Welcome from the Rector of University of Indonesia

I am honoured to have the opportunity to officially welcome you to the 11th International Conference on QiR (Quality in Research) 2009. The conference provides an excellent forum for engineering professionals, business executives, industry practitioners, and academicians to exchange ideas and to share their experience, knowledge and expertise with each other. I believe the participants will also learn about the latest trends in the development of new tools, knowledge and skills in various engineering design and technology.

As we agree that engineering products or projects bring together resources, skills, technology and ideas to achieve business objectives and deliver business benefits and it comes in all shapes and sizes from the simple and straight-forward to the large and unmentionably complex, thus we need an application of knowledge, skills, tools, and techniques necessary to develop and successfully execute the products or projects plan so it will meet or exceed our customer and stakeholder needs and expectations.

The ultimate concern of engineering product or project is three-fold: the product/project meeting its targets and purposes, the product/project on schedule, and the product/project cost within budget. As the Indonesian economy is growing, local enterprises are obliged to upgrade their skills in innovation and product design. There are also increasingly aware of the importance of professionalism in various engineering areas for industries needs and many professionals are keen to upgrade their capability.

Having said that, I hope this conference can be a kick-off for strengthened our action and partnerships on creating a platform for us; national and international thinkers, academics, government officials, business executives and practitioners, to present and discuss the pivotal role of engineers in the achievement of excellence organizations.

I am sure you will find the 11th International Conference on QiR (Quality in Research) 2009 both informative and stimulating. I would like to thank the Faculty of Engineering, University of Indonesia for organizing this meaningful and timely event, and the supporting organizations for their participation and contributions. With this, I wish you all a fruitful conference. Thank you.

Prof. Dr. der. Soz. Gumilar Rusliwa Somantri
Rector of University of Indonesia
University of Indonesia

Welcome from Dean of Engineering University of Indonesia

On behalf of the Faculty of Engineering, University of Indonesia, it is my greatest pleasure to extend our warmest welcome to all of you to the 11th International Conference on QiR (Quality in Research) 2009. As we know that this conference is conducted to cover a wide range of engineering design and technology issues. I hope these four days of the conference will be spent in interesting discussion and exchange of ideas. I also hope this conference would be able to provide a state-of-the-art information and knowledge in the challenging world of engineering design and technology. The growing success of our institutions and expertise should urge us to develop our competitive capabilities, especially as we face certain challenges which would be overcome with more hard work and working together hand by hand. We will work together to develop a common path and collaboration opportunities for future action and research on multi disciplinary engineering areas.

I am delighted that you have accepted our invitation to this conference in such large numbers as indicated that we will have many international keynote speakers' lectures and papers from various countries to be presented and discussed during these two days conference. We will explore various engineering techniques and tools in various industries that can be used to build better stakeholder performance and relationships, to enable us to create wealth through innovation, to promote productivity through technology, and to foster our collaboration.

I would like to thank you to our sponsors, supported bodies and various contributors for their generous support of this conference. I would also like to thank our distinguished speakers for agreeing to share their insights with us. To our friends from overseas and other provinces of Indonesia, I would also like to extend a warm welcome to you and wish you an enjoyable stay in Jakarta. Last but not least, I would invite you to join me in thanking the committed staff that made this conference happen and to make it a success.

I wish you a very pleasant stay here in Jakarta and a successful and productive discussion at the conference. Thank you.

Prof. Dr. Bambang Sugiarto
Dean of Engineering University of Indonesia

Welcome from the QiR 2009 Organizing Committee

On behalf of the Organizing Committee, it is my greatest pleasure to extend our warmest welcome to all of you to the 11th International Conference on QiR (Quality in Research) 2009.

I am sure that you will all find this conference stimulating and rewarding. As we are aware of, the impact of globalization has resulted in a very competitive business environment that makes the fulfillment of customer/clients' ever-sophisticated project or product or service needs most challenging. Without any doubt, a good engineering design and technology is powerful in helping our industries to enhance their productivity and competitiveness. Thus, it is our aim and hope that the conference would be able to provide an international forum for exchange knowledge and research expertise as well as to create prospective collaboration and networking on various fields of engineering and architecture.

With its continuous presence in the last 11 years, QiR has become an icon of Faculty of Engineering University of Indonesia in serving the objectives to provide engineering excellence for both national and international needs. The QiR 2009 consists of 2 special issues and 4 symposia covering almost all aspect in engineering, design and architecture. I am delighted to inform you that we have such large numbers of participants today as indicated that we will have 7 keynote speakers' presentation and more than 240 papers from various countries to be presented and discussed during these two days conference. We are fortunate to have a lot of good quality of papers that belongs to:

70 papers on Radio Frequency Identification (RFID) as a Bridge between Computing and Telecommunication
36 papers on Green Infrastructure for Sustainable Development and Tropical Eco-Urbanism.
56 papers on Industrial Engineering Approach for Productivity Improvement
56 papers on Advanced Materials and Processing
30 papers on Energy Conservation through Efficiency in Design and Manufacturing

I would like to thank you to various contributors, speakers and participants for your generous support of this conference. It is my pleasant duty to thank all the members of Organizing Committee and the International Board of Reviewers for their advices and help. We are grateful to all the Sponsors, Supporters and Exhibitors for their spontaneous response and encouragement by way of committing funds and extending help in kind.

I would like to sincerely thank the Dean of Engineering, for fully supporting the Committee and providing all supports to make this conference happen and to make it a success.

I wish you a very pleasant stay here in Jakarta and finally, let me wish all of you a meaningful and fruitful conference. Thank you and hope to see you again in QiR 2011.

Dr. Bondan T. Sofyan
Organizing Chairperson of QiR 2009

ABSTRACT

The development in the field of health care has been a major concern nowadays. Lab-on-a-chip (LOC) is one form of realization of the progress. LOC has most of the ability that a laboratory actually can do, and packaged in a smaller scale. Such size gives a number of advantages and challenges. With changes of scale, factors such as characteristics of the fluid flow are also changed. This paper reports experimental study on one of phenomena in LOC systems, namely electro-osmosis (i.e. electrically-driven fluid transport) in micro-scale straight channels. The electrical characterization of this phenomenon is performed by measuring the electrical current (which is proportional to the speed of electro-osmotic flow, EOF) of various electrolyte concentrations and length of channels of microfluidic prototype chips. The chips are customarily made by using plates of PMMA that sandwich a layer of double-sided sticky tape (with layer thickness in the order of ~100 microns), which thickness determines the micro-scale channel depth. Several parameters that we investigated in order to find the relevance with the EOF velocity in the channel are electrolyte concentration, channel length, and source's voltage.

