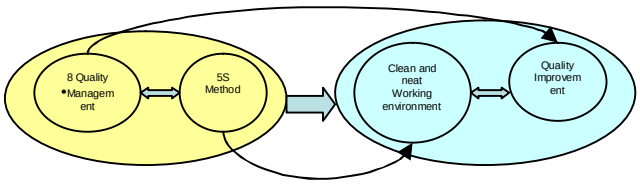

Figure 1: Integration of 5S method and 8 quality management principles to improve quality

4. RESULTS AND DISCUSSION

First of all, matrix of Quality Management and 5S is made to find the connection between 5S and eight quality management principles. The matrix as shown bellow:

Table 1: Matrix of 8Quality Management principles and 5S

No	8 Quality Mangement Principles	SEIRI	SEITON	SEISO
1	Customer Focus Organization	*Collect the customer's database *Collect the sales/purchase return items in different place *Collect the customer's complaints data	*Classified each purchase/sales return (based on type) *Keep good relation with customers	*Clean up the packaging/finished good area, so that customer will received the item in good and clear condition.
2	Leadership	*Separate all stuff that not really need for work (individual stuff) without any pressures *Inform the enterprise vision and mission and each worker should have the same vision toward goals achievement	*Good arrangement for all products and material *Creating good coding and filing in all area *evaluate the worker performance monthly *Periodically meeting to increase good communication	*Clean up all stationery and office inventory from dirt *cleanup schedule for every workplace area
3	Involvement of people	*Save the worker's database *unimportant stuff should be throw away	*clean up each workplace *put on the initial place (for the stuff being picked) *Classified stationery in one place	*Periodically clean up the working area
4	Process approach	*Give labels on all inventory * Collect the sales/purchase return items in different place	*Job description available for each worker *Try to make working process more efective	*Periodically clean up the working area
5	System approach to management	-	*Make sure that every inventory stack neatly, to make it easy to take *every workers do their job based on the job description	Have responsibility on their on working area (cleanliness)
6	Continual improvement	* Give training to all workers (routine)	*put on the initial place (for the stuff being	*Periodically clean up the working area

			picked)	
7	Factual approach to decision making	*Separate files based on function	*Classified files based on function	* clean up the working area from dirt, trash, dust and paper scrap
8	Mutually beneficial supplier relationships	*Save the supplier's database *do the filing if the supplier deliver reject items *Coding o all raw material	*Classified purchase invoice based on delivery time	* clean up the working area from dirt, trash, dust and paper scrap

Table 1: Matrix of 8Quality Management principles and 5S (continued)

No	8 Quality Management Principles	SEIKETSU	SHITSUKE
1	Customer Focus Organization	-	*Good response for each customer complaint *Communicate/inform all customer's complaints to the workers
2	Leadership	*Obey the rules and each punishment *Doing the first 3S without pressure *Supervising worker's performance	*Continuous audit every month by the supervisor *create discipline (reward and punishment) to create 5S habits and culture *Give responsibility and trust the worker
3	Involvement of people	*Spent 5 minutes daily(before and after work) to do the 3S before *Discuss every problem occur *Worker can give their opinion/suggestions	*Bottom up (always listen the worker's opinion) for enterprise development *Supervise the worker * Give responsibility and trust the worker
4	Process approach	*Periodically clean up the working area	*Evaluate worker's performance monthly (target achievement)
5	System approach to management	-	*Evaluate worker's performance monthly (target achievement) *Good communication between management and workers
6	Continual improvement	*Always check on the checklist	*Create habits to spent time 5 minutes daily to clean up working area *Give the rewards to the workers that achieve target. *Do continuous improvement to the product and process *Improvement on 5S
7	Factual approach to decision making	Hear the workers opinion based on facts	Find the accurate solutions
8	Mutually beneficial supplier relationships	-	*always check the quality of finished goods *Give inputs to supplier to improve their performance too

After mapping the 8 quality management principles to 5S, than form audit 5S is created as follow:
The point is 1 to 4 (1= Very poor/not appropriate; to 4= Very good/very appropriate)

Table2: Audit 5S' form (SEIRI)

			Point
			1 2 3 4
1	Drawer	There's no individual stuff	*Filled by the workers
2	Table	There's no paper document on the table	*Filled by the workers
3	Visual control	Needed stationery or files easily to get/reach	*Filled by the workers
4	Recycle standard	Recycle standard is applied (time, place)	*Filled by the workers
5	Filing cabinet	Every file is for routine activity (there is no other division file)	*Filled by the workers

Table 3: Audit 5S' form (SEITON)

			Point
			1 2 3 4
1	Labels for storage	Labels are clear, make easy it identify the stuff	*Filled by the workers
2	Label for stationery	Everything is easy to identify	*Filled by the workers
3	Ease of use	The storage is designed to make it easy to use	*Filled by the workers
4	Good arrangement on storage	Everything is put on its place	*Filled by the workers
5	Aisle	Every aisle looks clearly	*Filled by the workers

Table 4: Audit 5S' form (SEISO)

			Poin
			1 2 3 4
1	Floor	Clean and clear floor	*Filled by the workers

2	Dust and trash	Window, ceiling, table, filing cabinet and all drawers are clean	*Filled by the workers
3	Cleanliness responsibility	There are rotation and schedule to clean the workplace area	*Filled by the workers
4	Dust bin	Separated between dry and wet trash	*Filled by the workers
5	Clean habit	Swipe and mob as a routine	*Filled by the workers

Table 5: Audit 5S' form (SHITSUKE)

			Poin
			1 2 3 4
1	Ventilation	Clean air, not stinky, free of smoke cigarette etc)	*Filled by the workers
2	Lighting	The angle and luminance of the lamp or every lighting is suitable for the working area	*Filled by the workers
3	Environment	The environment is good (color, air, lamps, etc)	*Filled by the workers
4	Noise	There's no loud noise (the workers can concentrate)	
5	First 3S	System to maintain 3S is exist	*Filled by the workers

Table 6: Audit 5S' form (SHITSUKE)

			Point
			1 2 3 4
1	Inter personnel relationship	The environment is comfort, people greeting each other	*Filled by the workers
2	Entrance time, break time, end of time, meeting time	Everyone is on time	*Filled by the workers
3	Telephone ethics	Everyone can answer clearly, keep polite.	*Filled by the workers
4	Rules and obligation	Every rules are obey without any pressure	*Filled by the workers
5	Rewards and punishment	Transparent rewards and punishments applied	*Filled by the workers

For each form, the maximum point is 20 (the tip of pentagon). The closest to 20 point for each S, shows the better implementation of 5S in the enterprise. The radar curve showed in figure 1.

While the mappings of each S on the radar have not reach 20point, it shows that the implementation should be improved. It can be done by doing supervise tighter, or make the shorter periodic checking (eg. The previous checking in every 2 weeks become every week).
While it's reaching 20 point, it shows that implementation was done well. The next step is how to make it sustain.

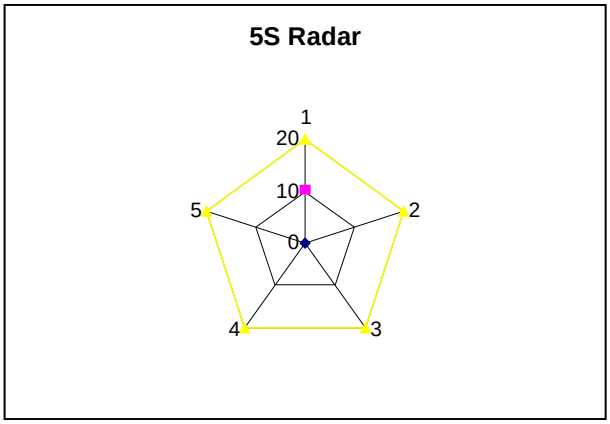

Figure 1 : 5S radar(1: Seiri point *;* 2: Seiton point *;* 3: Seiso point *;* 4 : Seiketsu point*;* 5 : Shitsuke point)

Due to the implementation in some enterprises, it's found that sometimes declared as very well sustained and sometimes declared as very badly sustained. This confirms that the sustainability of a process does not depend solely on the process itself, but is also very much related to the specific action which are carried out with an aim of making it sustainable. After identification, from the evaluation in which 5S application did not sustain as the expected before, it was found some factors which affect, illustrated on table 7.

Table 7. Identification factors from 5S application in tern of 8 Quality Management Principles

No	8 Quality Management Principles	Factors
1	Customer Focus Organization	• Employee feels unrelated directly to the customer
2	Leadership	• Lack of management's consistency and commitment • Involvement of top management • Implementation of 5S as a trial and error project (unserious preparing the goals)
3	Involvement of people	• Look down 5S role in productivity • Does not declare in job description • Less understanding the objective of 5S
4	Process approach	• Feel that implementing 5S increasing their workload • Lack of awareness in maintaining 5S
5	System approach to management	• Minimize of reward and punishment system • Lack of facility to support the implementation (shelf, cupboard, etc)
6	Continual improvement	• Lack of evaluation and controlling from the supervisor • Does not make 5S become routine activity
7	Factual approach to decision making	• Decrease on monitoring process (did not provide data

		on 5S appraisal) • Focus on qualitative measurement but not provide quantitative data • Subjective assessment (without any standards)
8	Mutually beneficial supplier relationships	• Does not align as quality culture

Based on the results above, to sustain an improvement process over time consists in grouping these factors into 3 categories which are:

1. Top Management awareness
2. Employee involvement
3. Facility

Category 1: Top Management Awareness

These indicate the intensity and willingness of the management in order to pursue 5S sustainability. In active participation from top management will affect the enterprise atmosphere. Top management should evaluate, whether the design and preparation of 5S implementation was poor from the first time. To reach top management awareness thus consist specific actions which must be asked:

1. How can the objective related to the improvement process be integrated into personal objectives of all employees?
2. How can the benefits obtained by the project and the future benefits be communicated
3. How can the entire hierarchy be involved in the continuity of the improvement process decided upon?
4. Which of the company value is the sustainability based on?

Category 2: Employee involvement

To reach good employee involvement thus consist in asking everyone a certain number of questions:

1. How can the procedure be simplified so that it can be applied naturally without any pressure?
2. How can the procedure be standardized so that it can be integrated into the company culture?
3. Which training courses must be organized in order to improve the personnel?
4. How can standard method and process be integrated into the development of new products?

Category 3: Facility

To define the specific actions to carry out on the facility, the following questions must be asked:

1. Which training course must be set up to train the operators to carry out the action?
2. Which type of assistance can be proposed to the operators to facilitate their execution of the action?
3. Which facilities needed to support the implementation?
4. How can the procedures in progress be simplified while yet sustaining the level of performance reached?

After try to answer these questions, hereby in table 8 the several generic actions which can be done to maintain the sustainability. It can be the design in a checklist, so that can be found which generic activities which have not applied.

Table 8. Generic actions in Maintaining 5S

No	Generic actions of sustainability	Yes	No
1	To make the objective of the sustainability, clear for all the personnel and try to help everyone work in this direction		
2	To clearly identify the project manager and to give him/her the means to be successful		
3	To set up the management of the project with objectives, indicators and piloting meetings at regular and frequent intervals		
4	To reveal the interest of the sustainability to show its correlation with a strategic objective		
5	To communicate these new values and to share them to all workers		
	To create a progress culture in which several improvement projects are implemented at the same time without competing with each other		
6	To control the negative actions of the people who would wish to slowdown the progress		
7	Not to change direction too early and too often. A new Manager must sustain continuity		
8	To plan regular reviews to validate that the marked values identified remain relevant		
9	To communicate on the project (internal newspaper, poster, etc)		
10	Involvement from the top management in the sustainability process		
11	Involvement of all hierarchy to designate the responsibilities		
12	Everyone must know which part of the sustainability his job belongs to		
13	Make sure that “experts” will be available throughout the sustainability phase in order to correct variation, to deepen and enrich the approach and always give further training		
14	To develop or invest in technical devices to simplify the tasks carried out by the personnel		
15	To set up the necessary training		
16	To develop the stuff and/or resources to support the implementation		
17	To standardize, to define coherent and specific missions		
18	To adapt the method to the company, to improve efficiency if required		
19	To Train the new recruits		
20	To systematically reposition the project within the total strategy of the company. How will this project enable to progress in company objective		

As long as these 20 variables done by the enterprises, sustainability can be reached constantly.

ABSTRACT

Nowadays, autism generally found among us. Autism spectrum disorders (ASD) might occur from childhood to adult. One serious problem which almost exist in all autism patients is communication problem. To overcome this problem, this research is being done to design communication tool using PECS' method. While doing the observation, it's found that the existing picture media is easily broken and sometimes the card is harmful for autistic children. It caused by the material (because they usually put it into their mouth) has no round tip for each card corner.

The purpose of this research is to design communication tool that's ergonomic for autistic children. The design process is using the theory of product design and development, which consist of some steps.

In identifying customer needs, it's found that they need communication tools which have these criteria: safe, the pictures should be clear enough and uneasily to be tore or broken, the pictures can represent the real object. While doing the prototype, the picture should be stuck on the both side of card, so that they can easily learn or understand the picture. These cards are categorized into some groups, such as: alphabeth, number, sports, musical equipment, flowers, animals, and much more.

From the implementation result to 10 therapists of autistic children, 100% therapist states that this tool can facilitate them in providing, use, and keeps picture in good condition. According to the therapists, this tool is safe and comfortable enough while used by the autistic children and they can learn more effective.

Keywords: PECS method, Autism Spectrum Disorders, Ergonomics tool, Product Design

1. INTRODUCTION

Autism Syndrome Disorders (ASD) might occur from childhood to adult. Nowadays, numbers of autistic children increase quiet significant. Government seems like don't really care about it and it cause high cost in their treatment. Less of people knowledge about autism is also contributing in this costly treatment. One serious problem which almost exist in all autism children is communication problem. PECS is found as an effective method to train autistic children to communicate using pictures as the media. Unfortunately, PECS method is not too familiar in Indonesia because less information about it. Recently, parents are also using picture card to communicate with their children, but from the survey, it's found that parents usually hard to find/prepare the pictures. Here are the problems occur: color of the picture is blur, picture's size (too small or even too large), unsafe card design, inappropriate picture with the meaning, broken easily(tear, wet, mess) and the most important is they don't know about PECS method.

2. LITERATURE REVIEW

Autism is development disorders which symptoms are deficiency in cognitive, language, behavior, communication and social interaction.[1]

a. Verbal and Non verbal communication disorders: deficiency in speaking and even can not talk; using word without knowing its meaning; using body language and only communicate in short time period; copycat what people say without knowing the meaning; monotonous intonation like robot; talking but not communicate; plain/no expression.
b. Social interaction disorders: no eye contact; look around while people call, many people think they're deaf; don't like being hugged; if they want something, they will pull other people arms (the nearest people) and ask them to do that for him/her; usually introvert; go away while people get close to them; no interaction with others.
c. Playing disorders: very monotonous playing, like turning balls or cars and watching the object steadily for a long time; have pacifier that can not be released from them; while they like a toy, they don't want another toys; don't like dolls, they like "uncommon" stuff like bottle, battery, rubber band, etc; have no reflect and don't have imagination while playing; can not pretend and copycat

what their friends do; usually watching their own fingers, moving object (fan), etc

d. Behavior disorders: hyperactive, moving around, run away with no destination; hurt themselves (hit their head to the wall, hit their head with their arms); petrifaction (no eye contact); anger easily without any reasons; very aggressive to other people (like to hit); hard to sleep, gastro intestinal disorders and metabolism.
e. Emotional disorders: laughing, crying and angry without any reasons; temper tantrum, especially while they didn't get something; lower empathy, while look at other children crying, they just hit the child.
f. Sensory perception disorders: very sensitive to an extra lighting, sound, touch, etc; bite, leak or smelling every stuff around them, shut their ears while hearing very loud noise; always crying while doing the hair wash, feel uncomfortable while wearing unusual fabric for their clothes.

PECS is one of non verbal communication method for the autistic children. It using pictures which can be made by drawing or take picture of the objects that will be communicate to them, such as brush, drink, eat, etc. PECS consist of 6 phases: physical exchange, spontaneity, picture classification, arrange a sentence, answer the questions and give spontaneous response.

ERGONOMICS

The aim of Ergonomics in this research is to increase comfortableness of autistic child in using communication tools and ease the parents to prepare the tools, so that the training can be more effective. [2]

To reach the purpose, theory about alphabet color and size need to be known as well. The colors of alphabet affect its ability to be read. Here are the combinations of alphabet and background color:

Table 1: Alphabet and background color combination

Level of easily reading	Color combination
Very good	Black alphabet with white background Black alphabet with yellow background
Good	Yellow alphabet with black background Dark blue alphabet with white background White alphabet with black background Green alphabet with white background
Enough	Red alphabet with white background Red alphabet with yellow background
Bad	Green alphabet with red background Red alphabet with green background Orange alphabet with black background Orange alphabet with white background
Very Bad	Black alphabet with blue background Yellow alphabet with white background

ANTHROPOMETRY

Antropometry comes from words "anthro" and "metrein" which mean human body dimension [2]. For anthropometry data, usually normal distribution is applied. In statistic, normal distribution is formulated from the mean and standard deviation of the existing data. Percentiles than can be calculated using probability table of normal distribution as follow:

Table 2: Normal distribution and percentile calculation

Percentile	Calculation
1st	Mean - 2.325.stdev
2.5th	Mean – 1.96.stdev
5th	Mean – 1.645.stdev
10th	Mean – 1.28.stdev
50th	Mean
90th	Mean + 1.28.stdev
95th	Mean + 1.645.stdev
97.5th	Mean + 1.96.stdev
99th	Mean + 2.325.stdev

PRODUCT DESIGN AND DEVELOPMENT

In designing the product, the steps as follows[3]: Identifying customer need, product specification, concept generation, concept selection, concept testing, prototyping.

3. RESEARCH METHODOLOGY

This research is start with identification on increasing numbers of autistic children and find out the using of PECS method. Questionnaire is given to 25 autistic children's parents, 25 usual parents. Respectively, it's given to 10 therapists in Terapi Bangun Bangsa (therapy centre for autistic children) and 10 teachers for autistic students in SDN Klampis Ngasem I/246 (Inclusive Primary School). Literature review than be done in this product design. For data collection, here are the data being collected: data about usual development and educational media for children, people knowledge about autism, ability and constraint of autistic children, weakness of existing PECS, needs for new PECS method, type of picture which suitable with autistic child, and anthropometry data. Using the product deign phases, ergonomics PECS communication tools were designed until creating the prototype and implementing the prototype, than analyze the results.

4. RESULTS AND DISCUSSION

From the questionnaire, we can get the customer need (therapists and parents) to design the new PECS. Here are the steps:

1. Existing PECS: Some weaknesses of the existing cards are uneasy to find appropriate picture to the need, size of the picture (too small) so that it has to be zoomed out while copy or sometimes too large so it has to be zoomed in, uneasy to understand, not suitable with characteristic of Indonesian people because there's no PECS in Indonesian, picture were taken from magazine or newspaper which too colorful so they can not focusing on the object, Picture's material is easily to be broken (from paper or laminated picture), for laminated picture, the corner is usually not round (it can hurt their arm), small size of the card (might be swallowed because their habit is biting objects), don't know how to use PECS correctly.
2. Here are the needs from the therapist:

    a. Therapist need pictures which can be represent what they want to say: represent every themes, autistic child can understand easily, almost the same with the real object.
    b. Therapist expected on suitable picture size: very ideal/clear while looking from the front side, easy to be grasped, bigger picture, so that easily to be recognized and remembered, the ideal size is 7x7 cm or 7x6 cm.
    c. Therapist advice on picture color: use the bright and clear color with good contrast, do not blur, large spectrum of color so that they can recognize so many color, it has to be in good contrast between picture and its background to reduce distraction (for example black and yellow, do not pink and red), for the first step, just using black and white, especially for alphabet and number.
    d. Therapist expected on the picture media that can be use for a long time: can be use repetitive at about one year usage, picture card not blur, and material for the card is not rigid (not from multiplex or wood)
    e. The tools should be safe: non toxic material, don't hurt the child while holding the card, don't make them worry (create sound), round tip for each corner, don't harm while it falling down.
    f. For the container: classification for each theme, neat, safe and simple, easily to be reached and carried by the child
    g. Can be used for many phases development: easy to understand, make them more independent, efficient and effective
    h. Description of the picture should be separated from the picture: to reduce their rigidity.

Table 3.Level of importance of each need

Criteria	Weight	Rank
1. Proper picture with the meaning	19.78%	1
2. Safe in use	12.50%	5
3. Picture's color	15.66%	3
4. Flexibility	11.55%	6
5. Picture's size	16.46%	2
6. Life long usage	9.02%	7
7. Easy to keep	15.03%	4

Knowing the weight and the rank of importance level, is needed, so it can be determine, which part of the design that become main priority (to fulfill the need), so that the new PECS design will meet the customer need.

Table 4. Need Metric for New PECS design

Need \ Metric	Picture with theme	Real object picture (almost the same)	Considering anthropometry data for the size	Cosntrast (color)	Picture's material	Layer's material	Design of picture's container
1. Proper picture with the meaning	*	*					
2. Safe in use					*	*	*
3. Picture's color				*			
4. Flexibility							
5. Picture's size			*				
6. Life long usage					*	*	*
7. Easy to keep							*

Table 4. Need Metric for New PECS design(continued)

Need \ Metric	Weight of picture	Types of printing ink	Can be use for many steps of development	Picture's design	Container's size	Weight of container
1. Proper picture with the meaning						
2. Safe in use	*	*		*		*
3. Picture's color		*				
4. Flexibility			*			
5. Picture's size						
6. Life long usage		*		*		
7. Easy to keep	*			*	*	*

Need-metric should be made to specify how to fulfill the need (metric). String mark (*) shows the correlation between need and the metric.

To accommodate therapists' need and overcome the weaknesses of the existing PECS, new design of PECS consider these criteria:

a. Picture are accommodate from CD Pics for PECS 2007 which should be adjusted (language and graphics) to Indonesian user. It will be divided into 20 categories: activity in the water, musical instruments, transportation, alphabet, number, prefix, human body, shape, weather, emotion, animals, verb, adjective, location, food and beverages, clothes, profession, vegetable and fruit, color, etc.
b. Material for the layer is made from Eva mate which is soft, untearable, flexible, water resistant light and thick (like a sponge), so that the autistic children feel comfort and safe while using it.
c. Picture being printed with clear and bright color
d. Picture being laminated by food grade plastic material, so that the picture not easily to be broken and avoid them from the ink on the picture
e. For the container, it consists of 9 picture cards for each sleeve, put them in the binder, which packed in a backpack. Each category is separated with partition.
f. The dimension for new PECS, using anthropometry data for 3-11 years autistic children and calculation of the font size and picture's description:

Table 5: Card design dimension.

Component	Body dimension and percentile	Calculation
Length and width	Hand's width; 5th percentile	Max. width = mean- (1.645 stdev) = 12.065-1.645*1.352 =9.84 cm Choosen: 7cm, as the input from therapist
Length of container	Length from shoulder to waist; 5th percentile	Max. length = mean- (1.645 stdev) = 36.9-1.645*1.308 =34.748 cm Choosen: 34 cm
Width of container	Width of the shoulder ; 5th percentile	Max. width = mean- (1.645 stdev) = 32.6-1.645*1.174 =30.669 cm Choosen: 30 cm
Width of backpack's webbing belt	Width of half shoulder (one shoulder only) ; 5th percentile	Max. width = mean- (1.645 stdev) = 11.10-1.645*0.615 =10.088 cm Choosen: 6 cm, as commonly backpack's webbing belt
Width between 2 webbing belts	Width of neck nucleus and width of the centre shoulder + webbing belt; 5th percentile	Minimum= 8cm Max. width = mean- (1.645 stdev) + 6cm = 21.5-(1.645*1.155) + 6 =25.6

PECS cards as shown below:

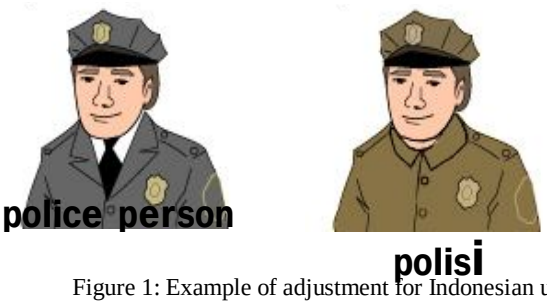

Figure 1: Example of adjustment for Indonesian user

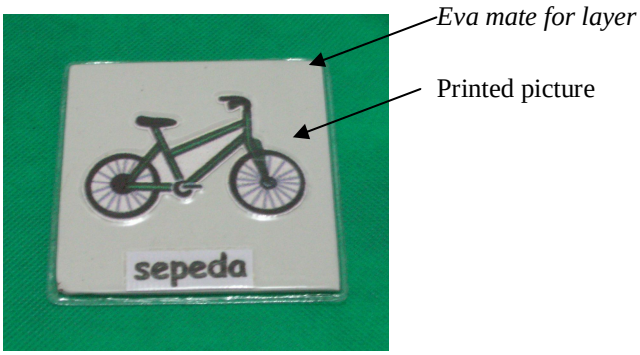

Figure 2: Example of PECS card (bicycle)

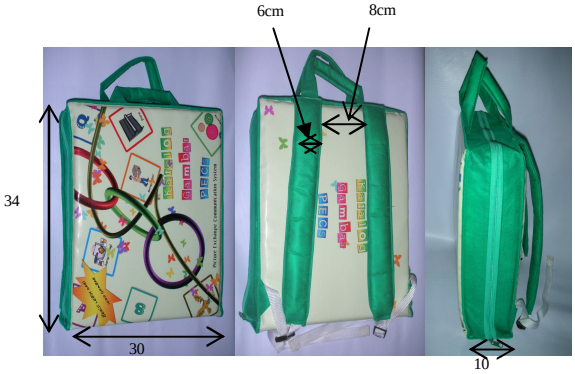

Figure 3: Backpack to pack the card and binder

For the font size, the specification as follow:

Tabel 6: Font size recommendation

Component	Theoretical	Accommodate

		(adjustment by considering therapist's input)
Height of alphabet	= Length of view (mm) /200 = 300mm / 200 = 1.5mm	Min = 0.5cm Max = 0.7cm
Width of alphabet	= 2/3 of height = 2/3 * 0.15cm =0.1cm	Min = 0.3cm Max = 0.5cm
Space between alphabet	= 1/5 of height = 1/5 * 0.15cm	Min = 1mm Max = 1.5mm
Space between word	= 2/3 of height = 2/3 * 0.15cm =0.1cm	Min = 0.3cm Max = 0.5cm

Product Testing/Implementation

Product testing was done to 10 therapist and 10 parents, they really satisfied with the new PECS. From the trial to the autistic children (15 children), with 10 repetition, it's found that there's reduction in picking up time (pick the card).

Existing (laminated card) = 5.61 second

New PECS (Eva Mate + printing) = 0.89 second

This improvement has good impact in their communication ways, so that they can communicate easily by picking up the card.

5. CONCLUSION

Here are the conclusions of this research:

1. Parents can do training at home and they don't need to worry in using the new PECS, because it's safe, comfort and life long.
2. PECS tool really helpful for parents, therapist and children to communicate
3. PECS catalogue increasing knowledge of the society about PECS

6. APPENDIX

Pervasive Developmental Disorder Screening Test (PDDST-II)

Give (v) mark to Yes or No answer which is appropriate

Table 7: Screening I (12-18 months toddler)

No	Variables	Yes	No
1	Do your baby often seems boring or unenthusiastic to their surrounding activity?		
2	Do your baby often doing something or playing with their toys repetitively in very long period (monotonous)?		
3	Do your baby often not turn their head while someone call out their name?		
4	Do your baby late to walk?		
5	Do your baby only play with one toy that he/she likes?		
6	Do your baby like to touch /felt a "weird" stuff? Like carpet, cotton, rough fabric		
7	Do you ever heard your friend or your family told that your child has disorder on their hearing senses?		
8	Do your baby often watching on their own fingers and play with their finger seriously?		
9	Do your baby can't say/express what they want, by using words or body language?		

Give (v) mark to Yes or No answer which is appropriate

Table 8: Screening II (18- 24 months toddler)

No	Variables	Yes	No
1	Do your baby unenthusiastic to learn how to talk?		
2	Do your baby has no fear to harmful stuff or animals?		
3	Do your baby hard to have eye contact with you?		
4	Do your baby like to running, but they don't like to play pick a boo?		
5	Do your baby ever seems like unenthusiastic to their toys?		
6	Do your baby avoid dolls or feathers toys?		
7	Do you baby doesn't like to play with dolls or feathers toys?		
8	Do your baby looks so impressed with the moving objects, like turn cars' wheel, look at the water flow, look at the moving fan?		
9	Do your baby often doesn't care whether you're around them or not?		
10	Do your baby moody (without any reasons)?		
11	Do your baby often hard to play with new toys? (rigid and dependent to one toy?		
12	Do your baby never use body language like waving hand, kiss your cheek?		
13	Do your baby often wave their hands up, down, front and to their body's side while they feel happy?		
14	Do your baby always crying while you left them go, but they don't care while you're coming/come back?		

This two screening can be use by all dear parents to check individually at home, whether their child is needed extra attention or not.
For each table screening:
If there are 3 or more on "YES" answer for the odd number of all the variables, maybe you need to check out whether they get autism or not (ask the expert).
If there are 3 or more on "YES" answer for the even number of all the variables, maybe you need to check out whether they get another disorder besides autism (ask the expert).

Usability Evaluation and Design Improvement on Electronic Device (Case Study: 6 in 1 Magic Jar)

Linda Herawati Gunawan[1], Utomo[2], Fransiska[3]

Email: [1]linda@ubaya.ac.id, [2]puspo@ubaya.ac.id
Engineering Management Laboratory- Department of Industrial Engineering
Engineering Faculty , University of Surabaya

ABSTRACT

Nowadays, Magic Jar was exists with many brands. Commonly, these brands have many similarities. Besides the strengths, there also found some weaknesses, such as the design, appearance, the way to operate the product, etc. Usability now becomes one of the considerations in deciding or choosing a product, especially electronic device. From the survey, it was found that many customers prefer to buy a multifunction product. On the other hand, they usually disable to use all of its function. In this research, benchmarking process was done in 4 brands: COSMOS type SRJ 351TS, MASPION type MRJ 2018, MIYAKO type MCM 706, DENPOO type DMJ 88A. The first analysis step is descriptive analysis to find out what's customer perception in those 4 brands. The second is quadrant analysis to find out the strengths and weaknesses of each brand. The third analysis is MANOVA to find out is there any gap between importance and satisfaction level among these 4 brands. After these three analyses, benchmarking was done then to decide what's should be adopted from the existing design and what should be redesigned.

Keywords: Usability, task analysis, quadrant analysis, MANOVA, Benchmarking,

1. INTRODUCTION

So many brand and function in Magic Jar which available now. From 2 in 1 (cook and warm only), 3 in 1 (cook, warm and porridge) and the latest technology is 6 in 1. Nowadays people prefer to buy 6 in 1 Magic Jar because they can use so many functions with reasonable price (not too much different with 2 in 1 or 3 in 1). Even it has 6 functions/features, there's still a problem. Commonly customers do not operate all of the functions with some reasons: can't use it (usually), not too need it, and not really sure with the results.
From the survey, it's found that sometimes they're not really understand about the function and they don't like to read the manual book, because it's too complicated (also the language). In this research four brands will be benchmarked to find the strengths and weaknesses of each brand. These four brands have the same features (6 in 1 Magic Jar), which types are: COSMOS SRJ35ITS, MASPION MRJ2018, MIYAKO MCM706 and DENPOO DMJ 88A.
The benchmark results will become the basic for recommended design (especially the control button) at the outer part of the Magic Jar and how to design the manual book which consists of "easy steps".

2. LITERATURE REVIEW

a. Usability of consumer electronic products
Usability of the product recently become important factor, so that the customer feels that the price is comparable with the function, quality and service [1]. Usability means the assessment of easiness usage of an object by anyone to reach a goal or specific job. At the beginning, usability concept is to measure how ease and efficient for a customer while doing a job (in HCI area) [2]. Nowadays usability is also use in measuring the effectiveness of consumer electronic products which have different indicator in HCI. On subjective aspect, image and impression has the same value with objective aspect.
The main reason why consumer product usability is different from HCI:

1. Electronic product is different from software product
2. In designing the control button (shape and color) should consider that it can give the good perception how to operate it
3. Using electronic product is not the same with using/operate software

Usability of electronic products consist of 2 aspect : performance and image/impression.
In performance aspect, there are three groups of indicators which have these dimensions: Perception/cognition (the dimensions are directness, explicitness, modelessness, observability, responsiveness, and simplicity); Learning/memorization (the dimensions are consistency,familiarity, informativeness, learnability, memorability, predictability); Control/action (the dimensions are accessibility, adaptability, controllability, effectiveness, efficiency, error prevention, flexibility, helpfulness, multithreading, recoverability, task conformance.
In Image/impression aspect, there also three groups of indicators which have these dimensions: Basic sense (the dimensions are shape, color, brightness, texture, translucency, balance, heaviness, volume); Description of image (the dimensions are metaphoric design image, elegance, granularity, harmoniousness, luxuriousness, magnificence, neatness, rigidity, salience, dynamicity); Evaluative feeling (the dimensions are acceptability, comfort, convenience, reliability, attractiveness, preference, satisfaction).

b. Quadrant Analysis

Main priority (IV)	Maintain performance (I)
Attribute to Improve (III)	Overacting (II)

Axis : Satisfaction level
Ordinate: Importance level
Quadrant analysis is use to find the strength and weakness of the products or services. It is mapped on satisfaction level and importance level. There four quadrant being created:

c. MANOVA
It's use to measure the difference between mean of group respondents. MANOVE is use to analyze total variation which consist of many factors that's affect in one or more variables.

d. Theory of benchmarking
Benchmarking is product assessment to the competitor, of which steps are:

1. Identify the subject being benchmarked
2. Identify the competitors
3. Define the gap
4. Create the development
5. Adjust the benchmark measurement

3. RESEARCH METHODOLOGY

Survey being done to get the strengths and weaknesses of each brand. Aims of the research are: benchmark in four brands, doing the usability testing, new design of 6 in 1 magic jar (especially on its appearance), button and manual book.
Data being collected are: questionnaires to find out respondents complaints while using 6 in 1 Magic Jar, usability testing (how fast in operating 1 task), sequences steps of each function/feature. From these data, than MANOVA, quadrant analysis and benchmarking done respectively.
The last step is designing new concept of Magic Jar, with unique push button and appearance.

4. RESULTS AND DISCUSSION

From the questionnaires results, description analysis was done:

1. Women are the dominant user
2. They choose 6 in 1 because the price is almost the same with 2 in 1 and 3 in 1
3. At the first time they use it, they don't read manual book (just trial and error) in pushing the button and predicts its function
4. Respondents said that the availability of manual book is preferable as long as it's easy to understand (language and flowchart)

Here by the strengths and weakness of each brand:

1. COSMOS
   Strength: easy and comfort to be used
   Weakness: manual book is difficult to understand; not really satisfied having Cosmos; takes time to understand how to use it for the very first time; steps of operation is difficult to remember and complicated.
2. MASPION
   Strength: easy to operate; simple, uncomplicated
   Weakness: manual book is difficult to understand; takes time to understand how to use it for the very first time; manual book consist of so many text

without picture; commonly they don't really satisfied in using Maspion

3. MIYAKO
   Strength: easy and comfort to be used
   Weakness: manual book is difficult to understand; takes time to understand how to use it for the very first time
4. DENPOO
   Strength: simple, uncomplicated
   Weakness: manual book is difficult to understand; takes time to understand how to use it for the very first time; the color is not suitable (not so good)

MANOVA results as shown below:

Table1: Level of satisfaction of 4 brands

No	Variables	Sig. Value	Result	Addition
1	Appearance of Magic Jar: simple, uncomplicated	0.005	Difference exist	Highest score: Denpoo
2	Appearance of manual book:simple, uncomplicated	0.027	Difference exist	Highest score: Denpoo
3	Steps to operate: not complicated	0.167	No difference	The same for all brands (medium)
4	Times need to use it for the first time	0.000	Difference exist	Highest score: Miyako
5	Steps to operate : easy to remember	0.173	No difference	The same for all brands (medium)
6	Easy to operate	0.009	Difference exist	Highest score: Miyako
7	Accurate in attaining goals (each task)	0.197	No difference	The same for all brands (medium)
8	Task can be done effective and efficient	0.200	No difference	The same for all brands (medium)
9	Ability to reduce error	0.051	No difference	The same for all brands (medium)
10	User reaction to improve from error/mistake	0.000	Difference exist	Highest score: Miyako
11	The shape of the Magic Jar	0.011	Difference exist	Highest score: Cosmos
12	The color is suitable and looks good	0.000	Difference exist	Highest score: Cosmos
13	Composition looks balance	0.187	No difference	The same for all brands (high)
14	Magic jar look clean, neat and well organized	0.231	No difference	The same for all brands (medium)
15	Simple manual book	0.891	No difference	The same for all brands (medium)
16	Easy and comfort with the magic jar	0.055	No difference	The same for all brands (medium)
17	Customer feels satisfied with the magic jar	0.005	Difference exist	Highest score: Miyako
18	Customer feels satisfied with the manual book	0.841	No difference	The same for all brands (medium)

Benchmark analysis according to quadrant analysis:

Table 2: Benchmark of 4 brands based on quadrant analysis

No	Variable	COSMOS	MASPION
1	Appearance of Magic Jar: simple, uncomplicated	Attribute to improve	Main-tain perfor mance
2	Appearance of manual book:simple, uncomplicated	Main priority	Main priority
3	Steps to operate: not complicated	Main priority	Main priority
4	Times need to use it for the first time	Main priority	Main priority
5	Steps to operate : easy to remember	Main priority	Main priority
6	Easy to operate	Main priority	Main-tain perfor mance
7	Accurate in attaining goals (each task)	Overacting	Main priority
8	Task can be done effective and efficient	Attribute to improve	Overac ting
9	Ability to reduce error	Attribute to improve	Attribu te to improv e
10	User reaction to improve from error/mistake	Attribute to improve	Overac ting
11	The shape of the Magic Jar	Overacting	Overac ting
12	The color is suitable and looks good	Overacting	Overac ting
13	Composition looks balance	Overacting	Maintai n perfor mance
14	Magic jar look clean, neat and well organized	Overacting	Overac ting
15	Simple manual book	Attribute to	Main

		improve	priority
16	Easy and comfort with the magic jar	Maintain performance	Main priority
17	Customer feels satisfied with the magic jar	Main priority	Main priority
18	Customer feels satisfied with the manual book	Main priority	Main priority

Table 2: Benchmark of 4 brands based on quadrant analysis (continued)

No	Variable	MIYAKO	DENPOO	Decision
1	Appearance of Magic Jar: simple, uncomplicated	Maintain performance	Maintain performance	Adopted
2	Appearance of manual book:simple, uncomplicated	Main priority	Overacting	Improved
3	Steps to operate: not complicated	Main priority	Attribute to improve	Improved
4	Times need to use it for the first time	Overacting	Maintain performance	Adopted
5	Steps to operate : easy to remember	Maintain performance	Maintain performance	Adopted
6	Easy to operate	Main priority	Maintain performance	Adopted
7	Accurate in attaining goals (each task)	Overacting	Attribute to improve	Improved
8	Task can be done effective and efficient	Overacting	Maintain performance	Adopted
9	Ability to reduce error	Overacting	Main priority	Improved
10	User reaction to improve from error/mistake	Overacting	Attribute to improve	Improved
11	The shape of the Magic Jar	Overacting	Overacting	Improved
12	The color is suitable and looks good	Attribute to improve	Main priority	Improved
13	Composition looks balance	Overacting	Over acting	Adopted
14	Magic jar look	Main	Maint	Adopted
	clean, neat and well organized	priority	ain performance	
15	Simple manual book	Over acting	Attribute to improve	Improved
16	Easy and comfort with the magic jar	Maintain performance	Maintain performance	Adopted
17	Customer feels satisfied with the magic jar	Maintain performance	Main priority	Adopted
18	Customer feels satisfied with the manual book	Main priority	Main priority	Improved

From the quadrant analysis, it's found that 9 variables need to improved, and the others should be maintain (customers feels satisfied enough). How to determine adopted variable, if there's 1 brand that result on "maintain performance", and the brand being adopted its feature.

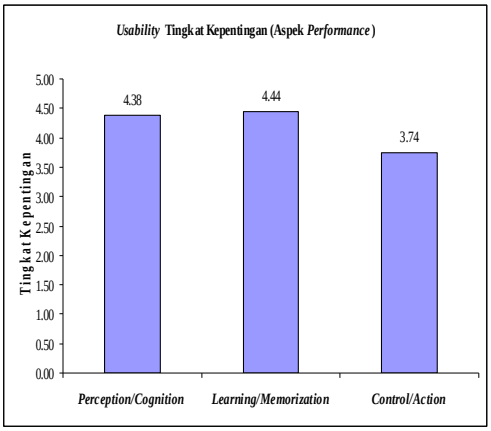

Figure 1. Level of importance (usability-performance)

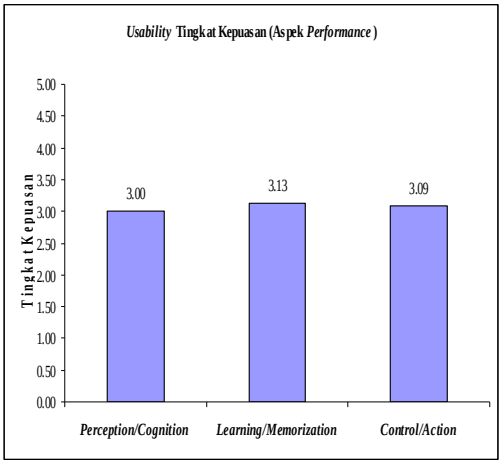

Figure 2. Level of satisfaction (usability performance)

Refers to figure 1 and 2, it's shown that there's gap between customer expectation and customer need. The top two needs are Learning and Perception, but they don't really satisfied on the existing products.

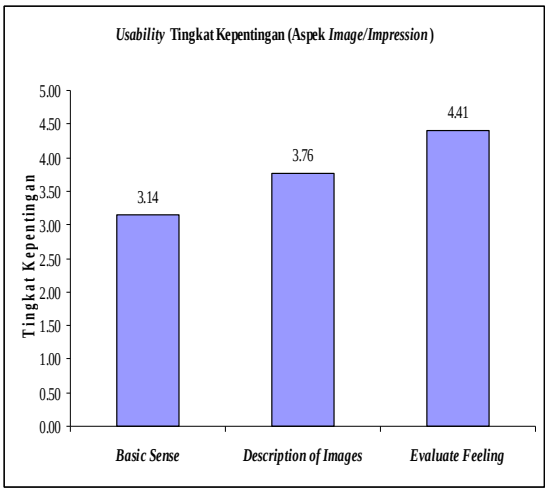

Figure 3. Level of importance (image/impression aspect)

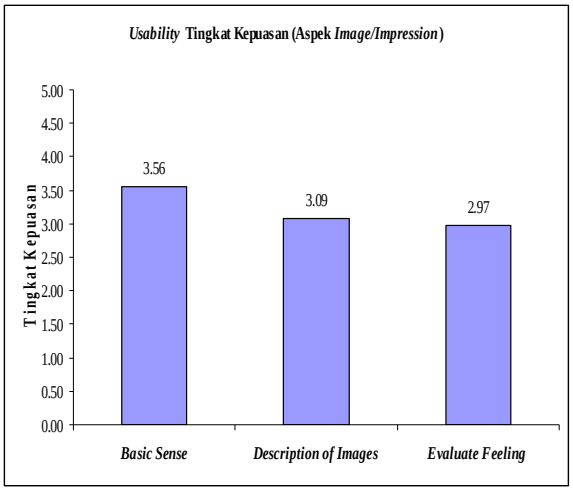

Figure 4. Level of satisfaction (image/impression aspect)

Refers to figure 3 and 4, it's shown that gap is also occur between customer expectation and customer need. The top two needs are Description of images and Evaluate feeling, but they don't really satisfied on the existing products.

Improvement than applied in the new design as follow:

1.Appearance of manual book: simple, uncomplicated, is improved by designing a systematic manual book, using more picture and chart.
2. Steps to operate: not complicated, is improved by designing "one touch button" system (push 1 button only to define what function need to be done)
3. Accurate in attaining goals (each task). By designing one touch button, make it accurate for each operation/feature.
4. Ability to reduce error, is improved by creating cancel button to cancel the process
5. User reaction to improve from error/mistake: in every feature/function process, there's a display so that the user can detect error faster than before (if the display didn't match with the condition that needed/set)
6. The shape of the Magic Jar, new design is ellipse, looks like tube
7. The color is suitable and looks good, simple but elegant, using millennium color, that being surveyed as the symbolized of technology.
8. Simple manual book: giving sketch of the product and each detail component
9. Customer feels satisfied with the manual book: systematic manual book with picture/figure to make it clear.

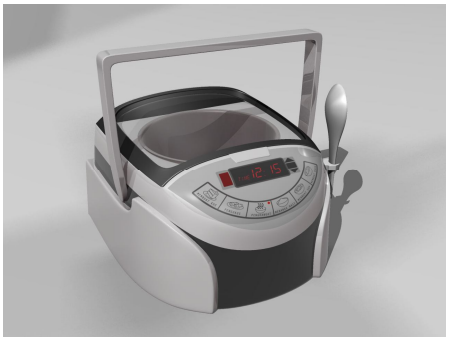

Figure 5. New Design- Magic Cooker

Figure 6. Top view – Transparent top cover

Figure 7. Display of each function

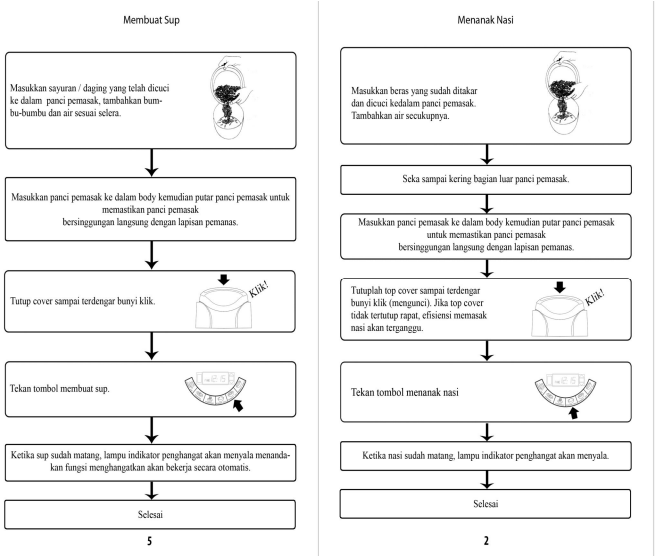

Figure 8. Design of systematic manual book

Feature of 6 in 1 Magic cooker:

1. Millenium theme, shows on color and its shape
2. Simple, elegant and look balance
3. Timer, to define processing time
4. Cancel button is applied
5. One touch button is applied
6. Easy button consist of picture that shows it function, and fulfill with lighting
7. Transparent top casing, to check the condition of the food being cooked
8. Handle is designed to make it easy to lift or move.

After the design being applied in paper prototype, than usability testing was done to 10 users. Each function was tested (using existing Magic Jar and new design). Time process being calculated to check is the new design more effective than the old ones. And the results as follow:

Table 3: Usability testing of all brands

Process	COS MOS	MASPION	MIYAKO
Cooking rice	15.13	16.11	9.26
Warm	12.38	12.93	7.95
Steam	11.41	11.25	7.92
Cooking soup	12.47	11.91	7.41
Cooking porridge	10.88	10.76	7.57
Making Cakes	10.54	11.16	6.05

Table 3: Usability testing of all brands(continued)

Process	DENPOO	Mean Four brands	MAGIC COOKER
Cooking rice	11.05	12.89	5.51
Warm	6.17	9.86	3.71
Steam	8.28	9.72	4.11
Cooking soup	7.51	9.83	4.90
Cooking porridge	8.81	9.51	4.10
Making Cakes	6.80	8.64	3.55

Based on the result above, it's found that the new design, MAGIC COOKER, is better than the other brands. The user can use all the function easily and effective.

5. CONCLUSION

From this research, can be conclude that mew design of MAGIC COOKER has a simple design, not complicated, with futuristic shape and color. And one touch button system with description process in Indonesia plus icon of the function, make the user more satisfied.
New design of manual book consist of flowchart of each function to make easy to understand, and give more picture.

Abstract

The importance of productivity management in the service industries is widely accepted. Multifactor Productivity Measurement Model determines the total productivity into key terminal parameters (KTPs) and subkey terminal parameters (SKTPs). KTPs divided into static indicators and dynamic indicators, while as SKTPs are development indicators. To concise the assessment, this research integrate Multifactor with Multi Level Objective Matrix (MULOMAX) framework, Pairwise Comparison to estimate the weight of indicator, Radar Curve, and Ishikawa analysis to develop the problem solution. The application of this integrated model implemented in House of Sampoerna Café, one of the popular boutique café in Surabaya. Begin with the deployment of vision, mission and strategy that breakdown into Key Result Areas (KRAs), the indicators have been clustered in Static, Dynamic and Development indicators, in the organization functions (division) that are kitchen, steward, service, bar, cashier, public area, and purchasing in internal café.

Keywords:
multifactor productivity, indicator, Café

1. INTRODUCTION

Majority of service organizations still use production surrogates such as, number of customers served output, and time consumed to serve customers as input. The intangible nature of service adds to the complexity of measurement, requiring a multi-dimensional analysis [1]. Few organizations appear to have systematic processes in place to ensure that their performance measurement systems continue to reflect their environment and strategies [2]. Most services are provided through facilities and it has been suggested that the measurement of facilities should relate to the core business objectives such as customer satisfaction [3]. Multifactor productivity measurement model is one of service performance measurement model that infuse this complexity with the terminology of static, dynamic and development indicators through the data identification. However, this model lack of structure in how to arrange all indicators to be a link structure and tend to perform in partial measure. Regarding to this weakness, this research combine Multifactor with Mulomax method that have hierarchy structure to relate all indicators to be one measurement. The case study has been carried out in House of Sampoerna Café in Surabaya.

2. LITERATURE REVIEW

This research classify studies into two themes of model as follows

2.1 Multifactor Productivity Measurement Model for Service Organization

Sahay [1] has developed this model based on productivity indices of the multifactor key terminal parameters (KTPs) and sub key terminal parameters (SKTPs). KTPs act as output of the organization. These parameters have further been segregated into static parameters and dynamic parameters. Static parameters are those criteria measure which captures the performance of organization is making use of its resources. Dynamic parameters are those criteria measures which identify different activities which impose immediate cost on the organization bestow results sometimes in future. Productivity index for KTPs is the sum of productivity indices of static indicators and dynamic indicators. The productivity indices for static and dynamic indicators depends on actual and target productivity factor values and the weight age of the corresponding factors.

Subkey terminal parameters (SKTPs) are basically development factors which create a strong knowledge and database for the organization's internal usages to improve its efficiency and productivity, and if needed could also be used by other agencies as intellectual property created by the organization. Development indicators divided into four indicators that are business development index, vendor development index, research & development index, and standardization index.
Total productivity index (TPI) for a service organization may be computed as follows:

$$TPI = PI_{KTP} + PI_{SKT}$$

$$PI_{KTP} = PI_{SI} + PI_{DI}$$

ISSN 114-1284

$$PI_{SI} = \frac{\sum_{i=1}^{n} W_i . P_{SIi}}{P_{STi}}$$

$$PI_{DI} = \frac{\sum_{j=n+1}^{m} W_j . P_{DIj}}{P_{DITj}}$$

$$PI_{SKT} = \sum_{k=m+1}^{0} W_k . P_{SKTk}$$

$$TPI = PI_{SI} + PI_{DI} + PI_{SKT}$$

$$= \frac{\sum_{i=1}^{n} W_i . P_{SIi}}{P_{STi}} + \frac{\sum_{j=n+1}^{m} W_j . P_{DIj}}{P_{DITj}} + \sum_{k=m+1}^{0} W_k . P_{SKTk}$$

where:

TPI = Total productivity index
PI_{KTP} = Productivity index of key terminal parameters
PI_{SKT} = Productivity index of sub-key terminal parameters
PI_{SI} = Productivity index of static indicators
P_{SIi} = Productivity factor values for static indicators of key terminal parameters
P_{SITi} = Target values of productivity indicators for static indicators of key terminal
PI_{DI} = Productivity index of dynamic indicators
P_{DIj} = Productivity factor values for dynamic indicators of key terminal parameters
P_{DITj} = Target values of productivity indicators for dynamic indicators of key terminal
P_{SKTk} = Productivity index of sub-key terminal parameters $W_i + Wj + W_k = 1$
Wi = Weighted attached to static indicators of key terminal parameters
W_j = Weighted attached to dynamic indicators of key terminal parameters
W_k = Weighted attached to sub-key terminal parameters

A participative methodology has been adopted for measurement of multifactor productivity that includes:

1) analysis of corporate mission, objectives and functions of the organization
2) study of various departments/sections and find out goals and key result areas (KRAs)
3) design multifactor productivity model
4) select relevant productivity indices
5) calculate productivity indices and validate results
6) develop action plan for implementation and monitoring of the model

2.2 Multi Objective Matrix (Mulomax)

Mulomax is the performance measurement model developed from original Objective Matrix (Omax). In this research Mulomax used to fill the disability of Multifactor productivity in indicators structure arrangement [4]. Due to many functions/departments in organization which obtained many criteria to become indicator measures, Mulomax approach can facilitate the hierarchy of KRAs among the functions and cluster those in terminal parameters of Multifactor productivity. In figure 1 describe the structure of Multifactor productivity using Mulomax.

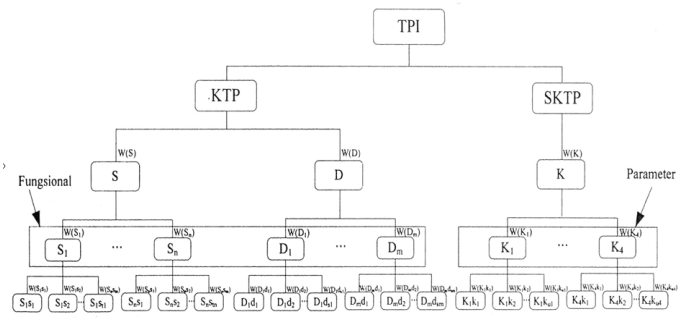

Figure 1. Multifactor Productivity Measurement Model for Service Organization in Mulomax Structure

where:

KTP = key terminal parameter value
SKTP = sub-key terminal parameter value
S = static indicators value
D = dynamic indicator value
K = development indicators value
W(S) = weight of static indicators
W(D) = weight of dynamic indicators
W(K) = weight of development indicators
$W(S_x)$ = weight of x-function in static indicators, x = 1,2……n
$W(D_y)$ = weight of y-function in dynamic indicators, y = 1,2……n
$W(K_z)$ = weight of z-function in dynamic indicators, z = 1,2……n
$W(S_nS_{xn})$ = weight of x_n- criteria in static indicators
$W(D_md_{ym})$ = weight of y_m criteria in m-function in dynamic indicators
$W(K_ud_{zu})$ = weight of z_u criteria in u-function in development indicators
S_x = value of x-function in static indicators
D_y = value of y-function in dynamic indicators
$S_n s_{y_n}$ = score of x_n criteria in n-function in static indicators
x_n = $1 \ldots t_n$ → t_n = sum of criteria in n-function
$D_m d_{y_m}$ = score of y_m criteria in m-fucntion in dynamic indicators
y_m = $1 \ldots s_m$ → s_m = sum of criteria in m-function

ISSN 114-1284

3. RESULTS AND DISCUSSION

The discussion below will show the modify Multifactor with Mulomax, and for the research object, the measurement in House of Sampoerna Café as the case study also included.

3.1 Productivity Indicators Determination

KRAs determination deploy from the Café vision, mission, and goals. The Café has 7 functions, those are kitchen, steward, service, bar, cashier, public area, and purchasing functions. Based on the analysis of the KRAs and singularities of the organization, KTPs and SKTPs are selected. Table 1 denotes the KRAs in the each function, which are occurs productivity indicators with static, dynamic and development terminal parameters.

Table 1. Productivity Indicators for KTPs and SKTPs

Key terminal parameters		
Static indicators		**Productivity indicators**
Function	Kitchen	Full-time cook staff attendance (A)
		The rate of energy consumed (B)
		The percentage of spoiled foodstuff (C)
	Steward	Steward staff attendance (D)
		The number of broken/stolen equipment (E)
	Service	Service staff attendance (F)
		VIP room utilization (G)
		Function Hall utilization (H)
	Bar	Full-time bartender staff attendance (I)
		Machine utilization (J)
	Cashier	Cashier staff attendance (K)
	Public Area	Public area staff attendance (L)
	Purchasing	Purchasing staff attendance (M)
Dynamic indicators		**Productivity indicators**
Function	Kitchen	The rate of income on food sales (N)
		The number of complaint in food (O)
		The achievement rate of Chef-special menu promotion (P)
	Bar	The rate of income on beverage sales (Q)
		The number of complaint in beverage (R)
		The achievement rate of Bar-recommended menu promotion (S)
	Service	The number of complaint in server service (T)
		Sales growth revenue (U)
	Cashier	The number of complaint in cashier service (V)
		The amount rate of cash payment (W)

Sub-key terminal parameters		
Development indicators	**Criteria**	**Productivity indicators**
Business development index	To measure Café capability in building capability in market through technology development	The rate of accomplishment on Wi-Fi service for free of charge (X)
Vendor development index	To measure Café capability in building capability in market through business development	The degree of cooperativeness with food & beverage supplier (Y)
		The degree of cooperativeness with Travel Agent (Z)
		The market enhancement rate of advertisement (A1)
		The market enhancement rate of discount promotion (The degree of cooperativeness with Bank's credit card) (B1)
Research & development index	To measure Café capability in building capability in market through research and development	The achievement rate of 'happy hour' program (C1)
		The achievement rate of Live Music program (D1)
Standardization index	To measure Café capability in building capability in market through standardization process	The rate of accomplishment on sstandard of service development (E1)

3.2 The measurement method

Since Mulomax adapted from OMAX, therefore the measurement of key terminal parameter indicators use 0 to 10 degree of level to represent score in order to show the achievement value. Level 0 means the degree of the worst acquisition, level 3 means the degree of standard, and level 10 means the degree of the best achievement that organization ever acquire. Thus, the value for levels between 0, 3, and 10, obtained through interpolation calculation. For sub-key terminal parameter, the indicators assessment value started in range point 1 to 4 with score 4 for very good till score 1 for very poor. Subsequently, justification to Mulomax score (0 to 10) are needed to compose same measurement result with KTPs.

The weight of indicators and functions utilize Pairwise Comparison, adapted from Analytical Hierarchy Process [5]. This method selected due to similarity hierarchy structure like Multifactor model, and has consistency testing as its strength. Table 2 depicts the aggregate value of weight in each indicators and functions.

3.3 Productivity Evaluation

Based on the above indicators and data availability, the measurement operated for every indicator in every function in term of terminal parameters. This section divided into 4 part, evaluation in static indicators, evaluation in dynamic indicators, evaluation in development indicators, and for the final result is overall evaluation.

Table 2. Aggregate Weight

Name	Weight (%)
Static Indicators	26,05
Kitchen Function	14,29
Indicator A	58,89
Indicator B	15,93
Indicator C	25,19
Steward Function	14,29
Indicator D	83,33
Indicator E	16,67
Service Function	14,29
Indicator F	58,89
Indicator G	25,19
Indicator H	15,93
Bar Function	14,29
Indicator I	80,36
Indicator J	13,39
Cashier Function	14,29
Indicator K	100
Public Area Function	14,29
Indicator L	100
Purchasing Function	14,29
Indicator M	100
B. Dynamic Indicators	63,33
Kitchen Function	25
Indicator N	59,07
Indicator O	7,55
Indicator P	33,38
Bar Function	25
Indicator Q	59,07
Indicator R	7,55
Indicator S	33,38
Service Function	25
Indicator T	12,5
Indicator U	87,5
Cashier Function	25
Indicator V	33,33
Indicator W	66,67
C. Development Indicators	10,62
Bussines Develop Index	9,48
Indicator X	100
Vendor Development Index	36,69
Indicator Y	32,14
Indicator Z	32,14
Indicator A1	32,14
Indicator B1	3,57
Research & Development Index	13,57
Indicator C1	12.5
Indicator D1	87,5
Standarisation Index	40,26
Indicator E1	100

1. Static indicators

Static indicator is productivity measurement criteria to find degree of accomplishment of resources efficiency. Therefore the assessment does in each productivity indicator and each function. However, because of many measurements actionable, in this paper only showed one indicators which is 'Full-time cook staff attendance' in table 3. All the productivity indicators in static indicators outlined as radar curve in figure 2.

Table 3. Degree of achievement of Full-time cook staff attendance

Period	Actual working hour	Standard working hour	Ratio	Score	Percentage of ratio deviation
1	320,3	350	0,9151	3	-
2	307,78	350	0,8794	0	-0,0391
3	330,5	350	0,9443	5	0,0738
4	320,9	350	0,9169	3	-0,0290
5	329,28	350	0,9408	5	0,0261
6	325,94	350	0,9313	4	-0,0101
7	330,06	350	0,9430	5	0,0126
8	336,33	350	0,9609	6	0,0190
9	330,58	350	0,9445	5	-0,0171
10	332,33	350	0,9495	5	0,0053
11	328,92	350	0,9398	5	-0,0103
12	321,79	350	0,9194	3	-0,0217

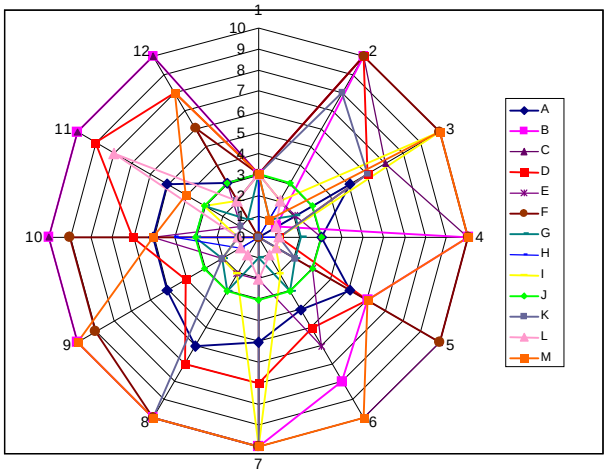

Figure 2. Radar Curve for Static Indicators

Regarding to percentage of ratio deviation and radar curve, it seen that all the indicators in static indicator have different score, and none get the highest score in all period.

Now, the evaluation continued for the function that related with static indicators. With same reason, only one function from 7 functions will be describe, 'kitchen' function in table 4 and productivity value in figure 3 for all of the functions.

Table 4. Productivity value of Kitchen function

Period	Value	Percentage of value deviation
1	0,4287	-
2	0,5876	0,37053

3	0,6955	0,183633
4	0,8401	0,207845
5	0,9173	0,091959
6	0,8787	-0,04211
7	1,0084	0,147585
8	1,0925	0,083455
9	1,0084	-0,07703
10	1,0084	0
11	1,0084	0
12	0,8401	-0,16691

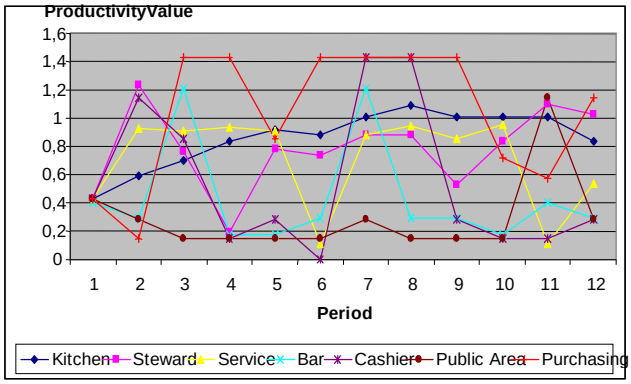

Figure 3. Productivity value for all function in static indicators

The calculation to get value is:

Value = weight of kitchen function x $\sum_{i=1}^{n}$(weight of *i* indicator x score of *i* indicator)

2. Dynamic indicators

Dynamic indicator is productivity measurement criteria to find degree of utilization of resources effectiveness. Similar with static indicators, the measurement run in productivity indicators and the functions. Figure 4 shows radar curve among indicators and productivity value in figure 5 for all of the functions.

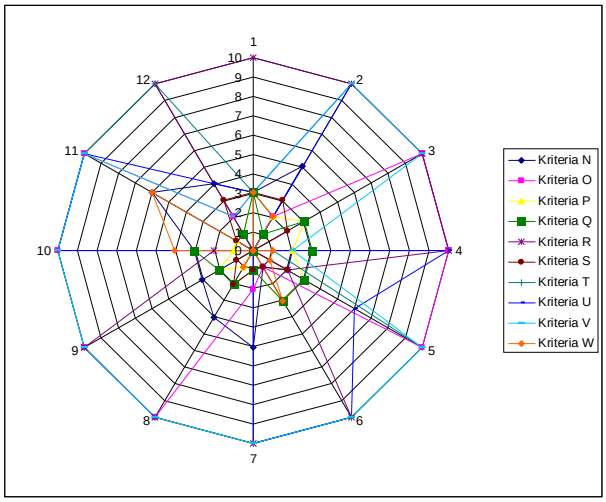

Figure 4. Radar Curve for Dynamic Indicators

The weight of dynamic indicator is higher than static and development indicator. For further development the weight proportion can be change based on the business plan. There are some criteria that have been used to arrive at the weightages, such as:

- Organization business strategy
- Degree of alignment with organization objectives
- Contribution analysis by improvement of individual factors
- Needs and scope for improvement. Customer and others stakeholder rewuirement
- Characteristics and degree of variability of factors

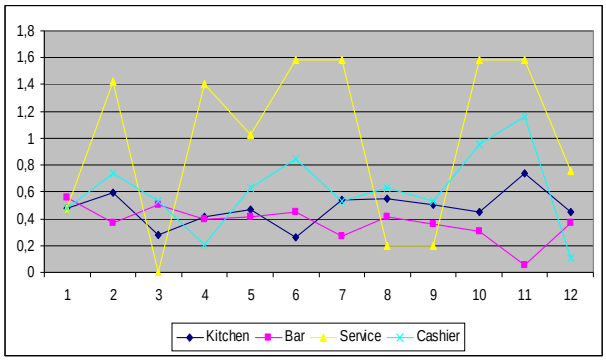

Figure 5. Productivity value for all function in dynamic indicators

3. Development indicators

Development indicator is productivity measurement criteria to find degree of enhancement of business development. The productivity index of SKTPs depends on business development, vendor development, R&D, and standardization. The depth of coverage of these parameters are measured based on the specific achievement with strong support from top level management. Here in table 5 shown score of productivity indicators in this area, and productivity value of SKTPs parameter in table 6.

Table 5. Productivity indicators of development indicators

Productivity indicators	Score
The rate of accomplishment on Wi-Fi service for free of charge	7
The degree of cooperativeness with food & beverage supplier	10
The degree of cooperativeness with Travel Agent	10
The market enhancement rate of advertisement	3
The market enhancement rate of discount promotion (The degree of cooperativeness with Bank's credit card)	0
The achievement rate of 'happy hour' program	0
The achievement rate of Live Music program	10
The rate of accomplishment on sstandard of service devevelopment	10

Table 6. Productivity value of sub-key terminal parameter

Parameter	Weight	Value
Business development index	0,0948	0,6636

Vendor development index	0,3669	2,7122
Research & development index	0,1357	1,1874
Standarisation index	0,4026	4,0260
		8,5892

4. Final result

The final result is total measurement for House of Sampoerna Café. Summary for measurement in KTPs (static & dynamic) and SKPTs (development) listed in table 7.

Table 7. Productivity value in key terminal parameter and sub-key terminal parameter

Period	Static indicators	Dynamic indicators	Development indicators
1	0,7748	1,9835	0,9122
2	1,2004	3,1325	0,9122
3	1,5646	1,3116	0,9122
4	1,0039	2,4286	0,9122
5	1,0616	2,5376	0,9122
6	0,9336	3,1445	0,9122
7	1,8539	2,9212	0,9122
8	1,6180	1,7899	0,9122
9	1,1799	1,5908	0,9122

We can see that dynamic indicators reach higher value compared with two others indicators. It makes for total productivity (TP) value, KTPs more dominant than SKTPs. However, important factor we have to consider is that these assessments include degree of weight which could dynamic indicator as though as the biggest contribution in TP value. In fact, perhaps the original score of dynamic indicators, insides of the degree of weight included, lack of difference with two others indicators. Therefore, this might be weakness of Multifactor measurement, with the intention of how large degree of weight given.

Table 8. Productivity value of House of Sampoerna Café

Period	Value	Percentage of value deviation
1	3,6705	-
2	5,2451	0,4289
3	3,7884	-0,2777
4	4,3447	0,1468
5	4,5114	0,0384
6	4,9903	0,1061
7	5,6873	0,1397
8	4,3201	-0,2404
9	3,6829	-0,1475
10	5,2371	0,422
11	5,6075	0,0707
12	3,7402	-0,333

Café achieve the highest value in period 7 and the lowest in period 1. However, all of the period's value reaches above borderline (score 3) that means Café performance is good enough. For further improvement, this research uses Ishikawa Diagram to identify the possible factors influence that could be improved in order to increase the performance value.

4. CONCLUSION

This paper has outlined a Multifactor productivity measurement model to measure in service organization, which represented by House of Sampoerna Café. The basic objective of productivity measurement is to establish the potential for improvement and make people accountable for the state of productivity. The case study has shown how different factors of static, dynamic and development parameters can be taken into account to calculate the total productivity of the organization. Although, the weakness of this model is rely on the subjectivity on degree of weight, it is important to highlight that the characteristic of the services itself are very subjective to measure, and the acknowledgement that benchmarking should not be the only performance mechanism within an organization overall system [6].

Though the Multifactor productivity is good for the organization, this gives opportunity to identify area for further development. The difficulty in kind of research is to identify productivity area in order to obtain accurate indicator measures. The productivity indicators calculations are carried out for key result areas, thus expecting the responsibility from management officer.

Abstract

Social organization is the enterprise that priorities the organization as the enterprising entity rather than the individual entrepreneur. Social organization owned by the private or not for profit sectors. As a consequence of the emphasis on the organization versus the individual entrepreneur, the performance measurement systems have potentially overemphasized the role of the stakeholder, versus creating a mechanism for looking at financial performance. This paper presents a knowledge-based framework for designing the performance of NPO using a model based on Malcolm Baldrige National Quality Award (MBNQA) criteria and Social Enterprise Balanced Scorecard (SEBC) approach. The purpose is capturing both the benefits and consequences of those models by integrating their perspectives and categories into a comprehensive model. Using this comprehensive model, hopefully social organization could easily deploy their strategies into indicator criteria and measure its in order to encourage social organization get best achievement.

Keywords:
Social organization, SEBC, MBNQA

1. INTRODUCTION

Social organizations provide important contribution services throughout the world [1]. Social organization, which the other statement called Non Profit Organization (NPO), are today commonly operating in a highly competitive environment that is characterized by increasing demand of services from the community, growing competition for contracts with the public and for-profit sector, as we also called Profit Organization [2]. The trigger of this growth was social movement increase that concern from many level in society [3]. This exponential growth also happened in Indonesia as developing countries. A lot of corporate social responsibility program rise in order to facing social problem. The World Bank defines NPOs as 'private organizations that pursue activities to relieve suffering, promote the interests of the poor, protect the environment, provide basic social services or undertake community development' [1]. This significant development more complex recently because of many factors, such as quality program demand, number of program and its variation that suitable with community requirement, more service expanded interrelation with public and business organization, and many more. Social organization management should organize more professional, modern, accomplish by strategic management, thus competitive advantage could be achieve and reach high performance value [4, 5].

1.1 Need for Performance Measurement

The important point in professional organization arrangement is performance measurement. The fact, however, many performance measurement method had been developed to profit organization and less for social organization. Why these NPOs need specific performance measurement model? One of the principal differences between NPO and profit organization is that they have different reasons for their existence. In oversimplified terms, it might be said that the ultimate objective of a commercial organization is to realize net profits for its owners through the provision of some product or performance of some services wanted by other people, whereas the ultimate objectives of a NPO is to meet some socially desirable need of the community. The basic different that arises is that as there is no profit motive in the NPO sector, and thus no single indicator of performance comparable to business enterprise is bottom-line. It may be stated that the best indicators of the performance of NPO are generally not measurable in currency terms, though currency is the language of financial reporting. That indicates that is more difficult to measure performance in NPO than in profit organization.

The performance measurement models that implemented nowadays mostly adopted from performance measurement models used from profit organization [1,3,6,7]. *Balanced Scorecard* (BSC) which admitted as powerful strategic management tool, is model applied frequently in this decade [8]. BSC also influences social organization in many researches [9,10,11]. Nevertheless, Somers [12] modify BCS model into *Social Entreprise Balance Scorecard* (SEBC) that amended in fill the gap in NPO performance measurement model.
The reason is even though BSC is popular performance framework but it has inadequacy. Kaplan and Norton in their book, BSC for NPO [13], discuss the difficulty to rely intangible asset on organization strategy, which only capture in learning and growth perspective. Integration of Social Enterprise Balance Scorecard (modeled closely to

BSC for NPO specification) with Malcolm Baldrige National Quality Award (MBNQA) try to develop a unified framework for translating the award requirements into a set of objectives and measures to achieve the ultimate results. Hope, both models with strengthens and weakness can create a synergy model suitable with NPO characteristics.

2. NON PROFIT ORGANIZATION

Social organization is enterprise structure which social mission to achieve. Similar terminology states Non Profit Organization (NPO) or Not-for-profit organization. Social organization has many definitions depend on the willingness we see. World Bank in their definition above notes the humanity point of view. Other states that social organizations have a form an intermediate structure between the market (private/for-profit sector) and government (public sector) [1]. However, goes on to argue that focusing on the differences seems to widen the divide between the two sectors and, that it is far more beneficial to focus on the similarities. Table 1 describes the diverse between NPO and profit organization [14].

Tabel 1.. Differences between Profit Organisation and Non Profit Organisation

No.	Profit Organisation	Non Profit Organisation
1	Focus on bottom line	Focus on social good
2	Aim to create shareholder value	Aim to provide a service to those in need
3	Rely on hired managers to run their operations	Rely on volunteers
4	Sources of revenue come from sales of their goods and services	Sources of revenue rely on donation and government funding

Future economic success of social organizations depend not only the quality of its social and economic activities, but also on communicating their performance to the multiple and diverse stakeholders. The Performance Prism developed by Cranefield School of Management (formerly at University of Cambridge) states that the focus of any organization whether for profit or non-profit should be on stakeholder satisfaction and stakeholder contribution. It should find relevant answers to five basic questions in order to assess its performance objectively:

1. *Stakeholder satisfaction* – who are the key stakeholders and what do they want and need?
2. *Strategies* – what strategies do we have to put in place to satisfy the wants and needs of these key stakeholders?
3. *Processes* – what critical processes do we require if we are to execute these strategies?
4. *Capabilities* – what capabilities do we need to operate and enhance these processes?
5. *Stakeholder contribution* – what contributions do we require from our stakeholders if we are to maintain and develop these capabilities?

From these 5 questions chain, we can summarize what social organization need to measure its performance, is a model that:

- Concentrate in organization strategic planning and the key result areas that delpoy from vision and mission.
- Implicate stakeholder in organization internal activities
- To measure capability not only from *tangible asset* but also *intangible asset*
- Focus on *critical success factors* balanced in term of their weight and for further improvement

3. MALCOLM BALDRIGE NATIONAL QUALITY AWARD for NON PROFIT ORGANIZATION

Since its inception in the US Congress in 1987 to promote quality awareness towards performance excellence, the Malcolm Baldrige National Quality Award (MBNQA) is now been accepted widely as a standard for performance excellence. From 1987 to present, MBNQA had been changed many times to ensure the continued growth im competitiveness. The MBNQA has 2 objectives, (1) To aware performance excellence as an increasingly important element in competitiveness, (2) To share information of successful performance strategies and the benefits derived from using thes strategies [15].

The award eligibility organization categories into:

- Manufacturing businesses
- Service businesses
- Small businesses
- Education organizations
- Health care organizations
- Non profit organizations

The system perspective of non profit organizations has same with manufacturing businesses, therefore they has identical criteria framework also. The Baldrige Award framework as describes in figure 1 shows the relationship between those criteria.

To explain the relationship among the categories, as we can see in figure 1, there are 7 categories that composed of the six categories in the center and one category in the foundation. Leadership (category 1), Strategic Planning (category 2), and Customer Focus (category 3) represent the leadership triad. These categories are placed together to emphasize the importance of a leadership focus on strategy and customers. Workforces Focus (category 5), Process Management (category 6), and Business Results (category 7) represent the results triad. The organization's workforce and key process accomplish the work of the organization that yields the overall performance results. The horizontal arrow in the center of the framework links the leadership triad to the results triad, a linkage critical to organizational success. Furthermore, the arrow indicates the central relationship between Leadership and Results. The two-headed arrows indicate the importance of feedback in an effective performance management system. Measurement, Analysis, and Knowledge Management (category 4) serve as a foundation for the performance management system.

This category is critical to the effective management of organization and to a fact-based, knowledge driven system for improving performance and competitiveness.

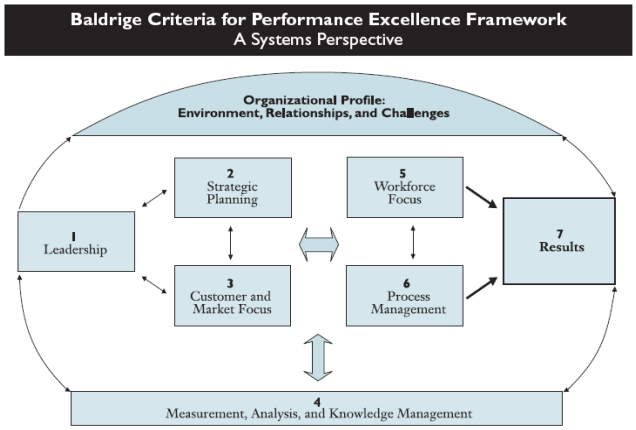

Figure 1. MBNQA framework

In term of Total Quality Management (TQM), one of the major obstacles to empirical investigations of quality in organizations has been the difficulty id defining precisely what quality is. Although is has been many variety of attributes as core aspects of organizational quality, those are not comprehensive due to point out the tremendous diversity of dimensions, attributes, and definitions that are discussions of quality [16]. Therefore, when MBNQA created, there is some examination of this model framework to accomplish that significant step forward. As illustrated in figure 2, the categories are structured in driver, system and outcomes classification.

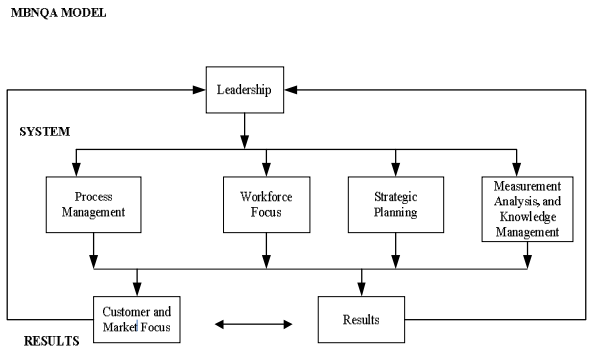

Figure 2. Classification of MBNQA framework

The Leadership category is classified as a *driver* of quality. Four categories - strategic planning, measurement analysis and knowledge management, workforce focus, and process management – are classified as *systems*. Two categories are assumed to be desirable *outcomes*, namely, customer and market focus, and results. This framework specifies that the driver of quality has both direct and indirect impact on outcomes and that the systems mediate the driver as well as has direct impact on the quality outcomes.

4. SOCIAL ENTERPRISE BALANCED SCORECARD MODEL

Social Enterprise Balanced Scorecard was created by Somers in 2005 when he done his research in UK social organization [12]. Inspired from Kaplan original BSC framework to NPOs which is illustrated in figure 3 [17], there were three changes adjusted: an additional layer was added in which social goals are articulated above the financial perspective. The financial perspective was broadened to focus on sustainability, and the customer perspective was widened to capture a larger number of stakeholder groups.

Figure 3. Balanced Scorecard for Non Profit Organization

In SEBC framework showed in figure 4, social enterprises begin by stating their social goals as desired outcomes, and then move into perspectives. In the financial sustainability perspectives, each bubble represents an objective. The stakeholder perspective is the advantageous from this model. Pearce [18] state stakeholder definition is those people or groups who are either affected by or who can affect the activities of an organization. Thus in SEBC model, the customer perspective has to consider as more stakeholders as well as the organization's wider impact. Since social organization is a response for greater community and employee involvement in, and ownership of, it is important for managers to be able to distinguish between those who pay for a service, those who use them, those who benefit from the intervention in the long term, and those who consume it (donors, grant funders, employees, and the wider community), as these are not always the same. The arrows illustrate cause and effect chain from the strategy map.