Keywords

electrical characterization, electro-osmosis, straight microchannel, microfluidics, pulsed dc source

1. INTRODUCTION

Research on process in micrometer and nanometer scale are still new and growing. This area is very prospective because there is a big chance to have innovative breakthroughs. On this scale, technology allows increased flexibility and capability beyond the macro scale, and when combined with science, will bear a new breakthrough in fields like health care. One example is Lab-on-a-chip (LOC), which is in the areas of micro-and nano-fluidic, with applications in the field of biomedical.

LOC is a technology of the future, as it combines an actual ability of a laboratory with the portability and a quick analysis features. As in a laboratory on general macro scale, LOC is designed to analyze the liquid, ion, and other particles. The only difference lies on the scale that the analysis is conducted where the portability feature can be employed.

In its development, LOC incorporates many disciplines. To learn its nature, characteristics, and how fluid works in micro-channels or even nano-scale, a physicists are needed. When it involves substances or a mixture of chemistries needed in the analysis, it is a biologist or chemist area of expertise. Manufacturing techniques of chips with micro or nano-channels, are area of expertise of micro-technology engineer. Sensor design and supporting instrumentation requires an electrical engineer's expertise.

This complexity makes LOC interesting to be studied. Therefore, study on the basic principles of controlling nanoliter liquid flow is indispensable. One way of controlling fluid flow in microchannels is using electronic methods through the electro-osmosis phenomenon.

2. ELECTROOSMOSIS

In LOC, there are two types commonly used actuator, namely hydrodynamics which utilizes pressure in controlling flow of fluids, and electrokinetics that utilizes the difference in voltage to control the flow of fluids. In this paper, we are experimenting on one of the electrokinetic phenomena known as the electro-osmosis [4].

Electro-osmosis is the flow of fluids, relative to the stationary surface, influenced by the electric field. There are two factors that influencing the electro-osmosis: (1) electric

double layer or EDL, and (2) external electric field applied across the channel.

2.1 Electric double layer

EDL is composed of two parts, namely a fixed layer of counter-ion (Stern layer) and a moveable layer (Gouy-Chapman layer). These layers contribute to the flow when combined with external electric field applied on the channel because of the attract and repel situation between ions. The EDL is illustrated in Fig. 1.

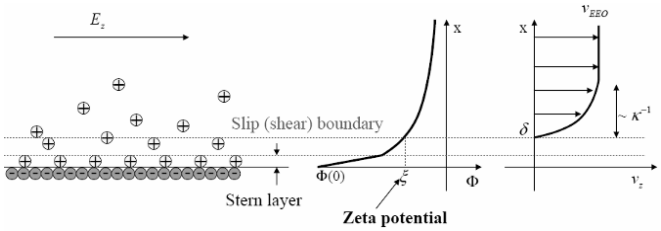

Figure 1. Electric Double Layer (EDL) [1].

2.2 Zeta potential

In order to find electro-osmosis speed of flow, we need to find potential differences between its fixed layer of counter-ion (Stern layer) and moveable layer (Gouy-Chapman layer). The electrical potential on the shear plane also called zeta potential (ζ).

For most applications of electro-osmosis, scale of ζ that can work well for various type of concentration is ζ ~ pC or equal to ζ ~ - log C, where C is the concentration of the substrate [2]. The relationship between zeta potential with the substrate concentration for composition relevant to our experiment can be represented by following equation [2],

$$\zeta = 15\,(-\log(C)). \qquad (1)$$

which is illustrated in Fig. 2.

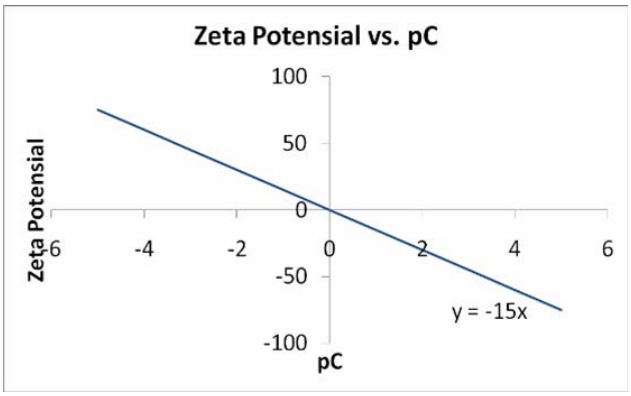

Figure 2. A plot of equation 1, which is describe the relationship between Zeta potential vs pC [2].

2.3 Flow speed

The electro-osmosis flow speed can be found by using [3]:

$$\mathbf{v}_{EO}(x,y,z) = (\varepsilon\varepsilon_0 / \mu)\,(\psi(z) - \zeta)\,\mathbf{E} \qquad (2)$$

with,

$$\partial^2\psi(z) / \partial z^2 = (2n_\infty Ze) / (\varepsilon\varepsilon_0)\,\sinh\,(Ze\,\psi(z) / k_bT) \qquad (3)$$

where **E** is the electrical field, induced by the electric voltage difference between the ends of the channel.

In special cases, where the width of the EDL is much less than the channel width, the value of the average flow speed in every point on the channel can be expressed with the Helmholtz-Smoluchowski formula below.

$$\mathbf{v}_{EO}(x,y) = (\varepsilon\varepsilon_0 / \mu)\,(-\zeta)\,\mathbf{E}(x,y) \qquad (4)$$

3. DESIGN & CIRCUITS

Our work consists of 3 parts, i.e. (1) fabrication of the prototype chips (2) the DC characterization circuit design, and (3) the pulsating circuit design.

3.1 Chip fabrication

The fabrication of these chips does not require sophisticated technology. It can be done with simple tools. Selected materials, which are required in the fabrication of the chips, are also easily obtained and inexpensive. They are commercial PMMA board, known as acrylic, and commercial double-sided sticky tape that can be found in any bookstore.

PMMA works as the foundation and cover for the channel. The wall of the channel is made of double-sided sticky tape. The double-sided tape does not have to have any special specification, except the width of the tape should be adjusted to the width of acrylic. In this experiment, we were using 1" wide double-sided sticky tape with thickness about 0.01 cm and a 4 cm x 6 cm x 0.2 cm PMMA board. Fig 3 shows the schematic cross-section of the chips. Fig. 4 shows the fabricated chips.