In Financial Sustainability perspective, the main focus is not increasing productivity for financial gain from product sales revenue, but to increasing productivity for social gain. For instance, a company produces soap. In term of achieving good earnings, profit organization will plan attraction promotion, boost their capacity, and manage the production schedule accurately, in order to estimate manufacture forecast and profit margin for further improvement. In social organization, however, the

objective mainstream is how healthiness impact to community. Do the effluent soap have negative effect for environment? Or do the soap ingredients or other product knowledge written in soap package to show transparent information to consumer. Then, to the employee itself, do they provide work safety policy tightly.

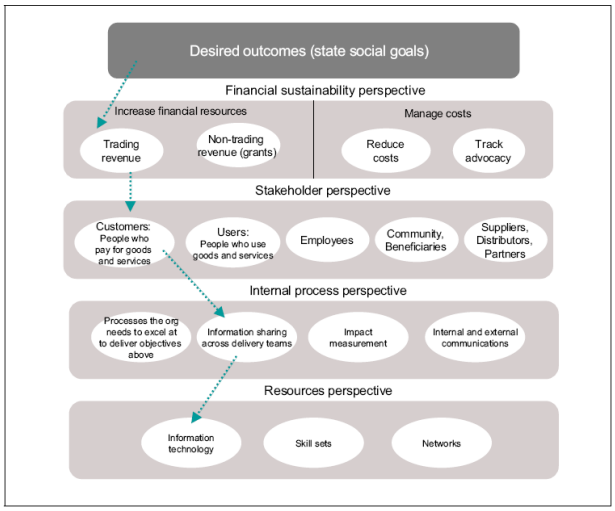

Figure 4. Social Enterprise Balanced Scorecard Model

The next perspective is internal process that has similarity with original BSC concept. The important point to note is that there are not only one stakeholder here, like shareholder in profit organization, but various stakeholders in social organization could make various impact to the process. The process need to attend communication relationship and information management in internal and external stakeholders. Regarding to this necessity, the resources perspective as the support for the internal process allocate and evaluation all of the resources required for the social organization operational.

5. LINK SEBC AND MBNQA

Chua [19] stated the framework for evaluating performance using BSC and Singapore Quality Award (SQA). Even though their model inspiring this research, however, it have never been tested empirically if the platform also alignmnet in social organization. The lack of how key performance indicators emphaized and how its measured also being limitation of their model. This paper has desirable objectives to bring to light how the MBNQA can be further leveraged upon with strategic tool like SEBC to capture the effect on financial performance due to the perceived impact of quality improvement activities. Through the model design by using MBNQA classification, the SEBC perspective took place in contribute the assessment in scorecard method.

While MBNQA regrouped into driver, systems, and results, thus the SEBC taking their four perspectives and incorporate them into another set of framework. Now, the integrated framework consist of (1) *driver* - MBNQA leadership and strategic planning categories, integrate with SEBC resources perspective (2) *systems* - MBNQA workforce focus, process management, measurement analysis and knowledge management categories, put together with SEBC financial and internal business perspectives, (3) *results* - MBNQA customer and market focus and results, integrate with SEBC stakeholder perspective. This groups listed in table 2 and framework illustrated in figure 5.

Table 2. Integration Model Group

Classification	MBNQA (category)	SEBC (perspective)	Key Result Area
Driver	• Leadership • Strategic Planning	Resources	• Leadership • Strategic Development • Strategic Deployment • Asset Management • Network & IT
System	• Workforce Focus • Process Management • Measurement, Analysis, and Knowledge Management	• Financial • Internal Business	• Funding & Expense Management • Employee (volunteer) availability • Information & Comunication • Operational Process • Audit, Monitoring & Evaluation • Knowledge Management
Result	• Customer and Market Focus • Results	Stakeholder	• Stakeholder requirement & expectation • Stakeholder Willingness • Community advantage • Relationship (customer, supplier, partner) • Society Need

5.1 Driver

Driver explains in how the management defines the organization goals, create the value, target, policy and drive those to excellent business performance and customer delight. The important point to note is that 'customer' here meaning person who serve and take advantage from organization with/out paying. In other word, customers in social organization do not have contributed to profit organization at all. This is seriously to understand because of the priorities of social organization determine in how best to achieve social outcomes than revenue outcomes. Therefore, in *driver*, leadership category focuses on how leaders' action guide and sustain the organization. For

social organizations that rely on volunteers to accomplish their work, responses to communication also should consider the efforts to communicate with and engage the volunteer workforce. As it stands, network and asset management from resources perspective, supported by information technology, become encompasses input to develop the strategy and corrective feedback for the next improvement.

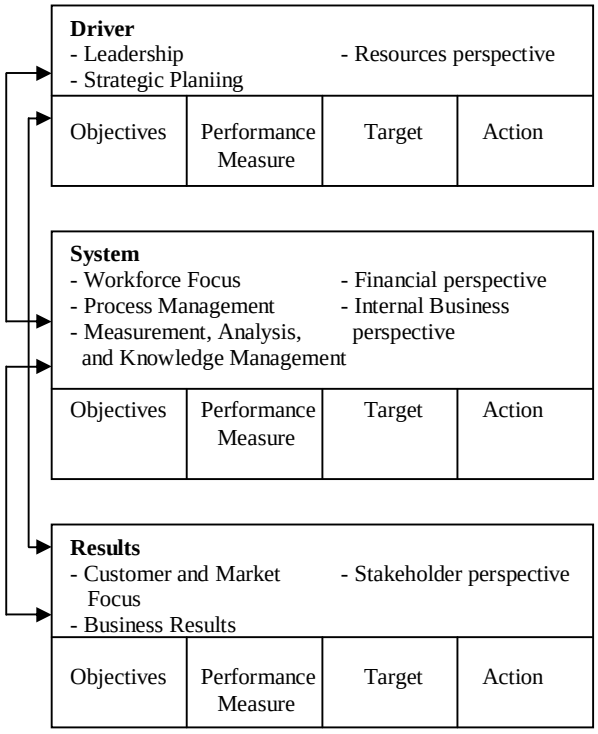

Figure 5. Integrate Framework of MBNQA and SEBC

5.2 System

In term of input process output, system is the process itself. System consists of well-plan activities that define systematically in order to fulfill the stakeholder requirement and perform the evaluation indeed. Due to driver value chain, system builds with most of MBNQA categories and couple perspectives of SEBC included cash flow. Financial perspective usually stated in top line of enhancement. This is main different between original BSC and SEBC. Stakeholder satisfaction is more essential than earnings collection. The ultimate objectives in social organization rely on social value added. However, this does not mean that financial is not important. Social activities needs money in run their operation, for communication, training, transportation, food, and other necessity. In order to ensure social mission focus, the categories and perspectives should be linked and oriented towards its social bottom line.

By this point of view, workforce in social organization term, are not limited in employees, who get salary from their work, but also volunteers. Therefore, workforce productivity can not measure only by the ratio of earning, thus feeling of social service willingness is the main motivation of this volunteers. This issue also make why social organization workforce measurement are more complex than commercial organization. This not only talked about how many working hour spend, or how much income the organization could have as the profit, but also social emotion that rely on the volunteers. That, perhaps, be the reason why social organization management lack of discipline and authority in managing their employees. Knowledge management could also assist in continuous improvement by addressing 'know how, know why, know what, know who, and know where'. Knowing these will help to streamline the organization's internal processes.

5.3 Results

Results discuss in how leadership and system emphasized the stakeholder performance, market and business. In term of customer, social organization states stakeholder as customer, supplier, donors, government, and widely community, and specially the client itself. Product offerings should consider all the important characteristics of products and services and their performance throughout their full life cycle and the full consumption chain. The focus should be on features that affect stakeholder preference and expectation. This feature makes differentiate between profit organizations that compete offering with other organizations, and socially improving impact in social organization. The results of performance measurement are not only useful in gaining additional funds but can also be used in the programs run by social organization, such as changing program design or operations, planning future programs, promoting the program to potential clients and improving outreach and public relations.

5.4 Measurement Deployment Model

To complete the integrate model measurement, it is necessary to construct the scorecard and the cause-effect relationship among the key performance indicator deployed from the MBNQA and SEBC items. As it stands in table 3 is the example scorecard for *driver* classification. The *system* and *results* classification can framed with the same deployment like *driver*.

Table 3. Scorecard for Driver

	Items	KPI	Objective	Target	Weight	Score Range	Score
DRIVER	Senior Leadership (D1)	K1	O1	T1	0.58	K1 ≥ T1 x1≤K1≤x2 K1 ≤ x3	3 2 1
	Governance & Societal Responsibilities (D2)	K2	O2	T2	0.42	K2 ≥ T2 x4≤K2≤x5 K2 ≤ x6	3 2 1
	Strategic Development (D3)	K3	O3	T3	0.47	K3 ≥ T3 x7≤K3≤x8 K3 ≤ x9	3 2 1
	Strategic Deployment (D4)	K4	O4	T4	0.53	K4 ≥ T4 x10≤K4≤x11 K4 ≤ x12	3 2 1
	Resources (D5)	K5	O5	T5	0.25	K5 ≥ T5 x13≤K5≤x14 K5 ≤ x15	3 2 1

where:

$D_i, i = 1,....n$ is items subsection from Driver

D1 and D2 items from MBNQA Leadership
D3 and D4 items from MBNQA Strategic Planning
D5 item from SEBC Resources perpective

$T_i, i = 1,....n$ is ultimate target to achieve of the KPI

$K_i, i = 1,....n$ is key performance indicator deployed from the items

$O_i, i = 1,....n$ is objective determined from the KPI

$x_i, i = 1,....n$ is score range for KPI

Score divided into three section, whereas (score) 3 when K_i achieve the target, and others two when it not meet the target.

Weight quotition differentiate between MBNQA items and SEBC items. As SEBC is modified model from original BSC, the weight from each perspective establish from the management priority. In this integrated model, we use equal degree of weight for 4 perspectives which is 0.25 each. For further application it can be change depend on the importance concern.

Degree of weight for MBNQA items adopted from the MBNQA point values. From MBNQA 2009 [15] point values have already stated for each categories and items. This MBNQA point values listed in table 4.

Table 4. Degree of Weight for MBNQA Items

Classification	Category	Point	• Item	Point	Weight
1. *Driver*	*Leadership*	120	• Senior Leadership	70	0.58
			• Governance and Societal Responsibilities	50	0.42
	Strategic Planning	85	• Strategic Development	40	0.47
			• Strategic Deployment	45	0.53
2. System	*Workforces Focus*	85	• Workforce Engagement	40	0.47
			• Workforce Environment	45	0.53
	Measurement, Analysis, and Knowledge Management	90	• Measurement, Analysis, and Improvement of Organizational Performance	45	0.5
			• Management of Information, Knowledge, and Information Technology	45	0.5
	Process Management	85	• Work Systems	35	0.41
			• Work Processes	50	0.59
3. Result	*Customer Focus*	85	• Customer Engagement	40	0.47
			• Voice of the Customer	45	0.53
	Results	450	• Product Outcomes	100	0.225
			• Customer-Focused Outcomes	70	0.155
			• Financial and Market Outcomes	70	0.155
			• Workforce-Focused Outcomes	70	0.155
			• Process Effectiveness Outcomes	70	0.155
			• Leadership Outcomes	70	0.155
Total		1000		1000	

The cause-effect relationship describes in figure 6 show the connection among the classification (driver, system, results) and their items. These relations indicate input direction through the indicators in order to support affect performance within the process. Performance measures with both lagging and leading, are then linked to strategic identified in organization mission, which align with the vision of the organization.

6. MODEL IMPLICATION

The measurement told the results of activities already taken. If any indicators can not meet the target determined, then some action to improve should be needed. This similar with the Deming quality cycle – PDCA (Plan, Do, Check, Action), that remind us the quality journey is always like a wheel in escalation way to consistently do continuous improvement. There are some implications of the integrate model that need some consideration, for instance:

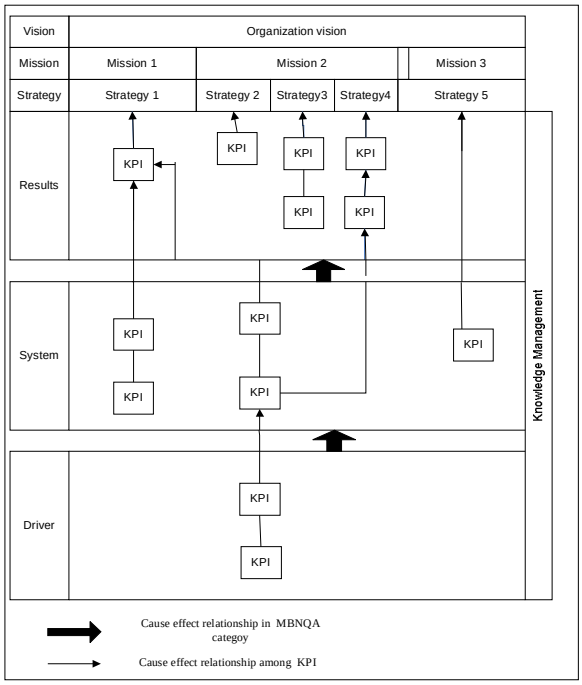

Figure 6. Cause Effect Relationship

- Strategy and performance measurement should focus on what output and outcomes of the organization intends to achieve, not what programs and initiatives are being implemented.
- Stakeholder, especially recipients, are more critical than other perspective
- Management of social organization should rely the policy on socially motif than commercial motif
- The organization should focus its limited resources on a limited set of objectives and constituents.
- Key performance indicators generate from MBNQA should consider in effectiveness results. As excellent model that cover up all aspect in the organization, MBNQA has widely attributes to assess, and lack of effective goals.
- In subsequence, key performance indicators generate from SEBC should concentrate in efficiency results. As excellent reporting tool with a discrete set of level indicators, provides management with a quick, comprehensive of organizational performance [3]. For this purpose, there is awareness that SEBC focusing in effectively more than its efficiency.

As a conclusion, measuring success in social organizations need three important lessons to learn, which are: measuring depend on the objectives, keep measures simple and easy to communicate, and stay focus on social line. This MBNQA and SEBC integrate model hopefully can give another measurement model in NPO that in today world changing, need humanity balance than just gaining more revenue.

ABSTRACT

In drilling process with standard twist drill usually roundness is deviate, because of single feed rate. To get desired roundness it needs advanced drilling. Another way to reduce processes step is modification of tool. In this method edge of $2k_r$ is reduced by cutting the ends. In this way, in one step of drilling there are two different feed rates. This research is focused on influence drilling parameters, i.e. cutting speed (V), feed rate (f) and depth of cut (a), on roundness of hole resulted of modified twist drilling tool. Each chosen parameters is varied 3 levels. Research developed using materials of ST 41 steel with dimension of h = 1 cm, d = 25.4 mm amount of 30 specimens. Ends of twist drill were cut from normal/standard half of k_{r1} (59°) to be 45° and length of lips is 0.2 x D. Variable response is value of roundness (MLA). Variation and combination of each parameters according Box-Behnken design experiment of Response Surface Method. Mathematical model roundness respond of a hole resulted from drilling for constant nominal relief edge (α) is $T=K/(V^m f^n \alpha^\gamma)$, where T is roundness respond. Logarithmic model is $\ln T = \ln K - m \ln V - n \ln f - \gamma \ln a$. Square regression of the model for roundness of standard tool is $\hat{Y}_{MLA} = 87.692 + 10 X_1 + 7.5 X_2 - 5 X_3 + 11.538 X_2^2 + 6.538 X_3^2$. Where X_1 is cutting time, X_2 is feed rate and X_3 is depth of cut. The developed model then tested by many tests. By the method it is found that the optimum V =15.000, f = 0.125 and a = 8.500 with roundness value is 83.2692 and desirability 0.91673. Where as for modified tool, the optimum predicted roundness is 64.7388 with desirability degree of 0.93526 when V = 15.0000, f = 0.1250 and a = 8.4832.

Optimization, drill, roundness, RSM

1. INTRODUCTION

In order to develop an adequate relationship surface finish and the cutting parameters (such as cutting speed, depth of cut, feed, etc), a large number of tests are needed, requiring a separate set of tests for each combinations of cutting parameters. This increases the total number of tests and as a result the experimentation cost also increases. As a group of mathematical and statistical techniques, response surface methodology (RSM) is useful for modeling the relationship between the input parameters and output responses. RSM could save cost and time by reducing number of experiments required.

In assessing machinability, some researchers have tried to employ response surface methodology to design their experimentations, and to establish the models. Alauddin *et al* [1], Ginta et al [2], and Mansour *et al* [5] applied response surface methodology to optimize the surface finish in milling. Manurung used RSM for optimizing transesterification of biodiesel processing [5]. Oktem *et al* used response surface methodology with a developed genetic algorithm (GA) in the optimization of cutting conditions for surface roughness [9]. Sharif *et al* used factorial design coupled with response surface methodology in developing the surface roughness model in relation to the primary machining variables such as cutting speed, feed, and radial rake angle [10]. In short, relative smaller number of designed experiments is required by applied the method to generate much useful information.

The main objective of this work is to find-out optimum roundness in drilling of ST 41 using modified tool. Roundness will be established based on cutting speed, feed rate and depth of cut. Box-Behnken with k = 3 used to design the experimentations. Minitab version 14 program will be used to analyze the data and to develop the models [3]. The adequacy of the model was tested at 95% confidence level.

2. BASIC THEORY

Element of Machining. There are five basic elements in maching i.e cutting speed (v) in m/minute, feeding speed (f) in mm/rot, depth of cut (a) in mm, cutting time (t_c) in min., rate of metal removal (z) in cm^3/min.

Twist drill is a cutting tool used for making holes in solid materials. It basically consist of two partas; the body cutting edges and shank which is used for holding purposes. This has two cutting edges and two opposite spiral flutes cut into its surface as shown figure 1.

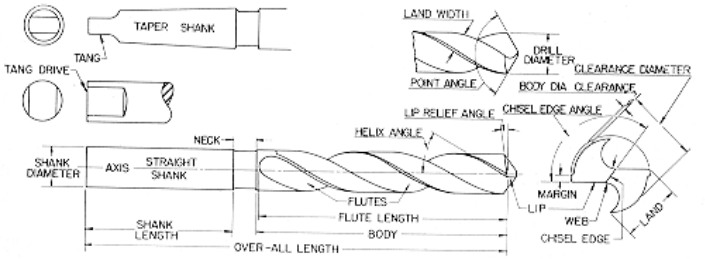

Figure 1—Illustrations of Terms applying to Twist Drills.

Modified Tool. Modification of tool end has been developed to reduce deviation in drilling by standard tool. One method to modify is by changing angle of $2k_r$ become two stages. In effect it will reduce value of unroundness, because tool not only to drill but also to bore. For ST 41 material optimum of $2k_r$ edge 118^0 [8]. End of tool is grinded up to k_{r1} half of end normal tool 59° and length of side k_{r1} 3/5 from normal tool. Therefore edge of $k_{r2} < k_{r1}$ i.e. 45° and lengrh of side is k_{r2}

3. EXPERIMENTAL METHOD

Research developed using materials of ST 41 steel with dimension of h = 1 cm, d = 25.4 mm amount of 30 specimens. Where as, diameter of twist drill used is 13 mm, 15 mm and 17 mm. Ends of twist drill were cut from normal/standard half of k_{r1} (59°) to be 45° and length of lips is 0.2 x D as shown in the following figure.

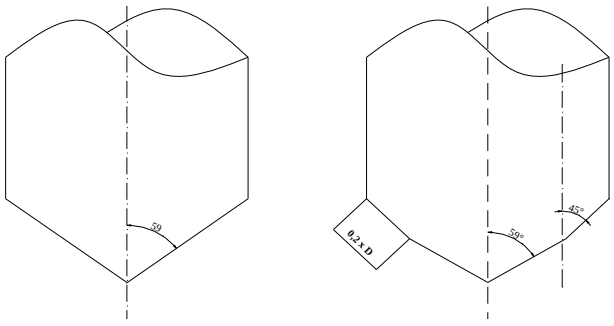

Figure 2. Comparison between standard and modified tool

Three process variables are chosen with three level of each one. Each level coded as lower level (-1), middle level (0) and upper level (+1).

Table1: Variation of parameters

Factor	Lower Level	Middle Level	Upper Level
Code	-1	0	1
cutting speed /v (X_1) in m/min.	15	17	20
feed rate /f (X_2) in mm/rot	0.125	0.200	0.315
depth of cut /a (X_3) in mm	6.5	7.5	8.5

Variable response is value of roundness (MLA). Those values are according to recommended ones for drilling with HSS tools and also number of feed available on the machine. Variation and combination of each parameters according Box-Behnken design experiment of Response Surface Method.

Table 2: Design experiment of Box- Behnken with k-3

No	X_1	X_2	X_3
1	-1	-1	0
2	1	-1	0
3	-1	1	0

12	0	1	1
13	0	0	0
14	0	0	0
15	0	0	0

Mathematical model roundness respond of a hole (T) resulted from drilling for constant nominal relief edge (α) is

$$T=K/(V^m f^n \alpha^\gamma) \quad \text{.....(1)}$$

where K, m, n, γ are constants.
Logarithmic model is

$$\ln T = \ln K - m \ln V - n \ln f - \gamma \ln a \quad \text{.....(2)}$$

Linier mode of the above equation (2) become:

$$\eta = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 \quad \text{.....(3)}$$

Second order equation for mathematics modeling is developed from equation 3 is:

$$Y = b_0 + b_1 X_1 + b_2 X_2 + b_3 X_3 + b_{11} X_1^2 + b_{22} X_2^2 + b_{33} X_3^2 + b_{12} X_1 X_2 + b_{13} X_1 X_3 + b_{23} X_2 X_3 \quad \text{.....(4)}$$

with: X_i = independent variable, i = 1, 2, 3... k
b_0 = constant
b_i = coefficient of model parameter, i = 1, 2, 3... k

4. EXPERIMENTAL RESULTS AND DISCUSSION

Results of experiments are shown in table 3 for standard tool and modified tool. From the data of table 3 then developed mathematical model for estimated coefficients using Minitab 14 program. Regression model for the model results the estimated coefficients as shown at table 4.

Table 3: Data of parameters and roundness

No	V (mm/min)	F (mm/rot)	a (mm)	MLA STD*) (μm)	MLA Modif**) (μm)

Table 4 Estimated Regression Coefficients for Roundness

Term	Coef	SE Coef	T	P
Constant	87.692	2.412	36.354	0.000
v	10.000	1.775	5.633	0.000
f	7.500	1.775	4.225	0.002
a	-5.000	1.775	-2.816	0.020
f*f	11.538	2.605	4.429	0.002
a*a	6.538	2.605	2.510	0.033
S = 5.021	R-Sq = 90.1%		R-Sq(adj) = 84.6%	

Square regression of the model for roundness of standard tool is $\hat{Y}_{MLA} = 87.692 + 10\ X_1 + 7.5\ X_2 - 5\ X_3 + 11.538\ X_2^2 + 6.538\ X_3^2$. Where X_1 is cutting time, X_2 is feed rate and X_3 is depth of cut.

The developed model then tested by lack of fit test. Analysis of variance (Table 5) shows that P-value lack of fit is 0.704, greater than $\alpha = 0.05$. It means that there is no lack of fit in the model or the model is suitable.

Table 5 Analysis of Variance for Roundness

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Regression	5	2066.41	2066.41	413.282	16.39	0.000
Linear	3	1450.00	1450.00	483.333	19.17	0.000
Square	2	616.41	616.41	308.205	12.22	0.003
Residual Error	9	226.92	226.92	25.214		
Lack-of-Fit	7	160.26	160.26	22.894	0.69	0.704
Pure Error	2	66.67	66.67	33.333		
Total	14	6.79209				

P-value for linear is 0.000 and for square 0.003; both are less than $\alpha = 0.05$. It means that all variable parameters X_1, X_2, and X_3 contribute significantly to the model (Iriawan, 2006). Determination coefficient (R^2) is 90.1 %, it means that response can be declared by regression model resulted. Residual test shows that chart of residual versus the fitted values for standard and modification tool are randomly distributed and do not form certain pattern. It means the identical assumption for roundness is fulfilled.

Three residual tests are also carried out i.e. identical test, independent test and normal distribution test. Chart of residual versus the fitted values for cycle time (Figure 3) is randomly distributed and do not form certain pattern. It means the identical assumption for cycle time is fulfilled.

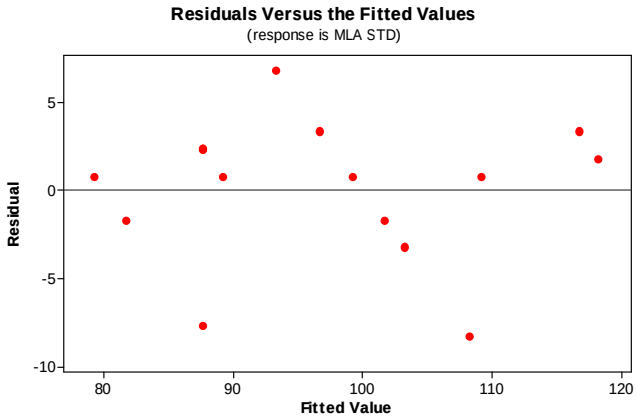

Figure 3. Residual versus the fitted values for response is roundness in standard tool

Normal distribution test (figure 4) ensures that line is plotted from left lower to right upper corner. It means the data is normal distributed.

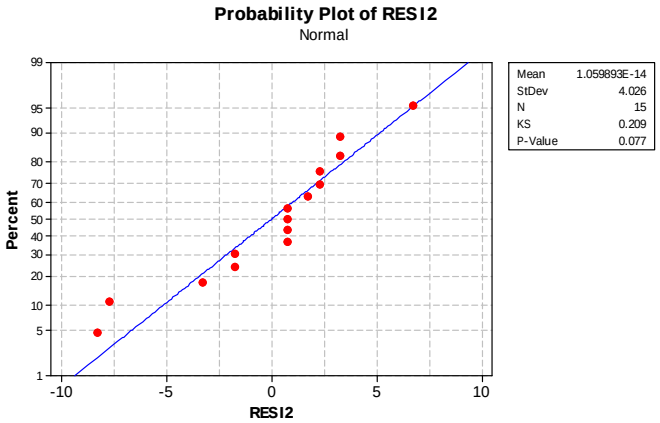

Figure 4. Probability Plot of Residual for normal distribution

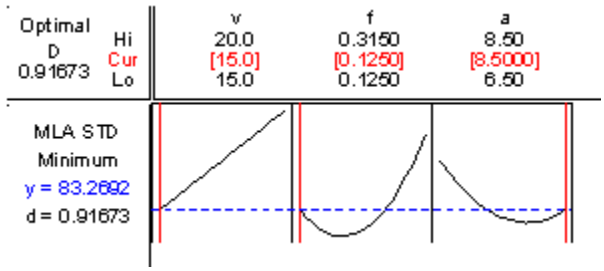
Optimization of cycle time is searched by Response Surface Method using Minitab 14 version. Desirability function used for respond is The Smaller is Better, which means minimum value is desired. By the method it is found that the optimum v =15.000, f = 0.125 and a = 8.500 with roundness value is MLA STD = 83.2692 and desirability 0.91673.



The same procedure was developed for modified tool which resulted Square regression of the model for roundness $\hat{Y}_{Modif\_MLA} = 77{,}143 + 7{,}5\ X_1 + 10\ X_2 - 5\ X_3 + 10.357\ X_3^2$. The developed model result in optimum predicted roundness of 64.7388 with desirability degree of 0.93526 when v = 15.0000, f = 0.1250 and a = 8.4832.

5. CONCLUSION

According to calculation using Minitab 14th version, variables influence cycle time in order are cutting speed, feeding rate, and depth of cut. By individual, the most influencing process variable onto roundness is cutting speed.

The optimum of roundness for normal tool is 83.2692 is achieved when cutting speed 15.000, feeding rate 0.125 and depth of cut is 8.500 with desirability 0.91673.

ACKNOWLEDGMENT

We would like to thanks to PT BBI Surabaya for their helpfulness during measuring session in the factory.

ABSTRACT

Chamomile is a package which is applied for cosmetic. In industry this package is being processed by blow molding. The project aim is to optimize time for processing the package. There are many parameters that influence cycle time during production; in this project only three of them were varied, i.e. blowing pressure (X_1), blowing time(X_2) and stopping time(X_3). Three level of each parameter are X_1 (0.1, 0.55, and 1.0 second), X_2(10.5, 11.5 and 12.5 second) and X_3 (4, 5 and 6 bar). Combination of among levels is based on Box Behnken design of Response Surface Method. Each combination is replicated 5 times and then averaged. The data then is processed by using Minitab version 14th. Square regression of the model for cycle time is $\hat{Y}_{CT} = 21{,}1300 - 0{,}0912\ X_1 + 0{,}2000\ X_2 + 0{,}6313\ X_3 + 0{,}6100\ X_1^2 + 0{,}6975\ X_2^2 - 0{,}1000\ X_1 X_2 - 0{,}1725\ X_1 X_3 + 0{,}1100\ X_2 X_3$. Optimization of cycle time is searched by Response Surface Method and it is found that the optimum of cycle time is 20.5 seconds. The optimum condition is achieved when stopping time is 0.1 second, blowing time 11.35 second and blowing pressure 5.1 bars.

Keywords

Optimization, packaging, RSM, blow molding, cycle time

1. INTRODUCTION

Processing time influences quality and quantity of product. The less processing time the more quantity but not must the more in quality. Chamomile is a plastic bottle applied for cosmetic product. At the moment, production of the bottle is not optimum yet, from target of 20.000 products per shift its only reach 9.870 for cycle time of 26 seconds and 5.000 for 23 seconds. There are many parameters that influence cycle time during production blowing pressure, blowing time and stopping time, temperature, and dry cycle; in this project only first three of them were varied. Choosing of these three parameters is in accordance with fish bone diagram. Stopping time is time need for stopping in order to open and close the mold. Blowing time is time need for blow and fills the mold cavity. If blowing pressure is less that its requirement product will not well performed but if it too high product will explode. The research aim is to find out the optimum cycle time by varying those three parameters. Optimization is carried out using response surface method. In this research we do not explore chemical content of plastic materials.

2. BASIC THEORY

2.1 Chamomile manufacturing

Chamomile 120 ml is manufactured in a blow molding machine through several steps as detailed below:

a. Preparation of materials; the bottle is made of High Density Polyetilene (HDPE) granules, a thermoplastics which have melting time of 177 – 260°C (A. Brent Strong, 2000). HDPE used is combination 50% new and the rest is after used one.
b. Processing; the mixed granules feed into a machine hooper then fed through an opening in the injection cylinder onto the surface of a rotating screw drive which carries them towards the mold. The rotation of the screw (at continuous speed of 26 rpm) forces the granules against the heated walls of cylinder, causing them to melt due to the heat of compression, friction, and the hot walls of the cylinder. When sufficient plastic materials is melted at the mold end

of the screw, the screw stops and by a plunger like motion ejects a "shot" of melted plastic (parison) through a die head and then places between the jaws of a mold. The mold is closed to pinch off the ends of the cylinder, and compressed air is blown in, forcing the plastic against the walls of the mold. In chamomile forming it no need of colorants because HDPE color has same color as final product.

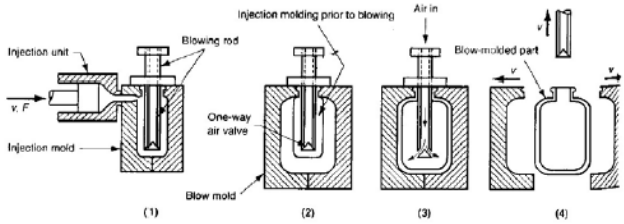

Figure 1. Blow molding; from parison to product

c. Last process is printing and labeling to the blown product

2.2 Cycle Time

Production cycle time is time needed for the machine to finish one product. In blow molding, one cycle is rotation of mold starts from opening the mold, followed by feeding of parison. Parison, then trapped by mold and blow pin come into the mold then controlled air compressed. Blow pin then taken out and follows by cooling. The last steps are opening the mold and ejecting. The process is return to the first step for next parison. One cycle time of chamomile processing is shown in figure 2.

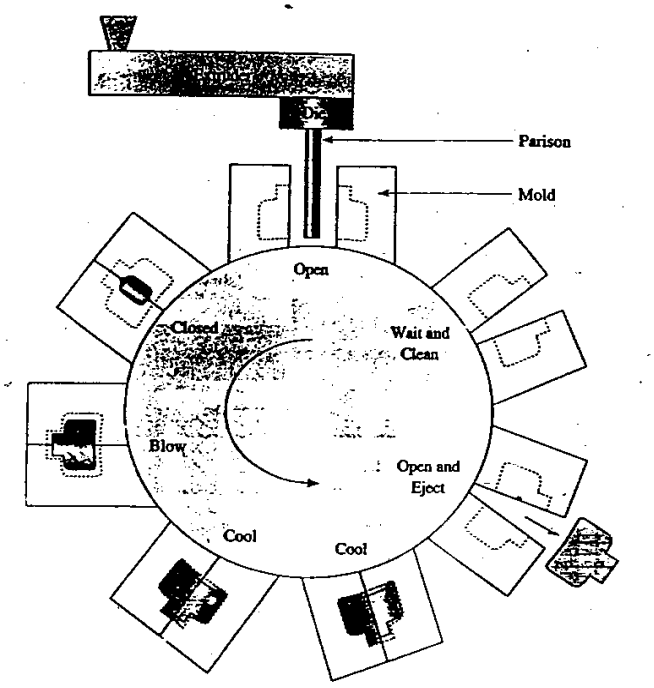

Figure 2. One cycle time for blow molding

3. EXPERIMENTAL METHOD

The project was carried out in a plastic manufacturing factory on Pandaan, East Java using blow molding Ekei Linier 4/8. The plastic material used is HDPE (*High Density Polyethylene*) which have specification: melting temperature 300 °C; specific mass 0,941-0,965 g/cm^3; crystalline degree 85-95 %; tensile strength 245-335 kgf/cm^2; elongation 100-25 %; impact strength 17-13 Kgf.cm/cm^2.

Three process variables are chosen with three level of each one. Each level coded as lower level (-1), middle level (0) and upper level (+1). For blowing pressure (coded as X_1) the level chosen are 4, 5 and 6 bars. Blowing time (X_2) is varied as 10.5, 11.5, and 12.5 seconds. Last process variable, stopping time (X_3), leveled as 0.1, 0.55 and 1.0 seconds. The experiment is developed according to Box Behnken for Response Surface Method as shown at table 1.

BT*ST	0.1100	0.03634	3.027	0.023
S = 0.07269	R-Sq = 99.5%		R-Sq(adj) = 98.9%	

From equation (1) we develop equation model according to table 2 and we find:

$$\hat{Y}_{CT} = 21{,}1300 - 0{,}0912\ X_1 + 0{,}2000\ X_2 + 0{,}6313\ X_3 + 0{,}6100\ X_1^2 + 0{,}6975\ X_2^2 - 0{,}1000\ X_1 X_2 - 0{,}1725\ X_1 X_3 + 0{,}1100\ X_2 X_3 \quad (2)$$

The developed model then tested by lack of fit test. In this test, first hypotheses (H_0= there is no lack of fit) is refused if P-value is less than α and vice versa. In this experiment α is 5%. Analysis of variance, as shown at table 4, shows that *P-value lack of fit* is 0.241, greater than α = 0.05. It means that there is no *lack of fit* in the model or the model is suitable.

Residual Error	6	0.03170	0.03170	0.00528		
Lack-of-Fit	4	0.02763	0.02763	0.00691	3.40	0.240
Pure Error	2	0.00407	0.00407	0.00203		
Total	14	6.79209				

It also clear stated from table 4 that, P-value for linear and square is 0.000; both are less than α = 0.05. It means that all variable parameters X_1, X_2, and X_3 contribute significantly to the model (Iriawan, 2006).

From table 3 we can see the determination coefficient (R^2) is 99.5% (nearly 1), it means that response can be declared by regression model resulted.

Three residual tests are also carried out i.e. identical test, independent test and normal distribution test. Chart of residual versus the fitted values for cycle time (Figure 3) is randomly distributed and do not form certain pattern. It means the identical assumption for cycle time is fulfilled.

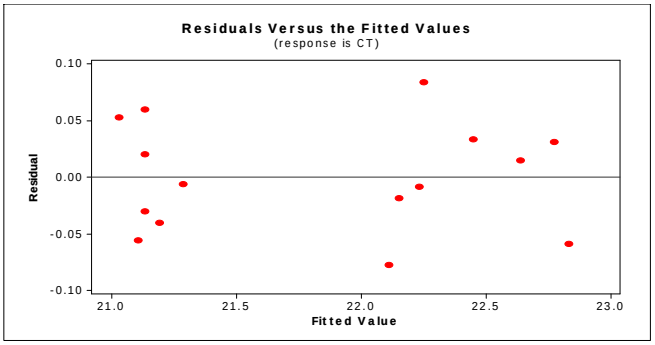

Figure 3. Residual versus the fitted values for response is cycle time

Independent test was carried out to ensure that observations have been done randomly or between observations there is no correlation (independent). *Auto Correlation Function* (ACF) plot (figure 4) shows that correlation values are in the interval of $\pm \frac{2}{\sqrt{n}}$ which means independency assumption is fulfilled.

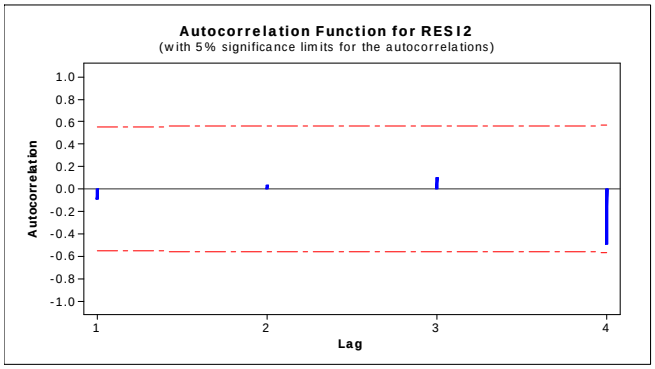

Figure 4. Autocorrelation Function for cycle time

Last test is normal distribution test. As shows at figure 5 that all plot distributed closed a straight line. It means that residual is normally distributed (figure 5).

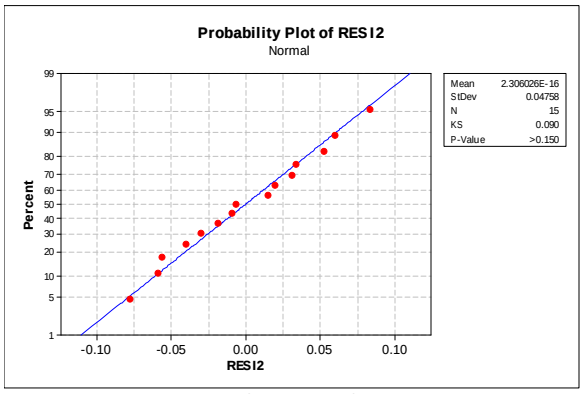

Figure 5. Probability Plot of Residual for normal distribution

Optimization of cycle time is searched by Response Surface Method using Minitab 14th version. The suitable method for this case is The Smaller is better which means minimum value is desired between values of 19 $\leq \hat{Y}_{CT} \leq$ 23 according to cycle time standard from the factory. By the method it is found that the optimum of cycle time is 19.20 seconds. The optimum condition is achieved when stopping is 0.1 second, blowing time 11.35 second and blowing pressure 5.1 bars with degree of desirability of 80.01%.

A graph of surface plot blowing pressure, blowing time and stopping time onto cycle time is shown at figure 6.

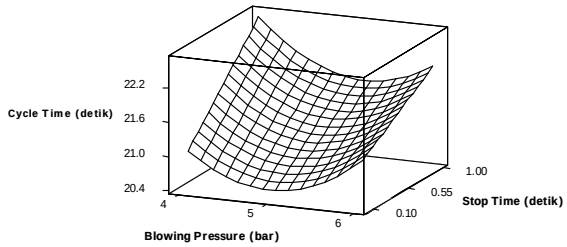

Figure 6. Surface Plot Blowing Pressure and *Stopping Time* onto *Cycle Time* at *Blowing Time* 11.5 seconds

5. CONCLUSION

According to calculation using Minitab 14th version, variables influence cycle time in order are blowing pressure, blowing time, and stop time. By individual, the most influencing process variable onto cycle time is stopping time.
The optimum of cycle time is 19.20 seconds is achieved when stopping is 0.1 second, blowing time 11.35 second and blowing pressure 5.1 bars with degree of desirability of 80.01%

ACKNOWLEDGMENT

We would like to thanks to PT Berlina plastic for their permission to do research in the factory.

Abstract

The purpose of this research is looking for appropriate method in Telecommunication Tower Construction Project Management by doing comparison between critical chain and critical path method.
Researching in project time management of telecommunication tower construction which researcher made two scheduling, critical chain and critical path, base on Project Management Body of Knowledge and compare the result with triple constraint factor and general factor as comparator factors.
The result of this research are total of duration of critical chain method is 197,75 days and total of duration critical path method is 207 days. Conclusion of comparison is critical chain method is better in scope, time and output factors whereas critical path method is better in input and process factors.

Keywords: *Project time management, critical path method, critical chain method, telecommunication tower construction.*

1. Introduction

Telecommunication industry in Indonesia growth rapidly at this term, it make telecommunication provider especially in cellular race to get market share by improve their service. One of the way to improve their service is enlarge the coverage area by add BTS tower in the blind spot area of signal. This phenomena also make demand of BTS tower increase, but if this phenomena are not supported by good project time management it will effect project delay. It come because their have limitation especially in resource and time.
Project time management is needed to solve delay problem in tower construction project and to improve project quality that are combination of triple constraint factors[1]. Expancement of project management knowledge is very fast, so at this time this knowledge is not only use in construction industry but it used widely in other industry like telecommunication industry.
Waktu, biaya, dan ruang lingkup merupakan tiga faktor dalam *triple constraint*, dimana untuk mendapatkan kualiatas proyek maka harus didapatkan titik optimum diantara tiga hambatan tersebut. Untuk itu diperlukan suatu metode penjadwalan yang baik yang dapat mengatasi masalah keterlambatan proyek tersebut. Maka dibuatlah penelitian dalam rangka menentukan metode terbaik dalam proyek pembangunan menara telekomunikasi yaitu memperbandingkan dua metode penjadwalan yakni *critical chain* dengan *critical path*. Perbandingan 2 metode penjadwalan ini pernah dilakukan tetapi dalam ruang lingkup yang masih terlalu besar yaitu karakteristik metode, dimana dihasilkan bahwa penurunan durasi proyek mencapai 25% atau lebih, memastikan proyek berjalan tepat waktu, dan tanpa adanya penambahan sumber daya[2]. Selain itu terdapat penelitian yang menyimpulkan bahwa metode *critical chain* dapat digunakan sebagai dasar penjadwalan dimana terdapat ketidakpastian dari segi durasi[3]. Ataupula terdapat penelitian yang melihat apakah metode *critical chain* merupakan metode baru atau hanya bentuk pengemasan baru dari metode *critical path*[4]. Untuk itu penelitian ini berfokus pada perbandingan antara dua metode pada bidang industry telekomunikasi, yaitu pada manajemen proyek pembangunan menara telekomunikasi.

Time, cost, and scope are three factors in triple constraint, so in getting good project quality we have to find optimum point among triple those factors. For the reason it need a good scheduling method to prevent project delay. This research was made to find best method in telecommunication tower construction project by compare two scheduling method there are critical chain and critical path method. Comparison between critical chain and critical path method have been made but the comparison only in wide scope and only touched the characteristic of method. Base on previous research result, using critical chain method scheduling will make reductions of 25% or more on project duration, ensure that each project finishes on time, and complete more project without adding

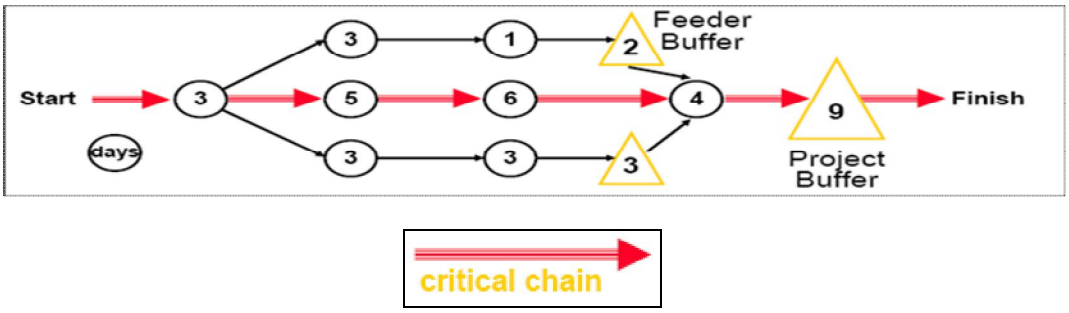
resources [2]. Another research show critical chain method can be use as scheduling baseline in uncertainty in project duration [3]. Previous research observed critical chain to answer the question, "is it a new method or only current method in new packaging?" [4]. There is no research that compare critical chain and critical path method deeply because of that this research is focusing in comparison between critical chain and critical path method on telecommunication industry especially in telecommunication tower construction project management.

2. Theory

Two methods that is compared have different characteristic on each project. It is very important to choose appropriate method on each project.

2.2 Critical Chain Method

Critical chain method was developed and publicized by Goldratt (1997). Critical chain method is an extension of Theory of Constraint (TOC) designed specially for project environment[5].
Critical chain method is scheduling method to protect the entire project from delays, caused by uncertainty and task duration variation, by inserting buffer in the end of the critical chain path of the project. Critical chain path is defined as a longest chain of dependent task and also consider about resources availability of each task. Critical chain method relocate safety time on each task and put it on the end critical chain path as project buffer, ideally it size 50% duration of critical chain path [6].



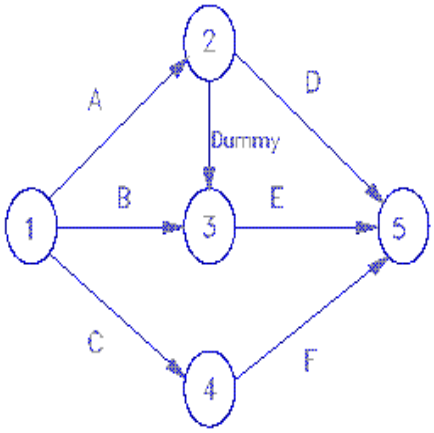
Picture 1. Critical Chain Network Illustration

There are 9 approaches on using critical chain method that are different with another scheduling method:

1. Estimating
2. Buffer
3. Student Syndrome& Parkinson's Law
4. Bad Multitasking
5. Early finishes
6. Backward Scheduling and As Late As Possible (ALAP) Scheduling
7. Relay Race Approach
8. Buffer management
9. Resource allocation

2.2 Critical Path Method

Critical path method in the first time was develop by DuPont in 1957, that used to handled project management of maintenance chemical plants. Critical Path Method is a procedure for using network analysis to identify those tasks which are on the critical path or mathematically based algorithm for scheduling a set of project activities.



Picture 2. Critical Path Method Network Illustration

In this method we can use two kinds technique to reduce project duration. First, fast tracking technique that make two task run parallel. Second, crashing the critical path that reduce duration by add resources of the task.

3. Methodology

In comparing two method, first we have to make scheduling with those methods and evaluate projects of telecommunication tower construction during June up to December 2007 that are 549 projects base on two methods. Methodology that used in make scheduling are base on project time management in project management body of knowledge. That are have six step in make scheduling [7]:

1. Activity Definition: identifying the specific schedule activities that need to be performed to produced to produce the various project deliverables.
2. Activity Sequencing: identifying and documenting dependencies among schedule activities
3. Activity resources estimating: estimating the type and quantities of resources required to perform each schedule activity.
4. Activity duration estimating: estimating the number of work periods that will be needed to complete individual schedule activity.
5. Schedule development: analyzing activity sequences, duration, resource requirement, and schedule constraint to create the project schedule.
6. Schedule control: controlling changes to the project schedule.

Methodology in evaluate project is looking for differences between actual project duration and schedule duration. Measurement in duration differences use two techniques, Time slip and Schedule Performance Index (SPI). Time Slip is technique to find differences between actual project duration and plan duration of the task in the project.

Time Slip = actual duration – Plan duration (1)

SPI is a technique to calculate comparison ratio between plan duration and actual duration of the task in the project. The best ratio of this technique is 1.

$$SPI = \frac{Plan\ Duration}{Actual\ Duration} \quad (2)$$

After get the result of scheduling and evaluation project base on two methods then next step is compare the result with triple constraint factor and general factor as comparator factor.

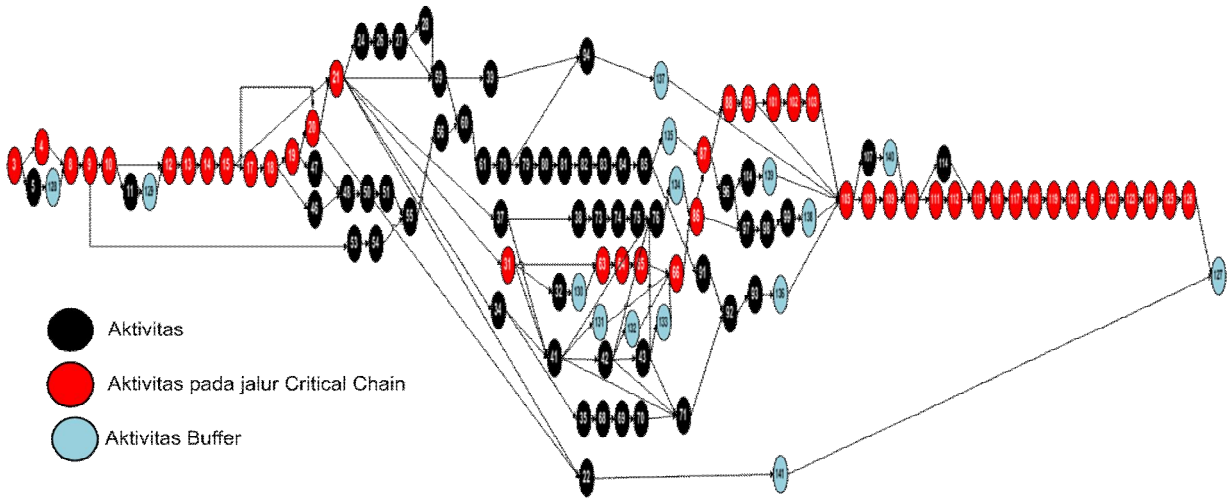
4. The Result

4.1 Scheduling Result

Scheduling that used critical chain method have total duration about 197,75 days. And there are 141 activities that included 14 feeding buffer activities and 1 project buffer activity. Schedule baseline and network diagram of this method will be show bellow.

Table 1. Schedule Baseline of Critical Chain Method

Schedule Baseline		
No	**Aktivitas**	Critical Chain
1	PO	-
2	PO - RFC	26
3	RFC - Konstruksi	6
4	Konstruksi - RFI	73
5	RFI - BAUF	18
6	BAUF - BAPS	28
7	BAPS - On Air	3



Picture 3. Network Diagram of critical Chain Method

4.2 Evaluation Project Result

Result of evaluation project that used critical chain method approach are: average differences between scheduling duration and duration of company target is 8,33 days; average percentage of project that finished on time is 44,7%; average time slip of each step is 18,1 days; and average SPI ratio of each step is 0,9.
Result of evaluation project that used critical path method approach are: average differences between scheduling duration and duration of company target is 16,67 days; average percentage of project that finished on time is 55,2%; average time slip of each step is 21,2 days; and average SPI ratio of each step is 1,17.

4.4 Research Result

Triple constraint factor and general factor used in comparison two methods as comparator factors. Triple constraint factor consist of three factors that are scope, time, and cost. Whereas general factors consist of three factors that are input, process, and output. Result of comparison two method in each factor are:

- Scope Factor

Critical chain method have total duration of schedule baseline up to 154 days, and average differences between scheduling duration and duration of company target in this method is 8,33 days. Whereas critical path method have total duration of schedule baseline up to 204 days and average differences between scheduling duration and duration of company target in this method is 16,67 days.

- Time Factor

Critical chain method have total duration up to 197,75 days; average percentage of project that finished on time on this method is 44,7%; average time slip of each step is 18,1 days; and average SPI ratio of each step is 0,9. Whereas Critical path method have total duration up to 207 days; average percentage of project that finished on time on this method is 55,2%; average time slip of each step is 21,2 days; and average SPI ratio of each step is 1,17.

- Cost Factor

There is no different between using critical chain or critical path method on cost factor because project contract is not base on duration project.

- Input Factor

Critical chain method need complex input because it need data of optimist duration estimation and need software that uncommon use in company. Whereas critical path method need simple input that is most likely duration estimation and this method can use common software to help in scheduling.

- Process Factor

Critical chain method have long process because it have to calculate buffer duration. Whereas critical path method don't have to calculate buffer duration because the process complete up to get critical path duration so this method have sorter process.

- Output Factor

Critical chain method have buffer management in the result. It is an added value that make process control easier. Critical path method doesn't have any added value in the result.

5. Conclusion

The result of this research is critical chain method scheduling have shorter total duration than critical path method scheduling. Total duration of critical chain method is 197,75 days whereas total duration of critical path method is 207 days.
Base on comparator factor that used, the conclusion are critical chain method is better in scope, time, and output factors. Whereas critical path method is better in input and process factors. There is no different between critical chain and critical path method in cost factor.
Conclusion of this research are critical chain method is better than critical path on project of telecommunication tower construction because this method have sorter total duration and have more number strength factor on triple constraint and general factors.

Abstract

Telecommunication holds a significant role as an information provider. Cellular phone customer themselves, with the CAGR of 26.7% will gradually increase into 122.1 million in 2010. The telecommunication tower provider company will take part in developing BTS (Base Transceiver Station) tower to all telecommunication provider service (cellular operator).
SERVQUAL method is used to identification customer's need and service succeeded by the company. Quality Function Deployment (QFD) method is used to arrange a new strategy for giving the best service to the customer. Data which writer got is from the questionnaire of all cellular operator managers.
Found that operator cellular's expectation only reached 67.41% with the effort that have been done by the tower provider company. Therefore, the service element priority (technical response) that ought to be done by the company is increasing coordination between cellular operator and tower provider.

Keywords: Quality Service, SERVQUAL, QFD

1. Introduction

Business globalization and international competition is assisted by improving technology, for instance in telecommunication industry. Telecommunication holds a significant role as an information provider. Improving Technology that support communication, makes information transmission become faster so that would make as though constrict [1]. Communication is a must because every human being always needs interaction and new information.

The more and more demand of telecommunication these days, the number of customer growth rate Cumulative Annual Growth Rate (CAGR) in all telecommunication business sectors in Indonesia keep increasing up to 20% per annual. This is including telecommunication service cellular based, fixed phone, internet, and wide type access. Cellular phone customers themselves with CAGR of 26.7% will gradually increase into 122.1 million in 2010. In the end of 2007, customer is forecasted reaching 78.5 million from 66.5 million in last year. Besides, fixed phone's customer either cable or noncable will gradually increase into 31.2 million in 2010 with 20.1% CAGR, as though in the end of 2007, customer is forecasted reaching 16.2 million from 14 million in last year.

Customer's wanted and need become important successful key. There are something that customer seek, something that makes them want to pay more, keep loyal on one brand or company, and which can make them recommended for others. Therefore, customers begin to selective in choosing operator. Thus, cellular phone operators must have the ability to fulfill customer's need. Even less competition in telecommunication becomes harder. With all of economical offer, cellular phone operators must increase good signal for their customer.

Telecommunication tower provider company is an organization which activity are building and lending BTS (Base Transceiver

Station) to all telecommunication tower provider services (cellular operator). The more tighten competition makes them have to increase customer satisfaction and create customer loyalty. How satisfy the cellular operator, BTS tenant, while using the service? This is a basic important question. So much complain about the efficiency of telecommunication tower provider company in receiving problems from their tower's user and the service speed they give. They need continuous quality service improvement, so that, the company still keep going and produce profit.

SERVQUAL is a method for measuring service quality based on five service quality dimension (Tangible, Reliability, Responsiveness, Assurance, and Empathy) by analyzing the gap caused of inappropriate between expectation and customers perceived.

The reason of hard competition, company should do loyalty program in order to keep holding out. Service development is one of the efforts which company does to give the best service for their customer. QFD (Quality Function Deployment) method can be used to measure how far the company has fulfilled the customer's need and it can be a basic in preparing new strategy for the company to fulfill the customer's need.

QFD is an important part of process development product and service whereas consist of human investment such as people who activate and information as the activator [2]. It needs tough cooperation in determining what customer's need and translating into design and specification of structured service that is produced to fulfill customer's need through service development.

2. Research Method

2.1. Measurement of Service Quality

A company should always introduce service culture as continuous improvement [3]. According to Cronin and Taylor, a manager has to understand certain aspect of good quality service. Furthermore, these aspects will become main company's power in competition with their competitors. In order to understand direct effect that is produced from each service they give ought to measure and compare the quality performance. Besides, it purposes to give illustration company's successfulness in satisfying their customers.

Many methods to do the measurement customer satisfaction, there are applying complain system and customer's suggestions kind of suggestion box, hotline, e-mail, etc. Another way, ghost shopper, is a method by asking someone to pretend as a shopper, and then he/she has to report anything that has judged satisfied and unsatisfied. Next method is organizing customer survey by means of questionnaire or interview. Knowing customer satisfaction could be done by analyzing missing customer to get information about their reason and cause.

2.2. SERVQUAL

Parasuraman et al. (1985), develop SERVQUAL instrument to measure service quality that customer's got according to gap model. SERVQUAL method is based on assumption that customer comparing performance service of relevant attributes with ideal/ perfect standard for each service attribute. If the performance suitable or above standard, so that perceive all of service quality will be positive as in the other hand. In other words, this method analyze gap between 2 main variables, that is expected service and perceive service.

Measurement of service quality in SERVQUAL method is based on scale items created to measure expected and perceives customer, and also the gap between in five dimension of service quality. Those five main dimensions spell out into two attributes detail for expected variable and perception variable which are arranged based on likert scale statements, from 1 (very unimportant) until 7 (very important) and 1 (very disagree) until 7 (very agree). Service quality evaluation by using SERVQUAL method include the difference calculation between result which given from the customer for each statements according to expectation and perception. Measurement of every service quality dimensions is using sum scale whereas respondent was asked to give the percentage for those dimensions, so that sum of all reaches 100 %. This main objective is to give a result of accuracy service quality.

2.3. Quality Function Deployment (QFD)

QFD is firstly developed in the end of 1960 in Japan by Yoji Akao [4]. Yoji Akao defined

QFD as a method and technique that used to develop quality design which its aim to satisfy the customer and translate what customer's need in design target and main service quality assurance to be used to production process [5].
QFD is listing voice of customer (VOC) or customer requirement into final product for assuring customer satisfaction. QFD has some objectives such as decrease the product developments cycle time and at once increase product quality along with deliver product which is cheaper. More objective of QFD is increasing company's target market. And of course product or service resulted pass trough QFD process is customer's want and appropriate with their needs.
Main tools in arranging QFD is HOQ (House of Quality). HOQ is matrix which fuses customer's need and the process that company should do in order to fulfill them. There are three phase of service based QFD process, such as [6]:

1. *Service planning*.
2. *Element planning*.
3. *Operations planning*.

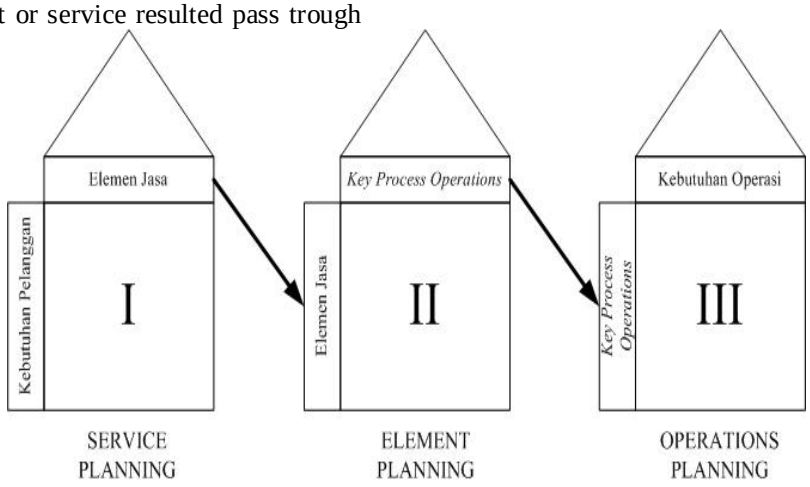

Figure 1.
Quality Function Deployment Process (Source: H. Brian Hwarng dan Cythia Teo, 2001, pg. 202)

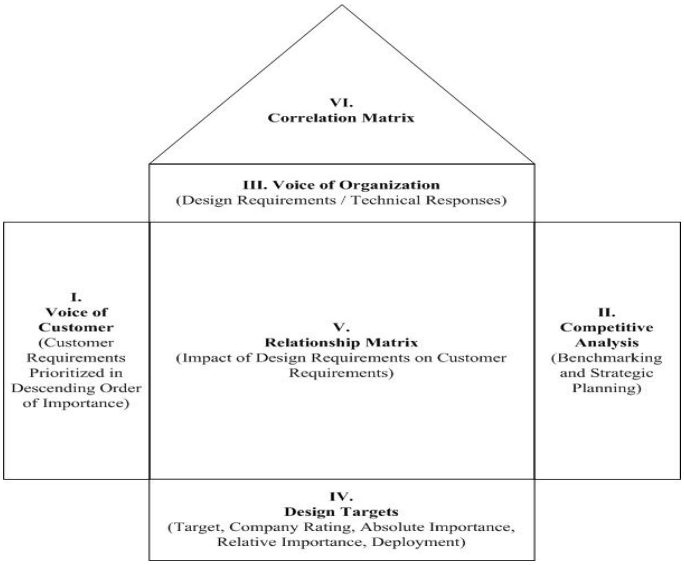

Figure 2.
House of Quality Structure (Source: S. Bruce Han, et. al., 2001, pg. 798)

3. **Result and Discussion**

3.1.Defining of Customer's need

Customer's need is an item that should analyze to create the research. These items are spelling out from 5 service quality dimensions which are used in SERVQUAL method. In this phase, will be indentified the research items which reflect the operator cellular's expectation in their tower provider's service by spreading the questionnaire. The questionnaire divided into three sections, such as:

1. First section
   There are two kind of this section, first for measuring customer's expectation and other for measuring customer's perception. There are 19 questions. Respondent is asked to give the appraisal about the expectation and perception by using likert scale.

2. Second section
   This section includes five statements which describe five dimensions of SERVQUAL. The objective of this measurement is measuring the expectation score of all dimensions by using sum scale. Respondent is asked to give the appraisal of each statement with the total of all is 100.

3. Third section
   The last section is some kind of giving critical opinion and suggestions from all cellular operator to their tower providers. Respondent feels free to write down anything about the service they got from their tower provider. Therefore, this last section would help writer to arrange the Quality Function Deployment (QFD).

This table below is showing the result of service quality calculation from all 5 dimensions.

3.2. Quality Function Deployment (QFD)Service element matrix is an element which is used to fulfill customer requirement by the company. In arranging this service matrix, writer had interviewed and consulted the one of Tower Provider Telecommunication Maintenance Manager.
After getting the item of customer's need and service elements to fulfill voice of

customer (VOC) or customer requirement, next step is making the service planning matrix. The making of service planning matrix include; Relationship between customer's need and service element, correlation between every service element, improvement direction of service element, and last is the calculation result of weighted service element.

Table 1.
Service Quality of 5 dimensions

No	Dimension	Expectation	Perception	SERVQUAL Score	Importance Score	Weighted SERVQUAL Score	Actual SERVQUAL Score
1	Tangible	4,27	3,15	1,12	0,175	-0,1960	73,77%
2	Reliability	4,77	3,05	1,72	0,210	-0,3612	63,94%
3	Responsiveness	4,76	3,14	1,62	0,240	-0,3888	65,97%
4	Assurance	4,63	3,20	1,43	0,170	-0,2431	69,11%
5	Empathy	4,76	3,06	1,70	0,205	-0,3485	64,29%

Table 2.
The Calculation Result of Weighted Service Element

Service Element		Absolute Importance	Relative Importance	Priority
TECHNIQUE	Routine preventive maintenance	43,2	1,58%	22
	Maintenance recapitulation	42,3	1,55%	25
	Repair recapitulation	42,3	1,55%	24
	Routine inspection to location	157,8	5,78%	5
	Good materials supplying	43,2	1,58%	21

	Good tools supplying	37,8	1,38%	26
	Good logistic system	55,8	2,04%	17
	Automatic recovery	43,2	1,58%	23
	Check list book	122,4	4,48%	8
	Log Book	86,4	3,16%	14
	Reward system	37,6	1,38%	27
COMPLAIN SERVICE	Quick respond	141,6	5,18%	6
	Follow up complain	127,8	4,68%	7
	Report system flow	99,6	3,65%	12
RECRUITMENT & TRAINING	Training program	89,5	3,28%	13
	Recruitment test for operator	84,6	3,10%	16
	Interpersonal skill	28,2	1,03%	28
OPERATOR	Operator identity system	110,4	4,04%	9
	Rotation operator system	14,7	0,54%	30
	Expert operator	171,9	6,29%	4
SITE ENTERING	Simple rule	44,1	1,61%	19
	Operator allocation	100,8	3,69%	10
	Total of operator	100,5	3,68%	11
COMMUNICATION	24 hours day call center	172,8	6,33%	3
	Evaluation / periodically report	86,4	3,16%	15
	Coordination between operator cellular and tower provider	341,1	12,49%	1
	PIC contact number is being cleared	186,3	6,82%	2
	Reconciliation of citizens	44,1	1,61%	20
SERVICE LEVEL AGREEMENT	Service Level Agreement (SLA) detail	27,9	1,02%	29
	Service Level Agreement (SLA) comprehension	46,9	1,72%	18

3. Summary

Refers to the objective of this research, to know the gap caused of inappropriate between expectation and customers perceived, writer could sum up that there is no reached expectation. Furthermore, based on telecommunication tower provider service quality development by using Quality Function Deployment (QFD), determined some service element priorities that company should do in order to decrease the service gap:

1. Coordination between operator cellular and tower provider : 12.49%
2. PIC (Person in Charge) contact number is being cleared : 6,82%
3. 24 Hours day call center : 6.33%
4. Expert operator : 6.29%
5. Routine inspection : 5.78%
6. Quick respond : 5.18%
7. Follow up complain : 4.68%

ABSTRACT

Quality control and improvement at the process level is a vital activity for the achievement of quality in products and services of organizations. This paper employs SPC (statistical process control) tools such as control charts and process capability ratio for quality improvement. The control charts employed are $\overline{X}$ *, s and the Exponentially Weighted Moving Average (EWMA). The process capability ratio employed is the centered process capability ratio (*C_{pm}*). These tools have been implemented to the manufacturing process of empty hard gelatin capsules as a case study. This implementation has led to an expected reduction in the number of defective capsules by 29% relative to the stage before implementation.*

Keywords: *SPC; control charts; capability assessment; EWMA; quality control*

1. INTRODUCTION

The implementation of SPC tools, mainly control charts and capability assessment, can significantly facilitate quality improvement through the reduction of process variability and shifts in process mean [1]. Application of these tools for quality improvement of manufacturing processes is widely popular in the literature [2-7]. Following the first control charts that were developed by Shewart in the 1930s, more types of control charts have been developed to deal with different situations that arise in practice [8]. In the last three decades, many studies have been devoted to new concepts such as adaptive and more economical control charts [9-11], control chart's pattern recognition [12], and design optimization of control charts [13].

However, these concepts have led to considerable complexity for applying the new control charts and were less desirable compared to traditional ones which are still the most widely used today. In this work, a practical implementation of a set of selected SPC tools, namely $\overline{X}$, s and the Exponentially Weighted Moving Average (EWMA) control charts combined with the centered process capability ratio (C_{pm}) is presented in the case of manufacturing process of empty hard gelatin capsules.

2. CASE STUDY

As a case study, SPC tools have been applied to the manufacturing process of *empty hard gelatin capsules* produced by the Arab Center for Pharmaceutical and Chemical (ACPC) Industries Co., Amman, Jordan. The product is used by many drug companies to sell their drug powders in the form of capsules. A capsule is composed of two pieces that are differently colored and joined together, as shown in Figure 1. The longer piece is usually called the *body* and the shorter one is called the *cap*. Because the two pieces are manufactured in the same manner, only manufacturing of the body is considered. Thereafter, the word *capsule* is used interchangeably with the word *body*.

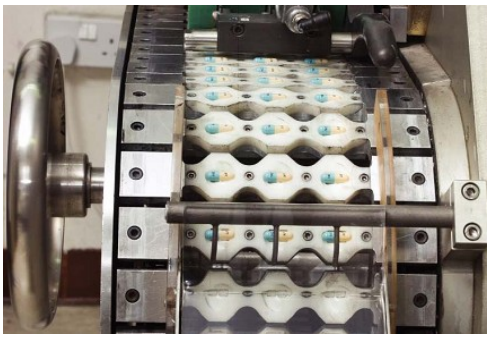

Figure 1: Finished capsules are composed of two pieces: body and cap

The first stage in the manufacturing of capsules is to immerse a set of steel pins in a pool of liquid gelatin, as shown in Figure 2. Then, capsules are formed on the pins due to adhesion between liquid gelatin and steel pins. Factors such as temperature of steel pins, immersion time and gelatin concentration and temperature have an effect on the characteristics of the final capsules in terms of weight, thickness, length, and surface defects. After the capsules are formed on the pins, the pins are steadily moved through a drying chamber under controlled conditions of temperature and humidity. This gives the capsules the required rigidity before they are stripped off the pins. The capsules are finally cut to size. However, due to factors such as thermal shrinkage and behavior of the cutting mechanism capsules are not always within specifications.

Figure 2: Formation of capsules after immersing steel pins in a pool of liquid gelatin

A number of defects may appear on a capsule such as uncut body, wrinkles, air bubbles …etc. However, the capsule's body length is considered the most important quality characteristic. Thus, it is selected in this study for quality control and monitoring. The standard size of the capsule's body length is 20.60 mm with lower and upper specification limits of 20.20 mm and 21.00 mm, respectively.

4. SPC IMPLEMENTATION AND RESULTS

In implementing SPC tools, twenty samples (each consisting of thirty observations of body length) were collected to construct $\overline{X}$ and *s* control charts. The charts were setup with the aid of Minitab® and shown in Figure 3. It can be seen in this figure that an out-of-control point exists on the $\overline{X}$ chart. Thus an *alarm* was issued confirming the process is out-of-control. After brainstorming by the quality management team and conducting CEA analysis, it was possible to identify one potential assignable cause which rendered the capsule manufacturing process out-of-control. This was the sudden change in the relative humidity of the facility atmosphere. After implementing a better monitoring policy and control of room humidity, a new set of samples was collected and used to reconstruct the $\overline{X}$ and *s* control charts. No out-of-control point was detected on the new charts.

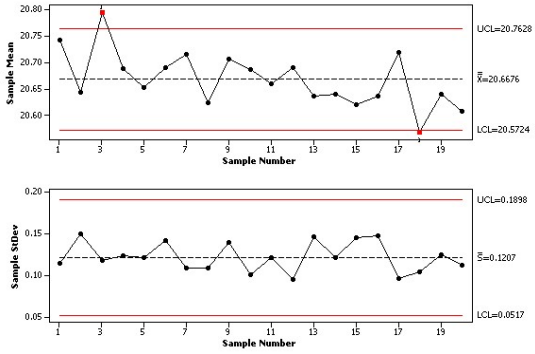

Figure 3: $\overline{X}$ and *s* control charts at the beginning of implementation of the three-phase scheme

The last set of samples was re-used to construct the *EWMA* control chart, as shown in Figure 4. As can be seen in this figure, an out-of-control point exists on the third sample. Therefore, other potential causes were further examined and focus was turned onto the repetitive screw adjustment in the cutting mechanism. After redesigning the cutting mechanism to eliminate the need to adjust the screw, the same procedure in Phase I was repeated and no alarms had occurred. Additionally, more *EWMA* control charts were constructed on weekly basis but no alarms had occurred. This continued for 17 weeks, which is the preset time, where the process capability was assessed.

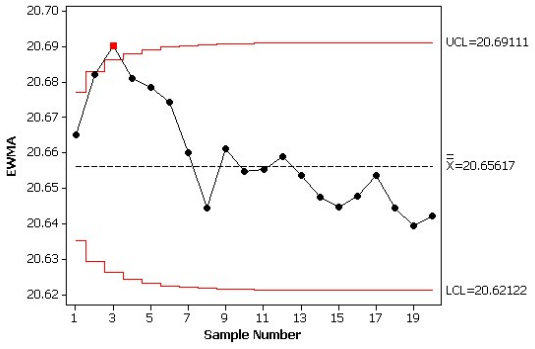

Figure 4: *EWMA* control chart after Phase I was completed

Figures 5 and 6 show process capability output at the beginning of implementation and after 17 weeks of implementation. It can be seen in Figure 5 that the process mean is initially off-target (sample mean = 20.6676 mm) with

C_{pm} value of 0.91. This corresponds to an expected number of 5219 capsules with body length out of specifications per million. Figure 6 shows that the process mean is closer to target (sample mean = 20.612 mm) with C_{pm} value of 0.97. This corresponds to an expected number of 3700 capsules with body length out of specifications per million. Therefore, an expected 29% reduction in the number of capsules that will not meet specifications due to improper body length can be achieved through the implementation of the SPC tools used in this study.

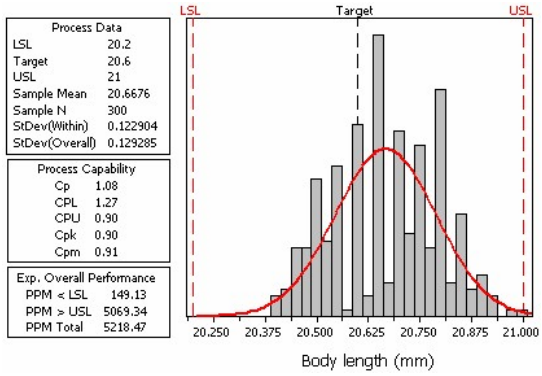

Figure 5: Process capability output at the start of implementation of the three-phase scheme

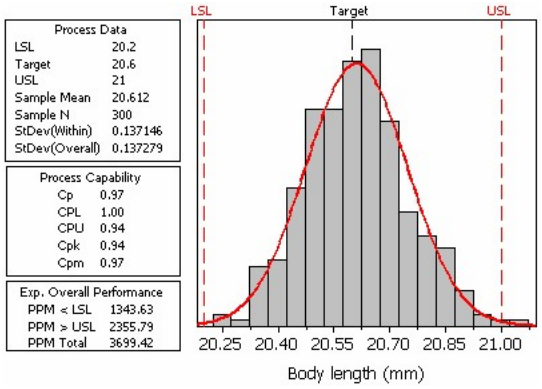

Figure 6: Process capability output after 17 weeks of implementation of the three-phase scheme

5. CONCLUSIONS

In this work, a set of SPC tools was applied to the manufacturing process of empty hard gelatin capsules as a case study. It can be concluded from the case study that by applying the proposed tools it was possible to:

1. Detect short term changes in process mean that resulted from variations in the relative humidity of the facility atmosphere and the repetitive screw adjustment in the cutting mechanism.
2. Detect gradual changes that occurred slowly over time due to poor lubrication of the cutting mechanism.
3. Assess process capability based on periodic basis, i.e. when $i = i^*$.

ABSTRACT

Common objective of a warehouse is to minimize cost and maximize service to internal and external customers. The purpose of the research is to attain a new system that would resolve the First In First Out (FIFO) system in the Finished Product Store (FPS) warehouse. Analysis of historical data comes out with a new solution designed for the system, that is a periodic arrangement of items in FPS. Forecasting technique is used to determine a review period for rearrangement of goods placement in FPS. It also adapts some important material handling principles in a warehouse. One consideration used is the popularity of the product. Based on this concept, identical products are placed in zones, in order that each zone consist of one or just two brand of flour products.
Some advantage expected to be gain by the enhancement of this storage and retrieval strategy is an improvement of FIFO system, also the ease of storage, retrieval, and identification of items which further would increase the FPS throughput.

Keywords

First In First Out (FIFO) system, warehouse

BACKGROUND

Warehouse must be able to meet customer demand with minimum cost. To be able to run effective and efficient operation of the warehouse, there are several factors to be considered, such as the availability of facilities and resources, production capacity, human resources, recording and documentation system, the market situation, and the distribution system.

This research was conduted at PT SRR, which produce finished product in the form of wheat flour with different kinds of variations. Products characteristics are:

- Wheat flour is frailty when stored too long.
- Finished product storage (FPS) is a temporary storage, before being distributed to the stock point or taken by the customer. The deadline is considered critical and product specification (best use of the product) for the storage of wheat flour is one month, starting from wheat flour is produced to finish in the hands of customers.
- If the time limit is exceeded, then the risk of being contaminated is greater due to the attack of head lice to the flour.
- Given the distribution chain wheat flour long enough, the storage in the FPS should be made with a certain time limit.
- Services provided to customers should consider the product quality, accuracy and the amount of time. In connection with this case, the storage of goods in the warehouse also prioritized the aspects of it.

PROBLEM DEFINITION

Based on the results of a Quality Audit, condition associated with the current FPS situation are:

- The problems appear after the system and procedures of FPS at this time cannot guarantee the success implementation of First In First Out (FIFO). FIFO cannot be run due to many factors, namely facilities, labor or based on direct loading instructions from management to the truck. One quite clear thing is the current system and procedure cannot trace the previously wheat flour used to enter FPS.
- Without the guarantee of FIFO implementation there is no certainty that storage time does not exceed the maximum time limit, ranging from flour handling time, including receiving, storage, and delivery at FPS or others stock point outside FPS. This will impact the increased risk of damage to wheat flour.

The increased risk of damage to wheat flour due to the failure of FIFO system at FPS and damage to wheat flour is related to the complaint of the buyer. A large number of customer complaints which are related to the quality of products, proving that it is time for PT SRR to evaluate the system of warehousing.

OBJECTIVES

Objectives of the research is to improve the system and procedures of FPS, such as:

- To generate a system and procedures that can guarantee the movement of goods in the FPS based on the implementation of the FIFO.
- To ensure information for the FPS, stock point, distributors and users about the date that is best use of the product.

PROBLEM LIMITATION

The problem is limited to the design of systems and procedures of the new FPS. The issues related to distribution and marketing must be solved first so that systems and procedures can be done well. In addition, the design of systematization storage procedure is made for the fixed production capacity, namely 35,000 wheat bags per day, without any additional production capacity.

RESEARCH METHODOLOGY

The steps of research methodology are:

1. The assessment of current FPS system and procedure
   The current system must be understood first before implementing the corrective action. By doing the assessment, the shortage, the system scope, problems and obstacles that are in it can be identified more clearly. The assessment also covers the facilities and manpower. The data collecting is done through interviews, direct observation and from primary and secondary data.
2. Making the plan of a new FPS system
   The making of this plan is done in the scope of the system, so that the collected data is not out of the determined scope, and the problem solving can be more focused.
3. Evaluation of the new FPS system
   Making the plan of a new system is not free from obstacles such as the cost, time, manpower, facilities and other resources, so that before the plan needs to be running, it needs a more mature consideration.
4. A good implementation procedure is required for the designed system to run well

The research was conducted based on consideration of stock location and order taking.

Stock Location

Stock location or warehouse layout in the storage area are related to the location where the goods are placed in a warehouse. Factors that need to be considered in the storage area design procedure are:

1. The commodity

Commodities are considered as factor that affecting the location and space needs, including:

a. Similarity
In general, materials are grouped in classes. Material has relevance (similarity) to one another.

b. Popularity
Level of turnover is another factor in choosing the location. For example, the goods with high level of turnover are placed at the front, and the lower turnover ones in the more remote locations.

c. Size
The consideration here is not only the size of unit, but also in the number of overall size.

d. Characteristic
Characteristics of the stored material should also be considered, such as:

- Dangerous commodity
- Frailty commodity
- High value commodity
- Short-lived commodity

2. The Space

Factors associated with the space are important to determine where the commodity can be stored. These factors are:

a. Space size (volume)
b. Nature of the location (a match with a certain type of goods)
c. Location-related with other relevant activities.
d. Availability when needed
e. Characteristics of the building, such as the capacity load of the floor, door (number, location, and size), loading facility, distance (pole field, size and number) and , limit height of stack
f. Area required for the function and activity of service
g. Space required for the gang.

There are two basic systems to assign a particular location with the placement of stock items: fixed location and floating location. Both systems are used with attention to the factors above.