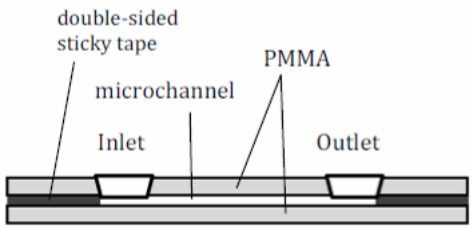

Figure 3. The customarily microfluidic chip made by using double-sided sticky tape sandwiched between two chips of PMMA fabricated in this work. The dimension of the channel inside the chip is 5 mm wide and has varied length from 10-20mm. Channel thickness is identical with the thickness of the double-sided sticky tape (±100 μm).

Figure 4. Photographs of the customarily microfluidic chips made by using double-sided sticky tape that are used in this experiment.

3.2 DC circuit

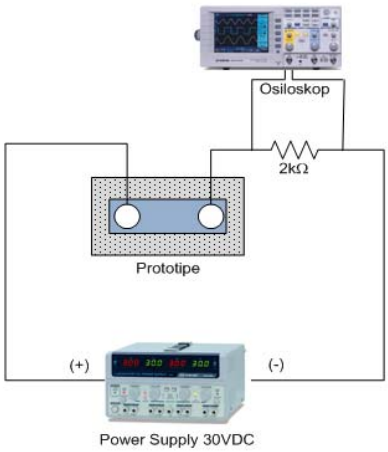

Figure 5. The diagram of the measurement setup used for electrical characterization of the prototype microfluidic chip. The chip and the 2 kΩ resistor are placed in series.

With NaCl solutions in the channel, the electro-osmotic flow reading is done by measuring the voltage on a resistor which can be converted into current flow by dividing its value with resistor's value (2000 Ohm). Such current flow is proportional to the speed of the electro-osmosis flow. Fig. 5 shows the measurement setup diagram while Table 1 shows the parameters for DC excitation experiments.

Table 1. DC excitation setup

Voltage source	30 VDC
NaCl Concentration	1M, 1.5M, 2M, 2.5M
Channel	Lenght 1cm, 1.2cm, 1.5cm, 1.8cm, 2cm Wide 0.5cm Height 0.005cm - 0.01cm

3.3 Pulsating circuit

Table 2. Pulsating excitation setup

Voltage source	Series of 30 VDC pulse
NaCl Concentration	1M, 1.5M, 2M, 2.5M
Channel	Lenght 1cm, 1.2cm, 1.5cm, 1.8cm, 2cm Wide 0.5cm Height 0.005cm - 0.01cm

In order to generate one second of on and off pulse width, we use electronic switch controlled by a microcontroller. The uses of microcontroller ease any modification which might be required for future experiments. We also use opto-couplers for the circuit to separate electrically between low voltage part and high voltage part of the circuit. Fig. 6 shows the schematic diagram of the pulsating circuit.

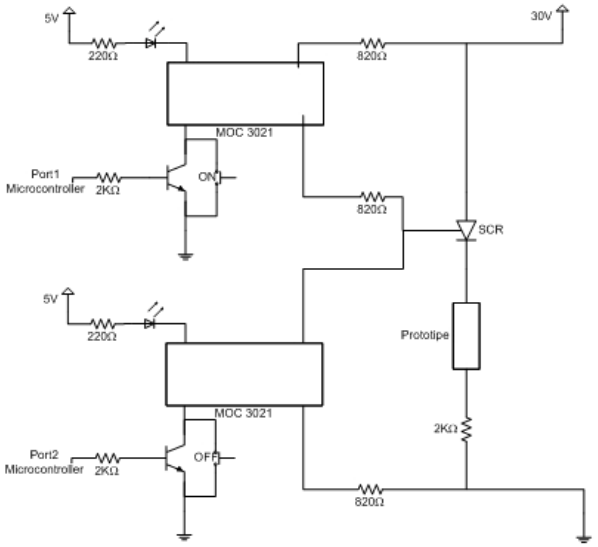

Figure 6. The electronic switch used for pulse excitation.

4. EXPERIMENTAL RESULT

4.1 Effect of Electrolyte Concentration

Using equation (4), we computed theoretical U_{EOF} to be expected in the channel. According to the concentration for each channel length, we grouped each section and computed theirs average. The results are shown in Table 3.

Table 3. U_{EOF} vs Concentration

	1M	1.5M	2M	2.5M
1.0cm	0	6.31113E-06	1.07935E-05	1.42718E-05
1.2cm	0	5.25928E-06	8.99456E-06	1.18931E-05
1.5cm	0	4.20742E-06	7.19565E-06	9.51451E-06
1.8cm	0	3.50618E-06	5.99637E-06	7.92876E-06
2.0cm	0	3.15557E-06	5.39673E-06	7.13588E-06
Average	**0**	**4.48792E-06**	**7.67536E-06**	**1.01488E-05**

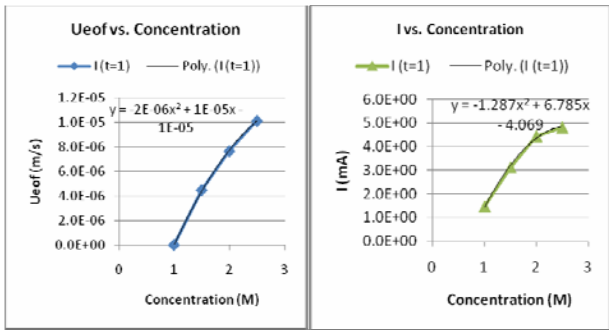

Figure 7. Theoretically computed graph of U_{EOF} vs. concentration (left) and graph of electrical current vs.

concentration derived from the experimental result (right) showing agreement in characteristic and trend.

Then, by plotting out the data, we can see that the trends of the theoretical and measured results agree well as shown in Fig. 7.

4.2 Effect of Channel length

Using the previously computed U_{EOF} data, we can plot another graph by grouping data into series of concentration which current is changing for variety of lengths. Figure 8 shows that channel length contributes to the shifting in the value of electrical field either in the experimental result or theoretical prediction.