The Order Taking and Collection

Once the order is received, the listed goods in the order must be taken from the warehouse, collected and prepared to be sent. All this activity requires labor and goods movement. This work should be arranged well in order to give desired service to the customer.

ISSN 114-1284

There are some systems that can be used to manage the work as follows :

1. Area system

Order taker walks around to select items that are in order, such as those who shop in supermarkets. The goods are then taken to the delivery area. This order has been collected by itself when the order taker is finished doing its work. This system is usually used in a small warehouse with fixed location.

2. Zone system

The warehouse is divided into zones, and the order taker is only working on their own zone. Orders are divided into zones, each order taker selects goods in the zone and takes them to the collection area where orders are assembled to be sent.

3. Multi-order system

This system is similar to the zone system. The difference is this system does not only deal with one order, but a number of orders are collected and the goods are divided by their zone.

DATA COLLECTION AND ANALYSIS

In general, the assessment of FPS is good, but it is still found areas for improvement, they are :

- Material handling that requires tow people, working with frequently hands, repetitive, and short distance.
- Difficulties in stock control

This difficulty occurs when the control is done visually to monitor whether any damage on packaging.

- Lack of Space

More clearly, the analysis of this case will be discussed in the utilization analysis. Lack of space occurs when the FPS wants to be improved its functionality into the wheat flour aging area.

- Unused overhead space

Overhead is a region at up of the range of people. In the current conditions, the overhead area, especially in the middle of the FPS is still very minimal use. The main cause why the overhead space not being used is the limitation of palette capacity. Based on interviews, the addition of stacked palette has been tried but the lower palette is not capable of holding the load. The effect of unused the overhead space is low utilization of FPS.

- Difficult access to take the goods

Orientation of good storage in the FPS is horizontal not vertical (non-accumulation). This results in a lot of wheat flour which is difficult to access, both to be controlled or to be taken. If the condition of FPS is full plus the use of additional los, the access of goods becomes more difficult because more additional los in the main street or alley for forklifts.

- Customer complaint

Customer of FPS is the buyer who wants to take the ordered wheat flour. The current customer complaint is particularly about the availability of goods in FPS so that they have to wait long enough in the PT. SRR until their order can be taken.

- Too Narrow Gang

Gang in the FPS is not planned layout. Layout are preferred to increase the storage capacity so that there are some narrow alleys. Especially when the additional los is used, the movement area will be more narrow.

- Stacking

Stacking is the accumulation attached to the wall. This causes problems of access, control, and taking.

- Low level of in and out flow material is stored in the front; High level of in and out flow material is stored behind; Material with the same level of in and out flow is stored in the same place. This is because the selection of storage (los) is based only on the currently empty los at that time. There is no consideration based on the frequency of movement of each type of wheat flour.
- Limited building hampering the storage method

The limited building can be observed through the dimensions of the FPS building that is different among the front, middle and back.

- Not planned material handling method

Theoretically, FPS should have a schedule of materials handling as well as the production division has a production schedule. With the schedule, the utilization of equipment, manpower and space will be able to be maximized.

Queue of truck

Gate Office (GO) is the entry gate for customers who want to take the ordered wheat flour. GO service is begun when the trucks arriving at the location of the factory until the truck leaving the factory. Last days, it is indicated that the truck queue is quite long, since they arrive to leave the factory.

The comparison of the total service time data, the loading time data with the queuing time data indicates the contrast difference, even the unit that is used is very different namely minute and day. This indicates a quite serious problem and must be handled to reduce losses, both losses in the PT. SRR and in the transportation.

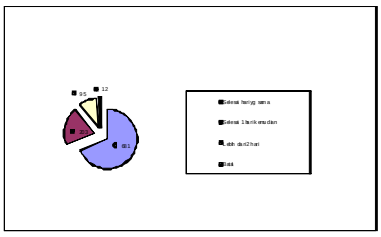

Figure 1: Queuing Time of trucks at Gate Office

ISSN 114-1284

Utilization of FPS

Utilization of storage space illustrates the comparison between the available volume of storage space (in cubic meters) with the available volume of room for storage (in cubic meters).

To calculate the available volume of warehouse space (Nett) then the number of cubic meters of warehouse space is subtracted from the part of the room that can not be used for storage, such as pole / column, space for movement, space and facilities. The available volume of FPS is 14,070.50 (max) and 12849.60 (normal) in cubic meters.

Volume of space that currently used for storage is calculated by counting the number of los and the stack. Los is the term currently used to describe the distribution of warehouse to be some place that can be filled with some palettes. There are various sizes of los namely los that can load 1 palette up to 9 palettes. In addition, there is also a temporary los that is only used when the warehouse full.

The current volume room used for storage in normal conditions is 2,862.09 (cubic meters). Based on the available volume of warehouse space and the volume of space that is currently used for storage, the utilization of FPS in normal conditions is 22.27%. Meanwhile, based on data storage, the utilization of FPS space in February was 18.42%.

Customer Complaints

Customer complaint data for 1 year was 44 complaints. This complaint data are grouped into 5 groups, namely: Expiration, contents do not match. After processed the product becomes worse, the stock and the number of deliveries, and quality (color, wad, wet). Based on this complaint, the largest number of complaints is about the results of processing wheat flour at PT. SRR which is considered less good finished products.

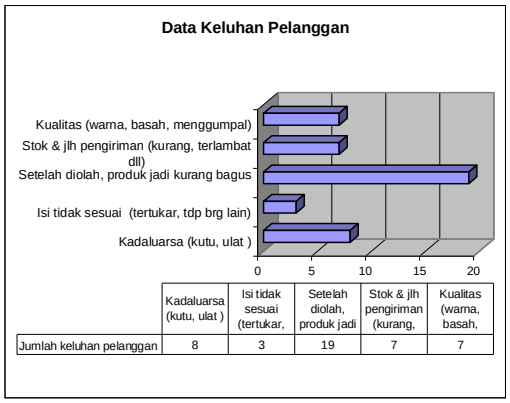

Figure 2: Number of Customers Complaints Data

From 44 customer complaints, it needs to identify the possibility of not running FIFO system. Identification is done by utilizing the existing product code on each bag. Product code consists of 5 digits. The first digit indicates the production month (A = January, B = February, and so on). Second and third digits indicate the date (01 to 31). Fourth digits indicate carousel (4 units have carousel). Last digits indicate the bin (A = bin 1, B = bin 2, etc). This identification product code show the date of production. Date of production then is compared with the date the complaint submitted by the buyer / user to obtain the time interval. Assuming the best time since the wheat flour from the date of production to 2 weeks is used mostly, and the transportation time from PT SRR to the location (e.g. food industry) is 7 days old, the complaint may be a possibility due to the nor running of FIFO system

ALTERNATIVE SOLUTION AND EVALUATION

Through analysis of various indicators of issues, then the main cause of not running FPS system is the difficulties in storage.
When examined further, it appears that this difficulty is influenced by the following conditions:

- Small size of FPS
  Small size of FPS limits the amount of products stored in there. In other words, the capacity becomes limited. The great number of demand makes the production to result a more output, while FPS is only able to accommodate as many as the production capacity of 2 days, namely 70,000 units sack of wheat.
- Low utilization of FPS
  With the limited storage capacity as described above, the space used for storage capacity is far below the available space.
- Not arranged storage and layout
  This can be identified from check sheet made by observing the FPS area directly. Products stored in the FPS are only based on the availability of empty los, and not considering the principles of material handling.

PERIODICAL GOODS STORAGE SYSTEMATIZATION

The effective and efficient alternative to implement is by storing the goods periodically. This alternative does not require great costs, simply perform the review of certain period to determine the amount of los allocation to specific products. Thus, FPS is able to provide more services to more popular products.

The proposal of this alternative is to assume that proportionality amount of wheat stored in the FPS is not arranged yet optimally according to the frequency and number of orders. So far, the popular products are

ISSN 114-1284

sometimes not able to be stored in the FPX, if the FPS is full. Under this circumstance, the direct loading is executed.

Determination Review Period

To set the storage periodically, the first note is how many times the storage systematization at FPS will be reviewed and changed in a year. The periodic time is determined in accordance with the fluctuation of pattern, so that FPS is still able to handle the fluctuation of demand under the period of observation.

The observation of storage systematization can be done more often when there are symptoms that the level of demand between products is fluctuation from time to time. However, the frequent changes of systematization way will be fussed over and not efficient. Therefore, the storage systematization should be done more frequently, that is to anticipate demand, but the period should be also long enough so that it is not too difficult to make changes in how the storage is.

In general, the steps undertaken to determine the frequency and period of time to change how the storage of goods in the FPS is as follows:

1. To make demand forecasting for each product and for some period of time.
2. To calculate the forecast error.
3. To specify the periodic time for observation according to the smallest error.

Creating Demand forecasting

Requests are evaluated by using fulfilled Delivery Order (delivered DO) data, as in table 1. From the table, it can be seen that the highest demanded product is NM and followed by BB. Evaluation based on the delivered DO with the reason the fulfilled DO is actual demand.

Forecasting is done by three methods, namely Moving Average method, Single Exponential Smoothing, and Double Exponential Smoothing. The calculation of forecasting was made with the help of MINITAB software.

Tabel 1: Delivered DO

Nov	116,030	169,017	34,768	93,230	460,550	0	78,500	**952,095**
Dec	69,298	82,515	14,168	34,800	253,297	0	43,778	**497,856**
	1,034,644	**1,689,150**	**421,403**	**594,230**	**2,476,012**	**50**	**676,740**	**6,892,229**

In forecasting method with Single Exponential Smoothing (SES) and Double Exponential Smoothing (DES), the weight used is the result of the calculation done by MINITAB to find the smallest value of the error (Square Error).

The time period tested in the forecasting is the multiplication factor 12, without using 2, that is 3, 4 and 6. So, an alternative way to observe it can be done every 3, 4 or 6 months. Time-periodic 2 months is not included because 2 months is considered too fast to do changes of storage at FPS.

Forecasting is done by using the actual data for the calculated period. Then, forecasting is done for some future period of time in accordance with the currently tested period. For example, a review conducted for 4 months, forecasting is done for 4 months in the future using the data from the previous 4 months.

Forecasting is done for each type of wheat flour produced by PT SRR for a year, so with a certain periodic time, it is known how many times the review should be conducted during the year.

Calculation of the error value of forecasting

The forecasting error is simply the diversion of forecast value to actual value. The small value of the error then the better the forecasting is done.

The best periodic time is chosen based on the smallest forecasting error for each of the tested periodic time. The forecasting error for a tested periodic time is compared with each type of wheat. The used type of error is Mean Absolute Deviation (MAD), Mean Absolute Percentage (MAP) and Mean Square Deviation (MSD).

Types of error that become main priority is MAD and is followed by MAP. MAD shows the average of the amount of wheat that are less or more than the actual amount of wheat required. MAP shows the average percentage of the diversion of wheat amount from the actual demanded wheat.

The chosen periodic time is especially focused for the popular products, the highest demanded products. It needs to pay attention to two products that have the highest demand, they are NM and BB. Table 2 and Table 3 respectively show the error value of the NM and BB forecasting, for each methods, and for each periodic time.

Tabel 2: Forecasting Error for NM product

Periodic Time	MA			SES			DES

Determining The Review Period

The review period or periodic time is determined based on the smallest error value of forecasting without considering the forecasting method used.

The choosing of the smallest error value is prioritized by considering the value of MAD first. MAD values in the table above shows the average amount of wheat flour that deviates from the actual required amount of wheat flour. This is the amount for a month. The second priority is to consider the value of MAP. MAP values in the table above shows the average percentage of wheat flour that deviates from the actual required amount of wheat flour. The percentage is derived from the deviation in the amount of wheat a month. Thus, for this case the value of MAD can be interpreted more easily.

The table 2 indicates that the minimum value for the MAD for the type of wheat NM occurs when forecasting is done for the period of 6 months, i.e. 59,240 units. With this value, it is estimated that FPS can meet with the lack or excess of NM production approximately 59,240 units per month. So it is MSE value which reaches the minimum value 15.54% for the same periodic time, i.e. 6 months. This MAP values can be interpreted that the FPS may be excess or shortage of stock of 15.54% of the NM quantity demanded.

Because the demand for wheat NM is greater than the BB, the priority can be given to more wheat flour NM periodically so that the time chosen to make the observation room is 6 months.

Demand patterns and forecasting for product NM are shown in the table 4. Forecasting is done in the diagram is the Single Exponential Smoothing (SES) method for the period of 6 months.

Table 3: Product NM 6 months period forecast with Single Exponential Smoothing

Month	Forecast	Actual	Error	ABSOLUTE ERROR	Square of Error	Percentage of Error
Jul	269295	340540	71245	71245	5.076E+09	0.209
Aug	269295	280895	11600	11600	1.346E+08	0.041
Sep	269295	327522	58227	58227	3.390E+09	0.178

Nov	269295	460550	191255	191255	3.658E+10	0.415
Dec	269295	253297	-15998	15998	2.559E+08	0.063

Making Procedure Storage Systematization

After the periodic time to perform storage review has been determined, that is 6 months, then the storage systematization procedure can be carried out every 6 months.

To be able to make the storage systematization, FPS (warehouse) is divided into three parts according to the Pareto principle, namely:

- Zone A, the front room of FPS that can be used to store the most high-frequency (high popularity) wheat flour.
- Zone B, the deeper room of FPS that is used to store for the lower frequency (the medium popularity) wheat flour.
- Zone C is the behind space of FPS that is used to store the most low frequency (low popularity) wheat flour.

To determine the capacity of zone A, B and C, it needs to observe the order frequency for each type of wheat, and the amount ordered. The frequency of ordered wheat determines whether a type of wheat are placed in Zone A, Zone B or Zone C. The quantity of order determines the capacity of each zone by considering the minimum stock.

Based on the Pareto principle, the product grouping used is a small part of high frequency order and a huge part of low frequency order.

In this way, products are grouped based on ABC classification. ABC classification of Pareto settles that:

- Class A is item with cumulative percentage 10% - 55%.
- Class B is item with cumulative percentage 56% - 90%.
- Class C is item with cumulative percentage 91% - 100%.

The steps of classification are as follows.

- The order frequency of each product is calculated in total.
- The ordered product is arranged by the order frequency.
- Create the percentage calculation of cumulative frequency.
- The classification is done based on ABC classification of Pareto.

Table 4: Order Frequency

Type	Frequency	Cumulative Frequency	Cumulative Percentage
NM	517	517	44.23%
BB	284	801	68.52%
TE	201	1002	85.71%
NB	121	1123	96.07%
PM	46	1169	100.00%

Table 6: The amount of ordered wheat

Type	Amount of order (unit)	Percentage
NM	2.476.012	39.84%
BB	1.689.150	27.18%
TE	1.034.644	16.65%
NB	594.230	9.56%
PM	421.403	6.78%
TOTAL	6.215.439	100.00%

Table 6 shows the order quantity for each type of wheat. NM ranks first with a percentage of 44.23%, so that items classified as group A. BB and PB belong to group B, while NB and PM are group C.

The size of the zones A, B and C are determined from the percentage of ordered wheat quantity.

- Zone A consists of wheat NM, with percentage of 39.84%. So that the capacity for the zone A :
  Zone capacity = 39.84% x 62,100 units
  = 24,740.64 units
- Zone B consists of wheat BB and TE, with percentage of 43.83%. Capacity for the zone B :
  Zone capacity = 43.83% x 62,100 units
  = 27,218.43 units

- Zone C consists of wheat NB and PB, with total percentage of 16.34%. Capacity for the zone C :
  Zone capacity =16.34% x 62,100 units
  = 10,147.14 units

Table 7: The Calculation of Capacity for Each Los

Los No.	Capacity (unit)	Cumulative Capacity (unit)	Los No.	Capacity (unit)	Cumulative Capacity (unit)
1	1620	1620	26	1620	41220
2	1620	3240	27	1620	42840
3	1620	4860	28	900	43740
4	1620	6480	29	900	44640
5	1620	8100	30	900	45540
6	1620	9720	31	900	46440
7	1620	11340	32	900	47340
8	1620	12960	33	900	48240
9	1620	14580	34	900	49140
10	1620	16200	35	900	50040
11	1620	17820	36	900	50940
12	1620	19440	37	900	51840
13	1620	21060	38	900	52740
14	1620	22680	39	540	53280
15	1620	24300	40	540	53820
16	720	25020	41	360	54180
17	1620	26640	42	720	54900
18	1620	28260	43	900	55800
19	1620	29880	44	900	56700
20	1620	31500	45	900	57600
21	1620	33120	46	900	58500
22	1620	34740	47	900	59400
23	1620	36360	48	900	60300
24	1620	37980	49	900	61200
25	1620	39600	50	900	62100

By observing Table 7, the boundaries of Zone A are los 1 to los 16 (total capacity of 25,020 units). The limit of Zone B is from los 17 until los 38 (total capacity of 27,720 units). Then, the remaining los, they are los 39 to los 50 are allocated as Zone C (total capacity of 9360 units). Recapitulation zone capacity can be seen in table 8.

The los allocation also must consider the minimum quantity to be saved for each product in each period. The quantity of stored product is determined based on the daily maximum demand occurred in the previous period (last six months).

If the minimum quantity of wheat excesses the zone capacity, then the zone capacity needs to be adjusted by taking one or more los to the nearest zone, so that the zone capacity can anticipate the minimum requirement.

The mechanism of the storage systematization is prepared to be additional procedures from the existing procedures of FPS.

Table 8: Recapitulation of Calculation for the Capacity of Los

Zone	Los No.	Capacity	Percentage
A	Los 1 - Los 16	25.020	40.29%
B	Los 17 - Los 38	27.720	44.64%
C	Los 39 - Los 50	9.360	15.07%
Total		62.100	100.00%

CONCLUSION

There are some conclusions derived from this research:

1. The main cause of not running FIFO system at PT SRR is the difficulty of wheat flour storage.
2. The storage difficulty is caused by a lot of factors, they are the limitations of FPS, such as :
   a. Capacity of FPS, which is only able to accommodate 70,000 bag (2 days of production)
   b. The low utilization, which is only 22.27% in normal condition.
3. The most efficient alternative in terms of time and money to solve problems and improve the system FIFO is making periodical storage systematization, which is written in the form of operational procedure.
4. The storage systematization is done periodically based on the popularity of the product, so that the high frequency wheat is placed on the front and the low frequency one is placed on the back of the FPS.
5. Based on the forecasting by using Single Exponential Smoothing method and historical data, the periodic time to conduct storage systematization is every 6 months.
6. To prevent the occurrence of the expired product delivery, the wheat bags are labeled with the date that is the best use of products.

ABSTRACT

There is no doubt that land transportation is the most dominant transportation mode compared to another transportation ways such as air and marine transportations in Java. This is shown that the most number of passengers and mails are using land transportations. As the transportation companies, there are many problems found and the one of those is the competition among companies which have the same route and market segmentation. The competition among bus companies becomes tighter and bloody, in other words, those companies are in the Red Ocean. The Porter's Five Forces Models and SWOT Analysis were used to identify the situation of Red Ocean. To escape from the Red Ocean, the company should be able to take some strategies, such as technological innovation, the innovation in services and the mix of them, so the newly and different innovation could be reached. Initial strategy canvas would be made based on result of the questionnaires. Finally, using the four action framework proposed by Kim and Mauborgne, the company will determine which factors that should be eliminated, reduced, raised and invented to create the innovative idea of the Blue Ocean Strategy.

Keywords

Porter's Five Forces Model, SWOT Analysis, Red Ocean, Strategic Canvas, Four Action Framework.

1. INTRODUCTION

Transportation has a major impact in the socio economic life of the country, transporting people and cargo, and connecting among islands, as a means to promote regional economic development, as a means to support other sectors, to increase and equalize people prosperity, to increase national industry competitiveness. It is indeed, national integration and unity, and poverty alleviation depends on good transport links [1].

Land transport is one of the important transport means to boost economic activities. There is no doubt that land transportation is the most dominant transportation mode compared to other transportation modes such as air and marine transportations in Java. This is shown that most of the passengers and mails are using land transportations [2]. Based on Ministry of Transportation Directorate General of Land Transportation data, the land transport is dominant mode with an estimate share of about 92 percent of total freight transport in tons, and about 84 percent passenger movements [3]. The acceleration of development activities will in turn need land transport improvement to make smooth mobility of passengers and goods from one place to another.

However, currently most land transportation modes in Indonesia do not show an efficient and sustainable service performance. This fact is indicated by many complaints from the passengers and the delivered goods [1]. The competition among bus companies becomes tighter and bloody, in other words, those companies are in the situation of Red Ocean [4]. The Porter's Five Forces Models and SWOT Analysis were used to identify the situation of Red Ocean. The potential value created with a new service provided by a bus company is given by the difference between its benefit, in the view of the customers, and the price that customers pay to the company. To what extent this potential value can be exploited as a market opportunity depends on the company's success in obtaining a competitive advantage over other autobus companies (competitors) in the transportation industry. In order to acquire a competitive advantage, a company must outperform its rivals in value creation [5].

Kim and Mauborgne [4] offer an innovative concept to strategy development. At the core of their approach is the

ISSN 114-1284

realization that it is much more valuable for firms to focus their strategy on finding or creating new, uncontested market space (a 'blue ocean') than to compete against incumbent firms on existing markets ('bloody oceans'). The main instrument for finding blue oceans is a 'strategy canvas,' a visual depiction of strategies as value curves allowing the comparison and differentiation of industries and competitors. Within this framework the Blue Ocean Strategy (BOS) can then be derived as the optimal choice of innovative strategy formulation. Therefore, the aims of this research are:

1. to identify the competition status among bus companies using the Porter's Five Forces Models and SWOT Analysis
2. to design Blue Ocean Strategy using strategy canvas and the four action framework.
3. to formulate some innovative strategies based on Blue Ocean Strategy result.

2. METHODOLOGY

2.1 Blue Ocean Strategy Methodology

The methodology developed here is based on the Blue Ocean Strategy model proposed by Kim and Mauborgne [4]. A methodology that will be utilized for developing an innovative strategy for an autobus company is shown in Figure 1. The methodology is categorized into three main phases. The first phase involves identifying current competition condition in autobus industry. This phase will include The Porter's Five Forces Models and SWOT Analysis that will be analyzed for describing the situation. The second phase is a Blue Ocean Strategy Design. It involves Strategy Canvas and Four Actions Framework. The purpose of strategy canvas is to visualize value curves allowing the comparison and differentiation of industries and competitors and by using the four strategic actions framework, the company will determine which factors that should be deleted, decreased, raised and invented to create the innovative idea. The last phase involves developing an innovative strategy based on the Blue Ocean Strategy.

Figure 1: Blue Ocean Strategy Methodology

2.2 Sampling

The questionnaire asked the respondents for their profile details, their customer satisfaction of existing attributes, and the expectation of those attributes and their future usage intentions for different bus. A survey amongst bus passengers was conducted and 100 responses were obtained. The objects of autobus were PO.X and its close competitors. The survey was conducted at several bus stations and bus agents in Jakarta. The purposive sampling technique was used to collect the responses. An attempt was made to see that there was diversity in the type of respondents that covered business executives, businessmen, academics, etc.

3. RESULT

3.1 Identifying the Competition Condition

Force factors that affect the conditions of competition need to be identified. Concept Five Forces analysis

introduced by Michael E. Porter helps the company to understand the competitive environment. It uses five forces which determine the competitive intensity and therefore attractiveness of an autobus market [6].

Beside that, the SWOT analysis is used to provide information that is helpful in matching the company's resources and capabilities to the competitive autobus industry's environment. As such, it is instrumental in strategy formulation and selection [7]. Figure 2 and Figure 3 in Appendixes show respectively the Five Forces Competitive Strategy analysis in autobus industry and how a SWOT analysis for autobus industry.

3.2 Blue Ocean Strategy Design

The main instrument for finding blue oceans is a 'strategy canvas'. It depicts strategies as value curves allowing the comparison and differentiation of a form and competitors based on customer satisfaction attributes from questionnaire's result. Figure 4 shows the initial strategy canvas for PO.X and its competitors.

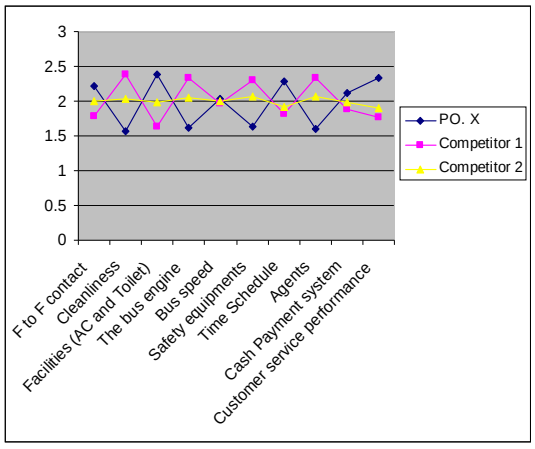

Figure 4: Initial Strategy Canvas

The strategic attributes that the industry competes on and invests in are displayed on the horizontal axis in Figure 4. The vertical axis shows the offering level buyers receive for each strategy attribute. Thus, strategic attributes can be viewed as attributes of the products or services being offered. Competitors are judged on the level of their offerings to the customer in each attribute and may be sorted into strategic groups, which are defined by equal or similar offering levels in each strategy factor. The result is a set of value curves for competing strategic groups in an autobus industry.

After describing the initial strategy canvas, the company will determine which factors that should be deleted, decreased, increased and created using four actions framework (Table 1).

Table 1: Four Actions Framework

Eliminated	Raised
Face to face contact	Cleanliness
Time Schedule	Facilities (AC and Toilet)
Agents	Safety equipments
	Customer service performance
Reduced	**Created**
Cash Payment system	On line payment system
Bus speed	New supporting facilities
	Kinship situation

Kim and Mauborgne [4], therefore, suggest to shift the market focus to alternative customers, who place less weight on the competitive strategy factors under consideration, while valuing other (new) attributes more strongly. As a consequence, some attributes can be reduced or eliminated altogether for strategy factors of lower importance, while relevant attributes can be expanded and new ones created. In Figure 5, future strategy canvas for PO.X illustrates the contrast to the two dominating strategic groups.

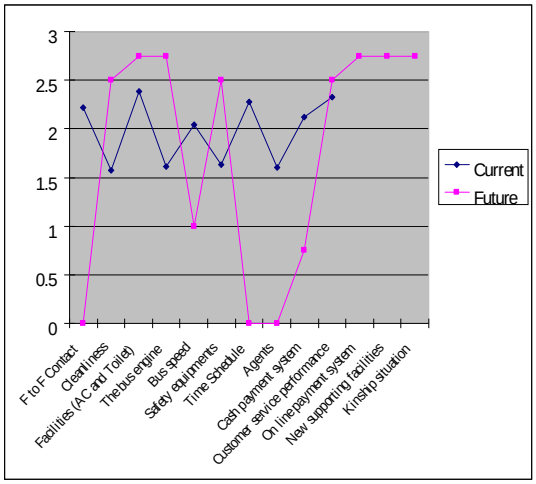

Figure 5: Future Canvas Strategy of PO.X

3.3 Creating Innovative Strategies

Then, the blue ocean idea will be formulated into two innovative strategies. They are marketing and product design strategies. The current company marketing strategies will be changed after the idea of Blue Ocean Strategy. Therefore, PO.X also need to focus or change their market target and do repositioning. Table 2 and Table 3 show the marketing strategy differences before and after the blue ocean idea.

Table 2: New Segmenting, Targeting and Positioning

STP	Current Strategy	Blue Ocean Strategy
Segmentation	Low, middle, high-middle segment	Low, middle, high-middle, and high segment
Targeting	Low and middle class group	High class group (business executives, businessmen, company)
Positioning	Public bus	Create new market as family bus

Table 3: New Marketing Mix (7P)

7P	Current Strategy	Blue Ocean Strategy
Product	Economy and executive bus	Super executive family bus
Promotion	Banners, Sponsorship	Radio advertising, newspaper, and internet
Price	Based on government policy	Depend on given facilities
Place	Convenience agents	On line order and payment
People	No attention	Training
Process	No attention	Has a new division to handle the process
Physical Evidence	No attention	More attention

Besides new marketing strategy, the company's product design approach must be linked to the Blue Ocean Strategy. The visualization of family bus is considered by the autobus industry.

4. DISCUSSION

The metaphor of red and blue oceans describes the market universe. Red oceans here are all autobus companies in existence today—the known market space. In the red oceans, autobus industry boundaries are defined and accepted, and the competitive rules of the game are known. SWOT Analysis and Porter's Five Forces Model were used to identify that situation [7]. Using SWOT analysis, PO.X can audit itself and its environment. It is the first stage of planning and helps PO.X to focus on key issues. Based on the SWOT results, the company should manage its internal and external factors. For internal factors, the company should enhance its strengths such as competitive price and good driver and should improve its weakness by updating the website. For external factors, the company should catch the opportunities up such as development of technology and niche market. Beside that, the company also should pay attention on the economic situation and the competitors.

While, Five Forces Analysis helps the company to understand a competitive environment. It has similarities with SWOT analysis, but tends to focus on the autobus business rather than a single product or range of products [6]. Five forces analysis looks at five key areas namely the threat of entry, the power of buyers, the power of suppliers, the threat of substitutes, and competitive rivalry [8]. Here, PO.X tries to outperform their rivals to grab a greater share of product or service demand. As the market space gets crowded, prospects for profits and growth are reduced. Products become commodities or niche, and cutthroat competition turns the red ocean situation.

Blue oceans, in contrast, denote the unknown market space in autobus industries not in existence today, untainted by competition. In blue oceans, demand is created rather than fought over. There is ample opportunity for growth that is both profitable and rapid. In blue oceans, competition is irrelevant because the rules of the game are waiting to be set [4], [9].

The initial strategy canvas is made as an elegant qualitative and didactic tool for understanding and explaining the strategic deviation of high performers from traditional market incumbents in creating value. Here, in the autobus industry, based on questionnaires result, it has been identified 10 critical factors influenced passenger satisfaction. They are face to face contact, cleanliness, facilities, bus engine, bus speed, safety, time schedule, agents, and cash payment system and customer service performance. However, it is easy to argue that a PO.X strategy must have been 'better' than those of its competitors, knowing that the company turned out to be successful.

To reconstruct customer value elements in crafting a future strategy canvas, we use the Four Actions Framework. As shown in Figure 5, to break the trade-off between differentiation and low cost and to create a new value curve, there are four key questions to challenge an industry's strategic logic and business model [4]:

1. Which of the factors that the industry takes for granted should be *eliminated*?
2. Which factors should be *reduced* that do not unsatisfy customers?
3. Which factors should be *raised well above* the industry's standard?
4. Which factors should be *created* that the industry has never offered?

Based on the result, there are some factors must be eliminated (face to face contact, time schedule, and agents), reduced (cash payment system and bus speed), raised (cleanliness, facilities, safety equipments, and customer service performance), and created (on line payment system, new supporting facilities and kinship situation).

After that, PO.X should change the current marketing strategy to gain niche market whenever it can attract new potential customers and make competitive forces with its rivals irrelevant. The company should do re-segmenting, re-targeting and re-positioning to reach its niche market. The focus of this marketing strategy is to make sure that products and services meet customer needs within that market and

developing long-term and profitable relationships with those customers [8].

To achieve this, PO.X will need to create an innovative strategy that can respond to changes in customer perceptions and demand because it can help company find new, uncontested market space that company successfully target. The visualization of this innovative strategy is a family bus concept. The family bus has 'rooms' and equipments like living at the home (see Figure 6). Finally, new segmentation, targeting, positioning, marketing mix, and bus design are needed in order to support this Blue Ocean Strategy implementation.

5. CONCLUSION

This research uses Blue Ocean Strategy model that proposed by Kim and Mauborgne to escape from bloody Red Ocean and to understand the demands of customers. The results not only can be used to identify the attributes of service elements, it also can suggest the attributes that should be deleted, decreased, increased and invented to create the innovative idea in blue ocean. This result is beneficial for PO.X management to formulate their strategy when they devote significant portion of their organizational resources to them

Despite the limitations resulted from the context of data collection and the sample, the research provides some valuable findings for PO.X management by identifying critical attributes as customer voices. It also contributes to future development of Blue Ocean Strategy model for other industries.

ABSTRACT

In his book, Operation Research, An Introduction (second edition; 1976), Hamdy A. Taha differentiated three kinds of models, a mathematical model, a simulation model and a heuristic model. Those three models in fact could be integrated in a way to solve a model of a real system under our investigation, either it is in engineering or non-engineering fields.
This paper is to show the integration of those three models through a simple mathematical manipulation; that is, by distinguishing endogenous and exogenous variables which contain in a system of simultaneous equations. The simultaneous equations represent a mathematical model of the system; the simulation proceeds by fixing the exogenous (or independent) variables of the equations with certain figures or quantity representing various possible events; and the heuristic approach is used to develop improved solutions to the system of equations until it reaches a set of convergence or unique solution.
The technique can be used in many fields of concentration, including engineering, economics, business, industry and social. That is, as long as a system of equations can be constructed to represent the model. A computer may help us to solve a complex model.

Keywords: *Simulation, heuristic, model*

Three types of models for a system has been mentioned by Hamdy Taha, in his book on operation research (Taha, 1978), which are mathematical model, simulation model and heuristic model. In a system under our observation, either in engineering or non-engineering field, such as economics and business, the three building models can be integrated in one, and solve the problem inside the model to reach a unique solution.

Mathematical Model of Simultaneous Equations

The mathematical model which will be discussed here is a simultaneous system of equations. The general format of system of equations can be written as follows:

F1(X) = **F**1[x1, x2, x3, ……, xn]
F2(X) = **F**2[x1, x2, x3, ……, xn]
:
:
Fn(X) = **F**n{x1, x2, x3, ……, xn]

Which is a system of equations with n number of equations [F1, F2, F3, …., Fn], and n number of variables [x1, x2, x3, …., xn], that is (nxn) simultaneous equations. The system of equations describes the behavior of the real world system under our observation. Each of the equations can be either linear or non-linear. The system of equations can be solved simultaneously to reach a unique solution for [x1, x2, x3, …., xn], therefore it can be written also in a new form as follows:

x1 = **G**1[x1, x2, x3, ……, xn]
x2 = **G**2[x1, x2, x3, ..…., xn]
:
:
xn = **G**n[x1, x2, x3, …..., xn]

A unique solution can still be reached, eventhough there are more than n number of variables, if and only if the value of each extra variables, say the **P**s and **E**s variables, are known. Involving these variables, then the above system of equations can be written as follows:
x1 = **G**1[x1, x2, x3, ……, xn], **P**1, **E**1
x2 = **G**2[x1, x2, x3,……., xn], **P**2, **E**2
:
:
xn = **G**n[x1, x2, x3, ……., xn], **P**n, **E**n

Here, the **X**(x1, x2, x3, ……., xn) variables are called endogenous or dependent variables, which value of each is determined simultaneously by the system; while the **P**n(p1, p2, p3, ……, pk) and the **E**n(e1, e2, e3, …., el) variables are called exogenous or independent variables, which value of each is known before hand.
In a system that we observed, the **P** variables are policy-variables, which value are under our control; and the **E** variables are external-variables which value are out-of our control.

ISSN 114-1284

Simulation Model

The above mathematical model is derived from the real world system under our observation. Each equation that constructs the model can be in many forms: (1) a causal relationship among variables, a relation which frequently subjective or depend on the objective of the observer or the modeler; (2) a specific equation, which depend on the behavior of the system or part of the system, such as physical equation; (3) a parametric relation, which includes some ratios, specific working factors, or coefficients resulted from observations or experiments, including a mathematical equality; and (4) a statistical or econometric relationship, if the factors or the coefficients involved are resulted from a statistical data processing.

Functionally, the relationship among variables can be technical, behavioral, legal, arithmetical, or just an identity. The overall relationships among variables, therefore, is more subjective in character, which depends on the way the observer designs the model, even though the objectivity of the model is still maintained within the whole system. Because of this subjectivity of the relationships, the model is categorized as a simulation model.

Besides, the word "simulation" is used to describe "the process to achieve a number of solutions from model". That is, to see how the model responds from a number of assumed changes, either the changes on the value of the exogenous variables, or the changes on the parameters involved in the model which are is considered significant.

A simulation model to find solution on the endogenous variables **X** which depend on or due to changes on the value of the exogenous variables **P** and **E**, can be shown in Figure-1 below:

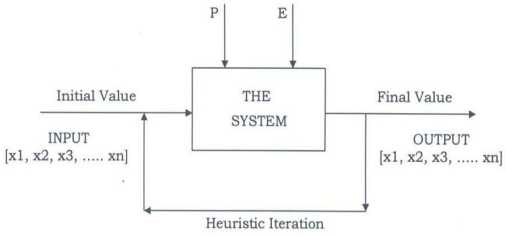

Figure-1: A process to find solution in a simulation model

The choice of value of the exogenous variables **P** and **E** will influence the final results on the value of the endogenous variables **X**[x1, x2, x3, ……, xn]. As long as the number of equations in the system of the model and the number of the endogenous variables are the same, that is (nxn), then a set of unique solution of **X** will always be reached. Any changes in the value of the exogenous variables **P** and **E** will always reach another set of unique solution. Simulation is the agenda to set values of **P** and **E**, each time to get a set of values of **X**.

Heuristic Model

A heuristic model is a model of a system which its solution needs a heuristic process, that is through trial & error, or through *approximation* procedure. Therefore, a heuristic model refers to the way it solves the model system.

Here, the writer uses a numerical method (*Burden and Faires, 1985*) as an approximation way to solve simultaneous equations. Figure-1 also describes the way the general numerical method works. A set of initial values of the endogenous variables **X** are assumed, say [0,0,0,…….,0], which values are feed-in as input into the system (the exogenous variables of **P**s and **E**s, with their values, are inclusive in the system.) The first round of output resulted from the system, which are new values of the endogenous variables **X**, is then feed-in again as second round input into the system. This process is repeated again and again until the final output, that is the unique solution to the simultaneous equations, converges to certain values of **X**.

In this paper the Gauss-Seidel technique is chosen. This technique can be used for linear and non-linear system of equations. Besides of some weaknesses, the Gauss-Seidel technique is relatively easy and brings a fast solution. Another numerical technique is the successive approximation which is also easy, but is not as fast as the Gauss-Seidel technique. Newton technique, on the other hand, is able to cover-up the weaknesses of the Gauss-Seidel technique, but the use of differentials and matrices in its initial procedures for solution are quite complex, especially for a large scale model.

The main weakness of the Gauss-Seidel technique is the possibility of no solution, due to output divergence. A unique solution can only be reached if the output from a step of iteration to the next converges. The ordering of the equations, and the degree of normalizing the values of each variable in each equation within the system are greatly influence the process of solution: it can be fast or slow; it may converge or diverge (no solution). After normalization, there is no certain rule for reordering the set of equations when the solution diverges, except a trial and error procedure (*Challen and Hagger, 1983*).

Using the Gauss-Seidel technique, the above system of equations can be written in an iterative way (with *superscript*-k) as follows:

$x1^{k+1} = \mathbf{G}1[x1^{k}, \; x2^{k}, \; x3^{k}, \ldots\ldots, xn^{k}], \mathbf{P}1, \mathbf{E}1$
$x2^{k+1} = \mathbf{G}2[x1^{k+1}, \; x2^{k}, \; x3^{k}, \ldots\ldots, xn^{k}], \mathbf{P}2, \mathbf{E}2$
$x3^{k+1} = \mathbf{G}3[x1^{k+1}, \; x2^{k+1}, \; x3^{k}, \ldots\ldots, xn^{k}], \mathbf{P}3, \mathbf{E}3$
:
:
$Xn^{k+1} = \mathbf{G}n[x1^{k+1}, x2^{k+1}, \; x3^{k+1}, \ldots.., xn^{k}], \mathbf{P}n, \mathbf{E}n$

where k indicates the number of iteration from k=0 to k=M (M is *stopping device*) which is the final iteration that converges to the *unique solution*.

ISSN 114-1284

Example of Cases

1. Linear System of Equations

An example of a linear system of equations (*Burden and Faires*, 1985, p. 428) is as follows:

$$\begin{aligned} 10x1 - x2 + 2x3 &= 6 \\ -x1 + 11x2 - x3 + 3x4 &= 25 \\ 2x1 - x2 + 10x3 - x4 &= -11 \\ 3x2 - x3 + 8x4 &= 15 \end{aligned}$$

X[x1, x2, x3, x4] is a set of endogenous variables which values are to be found; while the number in the right hand side [6, 25, -11, 15], are the value of the exogenous variables of **P** and **E**.

With the use of Gauss-Seidel technique the above system of equations is changed into the following:

$$\begin{aligned} x1^{k+1} &= 1/10\, x2^{k} - 2/10\, x3^{k} + 6/10 \\ x2_{k+1} &= 1/11\, x1^{k+1} + 1/11\, x3^{k} + 3/11x4 + 25/11 \\ x3^{k+1} &= -2/10\, x1^{k+1} + 1/10\, x2^{k+1} + 1/10\, x4 - 11/10 \\ x4^{k+1} &= -3/8\, x2^{k+1} + 1/8\, x3^{k+1} + 15/8 \end{aligned}$$

The results of the heuristic iteration are as follows:

	k=0	k=1	k=2	k=3	k=4	k=5
$x1^k$	0.0000	0.6000	1.0300	1.0065	1.0009	1.0001
$x2^k$	0.0000	2.3272	2.0370	2.0036	2.0003	2.0000
$x3^k$	0.0000	-0.9873	-1.0140	-1.0025	-1.0003	-1.0000
$x4^k$	0.0000	0.8789	0.9844	0.9983	0.9999	1.0000

By using a set of initial values of **X**[0, 0, 0, 0], the final result as the unique solution is reached at **X**[1, 2, -1, 1] at k=M=5. Some simulation agenda using different values of **P** and **E** will result at different values of unique solution.

2. Non-Linear System of Equations

Another example is shown for a non-linear system of equations (*Burden and Faires*, 1985, pp. 493-494):

$3x1 - \cos(x2x3) - \frac{1}{2} = 0$

$x1^2 - 81(x2 + 0.1)^2 + \sin x3 + 1.06 = 0$

$e^{-x1x2} + 20x3 + \frac{(10 - 3)}{3} = 0$

With the same procedures, by using initial values of **X**[0.1, 0.1, -0.1], a unique solution of **X**[0.50000000, 0.10000000, -0.52359877] is reached:

	k=0	k=1	k=2	k=3	k=4
$x1^k$	0.10000000	0.49998333	0.49997747	0.50000000	0.50000000
$x2^k$	0.10000000	0.02222979	0.00002815	0.00000004	0.00000000
$x3^k$	-0.10000000	-0.52304613	-0.52359807	-0.52359877	-0.52359877

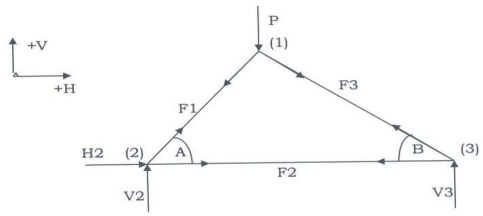
3. Actual Cases

Some examples of actual cases in engineering field, economics, business and industry are presented in the appendix.

APPENDIX

1. Case in Structural Engineering: *Truss*

The equilibrium of forces in horizontal (H) and vertical (V) direction at joints (1), (2) and (3) of a simple truss like the one below (*Chapra and Canale*, pp. 258-259) produces a system of six equations with six unknowns of endogenous variables and three exogenous variables:



$$\begin{aligned} -F1\cos A + F3\cos B &= 0 \\ -F1\sin A - F3\sin B &= P \\ F1\cos A + F2 + H2 &= 0 \\ F1\sin A + V2 &= 0 \\ -F2 - F3\cos B &= 0 \\ F3\sin B + V3 &= 0 \end{aligned}$$

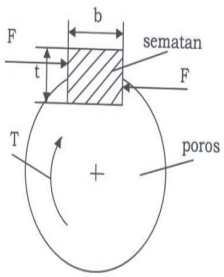
By giving values to exogenous variables A, B and P, the system of equations determines a unique solution of the endogenous variables of **X**[F1, F2, F3, H2, V2, V3]. Different values of the exogenous variables will produce different unique solution.

By the help of a computer, complicated trusses and frames with different values of exogenous variables can always be simulated quite easily to reach unique solution for each case.

2. Case in Mechanical Engineering: Machine Element

This is a design of a machine element, such as key (*Shigley, 1977, pp.265-266*), with length p, height t and width b, which transmits a rotation from a shaft. The shaft with D in diameter rotates with an angular velocity of N revolution per minute (rpm) and with a transmission power of HP (horsepower). The key material is a steel of UNS G-10350 (*yield strength*, Sy = 65 kpsi). The design of a key produces a system of equations of the following:

Torque : T = 63000 (HP/N)
Tangential Force : F = T/(D/2)
Shear Stress : Ssy = f (F/b.p)
Tension Stress : Sy = f (2F/t.p)
Stress Ratio : Ssy = r.Sy



From the above five equations there are eleven variables in total, six of them are endogenous variables. To reach a unique solution for the six endogenous variables, the dimension of the key [p; b; and t], the diameter of the shaft D, the torque T and tangential force F, the value of one of these six endogenous variables must be known or fixed as an exogenous variable. There were two options: whether the diameter D of the shaft was given a certain value; or D had to be determined as an unknown variable, then b and t could be assumed equal, such as b=t or a square key.

Other variables, which are N (rpm) and HP (horsepower); and f, Sy and Ssy, are exogenous variables which values are fixed or given. A simulation can be done for different values of exogenous variables.

3. Case in Economics: a *Macro-Economics Model*

A simple macro-economics model is proposed like the one below (*Dornbusch and Fischer, 1981, pp. 21*). Based on the model a system of equations is derived as follows (Pamungkas, 2005):

(1) National income identity: $Y = C + I + X + G$

where:

Consumption function: $C = Co + 0.6(Y - T)$

Tax level: $T = To + 0.3Y$

Investment function: $I = Io + 0.14Y - 5r - 0.35E$

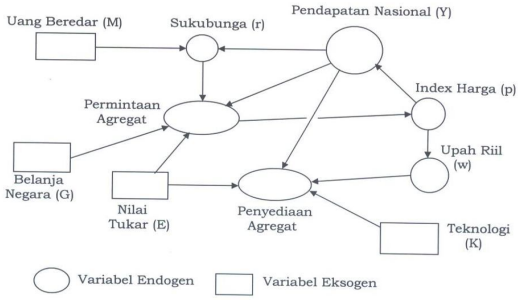
Net-export function: $X = Xo - 0.1Y + 0.4E - 250p$

(2) Aggregate Supply Equation: $Y = Yo + w(W/p)Y + k(K/E)$

where: w = real wage coefficient

k = technology coefficient

(3) Money market Equation: $r = 0.0015Y - 0.1(M/p)$



From those three equations a unique solution can be found for the three endogenous variables, which are national income Y, interest rate r (in percent) and the price index p. The value of the exogenous variables, such as government expenditure G, money supply M, exchange rate E (in Rupiah/Dollar), nominal wage W, and technology level K (a dummy variable which values are scaled between 1 and 100), including all autonomous factor (with *subscript* "o") and other coefficient (w, k) are all known. A simulation can be done to know the response of the system for different values of exogenous variables, especially the affect of different policies on G and M, or different values of external shocks such as E.

To bring the model more complete, that is to find the to number of labor employment N in the economy some more equations must be added, like production function Y = F(N, K), and demand function of labor W = F (N, p).

Many large scale economics model have been developed with many equations and variables including one by the writer (Pamungkas, 1984)

4. Case in Mathematical Programming: Input-Output

This is an example of an MP (mathematical programming) problem *(Pfaffenberger and Walker,* 1976, pp. 121-122):

Max: $Y = P'X$

St: $(I - A)X > G$: number of production output in industry

$Ao'x < Lo$: number of labor in industry

$X > 0$: non-negativity

Where **X**[x1, x2, …., xn] is output in industry 1, 2, ….N; **P**[p1, p2, …., pn] is price vector of *output in* industry 1, 2, …., N; and Y is national product (*Gross National Product*).

Matrix **A** represents input-output coefficients in industry, where (aij) showed a part of output in industry (i) which is used as input to produce output in industry (j); and **G**[G1, G2, …., Gn] is the government demand for each output; therefore $Ax + G < X$.

Where as Ao is the number of labor employed in each industry; and Lo is the number of labor in each country.

The above LP formulation is based on Leontief model on industrial data (NxN) which example is shown below, for N = 3:

By adding **S**[s1, s2, s3] as the number of unsold output (*inventory*), and **U**[u1, u2, u3] as the number of unemployed labor, the inequality in the above LP system can be changed into an equality of system of equations:

$$\begin{vmatrix} a11 & a12 & a13 \\ a21 & a22 & a23 \\ a31 & a32 & a33 \end{vmatrix} \begin{vmatrix} x1 \\ x2 \\ x3 \end{vmatrix} + \begin{vmatrix} s1 \\ s2 \\ s3 \end{vmatrix} = \begin{vmatrix} G1 \\ G2 \\ G3 \end{vmatrix}$$

and

$$[ao1 \quad ao2 \quad ao3] \begin{vmatrix} x1 \\ x2 \\ x3 \end{vmatrix} + \begin{vmatrix} u1 \\ u2 \\ u3 \end{vmatrix} = Lo$$

By considering the residuals of **S**[s1, s2, s3] and **U**[u1, u2, u3] as exogenous variables which values are known, and with the value of **G**[G1, G2, G3] and Lo are also known, the system of equations which originally is an LP type model with inequalities, now can be solved to find **X**[x1, x2, x3], by using a numerical technique in solving simultaneous system of equations

Notes:

(1) The above example problem is a typical MP problem (can be linear or non-linear) which solution is more complicated, because of optimality and inequality terms.

(2) It can be noticed, that the number of equations is greater than the number of endogenous variables; this frequently happens in an MP model. In that case, to find the optimum objective function, another step of solution procedure must be established; that is to search the optimum solution from a number of possible unique solutions.

(3) In general, the value of residuals **S**[s1, s2, s3] and **U**[u1, u2, u3] (or slack variables) are unknown, therefore the values must be found using a trial and error procedure such as a heuristic model.

ABSTRACT

Increasing of commercial cars demand in Indonesia, car producers compete in making commercial car with bigger capacity, more comfortable, more efficiency and globally acknowledged quality as well as reasonable price for Indonesian market as consequenes there is sliding door technology. One of the advantage sliding door is to provide wider space and more compactible. The manufacturing process of the sliding door is very crucial in car assembly. Until now, the fitting of roller is still conducted manually and pure performance or not good (NG) products are still resulted. The defecst are produced by the length unstandarize an, the highest level of the unsymetri door. This is to encourage PT Y to design a new tool (jig) to improve the product in line with the highest standard. In this paper, a new developing of the jig is proposed, while the manufacturing cost is main concern for the economic analysis .

Methodology of he research is based on the design scheme of a product design using Ullrich start, data collection and analysis in PT Y. To get the detail and the right design of the product, the consumer need identification, product specification, design concept, selection concept, testing concept, architecture concept, industrial design, manufacturing process design, economic analysis and product development to calculate the optimum cost by choosing the most efficient material.

Based on the whole steps, it is found that there are two alternative concepts of jig. Concept A is to using manual tools that consists of two mains supporting tools and the concept B is to operating semiautomatic tools by pneumatic force and consist of one main tool. Based on the data analysis, the reults show that the concept B of jig design has the more optimum and efficient to assembly process door roller fitting, reducing NG product to become zero and increasing of the cycle time.

Keywords : *NG Sliding Door, Design Jig, Zero Defect*

1. INTRODUCTION

Increasing of commercial cars demand in Indonesia, car producers compete in making commercial car with bigger capacity, more comfortable, more efficiency and globally acknowledged quality as well as reasonable price for Indonesian market as consequenes there is sliding door technology. One of the advantage sliding door is to provide wider space and more compactible. The manufacturing process of the sliding door is very crucial in car assembly. Until now, the fitting of roller is still conducted manually and pure performance or not good (NG) products are still resulted. The defecst are produced by the length unstandarize an, the highest level of the unsymetri door. This is to encourage PT Y to design a new tool (jig) to improve the product in line with the highest standard. In this paper, a new developing of the jig is proposed, while the manufacturing cost is main concern for the economic analysis. Some of research about jig and fitting design have been proposed such as: jig for fitting locks to door by Wilson, 1999; A jig for removable fitment along the edge of a door which provides a suitable combination of guides and stops to allow the location and operation of suitable cutting tools such as drill or router. A frame unit for tensioning a printing screen and a jig for fitting of print screen to remove the printing screen has been proposed by Keith, 2005. A frame unit for tensioning a printing screen, the frame unit comprises a frame including at least one of frame member, and at least one frame member comprise a supporting frame element.

2. SYSTEM MODEL

2.1. The Customer Need Identification

The customer need identification is used to evaluate the need of customers and effectively communicate to the developer team. The next step, the Matrix Design Requirements of Metric Tool is created as shown in Figure 1.

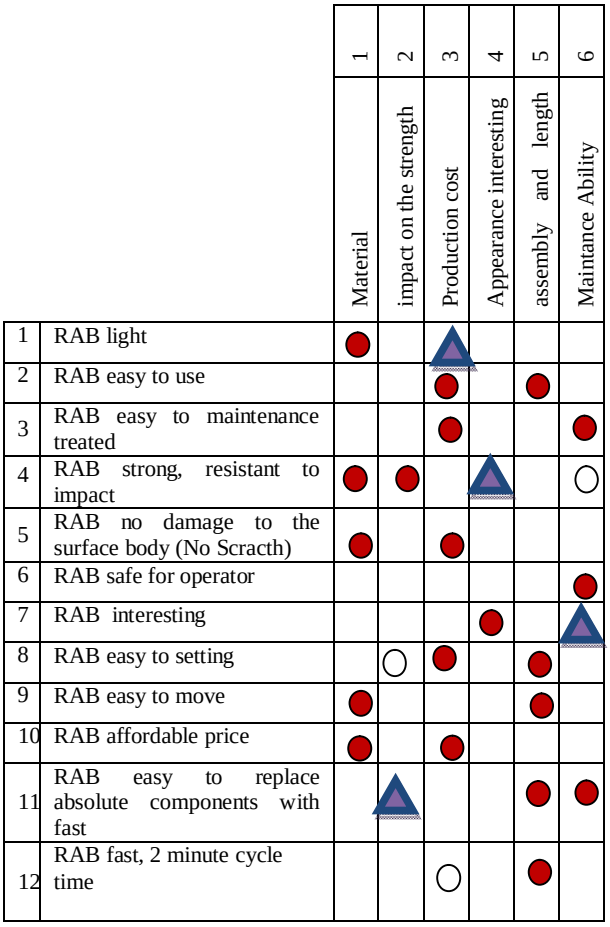

Figure 1. Matrix Design Requirements of Metric Tool

2.2. Product Specifications

The product specification of the design of the sliding door roller is shown in the attachement file 2 of this paper.

2.3. Concept of Product Design

The concept of product design is provided into two concepts, they are: the concept A is namely as two-way manual with the tool) and the concept of B is namely as a semi-automatic pneumatic booster and consists of a tool. The concept A proposed a way for clamping either manually, or setting screw, that consists of two tools to make the center of roller and the lower roller. The advantages of this concept ara: simple, faster to develop, nad the price is cheaper. The weakness of the design are: too heavy (weight of 1 jig around 3 kg. If one day the car should be up 100, the operator must lift the 2 x 100 = 200 times so that the total load is 200 kg x 3 = 600 kg, difficult operation, all manual clamping, the possibility of wound / lacerated body door is very high. The concept B is is propsoed with semi-automatic, manual positioning for the roller, and for the automatic clamping, positioning pins using wind energy (penumatic) that 1 unit consists of a tool with two functions for the lower roller and roller center at the same time. The advantages of this concept are easy to use, fast, accurate results, light, setting only once. The weaknessof this concept are : expensive, and takes longer time for manufacturing process.

3. METHODOLOGY OF RESEARCH

Methodology of research is based on the scheme of a product design using Ullrich start where a research, data collection and analysis is proposed in PT Y. To get the detail and the right design of the product, the customer need identification, product specification, design concept, selection concept, testing concept, architecture concept, industrial design, manufacturing process design, economic analysis and product development to calculate the optimum cost by choosing the most efficient material.

4. RESULTS

4.1. Screening of the Concept

Results from the screening of two concept are shown in Table 1.

Table 1. Screening of the Concept

Selection criteria	Concept	
	Concept A	Consept B
	Full Manual	Semi Automatic
Functional		
Light weight tool	-	+
Cycle time of rapid and permanent	-	+
Accurate	-	+
Comfort		
Bound on the rail	-	+
Comfort in the placement tool	-	+
Comfort in the use of	-	+
Ergonomic		
It takes less energy to setting up	-	+
Clamping/unclamping one movement	-	+
Ease of use	-	+
Resistance		
Long life	-	+
Other		
Cost	+	-
Manufacturing process	+	-
Ease to carry	0	0

Amount (+)		2	10
Amount (-)		10	2
Amount (0)		1	1
Net Value		-8	8
Ranking		2	1
	Continue?	Tidak	Ya

From Table 1. we can see that the concept B is better than the concept of A, where value of + in the concept B is much more than the concept A.

4.2. The Assessment Concept

The assessment concept of jig of fitting sliding door roller is shown in Table 2.

Table 2. The Concept of Assessment

Selection criteria	Weight	Concept			
		Concept A		Consept B	
		Rating	Value	Rating	Value
Ease of handling	5%	2	0.10	3	0.15
Ease of use	25%	3	0.75	5	1.25
Accuracy results	25%	3	0.75	5	1.25
Resistance	25%	2	0.50	4	1.00
Easy to make	10%	5	0.75	3	0.30
Price	5%	5	0.25	2	0.10
Ease to carry	5%	5	0.25	3	0.15
	Total value	3.10		4.20	
	Ranking	2		1	
	Continue?	No		Yes	

4.3 Testing and Design Concept

Testing of both concept, especially in product design jig of fitting sliding door roller, is to ensure that customer needs have been fulfilled by the product concept. Testing of this concept is only proposed to the product development team, to make photos and graphics (rendering) and the simulation of 3-dimensional images obtained from Catia. Testing of the concept of product design is proposed for the structure analysis using software.

4.4. Industrial Design

Product design jig of fitting sliding door roller is to have a high esthetic value. This product is designed to install a roller in accordance with the standards applicable to quickly and optimally. Assessment of the level of interest of the design industry for jig is shown in Table 3.

Table 3. Interest Level Industrial Design

Needs	Level Interest Low-Midle-High	Rank Description
Ergonomic		
Ease of use		Production capacity of 150 units per day, it becomes very important
Convenience Care		Need a little care
Updates the user interaction		There is a different pneumatic control equipment, in general, with many of the electric control.
Security		Importance so that security does not bind clamp
Esthetics		
Product differentiation		The tool is only available in Indonesia
Prestige of ownership		Plans become more bergensi using this tool
Team motivation		Kaizen tool to make operator creative

4.5. Design for Manufacturing

Design for manufacturing proposed for a variety of machinery and assembly. A suitable technique is proposed to know how to design manufacture mapping using the process operation. This mapping provides a description more carefully about the flow pattern. Detail of product figure is attached in the attachement file 1. And the product component is shown in the attcahement file 3. For simulation and design of slidding door is shown in the attachement file 4 and 5. Table 4 is the total cost of manufacturing jig.

Table 4. Cost Manufakturing

Cost Manufacturing		
1	Component-Component	
	a. Standar	
	Pneumatic	12,000,000
	Screw	500,000

4. CONCLUSIONS

Selection of concept B is based on the total assessment amounted to 4.20 points that compared to the concept A 3:10 points B with semi-automatic, which is a combination of pneumatic system. The concept B has several advantages as follows: a. Precision, because the position of roller always in right position with the locating pins and clamping using Pneumatic cylinder, b. Quickly, using this tool, the cicle time is increase to 2 minutes for a single assembly, c. Easy operation, one of things that are important for equipment operators is more simple, more tractable, and d. Although the relative price but the benefits are much helpful in the long term.

Materials that used is aluminum and because the light has a high aesthetic value with the total cost to make the tool manufacturing of sliding door roller fitting for the concept B is Rp. 99,599,200

ABSTRACT

Making improvements in products or in processes can be one of the most challenging tasks confronting an organization. One of the semi-finished products manufactured at Fujitsu Component Malaysia Sdn. Bhd (Batu Pahat, Johore) is made by bending and cutting operation at the slow speed hydraulic press machine. It has a standard cycle time 2.5 second per piece and monthly usage is 400k pieces per month. The company wants to eliminate waste by optimizing the cycle time without compromising towards product quality. This research's objective is to identify causes of defects associated with bending and cutting processes at each phases of operations. A detail of methodologies is offered through which an identification of defects and effective solutions for their removal could be done. This research also wants to show how the parameters of the problem could be established and how Design of Experiments (DOE) technique could be applied to achieve the stated objectives by using the Taguchi method and results at 18 test runs. A detailed ten-phase methodology is offered through which an identification of defects and effective solutions for their removal could be done. MINITAB software is used to analyze the data and result. Analysis of Variance (ANOVA), factor interaction and other method is used. The results of the initial experiments are subjected to a verification procedure to determine their viability and accuracy. As a result of this experiment, the company enables to make the changes need to reduce the cycle time requiring producing products and thus, increase productivity while maintaining high quality standards. The expected result from this project is the cycle time for the bending and cutting operation can be reducing by at least 20%. This will lead to cost reduction and increase profit.

Keywords
Design of Experiment (DOE), Taguchi Method, Analysis of Variance (ANOVA), Cycle time, Bending.

1. INTRODUCTION

Fabrication of strip metal for miniaturized components by progressive metal stamping is receiving greater attention because of the rapid growth in demand for such components in electronic and microelectronics industry. With a short cycle time, the high volume of production could lead to cost reduction while maintaining the high quality of the product. The combination of bending and cutting by progressive stamping with a single stroke is made possible by the aid of precision stamping machine. One of the semi-finished products manufactured at Fujitsu Component Malaysia Sdn. Bhd is made by bending and cutting operation at the slow speed hydraulic press machine. It has a standard cycle time 2.5 second per piece and monthly usage is 400k pieces per month. It was considered as a slight loss to the company as if they could reduce the cycle time and managed to increase their profit.

To eliminate this problem, in this study, the optimum level for parameters in the bending and cutting operation will be determined for the best yield of minimum time. Time is considered as an important factor that affects the productivity, hence affecting the profit as well as the production cost. To achieve the objective, Design of Experiment (DOE) approach will be implemented whereby it is a powerful technique used to study the effect of several process parameters affecting the response or quality characteristic of a process or product (Montgomery, 2005). Various parameters as assumed to be significant to the process are press holding time, press descending time, press variable tonnage, and the spring force of machine. However, all these parameters will be sort out according to their level of significance through screening test at the preliminary level of this study.

There are several previous researches that have been conducted research regarding the quality of bending and cutting parts by using DOE approach. Mkaddem and Bahloul (2007) used Response Surface Methodology (RSM) to

investigate the behaviors of automotive safety parts that obtained by successive sequences of blanking and bending. The results showed that the significant parameters are die radius and clearance while the responses are bending load and damage response. On the other hand, Mkaddem and Saidane (2007) also used RSM technique in their research to investigate the springback on bending part using wiping-die bending process. The parameters recognized are stroke, clearance, die radius, anisotropy and bobbing. Using Taguchi method, Dowlatshahi (2003) studied the cycle time reduction for injection molding process for five factors considering injection pressure, injection velocity, cure time, mould temperature, material melt temperature and percentage of regrind. Because the number of factors was more than four, Taguchi method is more practical in order to reduce cost, time and number of experiment.

2. EXPERIMENTAL PROCEDURES

The powder used in this study was phosphor bronze strip (PBS), a copper alloy that has good electrical conductivity and high fatigue strength. This alloy typically contains up to 16% of tin (Sn) to strengthen the alloy and 35% phosphorous to reduce the electrical conductivity dramatically.

For this study, the PBS used is F4-C5191R-1/2H with thickness of 0.2 mm and 21 mm width. The chemical composition by weight is shown in Table 1:

Table 1: Chemical composition by weight

Chemical Composition	Weight (%)
Cu + Sn +P	99.5
Sn	5.55 – 7.0
P	0.03 – 0.35
Cu	balance

Then, the alloy was tempered to ½ H (Hardness) grade between 150 Hz to 250 Hz before undergoing machining process through Japan Automatic Machine (JAM) bending and cutting machine model HYP505H. The main specification of the machine is listed in Table 2:

Table 2: Main specification of JAM Machine Model HYP505H

Press capacity (kN)	24.5 – 49
Stroke length (mm)	*30 – 150*
Ram approaching speed (mm/sec)	350
Ram pressure speed (mm/sec)	39
Press range (MPa)	3.9 – 7.7
Shank hole diameter (mm x mm)	25 x 60
Power	3 phases AC 200V 10A
Motor (kW)	1.5

In order to evaluate the process parameters's influence, holding time, descending time and press variable tonnage were varied at three levels according to Table 3:

Table 3: Description of factors and levels

Factors	Level 1	Level 2	Level 3
A: Holding time (s)	1.35	1.40	1.45
B: Descending time (s)	0.35	0.40	0.45
C: Press variable tonnage (MPa)	5.0	5.5	6.0

3. RESULTS AND DISCUSSION

This section discusses about preliminary experimental result to evaluate these factors' affect on the cycle time. Table 4 illustrates the data obtained after 9 run of experiments:

Table 4: Data for preliminary result

Run of Experiment	Factors			Response			
	A	B	C	Cycle Time (s)			
				Sample 1	Sample 2	Sample 3	Average
1	1,35	0,35	5,0	1,86	1,89	1,85	**1,87**
2	1,35	0,40	5,5	2,04	2,09	2,05	**2,06**
3	1,35	0,45	6,0	2,28	2,26	2,23	**2,26**
4	1,40	0,35	5,5	1,81	1,84	1,83	**1,83**
5	1,40	0,40	6,0	2,05	2,04	2,03	**2,04**
6	1,40	0,45	5,0	2,26	2,24	2,25	**2,25**
7	1,45	0,35	6,0	1,88	1,85	1,86	**1,86**
8	1,45	0,40	5,0	2,06	2,09	2,10	**2,08**
9	1,45	0,45	5,5	2,15	2,17	2,18	**2,17**

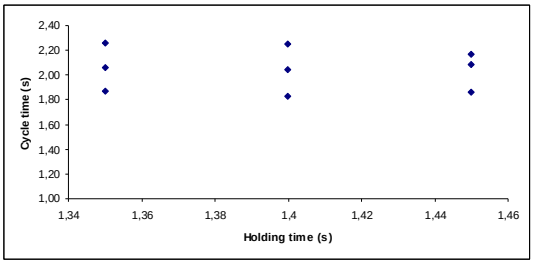

Figure 1: Cycle time as a function of holding time

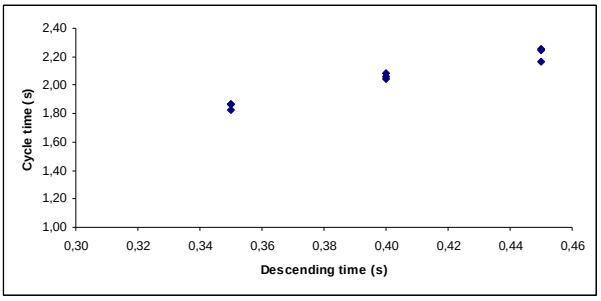

Figure 2: Cycle time as a function of descending time

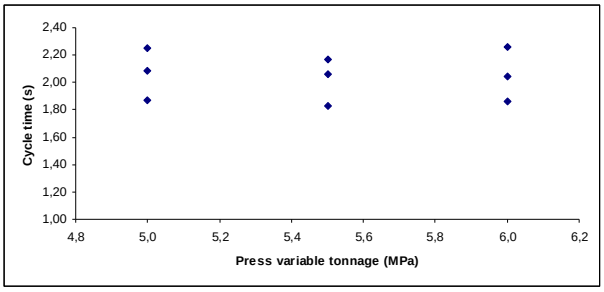

Figure 3: Cycle time as a function of press variable tonnage

Figure 1 until Figure 3 illustrate the interaction between the response function, i.e cycle time to the various factors, holding time, descending time and press variable tonnage. In general, the result shows that the holding time and press variable tonnage (Figure 1 and 3) give low impact to the cycle time, whereby the pattern data is about the same, with very low decrement or incremental. However, as shown in Figure 2, the compact's cycle time is proportional to the descending time. This has its significant because press descending time is period taken by upper die to rise up after the press holding stage that will affect the cycle time at the post processing level.

3.1 Analysis of Variance

One way analysis of variance (ANOVA) was conducted in order to see the level of significance for each factor to the response, i.e cycle time before being optimized by using Design of Experiment method. Significant level, α was obtained through F-test towards variance ratio of the factor. Critical F value is symbolized as F_{α,ϕ_1,ϕ_2} with α is significant level, ϕ_1 as factor's degree of freedom and ϕ_2 as degree of freedom for error. For example, for critical F value with significant level α of 0.01, it was written as $F_{0.01}$. It shows that it is 1% significant or ranking at 99% confidence level.

Table 5: ANOVA for holding time affect towards cycle time

Source	Degree of freedom (DF)	Sum of squares (SS)	Mean square (MS)	F value	P value
A: holding time	2	0.0013	0.0006	0.02	0.983
Error	6	0.2151	0.0359		
Total	8	0.2164			
S = 0.1754		R = 0.5%		R^2=0.0%	

Table 6: ANOVA for descending time affect towards cycle time

Source	Degree of freedom (DF)	Sum of squares (SS)	Mean square (MS)	F value	P value
B: descending time	2	0.2098	0.105	96.37	0.00
Error	6	0.00653	0.0011		
Total	8	0.2164			
S = 0.033		R =96.98%		R^2=95.97%	

Table 7: ANOVA for press variable tonnage affect towards cycle time

Source	Degree of freedom (DF)	Sum of squares (SS)	Mean square (MS)	F value	P value
C: press variable tonnage	2	0.0035	0.0017	0.05	0.953
Error	6	0.2129	0.0355		
Total	8	0.2165			
S = 0.1884		R =1.6%		R^2=0.0%	

Table 5 until Table 7 shows the ANOVA table for each factor towards the performance of cycle time. It can be concluded that, only factor B: descending time has a strong significance as the P value is less than 0.5 and has the highest F value among all, which is 96.37. The higher the F-value, the more likely the relationship is real. In addition, the R^2 value is the coefficient of multiple determinations and it measures how much the real model validates with existed model. In this case, since the R^2 value for factor B: descending time is almost full (95.97%), subsequently it strengthen the fact that only this factor (descending time) has significant factor towards the performance of cycle time in this project. While the other two factors (holding time and press variable tonnage) could be considered as unimportant factor due to their ANOVA table, as well as the similar graph's pattern for the preliminary result. These both factors should be eliminate and replace with any other factor that can be statistically significant through DOE method.

4. CONCLUSIONS

From the experiment carried out, it was concluded that, the significant factor for press bending and cutting operation was only press descending time and suitable in controlling the operation's cycle time. The results shows the holding time and press variable tonnage factors were less significant to the cycle time and should be considered for being eliminated. Thus, the objective for this preliminary study has been achieved, whereby we apply DOE in the early stage of experiment, to find out the most important variables that affect the performance measure, i.e the cycle time for the stamped part.

ACKNOWLEDGMENT

The author would like to express her token of appreciation to University of Tun Hussein Onn Malaysia for the research short term grant.

ABSTRACT

Industry environment is not just to meet customer requirement, but also to run their business effectively and efficiently in order to face the global competition. Although there are many methods have been developed, practitioner still finds difficulties when implement the methods. MIPI (Model-based and Integrated Process Improvement) by Sola Adesola and Tim Baines showed a holistic, structured and procedural guidance for improving business processes.

MIPI is developed by reviewing and analysing current methodologies and selecting a few frameworks against key performance indicators.. By using MIPI methodology, industry not only can identify non value added activities in their processes but also can align with organization vision and mision. Hence, practitioners can have structured steps which are consistent and efficient when improving business process.

Case study taken on hatchery produced Days Old Chicks (DOC) which identify business needs and problem areas using pareto chart shows that small and weak DOC is the highest rank (39%). As-Is Process Mapping also conducted to capture current business process architecture. Using Cause and Effect Diagram and Failure Mode and Effect Analysis (FMEA) organization can identify that improper heater control in hatchery machine is the main problem (Risk Priority Number : 36). Action plan created in to a matrix as road map for process improvement plan.

Key words *: MIPI, Seven Procedural Steps, Performance Indicator, Quality Improvement and FMEA*

1. INTRODUCTION

Growing and competitive industries creating high quality product or services as a compulsory requirement. While in the other side, company also requires to effectively and efficient in order to face dynamic business changes.
In order to survive in such environment, reviewing, evaluating and develop plans for improving business process performance is a must thing to do. These activities called *Business Process Improvement (BPI)*.

Business Process Improvement (BPI) can be recognizing as an organized and planned business activity improvement methodology.
Business Process Improvement is a structural approach to analyze and continuously improve company activity by focusing on waste elimination and bureaucratic.
Under big BPI umbrella there are three common strategy and activity adopted by organization: *Continuous Process Improvement (CPI), Business Process Re-Engineering (BPR)* and *Business Process Benchmarking*. Although there are many method of BPI has been developed, practitioner still found difficulties when implement the methods. MIPI *(Model-based and Integrated Process Improvement)*, a BPI method created by Sola Adesola and Tim Baines as a result from doctorate research showed a holistic, structured and procedural guidance for improving business processes.
Research conducted resulting on identifying company's criteria and target to improve its business process performance.

2. RESEARCH METHODOLOGY

Model-Based and Integrated Process Improvement (MIPI) methodology is a Business Process Improvement (BPI) methodology from a research program by Sola Adesola and Tim Baines on Cranfield University, 2005.
MIPI is a generic model of BPI consists of seven procedural steps as guidance for action and decision. MIPI methodology can be use for improvement process and engineering process initiative. This methodology describe "what" to do and "how" to make it happen. The structure for this methodology contains a hierarchical structure includes: *aim, actions, people involved, outcome/exit, checklists, hints and tips, and relevant tolls and techniques*
Model-Based and Integrated Process Improvement (MIPI) was developed from literature and discussion from practitioners. This methodology has been tested in two steps. First, a single case study was carried out which the researcher participated to nurse the newly formed BPI methodology through assessment. The second step by conducting case studies without direct involvement from researcher. Detail of BPI steps is shown in Table 1 below.

Tabel 1: BPI steps and techniques

	Step	Step Description	Techniques
1	Understand business needs	Develop vision and strategic objectives Perform competitor analysis Develop organizational model Evaluate current practices, prioritize objectives Scope change Establish measurable targets Develop process objectives and asses readiness Obtain approval and initial project resource Benchmark the process	Organization model SWOT analysis Force field analysis Readiness assessment Stakeholder analysis Process prioritization matrix Pareto analysis Process performance table
2	Understand the process	Identify the business process architecture Scope and define the process Capture and model AS IS process information Model the process	Xpat process IDEFO Walkthrough Process flowchart ABC Cause and effect analysis
3	Model and analyze the process	Verify and validate the model Measure the existing process performance Analyze the business process	Value added analysis
4	Redesign process	Benchmark the process Identify performance criteria for re-design process Identify focus of re-design activity Model and validate new TO BE process model Identify IT requirements Estimate performance of re-designed process	Benchmarking Creative silent workshop Brainstorming
5	Implement new process	Plan the implementation Obtain implementation approval Review change management plan Communicate the change Technological development Make new process operational Train staff Roll-out changes	
6	Assess new process and methodology	Conduct process deployment and performance data reflections Revise organizational approach	Action plan Evaluation measurement report Customer measurement survey
7	Review new process	Develop strategic view of the business Set process targets and performance Develop a plan to meet targets Implement	Process improvement matrix

3. RESULT

Data collection gathers by conducting interview and company documents. Data collected are:

- company vision & mission, strategy and organization structure;
- performance indicator;
- process flow;
- production capacity & location;
- product specification & quality;
- technology;
- resources & infrastructure;
- others.

Understand Business Needs

From data collection and interview with it was observed that company want to improve customer satisfaction and improving existing process performance. Process Improvement Team (PIT) consists of representative from each department also created to conduct business process improvement.

Understand the Processes

Deep understanding of business goals is very important in business process improvement program. Many efforts will be useless and program will not appropriately execute if improvement program not align with organization goals. This research continues by understanding existing processes after knowing company needs. Understanding processes is conducted by mapping existing process, method used was IDEF0 (*Integrated Computer Aided Manufacturing Definition),* one of modeling tools being use in business process improvement activity. IDEF0 format consist of diagram describing process or system. Using box connected by arrow line to show direction. Process, function or activity represent by boxes inside diagram while arrow line connected to box represent specific data such as object, information or data required or produced by a specific activity. Type of arrow line used in IDEF0:

(1) *Input*: class of arrow that express IDEF0 input. Input arrows are associated with the left side of an IDEF0 box. This arrow describe object or information which cab use as activity.
(2) *Output*: the class of arrows that express IDEF0 output, i.e.: the data or object produced by a function. Output arrows are associated with the right side of an IDEF0 box.
(3) *Control*: the class of arrows that express IDEF0 Control, i.e.: condition required to produce correct output. Data or objects modeled as controls may be transformed by the function, creating output. Control arrows are associated with the top side of an IDEF0 box.
(4) *Mechanism*: the class of arrow that express IDEF0 mechanism, i.e.: the mean used to perform a function; includes the special case of Call Arrow. Mechanism arrowa are associated with the bottom side of an IDEF0 box.

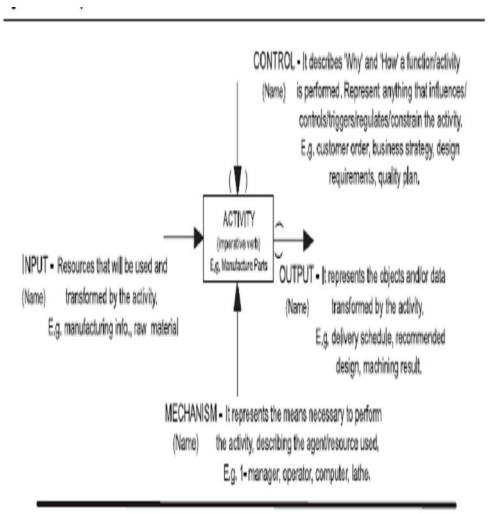

Figure 1. IDEF0 diagram

Below are IDEF0 diagrams for hatchery process PT. X:

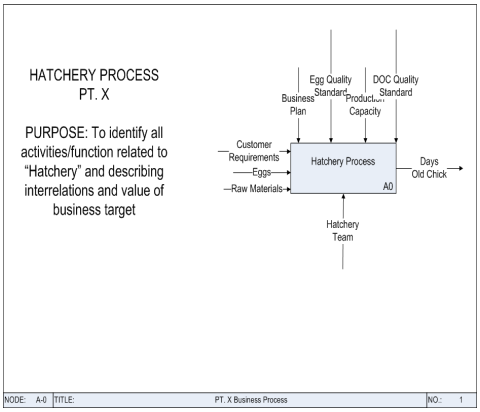

Figure 2. *Top Level Diagram* PT.X

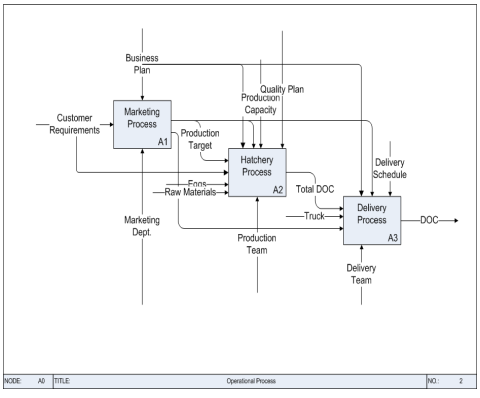

Figure 3. *Child Diagram* Operational Activity PT.X

Problem Area Identification

From brainstorming result, PIT team will focus on customer complaint. PIT team using Pareto Chart to identify the most frequent causes of customer complaint. From diagram created showed that the major problem was *small and week DOC (days of chicks).*

From Pareto Chart result, PIT team continue the research by develop a cause and effect diagram to identify root cause from small and weak DOC problem. Through discussion and brainstorming, PIT team develop probability from each nonconformance. Below is the cause and effect diagram from small and weak DOC (Figure 5). As the result from the diagram, PIT team can identify type of problems and each causes (Table 2.)