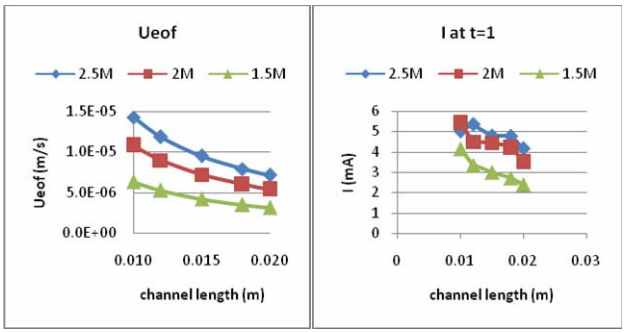

Figure 8. Theoretically computed graph of U_{EOF} vs. concentration (left) and graph of electrical current vs. concentration derived from the experimental result (right) showing agreement in characteristic and trend.

4.3 Voltage source

In this section, we observed the effect of using different kind of voltage source, by pulsating the 30VDC with 0.5 Hz frequency.

Using a digital oscilloscope, reading of voltage drop at the 2 kΩ resistor is noted every minute or when any changes occurred on the curve. When changes occur in the same minute, we compute average value of the data by summarizing the data from each screen capture.

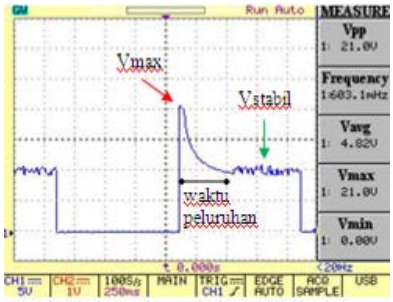

Figure 9. The 34th screen capture of experiment with 1.5M NaCl on a 10 mm channel length. Vmax is the peak value of the graph and Vstable is the value when the curve slope ~ 0.

When compared with the results of the DC excitation, different trend occurred. On DC experiment, we have velocity of the electro-osmosis flow being proportional to the concentration. On pulsating voltage source, there is slight difference, i.e. for concentration more than 2M, the velocity of the electro-osmosis flow is no longer proportional with the NaCl concentration.

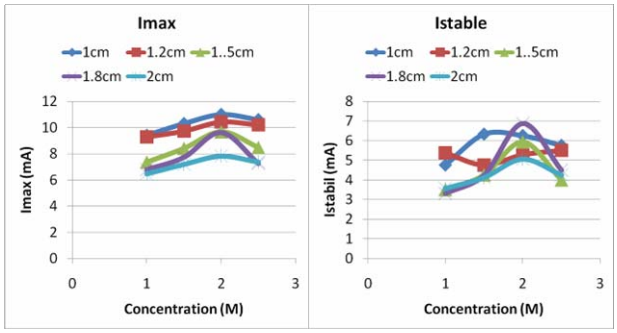

Figure 10. Graph of Imax vs. concentration (left) and Istable vs. concentration, showing anomalies on Imax ≥2M and random curve on Istable caused by pulsating voltage source.

The pulse experiments reveal unusual dynamic behavior of electrolyte flow, which still need further studies to understand it.

4.4 Concentration and saturation time

We also measured how much time is needed to reach stable condition from a peak. The results on various concentration show that all resemble a parabolic curve that looked like a "U"-shape. Higher concentration makes the minimum point of the parabolic curve shifted away from the y-axis, and the distance between peaks are getting farther apart, making it a larger curve as shown in Fig. 11.

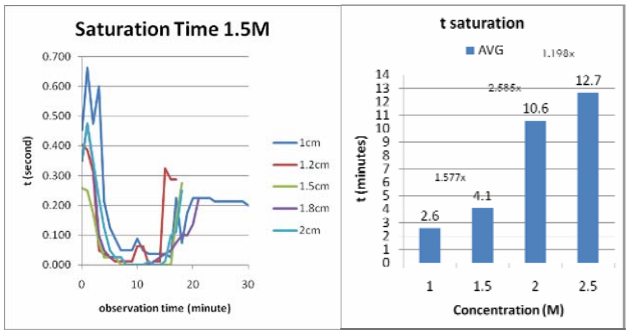

Figure 11. Track of time needed for 1.5M NaCl to became saturated (left) and average saturation time needed for each concentration (right) which are computed by averaging all value of the same concentrate.

4.5 Direction of electro-osmosis flow

During the experiment, observations on the electro-osmosis velocity are limited to visual observations. The direction of the electro-osmosis flow can be seen by observing a yellow color that appears in the inlet and outlet.

The color always occurs in every experiment. In the first minute, the yellow color appears on the negative electrode. It slowly moves toward the positive electrode and turns into green when comes near at the positive electrode.

ISSN 114-1284

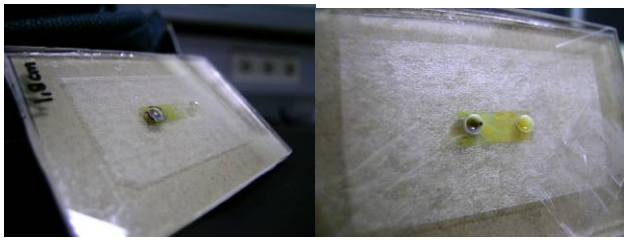

Figure 12. Photograph of the unexpectedly appeared yellow color inside the channel. The yellow color moves from cathode to anode.

This movement of the yellow color can be explained using equation 4 where the direction of flow is influenced by the values of the zeta potential and the electric field. In general, the direction of electro-osmosis flow is on the same direction of the electric field applied. Flow direction changed if the value of zeta potential is not negative. By using substance with concentration greater than 1M, the direction of electro-osmosis flow is contrary to the electric field. The relationship between zeta potential and the concentration being used can be found in equation 1. In this way, the electro-osmosis flow will be reversed, where fluids move from negative to positive electrodes.

5. CONCLUSION

From this work, we conclude that:

1. I (=Ueof) are proportional to the electrolyte concentration.
2. The use of pulsed voltage source affects the current reading. Observations through monitoring I_{max} and I_{stable}, show differences in trends.
3. Increased concentration also affects the time the current needed to reach saturation conditions.
4. In pulse excitation, the increased of concentration produces shifting of peak of the curve away from y-axis. This means that the time required to reach saturation for higher concentration will be longer than before.
5. Electro-osmosis velocity occured in the channel, marked with trace of yellow solution from the negative electrode to the positive.