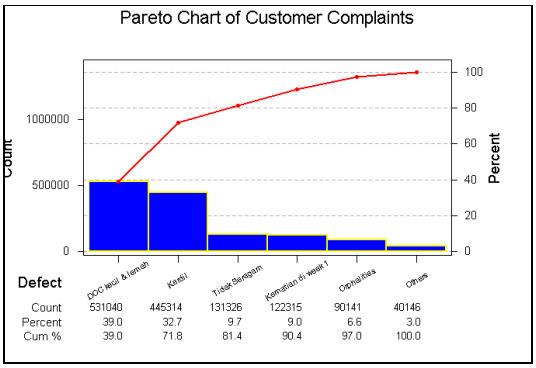

Figure 4. Pareto Chart of Customer Complaint

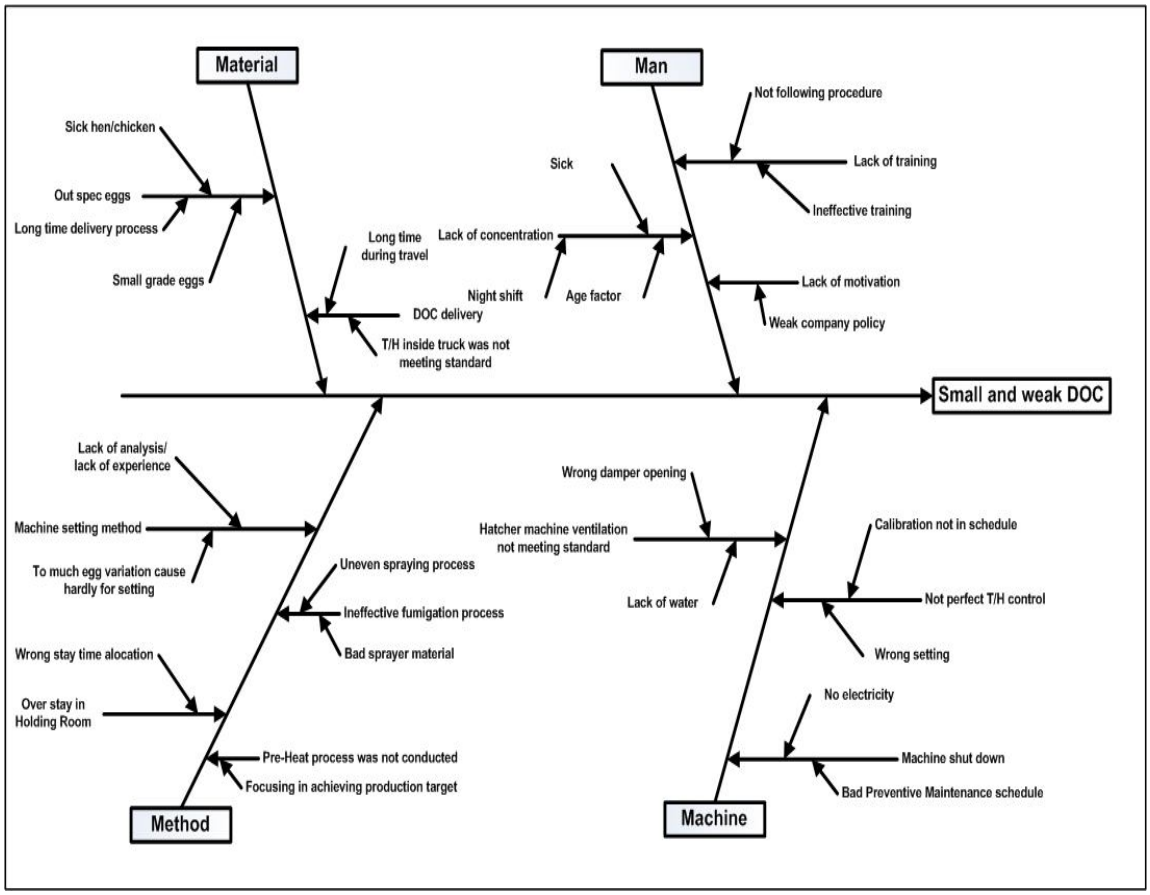

Figure 5. Cause and Effect Diagram from Small and Weak DOC

Factor		Problems	Causes
Man	1	Not following procedure	Employee doing their job as their own experience
Method	2	Pre-Heat process was not conducted	Focusing to achieve production target
	3	Over stay in Holding Room	Wrong placement
Material	4	Hen/Chicken not in god health	Lack of control of farm sanitation
	5	Over time during travel	Traffic Jam
	6	T/H inside truck was not meet standard	Limited truck with good standard T/H
	7	Small grade eggs	Limited of good quantity eggs from supplier
Machine	8	T/H control not meet standard (too cold of to hot)	Inappropriate setting, calibration not conducted as per schedule
	9	Machine shutdown	No electricity

Table 2. List of Problem Causes – Small and Week DOC

Analysis and Corrective Action Plan

During this step, FMEA or *Failure Mode and Effect Analysis* is as an improvement tool used to make prioritation of each failure mode from *Small and Weak DOC*. *Severity*, *Occurrence* and *Detection* criteria are created to identify the highest risk of failure modes and prepare the corrective action. Several failure modes with the highest risk selected as action plan.

In this research, action plans selected is detailed into matrix called *Process Improvement Matrix (PIM)*. PIM is a tool created to monitor the progress of process improvement activities. Each action plan are clearly described its progress using rating and Color Coding. Three Color Coding (Red/Yellow/Green) is use to describe its status againt deadline target.

Detail of process improvement matrix from *Small and Weak DOC* problem can be found in below table:

Process Improvement Matrix for Small and Weak DOC			Hatchery Manager	OA/OSHE Manager	Spv Preshabal	Spv Preshabal Mtenh	Spv Holding Room	Analis	Customer Care (Marketing)
Rank	Potential Failure Mode	Action Plan

4. CONCLUSIONS

From the business process improvement research using Model-Based and Integrated Process Improvement, criteria's and target shall executed by company has been identified. Several quality improvement plans created to ensure company to meet with the business needs. *"Small and Weak DOC"* was identify as the highest customer complaint and by using cause and effect diagram several causes has been identified, i.e.: *wrong setting; sick chicken; machine problem; temperature and humidity not meet with standard; over stay in holding room; pre-heat process was not conducted; long time delivery process; small grade eggs; not following procedure*. As per Risk Priority Number from FMEA, it was observed that the *"Wrong Setting"* has the highest RPN. To easily monitor the progress of action plan taken, the Process Improvement Matrix is being used.

ABSTRACT

Uncertain demand of garment products has become an obstacle in determining the amount of supply. Inventory management itself has an error perspective that the higher the uncertainty of demand, the larger the amount of supply required. There is also an error assumption in the usage of normal distribution for high uncertain demand where in it does not necessarily fit. Both of those perspectives have caused higher risk of lost.

This paper will conduct an analysis on characteristic of demands and inventory cost which might potentially influence the determination of base-stock level, but still considering maximum profit. Three types of approximations which will be utilized to determine a product's base-stock level are normal approximation, lognormal approximation, and maximal approximation.

It is found that distribution of a product's demand does not have any impact on the selection of the best approximation. The best approximation selection to be used in determining base-stock level is influenced by salvage price which is determined and stockout cost. On the other hand, level of uncertainty demand does not give any impact towards the selection of the best interpretation in condition where salvage price or stockout cost is ignored, or salvage price equal to unit cost.

Keywords

Base-stock level, Coefficient of variation, Inventory

1. INTRODUCTION

Inventory is one of the most important elements for production activity. Inventory itself sometimes depend to demand, which has different degree of uncertainty. One of industry with high degree of demand uncertainty is garment industry and this effect the level of inventory it has to keep. Inventory level can be shortage or spoilage without taking accounts the demand, and this will reduce potentials profits.

Inventory management sometimes has incorrect perception about demand and inventory level, the higher the demand uncertainty requires higher inventory level. On the other hand inventory management often used normal distribution assumption to describe demand uncertainty, which is not always true. Both perceptions create higher risk of lost for company. These are the reason this research is conducted to analyze effect of demand characteristic and inventory cost to determine level of inventory by considering maximum profit.

2. SINGLE ORDER PROBLEM

Single order problem is known with newsboy problem or Christmas tree problem. A product is a single problem product when it has demand that happened during specific time interval. Example of these products are perishable goods like newspaper and fresh product like fruits and vegetables.

Single order product has demand pattern with limited selling or usage period, because it has only has one change to order in the beginning of period. There is no second chance to order. This inventory has to fulfill customer demand for that period of time, because at the end of period the product will be not be valuable to sell anymore.

The amounts of product ordered effects company profitability. When demands overcome inventory level, this will caused loss of opportunity to gain profit. When demands below inventory level available this will cause overstock. There are three alternative for overstock products: being disposed because it parish or obsolete, sold at lower price or kept for the next season. Every alternative required cost.

3. COST MINIMATION

High coefficient of variation (cυ) become major issue for product with short lifetime. Demand assumed as non-negative random variable with mean (μ) and variance ($\sigma 2$). It is also assumed zero inventory level at the beginning of period.

Expected profit for order level $y > 0$ unit, can be calculated with equation:

$$\pi(y) = (p-c)\mu - G(y) \quad (1)$$

$$G(y) = h\,E(y-D)^{+} + b\,E(D-y)^{+} \quad (2)$$

Where:

p = product price per unit
c = buying cost per unit
s = salvage price per unit
g = ill-will cost
b = p-c+g = stockout cost
h = c-s = holding cost

The problem face by newsboy problem is how to minimized G(y) which is stock out cost (b) and holding cost (h). The condition where base–stock level do not equal product demand, G(y) has limited minimizer y*. Newsvendor problem often considered as cost minimizing problem, and analysis stopped when y* is found. Expected profit could be negative when Newsboy cost G(y*) is higher than profit.

There are three way to minimized cost (Gallego, Katircioglu, & Ramachandran, 2007) :

a. Normal approximation

Normal approximation caused y* to be linier for σ, this can be calculated using equation:

$$y^* = \mu + \sigma z_{\beta} \quad (3)$$

$$\pi(y^*) = (p-c)\mu - (h+b)\sigma\phi(z_{\beta}) \quad (4)$$

where $z\beta = \Phi^{-1}(\beta)$

b. Maximal approximation

Maximal approximation minimizes cost for worst non-negative distribution using mean and variance. Base-stock level can be calculated with equation:

$$y^* = \mu + \frac{1}{2}\sigma\left(\sqrt{\frac{b}{h}} - \sqrt{\frac{h}{b}}\right) \quad (5)$$

When $c\upsilon < \sqrt{\frac{b}{h}}$, profit is calculated using this equation:

$$\pi(y^*) = (p-c)\mu - \sigma\sqrt{hb} \quad (6)$$

When $c\upsilon > \sqrt{\frac{b}{h}}$, the result will be optimized if ordering not below maximal approximation.

c. Lognormal approximation

Random variable D which has lognormal distribution has mean parameter (v) and standard deviation (τ). When ln (D) has normal distribution it has mean parameter (μ) and standard deviation (σ>0)

Demand expectation for lognormal distribution known as $E(D^n) = \exp(n\mu + n^2\sigma^2/2)$. With parameters $v = \exp(\mu + \frac{\sigma^2}{2})$ and $\tau^2 = v^2\left(\exp(\sigma^2) - 1\right)$.

Parameters for lognormal distribution are:

$$\mu = \ln v - \ln\sqrt{1+cv^2} \quad \sigma = \sqrt{\ln(1+cv^2)}\,.$$

Base stock level for lognormal distribution can be calculated through this equation:

$$y^* = \exp(\mu + \sigma z_{\beta}) \quad (7)$$

while profit can be calculated through this equation:

$$\pi(y^*) = (p-c)v - (h+b)v\Phi(\sigma - z_{\beta}) + hv \quad (8)$$

4. RESEARCH METHOD

The research begin with data collection from fashion product case study. The data needed are product demand, purchase cost per unit, selling cost per unit, and salvage price from 8 different fashion product. These products grouped besed on its lifetime into: short lifetime (less than 1 year) and long lifetime (more then 1 year).

Product demand data is fitted to know its aproximation distribution and parameters. The goal is to find data coevicient of variation (cv), which shows level of demand uncertainty. The next steps is to calculate base-stock level and profit of the product using normal, lognormal and maximal approximation. These information used to do sensitivity analysis for cv, salvage price, and stockout cost.

Profit sensitivity analysis for cv fluctuation is done by changing mean and standard deviation consecutively. While salvage price sensitivity analysis is done by increasing it for every 10% of buying price. Stockout cost sensitivity analysis is done by changing stockout cost. Profit sensitivity analysis to salvage price changing also done by using few possibility of stockout cost and cv. Sensitivity

analysis for profit to stockout cost is done by using few possibility of cv and salvage price.

Those sensitivity analysis used to determined which is the best distribution approximation to overcome changes in cv, salvage price and stockout cost.

5. DISCUSSION

A case study in a fashion small enterprise is applied. The parameters and cost component of each item can be seen in the table 1 and table 2, respectively, as follows:

Table 1. The Distribution Parameter and CV of each Item

No	Item	The best approximation (% Purchase Price)		
		Normal	Maximal	Lognormal
1	X1	$90.03 \le s < 99.37$	$99.37 \le s \le c$	$0 \le s < 90.03$
2	X2	$96.43 \le s < 99.69$	$99.69 \le s \le c$	$0 \le s < 96.43$
3	X3	$94.55 \le s < 99.64$	$99.64 \le s \le c$	$0 \le s < 94.55$
4	X4	$96.72 \le s < 99.72$	$99.72 \le s \le c$	$0 \le s < 96.72$
5	X5	$96.06 \le s < 99.74$	$99.74 \le s \le c$	$0 \le s < 96.06$
6	X6	$96.28 \le s < 99.77$	$99.77 \le s \le c$	$0 \le s < 96.28$
7	X7	$97.79 \le s < 99.78$	$99.78 \le s \le c$	$0 \le s < 97.79$
8	X8	$96.47 \le s < 99.66$	$99.66 \le s \le c$	$0 \le s < 96.47$

Based on data above we calculate base-stock level and profit each item using three approximations. The best approximation of each item can be seen in table 3.

Table 2. Cost Component of each Item

No	Item	*Base -Stock Level* (Unit)	Profit (Rupiah)	The best approximation
1	X1	58.9	560,197	Lognormal
2	X2	14.7	537,735	Lognormal
3	X3	18.890	220,188	Lognormal
4	X4	3,972.8	1,239,270	Maximal
5	X5	2,217.1	271,316	Maximal
6	X6	1,565.1	183,680	Maximal
7	X7	1,007.3	406,308	Maximal
8	X8	980.68	360,223	Maximal

We can see demand distribution does not affect the best approximation to determine base-stock level each item. For example, X7 fits with a 3-parameter lognormal and has maximal as the best approximation. Therefore, we attempt to observe the effect of CV, salvage price and stockout cost to the best approximation.

Table 3. Base-Stock Level, Maximum Profit, and the best approximation each Item

No	Item	Distribution	Mean	Std.dev	CV
1	X1	3 parameter-Lognormal	16.1977	34.6701	2.140
2	X2	3 parameter -Lognormal	5.1301	5.5452	1.081
3	X3	3 parameter -Lognormal	4.9682	14.5770	2.934
4	X4	3 parameter -Weibull	41.5711	45.3952	1.092
5	X5	3 parameter - Lognormal	11.0291	27.9054	2.530
6	X6	3 parameter –Lognormal	8.3019	20.7582	2.500
7	X7	3 parameter -Lognormal	11.6657	10.6442	0.912
8	X8	3 parameter -Lognormal	12.0720	11.1849	0.927

Table 4. The Range of Salvage Price Related to Purchase Price

No	Item	p	c	S	b	h
1	X1	55	35	0.00	20	35
2	X2	135	105	0.00	30	105
3	X3	80	60	0.00	20	60
4	X4	145	115	114.99	30	≈ 0
5	X5	135	110	109.99	25	≈ 0
6	X6	127	105	104.99	22	≈ 0
7	X7	210	175	174.99	35	≈ 0
8	X8	125	95	94.99	30	≈ 0

Table 4 presents the maximum salvage price of each item for each approximation ; i.e., the maximum salvage price for item X1 for maximal approximation is purchase price. On the other hand, if the actual salvage price of X1 is less than it, the best approximation of base stock level is maximal. Moreover, if actual salvage price is greater than purchase price, item X1 should not be ordered.

The sensitivity analysis is also applied to several conditions of each item. It shows that if stockout is not ignored then salvage price, CV and stockout cost affects to the normal and lognormal approximation. Moreover, Lognormal approximation is the best approximation in determining base stock level when stockout cost or salvage price is ignored.The result also indicates that maximal approximation is affected by CV. These can be seen in appendix 1 and appendix 2. It is plausible since the result of maximal approximation never gives a loss.

7. CONCLUSION

Salvage price and stockout cost are key factors affect the best approximation to determine base stock level. Furthermore, a demand distribution does not affect the best approximation. Lognormal approximation is the best approximation in determining base stock level when stockout cost or salvage price is ignored. Maximal

approximation is only affected by CV. It is hoped that sensitivity analysis can assist practitioners and provides a basis for future research on allocation of fashion orders.

Abstract

Repairable system in engine operations is a complex system that has interval between failure where the failure does not follow equal distribution. Engine's condition as a repairable system has worn-out by time which the impact is on reducing the performance and increasing the cost. The impact is a critical problem especially in the operating of dump truck fleet in mining. It is difficult to estimate the time of engine overhaul because there is no guidance from the company to determine when the engine needs to be overhauled economically. Therefore, it is highly needed to design a model that is able to determine optimum overhaul time of engine dump truck.
In this design, Non Homogeneous Poisson Process (NHPP) model is used as initial estimate failure intensity method that can describe reducing of engine performance. If this model is not appropriate then the General Renewal Process (GRP) model is used. Result of choosing model combined with average maintenance and overhaul cost are used to determine optimum overhaul engine.
The following are the research results GRP model is the best model for repairable systems than NHPP model based on LKV value that is more positive.

Key words: *Repairable System, Reliability Analysis, Non Homogeneous Poisson Process, General Renewal Process, optimum overhaul.*

1. Introduction

Consumers' expectations toward product's and system's ability with their own functions are usually always high and even higher. The ability of product and system is called as reliability. While the expectation of consumers becomes higher, the chance for product to fulfill the expectation is decreasing. That fact has created a gap. For the gap to disappear, measuring and reliability boost toward the product and system are needed.

The objective of reliability can be understood through the phenomenon of estimation failure, reliability prediction, and optimization. Reliability is one of the characteristic that is important in defining the quality of product or system for manufacture and also consumer.

In running the major activity, coal mining company uses two main equipments which are loader and dump truck. Knowing how important these two equipments

are in the mining activity, it is vital to pay attention on their capability in the application. Failure on engine as a main component of a mining system can cause failure to the whole system.

System is a group of subsystem, assembling, or components that is assembled to achieve a particular function. Beside repairable system, there is also non-repairable system. That difference creates the need of different approach in analysis method in the closing stage. In this writing, analysis with stochastic process model is done because of the complexity of repairable system. Some warranty analysis on non-repairable system can use distributed analysis method which is mainly using weibull analysis. In the other hand, for repairable system, distributed analysis is not valid because it has the characteristic that makes the system cannot set off for new condition after it is fixed. Generally, the interval between failures of non-complex system is not equally distributed. When we do the cross-check on distribution, there is

ISSN 114-1284

assumption that an event is statistically independent and identically distributed (s.i.i.d.). The repairable system does not stick to that s.i.i.d. pattern.

After being fixed, commonly system can operate just like the original condition without having any improvement (as bad as old). That can occur in a complex system where replacement of a component does not give significant change in the reliability system. If we use the distributed analysis method, then we do not have to determine when the system needs to be overhauled. Distributed analysis is not the methodology to analyze repairable system because time between failures does not stick to the s.i.i.d (statistically independent and identically distributed). Therefore, we have to choose the analysis using stochastic process model like Homogeneous Poisson process (HPP), Non Homogeneous Poisson Process (NHPP), or General Renewal Process (GRP).

Engine condition as repairable system will be having worn-out through the time and it will cause performance declining and increasing cost. This is a serious problem, especially in designating the time of engine overhaul in PAMA on operating dump trucks. Considering the difficulty in estimating the time of engine overhaul that is caused by the unavailability of guideline from the company about determining when an engine needs to be overhauled economically, then it is necessary to design a model that can determine the optimum overhaul time of engine dump truck.

2. Methods

One of the considerations in decreasing the cost of maintenance for repairable system is by designing the overhaul policy that can decrease the total cost of system. However, the overhaul policy can be implemented only if $\beta > 1$. If $\beta < 1$, then there is no need to apply the overhaul policy because that condition is a sign of no wear out phase. If there is an assumption that there is lower value for system overhaul than continuing the repair, then we should know the time of overhaul that can reduce the total cost by considering the repair cost and the cost of overhaul.

In the calculation of optimum overhaul point, there are some input data such as C1, C2, C3, λ, and β. Parameter λ and β can be determined by using reliability model. Reliability model that is used in this research is stochastic point process model. This model is chosen because the system that is investigated is repairable system. In this repairable system, record of failures does not tag along the pattern of s.i.i.d. (statistically independent and identically distributed). This matches the assumption in stochastic point process model which does not go along the s.i.i.d. pattern. Non homogeneous Poisson process with Power Law model is used as the method in creating the hypothesis of failure intensity that can illustrate the reduction in engine performance. If that model is not suitable, then GRP model is used to illustrate the engine performance reduction. The result of the model combined with the maintenance cost will be used to determine the optimum time to overhaul engine.

In the calculation of optimum overhaul point, there are some input data such as C1, C2, C3, λ, and β. C1 is the average repair cost (unscheduled), C2 is overhaul cost, and C3 is average scheduled maintenance cost. Scheduled maintenance is done in certain period of time with S as time interval that has been determined. In addition, N1 is the amount of failure in [0,t] and N2 is the amount of changing in [0,t]. If $\beta > 1$, then average lowest cost when machine is overhauled happen when instantaneous maintenance cost is equal to the average system cost.

The formula of optimum overhaul point can be explained throughout these following sequences:
Total of system cost when overhaul or replacement is:

$$TSC(T) = C_1 E(N(T)) - C_1 - C_3 \frac{T}{S} \quad (1)$$

Therefore, the average cost becomes:

$$C(T) = \frac{C_1 E(N(T)) + C_2 + C_3 \frac{T}{S}}{T} \quad (2)$$

Instantaneous maintenance cost at T as time is:

$$IMC(T) = C_1 \lambda \beta T^{\beta-1} + \frac{C_3}{S} \quad (3)$$

According to the equations above, the optimum time to overhaul (T0) is:

$$C_1 \lambda \beta T_0^{\beta-1} + \frac{C_3}{S} = \frac{C_1 E(N(T)) + C_2 + C_3 \frac{T}{S}}{T} = \frac{C_1 \lambda T_0^{\beta} + C_2 + C_3 \frac{T_0}{S}}{T_0} \quad (4)$$

Then, the equation becomes:

$$T_0 = \left[\frac{C_2}{\lambda(\beta - 1) C_1} \right]^{1/\beta} \quad (5)$$

Based on the formula processing above, scheduled maintenance cost does not affect the equation of optimum time to overhaul (T0). Therefore, in this research, the data that is used as model is unscheduled maintenance data.

Data calculation based on failure truncated means that a data can be called as the last data if it is the time of last failure, not the time that is last examined. In doing this model, we use two softwares which are RGA 6 for Power Law model and Weibull++ 7 for GRP model.
In this case, the data that is tested is repairable at fielded systems and the model that is available in RGA 6 is Power

Law model, therefore the test is done using cramér-von mises method.

After doing statistical test with cramér-von mises method, it appears that not all system is suitable with Power Law model. For that reason, another model that can explain system reliability is needed. Based on the literature, the research is continued using GRP model that is built with Power Law model. The difference of these two models is on the level of restoration factor (RF). In Power Law model, the value of RF is 0 which means that repair does not cause change in system and only bring the system back to the original operation condition which is ordinary or we can also say that the condition is as bad as old. In the other hand, GRP model the value of restoration factor is 0<RF<1 which means that restoration makes the condition of system is between as good as new and as bad as old.

In the formulating of this model, we can see the general outline of how input and output of the research just like the diagram below

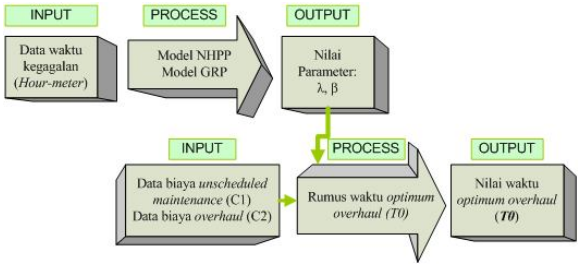

Figure 1. IPO (Input-Process-Output) Diagram

WO data processing generates parameter C1 as unscheduled maintenance and C2 as overhaul cost. The formulating of model generates parameter λ and β. The result of the formulation added with the result of WO data processing will become the input for the T0 formula just like in equation (5).

3. Results and Discussion

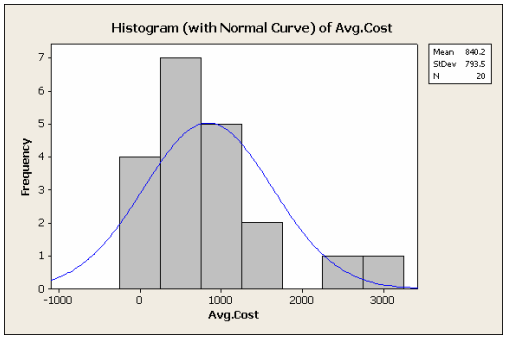

Figure 2. Average Maintenance Cost
(Source: Minitab)

Data of descriptive statistic shows that sample has average cost $ 840.2227258 with standard deviation of $ 793. Minimum cost is $ 39 and maximum cost is $ 3228, so data has range of 3189. Skewness value is 1.87 which means that the gradient is positive and most likely to the right. The gradient indicates that most of average maintenance cost is distributed on right area which means that the cost is relatively high.

3.1. NHPP Power Law Model

This assumption is used in the initial of the process because this model is already used commonly. Beside that, if there is any restoration on certain component in a system, usually the restoration does not change the system into something new, but only restore the operation condition to the original condition. In this model, the level of restoration factor (RF) is equal to 0, or the value of q in the model is equal to 1 where there is relation of RF = 1-q.

The objective in this model is to get the parameter β, λ, and LKV value. There is no LKV value in the result of RGA 6, so we still have to process it again using Weibull++7 with GRP 2-parameter model where the value of q is entered 1. Thus, NHPP Power Law in RGA 6 has similarity with the GRP 2-parameter model in Weibull++7.

From the figure below, can be seen how the pattern of time between failures is, whether it is packed or not at certain time. If each system has its own pattern, the failure that happens is independent and not statistically identical. Furthermore, this system does not tag along the pattern of s.i.i.d (statistically independent and identically distributed). For that reason, the assumption of using certain distribution is not suitable to analyze the repaired system.

From the table above, can be concluded that the value of T0 is inversely proportional with the value of β and cost (C1), and it is also indirectly connected with the amount of failure. The higher β and λ value, then there will be higher intensity value [u(t)]. The increasing failure intensity is causing faster speed sign of engine system in having failure and lower time between failures. Therefore, by knowing the existence of this intensity function, we can take the wise policy in implementing when the engine should be overhauled economically. According to the table above, instead of optimum time to overhaul (T0), there is only an information said "#NUM!" which means that the system is still in growth phase (baby mortality) because $\beta < 1$ so there is no importance to calculate T0 while the system is not in wear out phase yet.

Next, statistical test with cramér-von mises is done for model's suitability test. Go with the preliminary assumption which says that we are using Power Law model, then the most suitable test in this case is cramér-von mises.

There is null hypothesis to test if the data is suitable with Power Law model. The assumption of the null hypothesis is:

H0: Power Law is accepted

H1: Power Law is not accepted

The result of statistical test by cramér-von mises has two possibilities which are failed or passed. If the result is passed, then we accept H0 which means that Power Law model is suitable with the data in this case. Then, if the result is failed, it means the other way. According to the experiment, 13 out of 20 dump trucks are passed.

3.2. GRP I Model

If we assume that partially reparation will renew the system and it is not an as-bad-as-old condition after reparation, then Power Law model does not become the most suitable model in order to analyze the system.

Therefore, we can use General Renewal Process (GRP) Model instead. Kijima developed the imperfect repair (GRP) model by using the thinking of real aging process on repairable system. In Kijima I (GRP I) model, can be said that n repair can only vanish the coming damage only while in period between (n-1) and n failure. This data processing is done by using Parametric Reliability Growth Analysis (Parametric RGA) with GRP model that is built based on Power Law function.

Deviation of T0 value with standard overhaul time is not as big as the previous model. The three who have highest T0 value in the previous model are now having no T0 in this model because they all have $\beta < 1$. Biggest deviation is suffered by DT 3073 with T0 = $ 140,382 supported with β = 1.2727 which is the lowest β value compared with the system that has $\beta > 1$. In GRP I model, average β value is 1.603443 and average optimum time to overhaul (T0) is 53,599.97.

3.3. GRP II Model

In Kijima I model, it is said that n repair can only vanish the coming damage only while in period between (n-1) and n failure. In fact, on practice, n repair does not only depend on (n-1) repair, but also can depend on all of the repairs before. We assume that reparation can vanish all damage accumulation on n failure. That statement is developed become Kijima II or GRP II model.

Conceptually, this model is not significantly different with

GRP I model where the q, which is degree of n repair, has the value of $0 \leq q \leq 1$. In GRP II model, the analysis that is used is also using Maximum Likelihood Estimate (MLE).

Biggest deviation is suffered by DT 3085 with T0 = $ 126,261 supported with $\beta = 1.2265$ which is the lowest β value compared with the system that has $\beta > 1$. In GRP II model, average β value is 1.625463 and average optimum time to overhaul (T0) is 40,798.89.

Table 3. Result of GRP II Model

3.4. The Chosen Model

To decide which model is the best, then we need a standard of comparison indicator from all models. LKV value is the indicator to show how good a model is to suit our data. The more positive the LKV, the better that model is. This value is used in comparing some best models.

The LKV is only available in Weibull ++7, for that reason, we use the Parametric Reliability Growth Analysis with parameter-2. This parameter-2 indicates the output of a model is only two which are β and λ value. And for the parameter (1-RF), it is already set in the start point by filling the q value according to our assumption. Model with parameter-2 is arranged with q = 1 so we get the LKV for NHPP Power Law model. By setting the q = 1, it means that we have assumed an as-bad-as-old condition to the system. All of the GRP value parameter-2 with q = 1 has β and λ value that equal to the Power Law model from RGA 6.

On table below, the average $\beta > 1$, which is 1.6510253, so generally, the system is having deterioration and analysis of optimum time to overhaul is needed to be done to be able to reduce the cost. B value is around $0.5318284 \leq \beta \leq 3.0831163$ and λ value is around $2.18E\text{-}12 \leq \lambda \leq 0.0717$. From data, there are 7 dump trucks that is still in growth phase (baby mortality) with $\beta < 1$. For that reason, we do not have to do the analysis of optimum time to overhaul. From the chosen model, there are 4 kinds of dump truck that has q equal to 1; it means that on the system the all three models are already suitable. Based on the experiment, the model that is the most chosen is GRP model.

Table 4. Parameter of The Chosen Model

CHOICE MODEL				
Choice Model	LKV	Beta	Lambda	q
GRP II	-103.62	1.7632	8.45E-07	0.8657

GRP I	-130.36	2.4579	1.06E-09	0.6264
GRP II	-72.289	2.0753	8.61E-07	0.8179

4. Conclusions

Power Law model that is used as reliability model for the system of engine dump truck HD 785-5 at mining operation in PAMA is not suitable for all system that is examined. That based on the test result using cramér-von mises (CVM) which shows that not all are success, in detail, from 20 dump trucks that is examined, 7 dump trucks turn out to be failed.

Because of the test toward NHPP model of two available models is not suitable for all dump trucks, so the alternative model will be more suitable. That means that the suitable model is GRP. Furthermore, GRP model is the best for repairable system based on the most positive value of LKV

Calculation of GRP model generates the value of parameter β and λ. β value is around $0.5318284 \leq \beta \leq 3.0831163$, while λ value is around $2.18E\text{-}12 \leq \lambda \leq 0.0717$. By having average β value > 1, which is 1.6510253, means that, generally, the system is enduring the wear out phase.

Entirely, the value of optimum time to overhaul (T0) for each dump truck is:

1. DT 3049 = 56720 hmr
2. DT 3057 = 22181 hmr
3. DT 3058 = 50164 hmr
4. DT 3073 = 33719 hmr
5. DT 3075 = 12110 hmr
6. DT 3076 = 27397 hmr
7. DT 3083 = 25584 hmr
8. DT 3084 = 74703 hmr
9. DT 3085 = 38502 hmr
10. DT 3087 = 17123 hmr
11. DT 3099 = 9070 hmr
12. DT 786 = 28168 hmr
13. DT 787 = 11152 hmr

Therefore, the average for engine to be overhauled economically is 31,277 hour meter. In the other hand, 7 other dump trucks, the value of T0 cannot be calculated yet because it only has $\beta < 1$.

Abstract

Due to increasing of technology development, telecommunication corporate must provide more efficient data services on higher traffic data, and also introduce new services. GPRS can be a solution to achieve that things. Now application of GPRS technology is more developing and give a lot of advantages for user. That's why corporate telecommunication use GPRS to increase their value added services. But, there is potential failure risk on GPRS equipment, so risk analysis need to be done. Objectives of risk analysis in this research are to get idea of risk treatment action on GPRS equipment and scenario of treatment cost allocation. By using FMEA method, be able to have critical risk which will be further analysed using FTA to have basic event from those critical risk. And also by using OptQuest-Crystal Ball simulation can have optimal treatment cost allocation.

Keywords *: GPRS, risk analysis, FMEA, FTA, OptQuest-Crystal Ball simulation.*

1. Introduction

GPRS is a technology that can be used by GSM operators for providing data services on higher traffic data with low price to attrack market. For GSM operators, GPRS is a key to compete in market development especially in internet services. Rapid development in mobile communication motivate GSM operators for increasing kind of services to get higher revenue and create customer's loyalty. GPRS can be a solution to achieve more efficient data services on higher traffic data and also introduce new services. The point is, GPRS can create relation phase faster, still connect permanently, use faster data speed, dan only pay every transferred bit. The reason is clear, market tendency is away from technology that increase price.

Now, GPRS is also a corporate solution. GPRS can give solution for banking corporate in cost efficiency. Banking corporate can get more efficient bandwith lease by using GPRS for providing link service in ATM machine. GPRS can also make *Electronic Data Capture* (EDC) more flexible to use. EDC technology usually use in hypermarket and taxi company.

GPRS also use in Blackberry application. Blackberry can really support businessman in doing their job. So, by using GPRS corporate can have a lot of benefit.

GSM operators that use GPRS for increasing value added services must give attention to GPRS equipment. Maintenance of GPRS equipment is a must to have good performance. So, every potential failure can be avoided or eliminated and company goals can be achieved. The principle is to get customer loyalty and also have more customer because of excellent service.

For achieving excellent services, maintenance division must determine *Key Performance Indicator* (KPI). In this research, company determine 2 point of KPI, which is Attach Success Rate and PDP Context Success Rate. Attach Success Rate refer to success of having signal and PDP Context Success Rate refer to success of internet connection. The common problem is signaling and connection failure. Company can have loss revenue and give unsatisfaction to their customer because of those problem. Beside 2 factors of KPI, company also give attention in Attack Security because Attack Security can make fraud in GPRS system.

Every problem either ever happen or not is a potential risk. That's why, risk analysis is need to be done for identifying, measuring, and then making response

strategy. Risk management is a process to identify, assess risk, and then develop strategy to manage risks. By those background, I make this research which have title 'Failure Risk Analysis on Core Network of GPRS Equipment using FMEA & FTA method and Scenario of Treatment Cost Allocation'.

2. Methods

This research only review risks in operational and maintenance activity of GPRS equipment. Expert team that involve in this research are Network Service O&M Center General Manager, VAS Celullar Team Leader, and VAS Cellular Engineer which have more than 5 years experience.

Research method refer to standardization of FMEA step.

- Risk event identification
  To identify risk, previously we need to collect data. Data collection is done by collecting historical data of GPRS system failure, searching literature data, and then making *Cause Failure Mode Effect* (CFME) diagram, so risks can be identified and listed.
- Determine occurrence, severity, and detection rating
  Determination of occurrence, severity, and detection rating is done by expert brainstorming which is supported by literature data.
- Assess occurrence, severity, and detection of every risks
  Assessment of occurrence, severity, and detection is done by filling quesioner
- Calculate *Risk Priority Number* (RPN) and determine critical risks
  This step is done by calculating questioner result
- Analyze risks and develop risk response planning
  Fault Tree Analysis (FTA) is a tool that is used in this step. By FTA, can get root cause of critical risk so we can have idea of treatment action. Based on treatment cost that is need to do those treatment actions, so in this research also create scenario of treatment cost allocation for having optimal value by using OptQuest-Crystal Ball simulation. To run the simulation, it is need loss revenue data and treatment cost data which are get from historical data, expert judgment, and data analysis.

3. Result and Discussion

3.1 Risk Identification

Risk identification is the important step in risk management before doing next step. Risk identification involve risk determination which may be influence performance of GPRS equipment. The goal of this step is to know risk earlier so we can decrease or eliminate the impact.

After knowing every failure and potential failure which are get from expert brainstorming, historical problem, and literature, then Cause Failure Mode Effect (CFME) diagram is made. The result of CFME can make FMEA easier in identification, failure mode, and root cause. CFME diagram can be seen in picture 1.

3.2 Determination of Occurrence, Severity, and Detection Rating

In FMEA step, after having risk item, the next step is detemination of occurrence, severity, and detection rating. That determination will effect of having risk priority.

Rating determination is done by expert brainstorming in accordance with company condition. Occurrence rating is a quantification from level risk probability. The used scale is 1 - 5, which is value 1 refer to low probability and value 5 refer to high probability, that rating can be seen at table 1.

Severity rating is a quantification from level of impact from the risk. The used scale is 1 – 5, which is value 1 refer to no effect from risk and value 5 refer to fully system failure as impact from risk. That rating can be seen at table 2.

Detection rating is a quantification from level of risk detection. Detection fucntion is for knowing whether risk can be detected before the failure is happen and also knowing whether current detection is effective enough. The used scale is 1 -5, which is higher value showing that level of control getting lower of quality/effectiveness. That rating can be seen at table 3.

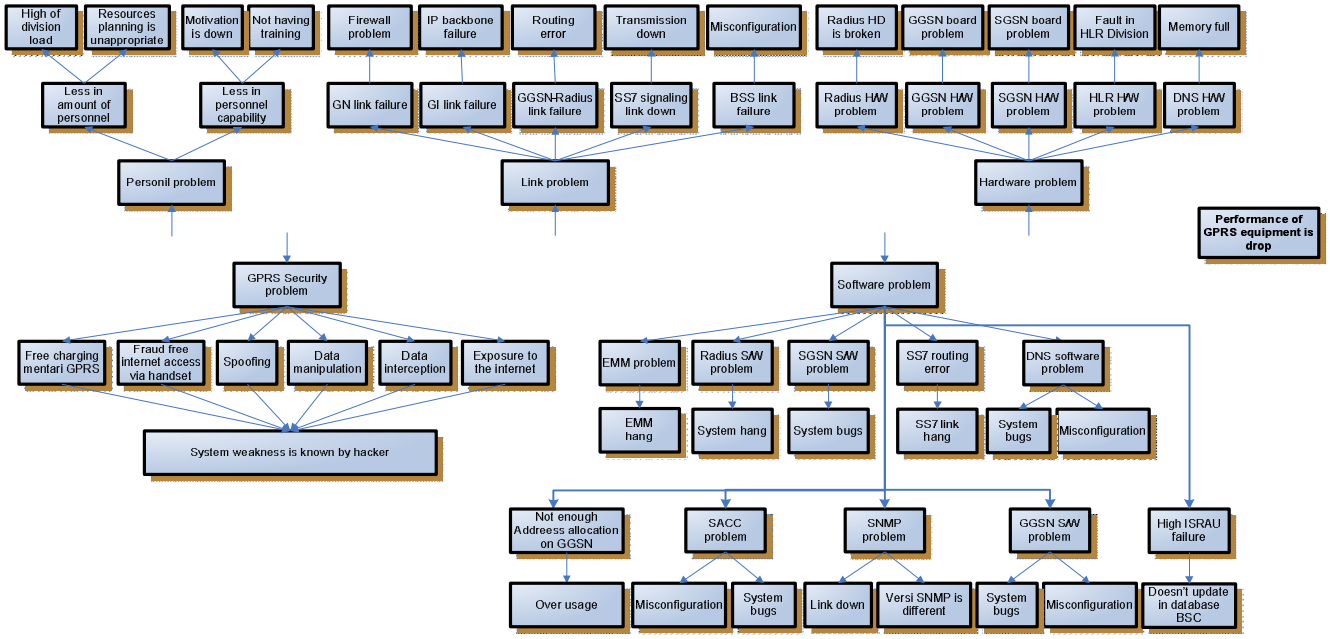

Figure 1: ***Cause Failure Mode Effect Analysis*** **(CFME) Diagram**

Table 1 Occurence Rating

Scale	Risk Probability	Note
5	Very high : can not be avoid	Risk probability per year : 81 - 100
4	High : repetitive	Risk probability per year : 61 - 80
3	Moderate	Risk probability per year : 41 - 60
2	Low : seldom	Risk probability per year : 21 - 40
1	Very low	Risk probability per year : 0 - 20

Table 2 Severity Rating

Scale	Risk Impact	Note
5	Emergency	Fully system failure, it cause loss of charging data
4	Critical	System error, the risk give impact to revenue management system
3	Major	The risk give impact only on certain work area not on entire system
2	Minor	Have minor effect to product function, but not give impact to service and data traffic
1	Warning	Does not give impact neither to service nor system

Table 3 Detection Rating

Scale	Risk Detection	Note
5	Very low	Detection method / alert system is not available
4	Low	Current detection method is not effective enough to detect the risk on time
3	Moderate	Current detection method is less effective, so it needs more time to detect the risk
2	High	Current detection method is effective enough to detect the risk
1	Very high	Current detection method is very effective to detect the risk real time

3.3 Assessment of Occurrence, Severity, Detection for Every Risk and Calcution of Risk Priority Number (RPN)

After risk is identified, the next step is determination of occurrence, severity, and detection value for every risk. This step is done by filling quesioner through expert brainstorming. The value of occurrence, severity, and detection for every risk can be seen at table 5.