ACKNOWLEDGMENT

ABSTRACT

In this paper, cavity filter is discussed due to advantages such as narrow bandwidth, better slope, and can be used for high power consumption application without changing or modifying the existing circuit. To decrease the size of the cavity filter, cylindrical design for the cavity & type of dielectric materials plays an important role. Meanwhile, in designing the cavity filter, the performance of the filter depends on several parameters. In this paper only dielectric constant and the dimension of the dielectric material inside the cavity will be discussed.

The cavity filter is designed by using Ansoft HFSS v.11 which uses the finite element computational method. The simulation results show that the dielectric constant and dimension of the dielectric material inside the cavity influence the resonant frequency in the cylindrical cavity filter.

Keywords
cylindrical cavity filter, dielectric material, resonant frequency

1. INTRODUCTION

Wireless communication is widely used in Indonesia due to its high mobility, can be easily accessed by everyone and without geography limitation. However, there is one major disadvantage which occurs to wireless communication namely interference.

Interference is caused by nearby frequencies from another system, which interferes with the resonant frequency of the used system. To overcome this interference, filter is used.

Microwave resonators are used in a variety of applications, including filters, oscillators, frequency meters, and tuned amplifiers. Resonators can also be constructed from closed sections of waveguide, which should not be surprising since waveguide are a type of transmission lines. Electric and magnetic energy is stored within the cavity, and power can be dissipated in the metallic walls of the cavity as well as in the dielectric filling the cavity [1].

Dielectric resonator is a term used by Richmeyer, who showed that a dielectric ring could confine high frequency electromagnetic waves and thus form a resonator [2]. In general a dielectric resonator is a disk of ceramic material with dielectric constant sufficiently high to contain an electromagnetic standing wave. A dielectric of this geometry will support many resonant modes. The most commonly used mode is the $TE_{01\delta}$ because it is a fundamental mode and has the highest unloaded Q [3]. Such dielectric resonators are similar in principal to the rectangular or cylindrical cavities. High dielectric constant of the resonator ensures that most of the fields are contained within the dielectric but unlike metallic cavities, there are some field fringing or leakage from the sides and ends of the dielectric resonator, such a resonator is generally smaller in size, and weight than an equivalent metallic cavity, and can very easily be incorporated into microwave integrated circuit and coupled to planar transmission lines [4].

This paper discusses the effect of the dimension and the dielectric constant (ε_r) from several dielectric materials inside cylindrical cavity resonator compared to the resonant frequency of the cylindrical cavity resonator with dielectric inside.

2. RESONATOR DESIGN

Figure 1 shows the geometry of a cylindrical cavity.

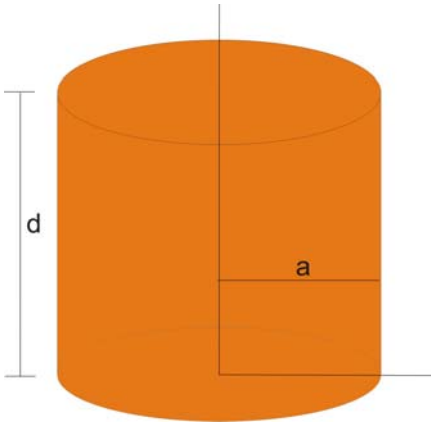

Figure 1: Cylindrical Cavity

The transverse electric fields (E_ρ, E_Φ) of the TE_{nm} or TM_{nm} circular waveguide mode can be written as

$$\bar{E}_t(\rho,\Phi,z) = \bar{e}(\rho,\Phi)\left[A^+ e^{-j\beta_{nm}z} + A^- e^{j\beta_{nm}z}\right] \quad (1)$$

where $\bar{e}(\rho,\Phi)$ represents the transverse variation of the mode, and A^+ and A^- are the arbitrary amplitudes of the forward and backward traveling waves, and the resonant frequency of the TE_{nml} mode is,

$$f_{nml} = \frac{c}{2\pi\sqrt{\mu_r\varepsilon_r}}\sqrt{\left(\frac{p'_{nm}}{a}\right)^2 + \left(\frac{l\pi}{d}\right)^2} \quad (2)$$

where
l = waveguide length
c = light velocity
ε_r = relative permittivity
μ_r = relative permeability
P'_{nm} = root from derivatives of Bessel function

Circular cylindrical dielectric resonators have been widely used because of their simple geometry, commercial availability, and easier to analyze. The geometry of the cylindrical dielectric resonator is shown in Fig. 2. The dielectric resonator is considered as a short length, d, and diameter of r, of dielectric waveguide open at both ends.

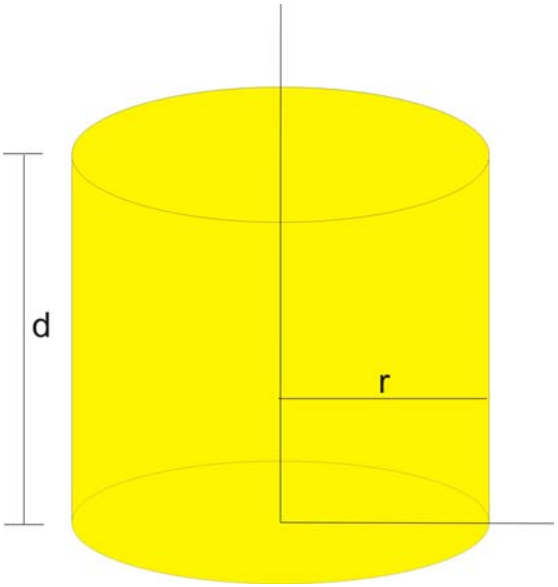

Figure 2: Dielectric Resonator

Because of the high permittivity of the resonator, the propagation along z-axis can occur inside the dielectric at the resonant frequency, but the fields will be cut off (evanescent) in the air region around the dielectric. Thus, the equivalent circuit of the resonator looks like a length of transmission lines terminated in pure reactive loads at both ends [4].

2.1 Cylindrical Cavity Resonator Design with Ansoft HFSS 11

From equations (2), with a and d respectively 50mm and 100mm, as shown in Fig. 3, the resonant frequency is obtained at 2.326 GHz using HFSSv.11 with Eigenmode solutions[5]. Eigenmodes are the resonances of the structure. The eigenmode solver finds the resonant frequencies of the structure and the fields at those resonant frequencies as from equation (3):

$$[S]x + k_o^2[T]x = b \quad (3)$$

Where S and T are matrices that depend on the geometry and the mesh, $\boldsymbol{x}$ is the electric field solution, k_o is the free-space wave number and b is the value of the source defined for the problem.

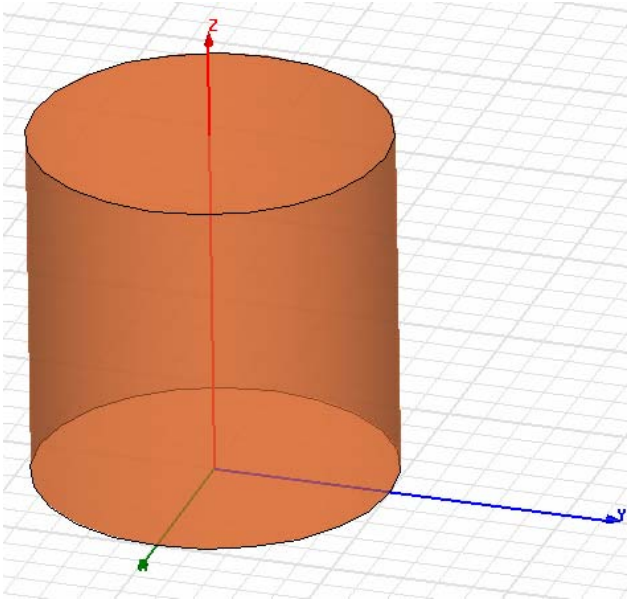

Figure 3: Cavity Resonator Design using HFSSv.11

However, in order to find the resonances of the structure, the eigenmode solver sets b to zero, and solves the equation as in equation (4):

$$[S]x + k_o^2[T]x = 0 \quad (4)$$

For the sets of (k_o,$\boldsymbol{x}$), there are one ko for every $\boldsymbol{x}$. The variable x is still the electric field solution, and k_o is the free space wave number corresponding to that mode. The wave number ko is related to the frequency of the resonant modes through the following equation (5):

$$f = \frac{k_o c}{2\pi} \quad (5)$$

This cylindrical cavity resonator design will be used for the next design of cavity resonator with dielectric material inside.

2.2 Cylindrical Cavity Resonator with Dielectric Material Inside Design with Ansoft HFSS 11

With the cylindrical cavity resonator shown in Fig. 3, the dielectric material design is placed inside the cavity, as shown in Fig. 4.

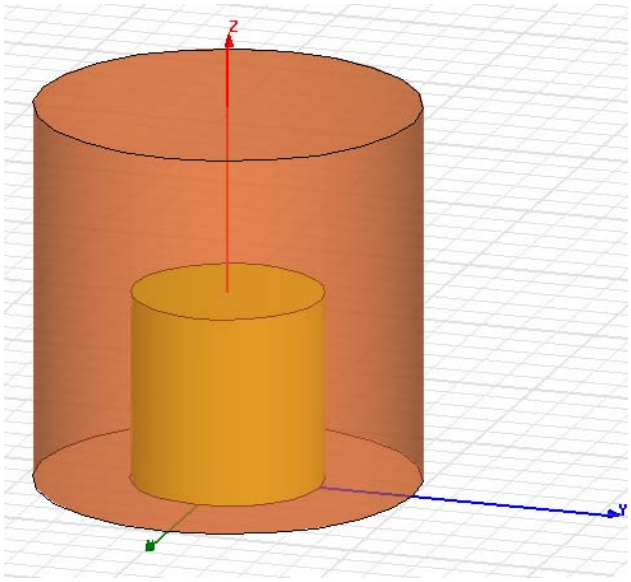

Figure 4: Dielectric placed inside the cavity

The dielectric material which is placed inside the cavity has the radius of r =25mm. In this paper, variation of height and dielectric materials are varied to see the impact towards the dimension of the resonator.

3. RESULT AND DISCUSSION

Simulation results were obtained from the variation of height (d) from 10mm to 100mm, and also from different kinds of dielectric materials. The dielectric materials chosen were Teflon (ε_r = 2.1), porcelain (ε_r = 5.7), Taconic CER-10 (ε_r = 10), and diamond (ε_r =16.5).

Figure 5 shows the influence of using the dielectric material Teflon to the resonator. The resonant frequency of the cavity resonator after placing dielectric material Teflon (εr = 2.1) inside, tends to decrease as the height increases. With the height 10 mm, the resonant frequency shows at 2.26 GHz

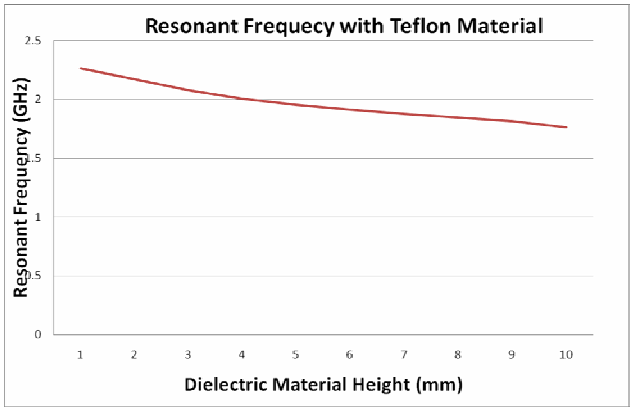

Figure 5: Graphic of Resonant frequency with Teflon material

The next simulation result is placing a higher dielectric material than Teflon, which is porcelain. The simulation result is shown in Figure 6 and shows a lower resonant frequency for the same height compare to Teflon. For the height d = 10 mm, the resonant frequency is 2.17 GHz.

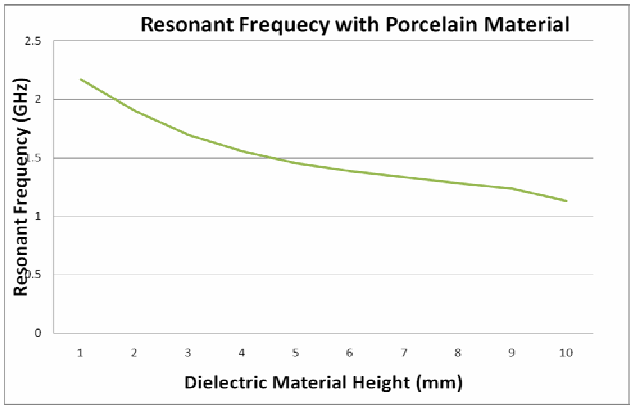

Figure 6: Graphic of Resonant frequency with porcelain material

The next dielectric material used is Taconic CER-10 with ε_r = 10 as the dielectric material. The simulation result depicted in Fig.7 shows that the resonant frequency of the cavity resonator became to 2.12117 GHz at d = 10 mm and shows a lower resonant frequency compared to Teflon and porcelain.