Calculation of RPN is important point in FMEA because from that we can have risk priority for further analyze. RPN can be calculate by this formula :

RPN = *Occurrence * Severity * Detection* (1)

Table 4 Occurrence, Severity, Detection and RPN Value for Every Risks

Risk ID	Risk on Core Network of GPRS Equipment	*O*	*S*	*D*	RPN
1	SGSN Hardware Problem	1	4	3	12
2	HLR Hardware Problem	1	4	3	12
3	SGSN Software Problem	1	3	3	9
4	SS7 signaling link down	3	4	3	36
5	BSS link failure	3	3	3	27
6	SS7 routing error	3	3	4	36
7	GGSN Hardware Problem	1	4	4	16
8	Radius hardware problem	1	4	5	20
9	GGSN Software problem	3	4	4	48
10	Radius sofware problem	2	4	5	40
11	GGSN-radius link failure	4	5	5	100
12	High ISRAU failure	2	3	4	24
13	Not enough address allocation on GGSN	2	3	3	18
14	EMM problem	5	5	5	125
15	SACC problem	1	4	5	20
16	DNS hardware problem	2	4	3	24
17	DNS software problem	4	4	5	80
18	GN link failure	1	4	4	16
19	GI link problem	4	4	4	64
20	Free charging mentari GPRS	1	5	5	25
21	Fraud free internet access via handset	1	5	5	25
22	Spoofing	1	5	5	25
23	Data manipulation	1	5	5	25
24	Data interception/unauthorized access to confidential data	1	5	5	25
25	Exposure to the internet	1	5	5	25
26	SNMP problem	2	1	2	4
27	Jumlah personil kurang	2	3	5	30
28	Kapabilitas personil kurang	2	3	5	30

After having RPN value for every risk, the next step is determine the critical risks. That critical risks will be further analyzed as first step of treatment action for having good performance of GPRS equipment. Risk is categorized as critical risk if having RPN value higher than critical value. RPN critical value is determined from average of RPN value from entire risks.

$$Nilai\ Kritis\ RPN = \frac{Total\ RPN}{Jumlah\ Risiko} = \frac{986}{31} = 31{,}81$$

According to RPN critical value and based on expert agreement, there are 8 critical risks, which those risks have RPN value more than 31,81. Those critical risks are:

- EMM Problem, RPN = 125
- GGSN-Radius Link Failure, RPN = 100
- DNS Software Problem, RPN = 80
- GI Link Problem, RPN = 64
- GGSN Software Problem, RPN = 48
- Radius Software Problem, RPN = 40
- SS7 Signaling Link Down, RPN = 36
- SS7 Routing Error, RPN = 36

3.4 Risk Analysis

Risk analysis is started by making fishbone diagram. Fishbone diagram is a tool for seeking root cause which is classified in 5M & 1E (Man/Personnel, Method, Machine, Material, Measurement, and Environment). Based on quesioner result, there are 3 classification, method, personnel, and equipment. Fishbone diagram is further developed by making Fault Tree Analysis (FTA). The result of FTA is having basic event of top event (critical risk).

FTA is a graphical model which is consist of many fault combination parallel and sequence that may cause failure event as top event. In this research, critical risk is determined as top event. Finally, we can get basic event which is root cause of top event, so the right action can be made for handling critical risk. After knowing the right treatment actions, then will appear treatment cost of those actions. Here is example of fault tree analysis for EMM problem.

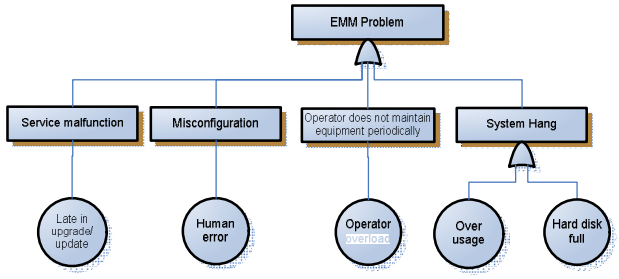

Figure 2: FTA of EMM Problem

After making FTA, then determine Cut Set from that FTA for knowing basic event of critical risk.

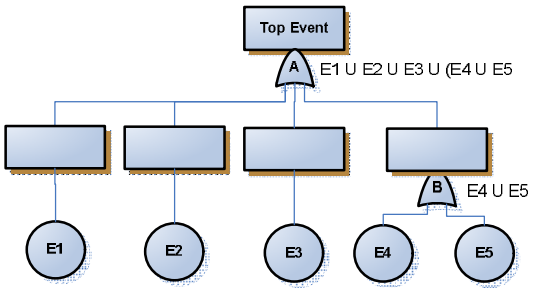

Figure 3: CutSet of EMM Problem

Cut set of this fault tree: E1 U E2 U E3 U (E4 U E5). It means if event 1 or 2 or 3 or 4 or 5 is happen will cause the top event.

- Top Event : EMM Problem
- Basic event 1 : Late on update/upgrade software
- Basic event 2 : Human error
- Basic event 3 : Operator overload
- Basic event 4 : Over usage
- Basic event 5 : Harddisk full

After knowing basic event of every critical risks, then appear treatment action. Treatment action is done by risk mitigation in 2 ways which are mitigate the risk probability and mitigate the impact from risk. Risk impact mitigation is done by doing remedy action. Remedy action is first action from operator when risk is happen. For having effective remedy action, based on data analysis and evaluation the suggestion are :

- Make automatic monitoring system for every equipment in GPRS infrastructure
- Make standardization of problem solving action
- Manage historical problem

If operator still can not solve the problem then it is escalated to the vendor (Risk Transfer).

To mitigate the risk probability, based on the result of FTA, the suggestion for entire critical risks are :

- Provide more operator for handling operator overload problem
- Give training for every person in charge in current problem
- Upgrade harddisk
- Ask vendor commitment not to late for upgrading equipment information
- Doing periodic maintenance for hardware and changing broken part immediately
- Coordinate with other division about IP routing, transmission, hardware HLR, and router internet gateway problem

3.5 Optimization of Treatment Cost Allocation using OptQuest Simulation

OptQuest is one of function in Crystal Ball. OptQuest can be used for determine cost allocation which give optimal benefit. There are many terms in OptQuest :

- *Risk cost/loss revenue* : appearance of cost / loss revenue when risk is happen.
- *Risk coverage* : risk cost / loss revenue that can be covered with given treatment cost allocation.
- *Decision* : variable for knowing how much fund allocation for any risk, the value is 1 if the risk is given fund allocation.
- *Advantage*: (risk coverage – treatment cost)*decision

For run the simulation, it needs data of loss revenue and treatment cost. For getting loss revenue, critical risks is classified in 3 groups. EMM problem refer to loss revenue historical data which is captured on GGSN equipment-duration based; DNS software problem, GI link failure, GGSN software problem, dan radius software problem refer to loss revenue historical data which is captured on GGSN equipment-volume based; SS7 signaling link down and SS7 routing error based on expert judgment. According to data collection, here are data of loss revenue for every critical risks.

- EMM problem (normal distribution) :
  - Mean : Rp 214.870.286
  - Standard deviation : 43856839
- DNS software problem, GI link failure, GGSN software problem, and radius software problem (normal distribution) :
  - Mean : Rp 345.108.000
  - Standard deviation : 87460770
- SS7 signaling link down and SS7 routing error (uniform distribution) :
  - Maximum : Rp 360.000.000
  - Minimum : Rp 12.000.000

Treatment cost is got from cost of treatment action which is resulted from FTA. Total treatment cost for entire critical risks is Rp505.000.000, and the detail are :

- EMM Problem : Rp 130.000.000
- DNS Software Problem : Rp 20.000.000
- GI Link Failure : Rp 20.000.000
- GGSN Software Problem : Rp 130.000.000
- Radius Software Problem : Rp 55.000.000
- SS7 Routing Error : Rp 50.000.000
- SS7 Signaling Link Down : Rp 100.000.000
- GGSN-Radius Link Failure :
  Fund allocation for GGSN-Radius link failure does not run in this simulation because that problem is connected with GGSN software problem and radius software problem are handled, which if those problems are handled then automatically GGSN-Radius link failure will solve.

Before running the simulation, it is need to determine assumption, decision, and forecast variable. Assumption variable is uncertainty values which have

certain distribution. In this model, risk cost/loss revenue is as assumption variable. Decision variable is fund allocation that is given for treat risk. And forecast variable is a cell that contain formula which is connected with assumption cell and decision cell, that is value of total advantage that is want to maximized.

Constraint in this simulation is treatment cost allocation ≤ budget. It is assumed that company provide 4 conditions of budgeting, which are ≤ 25%, ≤ 50%, ≤ 75%, and 100% from total treatment cost.

The next step is running the OptQuest simulation. Simulation is done for every condition. Every simulation is fun for 1000 trial. The simulation gives different result for every condition.

Table 7 The Result of Treatment Cost Allocation using OptQuest Simulation

Critical Risk	Condition of Budget Availability			
	≤ 25% from total treatment cost	≤ 50% from total treatment cost	≤ 75% from total treatment cost	100% from total treatment cost
EMM problem	Rp 0	Rp 0	Rp 4.704.900	Rp 130.000.000
DNS software problem	Rp 20.000.000	Rp 20.000.000	Rp 20.000.000	Rp 20.000.000
GI link problem	Rp 20.000.000	Rp 20.000.000	Rp 20.000.000	Rp 20.000.000
GGSN software problem	Rp 0	Rp 107.580.000	Rp 130.000.000	Rp 130.000.000
Radius software problem	Rp 53.657.000	Rp 55.000.000	Rp 55.000.000	Rp 55.000.000
SS7 signaling link down	Rp.0	Rp 0	Rp 99.481.000	Rp 100.000.000
SS7 routing error	Rp 32.593.000	Rp 49.727.000	Rp 50.000.000	Rp 50.000.000
	Rp126,250,000	**Rp252,307,000**	**Rp378,749,900**	**Rp505,000,000**

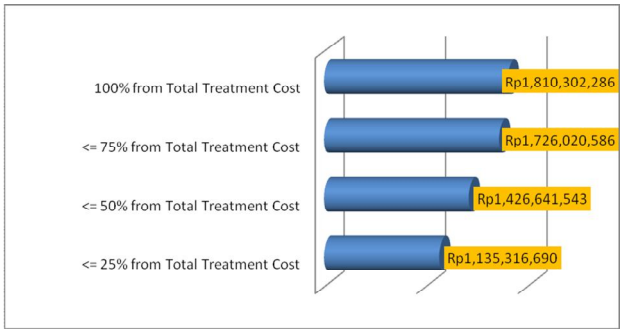

Figure 4: Total Advantage on Every Condition of Budget Availibility

Based on simulation result, it is shown that in higher fund allocation will give higher total advantage, it can be seen at picture 4.

Here are the result of cost allocation for every condition using OptQuest simulation.

- In condition ≤ 25% from total treatment cost, GI link problem and DNS software problem have full fund. Maximum total advantage is Rp. 1.135.316.690.
- In condition ≤ 50% from total treatment cost, GI link problem, DNS software problem, and radius software problem have full fund. Maximum total advantage is Rp. 1.426.641.543.
- In condition ≤ 75% from total treatment cost, GI link problem, DNS software problem, GGSN software problem, radius software problem, and SS7 routing error have full fund. Maximum total advantage is Rp. 1.726.020.586.
- In condition 100% from total treatment cost, entire critical risks have full fund. Total advantage is Rp. 1.810.302.286.

4. Conclusion

- There are 8 critical risks from 28 identified risks. The critical risks are EMM problem, GGSN-Radius link problem, DNS software problem, GI link problem, GGSN software problem, Radius software problem, SS7 signaling link down, and SS7 routing error.
- Every critical risk will have different treatment action. Treament action is done by 2 methods, which are risk mitigation and risk transfer.
- The result of cost allocation using OptQuest simulation can be seen in analysis data. Higher cost allocation that is given to treat critical risks it will give higher maximum total advantage.

E-mail : Yudha.satya@sheraton.com

ABSTRACT

In a competing market environment, improvement has been critical for company to survive. Six Sigma has been developed into a practical management system for continuous business improvement. Many company both manufacturing and services; have reported on their successive work with Six Sigma programs. In 2001, Starwood became the first hospitality company to embrace Six Sigma and began to develop a knowledge management system. Six Sigma e-Tools Knowledge Management System (SSeKMS) was initiated as an integrated systematic approach in managing all of information assets, including database, documents, as well as expertise and experience for improvement initiatives (Six Sigma Project) held by 1,081 hotel chains world wide. SSeKMS provides step-by-step templates and information about six sigma. SSeKMS enables each hotel property to identify improvement opportunities, develops innovative customer focused solutions, track the bottom-line result and transfer those innovations rapidly. This paper aims to give an overview of knowledge Management System implementation which supports the successive of Six Sigma adoption in hospitality industry

Keywords
Six Sigma, Knowledge Management, Hospitality, improvement

1. INTRODUCTION

In recent days the consumers is no longer in the passive market where goods or services are offered at the exact face value. Today consumers are more educated, and they demand more. The developments of recent technology have support them in providing information about market and its competition. This has initiated new and radical changes in the business world. Manufacturer or service provider has to fully respond to customer expectation and deal with societal, cultural, and technical challenges.

Many organizations see process improvement can help improve organizational process effectiveness, they see process improvement as the generic medicine that will solve all internal and external problems, improve the bottom line and win the competition.

However, many organizations still do not understand how process improvement can help them. They know process improvement is good, they learn tools and methodology and try to implement it, but the result is not essential for their company. The reason many organizations do not achieve sustainable progress is not result of lack of hard work or dedication. On the contrary most of the people involved with improvement activities have put in countless hours and effort to make them work. Here are some reasons of failure of process improvement implementation in company [1]:

1. **Lack of understanding on the level of maturity.** Process improvement initiative generally has experienced only modest success because organization fails to address culture or defining level of maturity. Too often, organizations decide to jump into process improvement without assessing current levels of understanding and the collective level of maturity in relation to process improvement. Support and recognition of the need for change from leadership team are critical before beginning a process improvement. Without the

support, resources will not be provided, roadblock will be established, and well intentioned effort will fail. In *Leading Cha*nge, John P Kotter reminds the need for leadership team to acknowledge that change is needed and leadership team willingness to take on change. The relationship of management and leadership is captured on figures below [2]

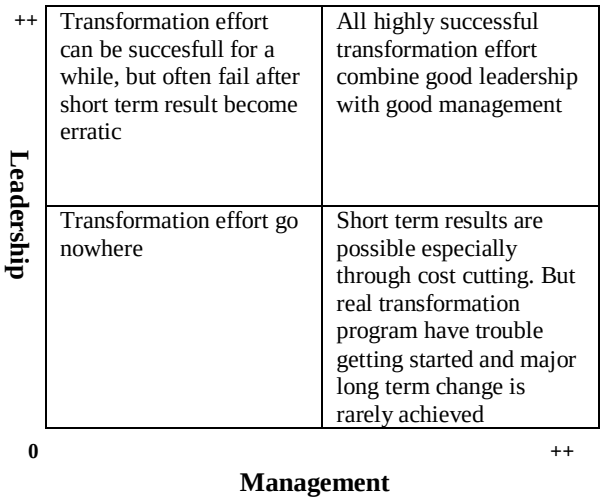

Figure 1: The relationship between leadership and management

The important of defining organization level of maturity that is well known to everyone in every aspect of the operation is a prerequisite for process improvement initiative. And it won't occur unless it is enabled by leadership commitment in an environment of innovation [3]

2. **Process improvement not link to the strategic plan and the criteria for success not establish.** Any successful process improvement implementation must be linked to organization's strategic plan. Strategic plans state organizational direction in a mission and vision statement with associated goals and objectives which then be measured. To ensure the goals and objectives were being met, criteria for success (CSF) need to be established and easily tracked.
3. **Inappropriate resource allocation.** Many organizations recognize the benefit of process improvement but they are unwilling to allocate the needed resources to make it happen.
4. **Lack of Training and Communication.** To implement a successful process improvement, employee must shift the way they think and work. Training is the critical initial step needed to initiate cultural change. Permanent shift in organization culture must involve all employees, and each employee must have at least a basic knowledge of what is expected and how the change will be accomplished. Beside training, communication also needed to create awareness. The difficult part of any process improvement program is the implementation and institutionalization of a solution. If people not engaged, the process improvement program doesn't become institutionalized, and then it could be the cost of poor communication [4]
5. **Lack of Coordination throughout the organization.** Organizations often fail to coordinate process improvement effort across and within organization. One section of the organization may improvement effort locally without any communication with leadership team, this result in sub optimization of process improvement. An effort to include every organization under one umbrella to ensure all employees speak with same language and the entire organization focuses on process improvement as part of its culture. People get enthusiastic when improvement process are well planned and executed
6. **Lack of Data Management.** Good improvement process generally starts with solid data collection and analysis [4] This involve all type of data such as measurement process, customer feedback, or service parameter which will aggregated, summarized, and presented in an integrated manner to become information. Weak data management will lead to failure of process improvement initiative.

ISSN 114-1284

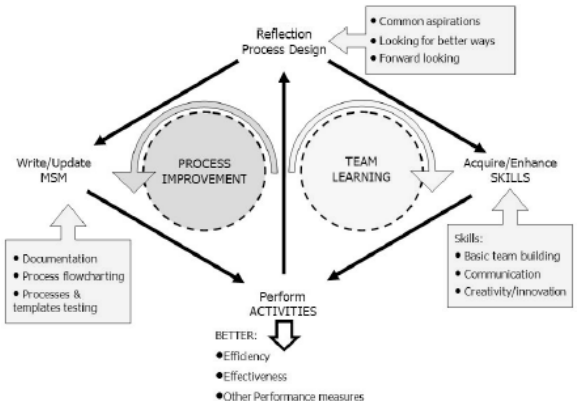

Figure 2: Embedding Learning in Process Improvement activities [5]

Process Improvement programs are seen as the desire to commit to learning in order to avoid making the same mistakes over and over again. "Learning organizations" are the result. It offers the following definition: "A learning organization is an organization skilled at creating, acquiring, and transferring knowledge, and at modifying its behavior to reflect new knowledge and insights" [6]. Knowledge can lead to competitive advantage and that knowledge-creating companies are those that will succeed in fast changing market conditions [7]. Drucker (1994) defines it in a very similar manner by saying that "knowledge has become the key economic resource and the dominant, if not the only, source of comparative advantage". Their main goal is "making personal knowledge available to others"

Process improvement and learning organization can achieve its full potential if only when people, culture, process, and system come together with the right tools, methodology, management, and technology.

2. SIX SIGMA AND KNOWLEDGE MANAGEMENT

Knowledge management and Six Sigma share a notable distinction in a corporate universe full of change initiatives and improvement philosophies. These two approaches have been integrated into regular operations at leading companies to guide and maintain the learning cultures within organizations [8]

2.1 Value of Six Sigma

Six Sigma provides set of tools, proven methodology, and management system to boost profitability, increase market share and improve customer satisfaction. As a result of those, Six Sigma eventually increases the company's competitiveness.

2.1.1 Six Sigma as a metric, methodology, and Management System

Six Sigma as a metric is represents how well a process is performing and how often a defect is likely to occur. It is labeled by sigma (6) as unit of measurement that designates the distribution or spread about the mean (average) of a process improvement. Six Sigma is the standard of excellent at only 3.4 defects per million opportunities.
Six Sigma methodology is described as DMAIC [9]

- **Define,** select the appropriate responses to be addressed
- **Measure,** gathering data to measure the response variable
- **Analyze** identify the root causes of defect, defectives, or significant measurement deviation whether in or out of specifications
- **Improve** reduce variability or eliminate the causes
- **Control,** with desired improvement in place, monitor the process to sustain the improvement

At the highest level, Six Sigma has been developed into a practical management system for continuous improvement that focuses management and the organization or four key areas [10]

- Understanding and managing customer requirement
- Aligning key processes to achieve those requirement
- Utilizing rigorous data analysis to understand and minimize variation in key processes
- Driving rapid and sustainable improvement to the business process

2.1. 2 Six Sigma Organization Structure

Prior to deployment, during deployment, and transition to the organization, there are critical role and responsibilities that ensure Six Sigma methodologies become ingrained in the business.

Understanding the roles and responsibilities for each activities will leads to effective deployment [11]:

- **Executives,** create the vision for the Six Sigma initiative and create an environment within the organization that will promote the use of Six Sigma methodology and tools
- **Project Champion,** Leads in project identification, prioritization, and defining the project scope. Select and mentors Black Belt also removes barriers and align resource
- **Master Black Belt,** assist champion and process owner. Trains, coaches, and mentors Black Belt and Green Belts in order to able to apply the methodology and tools
- **Black Belt,** assist in identifying project opportunities and refining project details and scope.
- **Process owner,** takes ownership of the project when it is complete, and responsible for maintaining the project's gain.
- **Green Belt,** works small scope projects, typically in his/her respective work area.

2.2 Knowledge Management

Knowledge management provides strategy of putting tacit and explicit knowledge into action by creating context, an infrastructure, and learning cycles that enable people to find and use the collective knowledge of the enterprises

2.2.1 Knowledge Definition

Knowledge is defined as "understanding gained through experience or study." It is "know-how" or a familiarity with how to do something that enables a person to perform a specialized task. It may also be an accumulation of facts, procedural rules, or heuristics. These elements are defined as follows:

- A fact is a statement of some element of truth about a subject matter or a domain.
- A procedural rule is a rule that describes a sequence of relations relative to the main.
- A heuristic is a rule of thumb based on years of experience

In his study of Smart Business, Botkin (1999) suggests six top attributes of knowledge products and services:

- **Learn**. The more you use them, the smarter they get and the smarter you get, too.
- **Improve with use**. These products and services are enhanced rather than depleted when used, and they grow up instead of being used up.
- **Anticipate**. Knowing what you want, they recommend what you might want next.
- **Interactive**. There is two-way communication between you and them.
- **Remember**. They record and recall past actions to develop a profile.
- **Customize**. They offer unique configuration to your individual specifications in real time at no additional cost

Knowledge also can be considered as the integration of human perceptive processes from data into information that helps them to draw meaningful conclusions

Figure 3: Wisdom, Knowledge, Information, Data

2.2.2 Type of Knowledge

Two different kinds of knowledge need to be distinguished from each other. External (or formal) knowledge that can be easily shared and is often well documented; its transfer is possible in an impersonal way, e.g. through written instruction [12]. Tacit (or informal) knowledge on the other hand is much more difficult to articulate;

it is very personal, context specific and transferred mainly through social interactions [8].

Table 1: The Four models of knowledge

	Tacit Knowledge	to Explicit Knowledge
Tacit Knowledge from	Socialization (sharing experiences with others)	Externalization (writing down tacit knowledge)
Explicit Knowledge	Internalization (embodying, i.e. „learning by doing")	Combination (systemizing it into a knowledge system)

The above model describes the contents of knowledge and applies to a learning organization where tacit knowledge is nurtured and converted into explicit knowledge and then back into tacit knowledge [13]

2.2.3 Knowledge-based Organization

Knowledge management helps organization reduce both time and costs by reusing existing knowledge and also enhance facilitate generating newer knowledge by using existing knowledge as a base [14]. Chase International Survey (1997) stated that knowledge management benefits are:

- Improving organization ability for decision making (89%)
- Improving response time to customer (82%)
- Improving work and process efficiency (73%)
- Improving ability to innovate (73%)
- Improving productivity of services (73%)

But, most of organization knowledge lies on employee brains (tacit).

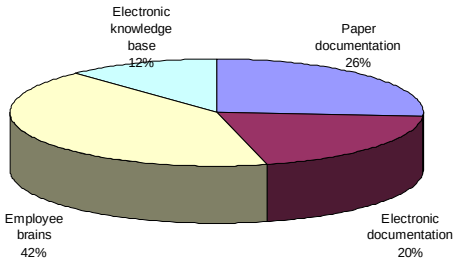

Figure 4: Repositories of Corporate Knowledge Resources [15]

In bringing knowledge management into organization, it needs to establish system that help organization to be better at creating, finding, acquiring, organizing, storing, accessing, sharing and using the knowledge and creating new knowledge as well.

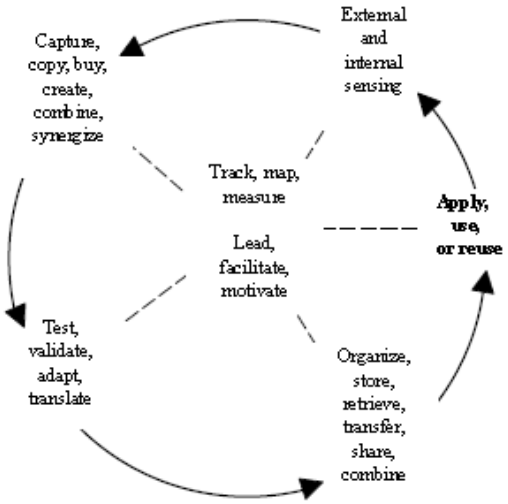

Figure 5: Knowledge Management Cycle [16]

The level of successfulness of knowledge management system is depending on the designing a mix of appropriate skills, relevant information, support systems (technology), and relational context which can produce better results

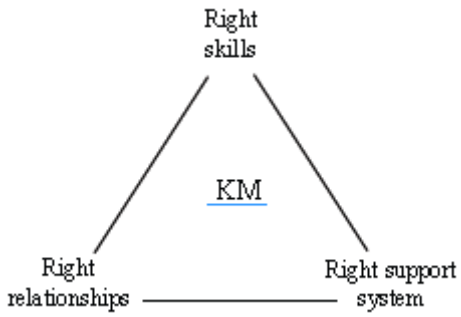

Figure 6: Effective KM requires Skills, System, and Relationship

The ideal knowledge organization is where people exchange knowledge across the functional areas of the business by using technology and established processes. People exchange ideas and knowledge for policy formulation and strategy. Knowledge is also internalized and adopted within the culture of the organization. All knowledge workers (people) are in an environment where they can freely exchange and produce knowledge assets by using various technologies.

3. SIX SIGMA IPLEMENTATION IN STARWOOD HOTEL & RESORTS

Starwood is the world's largest hotel and leisure. Starwood brand include: St. Regis, Sheraton, Luxury Collection, Le Meridien, W, Aloft, Element, Bliss, Westin, and Four Points. In 1990s Starwood began with a culture of creativity by introducing Starwood Improvement System (SIS) and Starwood Care Experience (SCE) before introducing the management tool.

In 2001, Starwood became the first hospitality company to embrace Six Sigma, an internationally recognized approach that enables associates to develop innovative customer focused solutions and transfer those innovations rapidly across an organization. Starwood developed a top-down give and take process for setting priorities and optimizing change investment. The objectives and process included [17]:

- Provide high level direction to local unit managers on high priority areas for improvement
- Allow local autonomy with localized guideline. The leadership team of each hotel responsible for developing its own list of priority projects (depending on the specific strength and weakness of the local operation
- Maintain high level review and control of the overall portfolio.

3.1 Six Sigma Organization Structure

In order to exceed its very audacious goals, Starwood has built a robust infrastructure. We have three defined roles at Starwood, each with a set of defined responsibilities:

- **Black Belts**: A full-time position that sits on a hotel's Executive Committee, a Black Belt works on projects that address Black Belts lead teams to gather voice of the customer, remove root causes and pilot solutions. Starwood employs approximately 150 Black Belts worldwide
- **Green Belts**: A part-time role, Green Belts transfer into their hotels the solutions that Black Belts create. Using project warehouse to access data, SOPs and dashboards, Green Belts can implement solutions from any hotel across the globe into their hotels. Starwood has developed over 2,700 Green Belts.
- **Master Black Belts**: MBBs are project portfolio managers who are deployed regionally. 53 MBBs worldwide drive a series of "creation" and "transfer" projects throughout operations.

Every Six Sigma project represents an integrated effort between the field and Six Sigma resources. Starwood has seven divisions: Asia Pacific, Latin America, North America, Europe & Middle East (EAME), SVO, Franchise, and Corporate. Each division's Six Sigma organization reports to divisional leadership and is aligned with the division's goals and priorities. Members of the divisional, regional and property leadership teams take on a variety of roles, including Sponsor, Process Owner and Team Member, in all stages of each Six Sigma project from proposal to completion.

Figure 7: Starwood Six Sigma Organization Structure

3.2 Six Sigma Deployment

Global, divisional, regional and property Six Sigma Councils meet throughout the year to determine priority initiatives, drive best practice transfers and ultimately determine which projects should become required for an area or group of properties. Six Sigma projects fall into three categories:

- **DMAIC projects** seek to uncover opportunities and root causes and make existing processes more efficient and effective. The acronym DMAIC refers to the five stages in the Six Sigma project process: Define, Measure, Analyze, Improve and Control.
- **Quick Hits** are small projects that can be quickly implemented, generally lasting 3 to 4 weeks, which typically can be completed within the boundaries of a single function or department. Quick Hit projects follow the general DMAIC methodology, but are not subject to as many "tollgate" reviews. They contain some Voice of Customer research and must involve a change in the process

Transfer Projects are Six Sigma projects (whether DMAIC project or a Quick Hit) which is can be implemented in many properties.

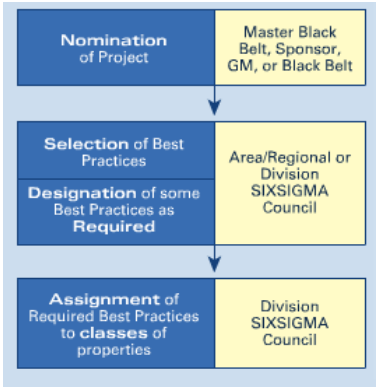
Each of property is responsible for researching solutions that may apply to face their problems. The benefits of project transfer are significant. The effort and resources in reinventing the wheel can be reduced or eliminated by learn to other properties and adopt the best practices. Project transfer can be divided into two: Required best practice and Optional best practice.

Figure 8: Six Sigma Project Type

To become a required best practice, a project should have characteristic as follow:

- Deliver a higher return on investment than other Six Sigma projects. The investment is the time and effort a team spends finding a solution and implementing it successfully. The return is the increase in guest and/or associate satisfaction produced by the solution, the revenue generated, and the cost savings.
- Easy to transfer to other properties, and should not require a dedicated black belt while implementing it because the project initiator has provides step by step and guideline how to implement it
- The best practices is adopting the way project being executed and learn from other company's experience, so the implementation of best practice could be fast and the benefit could be realized immediately.

To nominate, select and assign some of Best Practice projects the property, area, and division councils work together



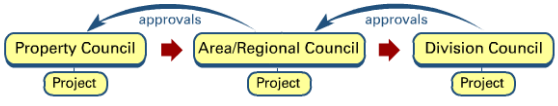


Figure 9: Approval Sequence for Best Practice

4. SIX SIGMA E-TOOL KNOWLEDGE MANAGEMENT SYSTEM

To retain knowledge and expertise in a whole 1,081 hotel chain world wide has been a challenge for Starwood. Knowledge and expertise are essential asset in order to maintain excellent work, process improvement, and continue being an industry leader. In 2002, with the advance of information technology, Starwood initiated Six Sigma e-Tool Knowledge Management System to speed up the learning process and projects transferability.

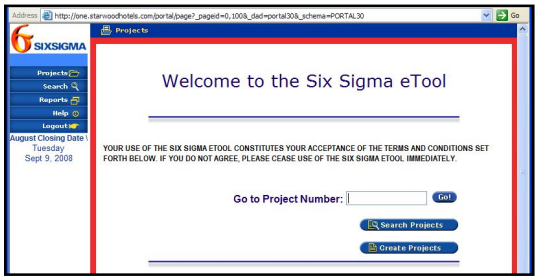

Figure 10: Six Sigma e-Tool Web Layout

4.1 The Knowledge Management Implementation

The Six Sigma e-Tool application is a web-enabled, global repository of Six Sigma projects. By integrating the document management system and database, The Six Sigma e-Tool enables project and financial tracking and senior leadership reporting.

4.1.1 Six Sigma e-Tool for Project Reporting and Tracking

Six Sigma e-Tool is a robust warehousing capability houses project information from the initial through the completed project. The format of the Six Sigma reports and document are standardized and regulated for projects progress and tracking.

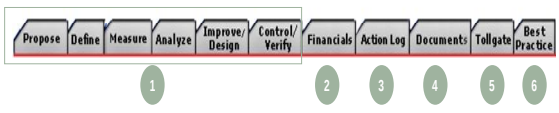

Figure 11: Six Sigma E-Tool's Report Element

Table 2: The Six Sigma e-Tool Element Description

Item	Name	Description
1	Six Sigma Process Phases	Each Tab is represents one phase of the Six Sigma process. Only a successful tollgate will advance the project to the next phase. Once a tollgate is complete, Users can only view information in past phases. Users cannot edit or add documents to past phases of a project.
2	Financials	Tab that allows View only details of project financials. Financials are only updated within the Financials subpage located within a Project Phase.
3	Action Log	Discussion Space for project participants to place comments/ issues regarding the project.
4	Documents Tab	Documents tab allows users to review all documents attached to project. Users can also attach new documents from this tab.
5	Tollgate Tab	View tollgate status. MBB access this page to approve, cancel, reject or place tollgates On Hold.
6	Best Practice	Only Active when the project is a Nominated, Optional or Required Best Practice.

Depending on type of project there are up to 8 phases within a project:

- A DMAIC project has eight phase
- A Quick project has five phase
- Project transfer (which known as i-DMAIC project) has four phase

Within a Phase, a project will also have a project status. Each phase within a project has more than one project status as defined in the table below.

When a project has been submitted for a tollgate review, the eTool adds a "-t" next to the project status to indicate the project is awaiting tollgate. When in tollgate review status, all items within the project are locked from editing/modification.

In most cases, only the MBB can tollgate a project to another phase

Table 3: e-Tool Project Status for each Project Phase

Project Type	Propose	Define	Measure	Analyze	Improve A	Improve B	Control	Complete
DMAIC	x	x	x	x	x	x	x	x
Quick Hit	x	x					x	x
iDMAIC	x		x		x		x	x

4.1.2 Six Sigma e-Tool for Financial Reporting and Tracking

Six Sigma e-Tool provides financial report for leadership council. The benefit from projects can be tracked and validated. Financial benefit for Quick Hit is recorded for 12 months; DMAIC and i-DMAIC are recorded for 18 months. In the e-Tool, financial benefit is categorized into 3 types:

- **Type 1**: Financial benefits that can be directly tied to the P&L. More specifically, there must be a quantifiable cause and effect relationship between the project deliverable and the reduction or increase in one or more general ledger accounts during a specified period. This will include revenue generating, cost reduction and cost avoidance projects
- **Type 2**: Benefits that have a financial impact but cannot be tied to the P&L during a specified period. The majority of type 2 project benefits will be realized in projects involving future focused revenue processes; for example, group room conversions from tentative to definite vs. using actualized bookings. Type 2 financial benefits will require RVP/AMD/Area Director, MBB and Regional Controller approval before the project is tollgated to Control for baseline and financial benefit calculations because of the added complexity of not knowing exactly when the benefits will show up on the P&L
- **Type 3**: Benefits including defect reductions, cycle time improvements, non-value added hours reduced (where we saved time in doing a certain task, but redirected that time spent to another, more valuable task, so we did not actually save payroll dollars), GSI (customer satisfaction index), ASI (Employee satisfaction), LRA improvements (Brand standard), conversion ratios, sigma levels, etc

Financials benefits are presented in the following format on the e-Tool:

- Incremental revenue, difference in revenue attributable to the process change. The calculation of incremental revenue should involving flow through % to EBITDA
- Cost reduction or expense reduction
- Non capital expense of implementing. startup costs related to the project, examples would include costs associated with mailing customer questionnaires or the purchase of equipment to small to qualify as capital
- Impact on working capital, this refers to movement in accounts payable, accounts receivable and inventory
- Non working capital investment. An item of cost for the project that is recorded against the balance sheet in an asset account other than working capital - a long-term asset, such as property, plant or equipment

For case study, below is the benefit figure of Asia Pacific division from 2002 up to YTD June 2009:

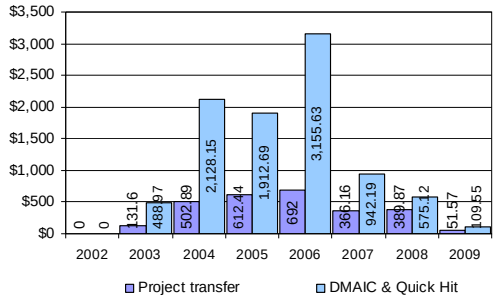

Figure 12: Six Sigma AP Division Type-1 Figure (number in thousands dollars)

The figure shows that more than US$ 12 millions have been generated by AP Division through DMAIC and Quick Hit (US$ 9.3 millions) and project transfer (US$ 2.7 millions)

4.1.3 Six Sigma e-Tool for Sharing Knowledge

As explained previously, the implementation of Six Sigma e-Tool knowledge management system is to speed up process learning. Different with DMAIC and Quick Hit project which starts with problem or opportunity and focuses on developing and implementing a solution, a project transfer (i-DMAIC) stars with a known solution and focuses on implementing that solution to address a problem that property has in common with the exporting property

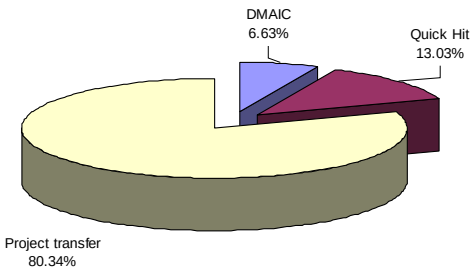

Figure 13: Proportion of Project Type in Starwood

In total, Starwood has generated 29,677 projects since 2001, where 80.34% is project transfer.

All Starwood Associates can access, view and search for projects in e-Tool. All Six Sigma Community members have the ability to view projects, create projects, edit projects, view reports and edit financials. Black Belts can only tollgate iDMAIC (Transfer) projects for the Propose, Measure and Control Phases only. And the Master Black Belts have the ability to Tollgate all projects

Table 4: the roles and rights for users of the e-Tool

Six Sigma Role	eTool Project Role	eTool Project Rights						
						Tollgate Ability		
		View	Create / Edit	View Reports	Edit Financials	DMAIC	(i) DMAIC	QUICK HIT
Green Belt	Proposed By	√	√	√	√

Black Belt	Proposed By	√	√	√	√			
	Project Leader/GB	√	√	√	√			
	Black Belt	√	√	√	√		P, M, C Phases Only	
Master Black Belt	Proposed By	√	√	√	√			
	Project Leader/GB	√	√	√	√			
	Master Black Belt	√	√	√	√	√	√	√
Financial Controller	Proposed By	√	√	√	√			
	Project Leader/GB	√	√	√	√			
	Controller	√	√	√	√			

5. CONCLUSION

Six Sigma is a proven management system for process improvement. On the other hand, Knowledge Management (KM) is a modern approach that deals with the greatest capital of organization. Six Sigma achievements are also based on proper knowledge and its flow. As a systematic approach to managing knowledge and process improvement activities with the aid of an information system in Starwood, Six Sigma e-Tool knowledge management system has been strongly emphasized and promoted throughout hotel chain. It has played important role in support growth, profitability and powerful tool to speed up organization learning process to become market leader.