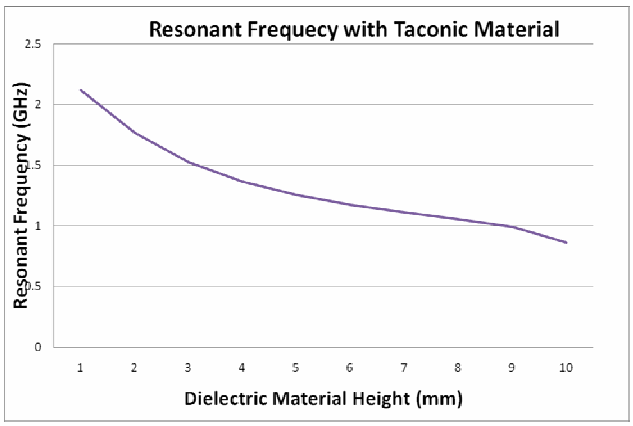

Figure 7: Graphic of Resonant frequency with Taconic material

The last material compared is diamond. Diamond (ε_r =16.5) has higher dielectric constant compared to the other materials. The simulation result as in Fig. 8 shows that the resonant frequency is lower than the other dielectric material which has smaller dielectric constant. The diamond shows at height 10 mm has a resonant frequency at 2.05 GHz.

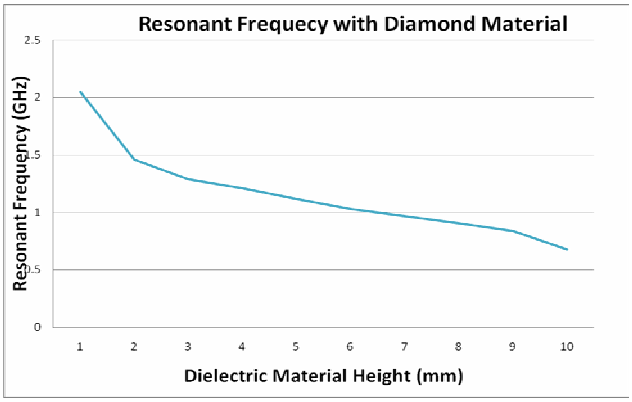

Figure 9: Resonant frequency with Diamond material

The simulation is than varied from height 10 mm to 100 mm and the result is shown in Table 1 and in Fig. 8. Before the dielectric is placed inside the cavity, the resonant frequency is 2.326 GHz. After placing the dielectric, the resonant frequency tends to decrease.

Table 1: Simulation result

d (mm)	*Teflon (GHz)*	*Porcelain (GHz)*	*Taconic CER-10 (GHz)*	*Diamond (GHz)*
10	2.26641	2.17048	2.12117	2.05045
20	2.17355	1.90001	1.76722	1.45818
30	2.08127	1.69362	1.52436	1.28741
40	2.01008	1.55578	1.36726	1.20981
50	1.95784	1.45319	1.25765	1.12059
60	1.91470	1.38467	1.17384	1.02978
70	1.88010	1.33057	1.11158	0.966764
80	1.84810	1.28305	1.05542	0.904497
90	1.81465	1.23217	0.996501	0.838119
100	1.76470	1.13055	0.864752	0.677936

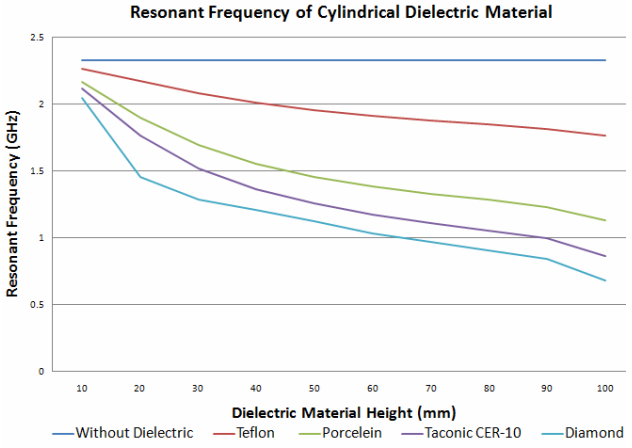

Figure 8: Resonant frequency of Cylindrical Resonator Cavity

The decrease of resonant frequency caused of different dielectric materials, also occurs for other dielectric materials. The higher the dielectric constant (εr) is, than the lower the resonant frequency decreases.

As shown in Table 1, using Diamond for the height of 100 mm results to a resonant frequency of 0.67 GHz compared to Teflon, Porcelain and Taconic CER-10 of 1.76 GHz, 1.13 GHz and 0.86 GHz, respectively.

This result confirms with the equation (2), which shows that high dielectric constant is very important for miniaturization of the resonator's size. The resonator is reduced by a factor of $\sqrt{\varepsilon_r}$. The dielectric constant must be sufficiently high for the operating frequency to provide enough miniaturization.

4. CONCLUSION

To design microwave resonator with low resonant frequency, dielectric material must be added inside it, to miniaturize the cavity resonator.

Simulation results show, that the use of dielectric material can decrease resonant frequency. Higher dielectric constant and dimension will influence greatly to the decrease of the resonant frequency.

ABSTRACT

Many problems are encountered in monitoring of power system. These problems come primarily from the nature of the measurement devices and from communications problems in transmitting the measured values back to operation control center. These like problems will be subject to errors. Further more, the errors can cause misinterpretation by those reading the measured values. For these reasons that power systems state estimation techniques have been developed. This paper shows an analysis of state estimation in power system to minimize small random errors in measurement.

Keywords:
analysis,measurement,estimation,power, system

1. INTRODUCTION

State estimation (SE)[2][3] is the process of assigning a value to an unknown system state variable based on measurement from that system or SE can be defined as a statistical procedure for deriving, from a set of system measurements, a "*best*" estimate of the system state[2][3]. In the field of power system, the objective is to provide a reliable and consistent data base for security monitoring, contingency analysis and system control. To meet the above objectives, SE is required to :

- Produce a "best" estimate of the state variable
- Detect, identify and suppress gross measurement errors
- Produce an estimate of non-metered or lost data points

A major factor in the success of producing a good estimate of the system state is the ability to handle errors that exist in the input to the estimation process[1][4][5]. Such errors may be classified as :

- Measurement noise
- Gross measurement errors
- Topological errors
- Model parameter errors

Measurement noise is handled inherently by the filtering process of the estimation algorithm itself. Gross measurement errors are detected and identified through suitable hypothesis testing on the measurement residuals. The identified gross errors are then suppressed from the estimation procedure. The models of the power system components used are taken as static with their reliability and accuracy usually established by extensive analysis prior to their use.

2.STATE ESTIMATION IN POWER SYSTEM

Centralized automatic control of power system dispatch requires knowledge of the steady-state performance of the system[1][2][3]. This performance must be inferred from system measurements communicated to the control center. If enough measurements could be obtained continuously, accurately, and reliably, this would provide all the information needed for control. However, a perfect data acquisition system is often technically and economically infeasible so that the control center must depend on measurements that are incomplete, delayed, inaccurate, and unreliable. The function of state estimator is to process whatever information is available and to produce the best possible estimate of the true state of the system.

2.1 Weighted Least Square Estimation (WLS)[2][3][5]

The development of the notions of state estimation may proceed along several lines, depending on statistical criterion selected. Of the many criteria that have been examined and used in various applications, WLS criterion is perhaps the most commonly used.

In WLS, the objective is to minimize the sum of the squares of the weighted deviations of the estimated measurements from the actual measurements.
The measurement state is related to the true state of the system by the equation

$$z^{meas} = f(x) + e$$

where :

z^{meas} = measurement vector
$f(x)$ = network model relating the state variable to the measurement set
x = state variable vector
e = measurement error vector

The WLS estimation procedure is then the minimization of the function

$$J(x) = \left[z^{meas} - f(x)\right]^T \left[R^{-1}\right] \left[z^{meas} - f(x)\right]$$

where :

$$[R] = \begin{bmatrix} \sigma_1^2 & & & \\ & \sigma_2^2 & & \\ & & \ddots & \\ & & & \sigma_{Nm}^2 \end{bmatrix}$$

= the diagonal matrix of measurement

$J(x)$ = measurement residual

Table Estimation Formula

Case	Description	Solution
Ns < Nm	over determined	$x^{est} = [[H]^T[R^{-1}][H]]^{-1}$
Ns = Nm	completely determined	$x^{est} = [H]^{-1} z^{meas}$
Ns > Nm	under determined	$x^{est} = [H]^T[[H][H]^T]^{-1} z^{meas}$

2.2 Bad Data Detection and Identification[1][4][5]

The detection of bad data is posed as a statistical testing problem of the following form :
H0 : For the given confidence level, no bad exists
H1 : Reject H0. For the given confidence level, error exist.

Chi-Squared Distribution
H0 : The overall estimate is good
H1 : The overall estimate is not good
Accept H0 if $J(x) < \chi^2(K)\ or\ J(x) < t_j$, reject otherwise

K = degrees of freedom of chi-squared distribution
K = Nm - Ns
where :
Nm = number of measurement
Ns = number of states = (2n-1)
n = number of buses in the network

Residual Test
H0 : a data point is good
H1 : a data point is not good
Accept H0 if
$y_i / \sigma_{y_i} < y_i^{norm}\ or\ (z - f)/\sigma_{y_i} < y_i^{norm}$
Reject H0 (Accept H1) otherwise

The form of the residual test above is referred to as the Weighted Residual test. A different form is the Normalized Residual test which has more discriminating properties in identifying bad data for low redundancy systems.

For a given estimate, the above tests are performed. The J(x) test evaluates the overall estimate for consistency. The residual test is used to identify individual data points which are likely to be in error. Those found to be most likely in error are suppressed and a new estimate is obtained. The process is repeated until a good estimate of the voltage magnitudes and angles of the network is produced. Present estimators stop at this point and use the estimated voltage magnitudes and angles to derive an estimate of the bus injections and branch flows in the system without regard to the possibility of topological errors. To the system operator, the only inkling to the presence of such configuration errors is suppression of measurements which appear to be good by human intuition. The effects could be disastrous, however, if the process proceeds and the estimates are used for controlling the system and performing contingency analysis.

3.DISCUSSION

An Example WLS State Estimation[2][3][4][5]

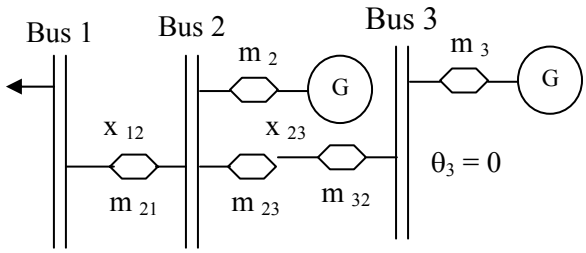

Figure 1 [2][3][4][5]

The network of example was solved using DC power flow with reactance (on 100 MVA base) as follows : x_{12} = 0,10 pu and x_{23} = 0,25 pu.
Some meter readings located as shown in Figure 1. Now investigate the case where all the meter readings have slight errors (σ = 0,01 pu). Suppose the reading obtained are :

m_3 = 102 MW
m_{32} = 98 MW
m_{23} = -135 MW
m_2 = 49 MW
m_{21} = 148 MW

The results :

$$H = \begin{bmatrix} 0 & -4 \\ 0 & 4 \\ -10 & 10 \\ -10 & 14 \\ 0 & -4 \end{bmatrix},$$

$$R = \begin{bmatrix} 10^{-4} & & & & \\ & 10^{-4} & & & \\ & & 10^{-4} & & \\ & & & 10^{-4} & \\ & & & & 10^{-4} \end{bmatrix},$$

$$z^{meas} = \begin{bmatrix} 0{,}98 \\ -1{,}35 \\ 1{,}48 \\ 0{,}49 \\ 1{,}02 \end{bmatrix}$$

$$x^{est} = \left[[H]^T [R]^{-1} [H] \right]^{-1} \left[[H]^T [R]^{-1} z^{meas} \right]$$

$$x^{est} = \begin{bmatrix} \theta_1^{est} \\ \theta_2^{est} \end{bmatrix} = \begin{bmatrix} -0{,}428071 \\ -0{,}274643 \end{bmatrix}$$

$$J(x) = \sum_{i=1}^{Nm} \frac{\left[z_i^{meas} - f_i(x) \right]^2}{\sigma_i^2} = 893{,}428571$$

(i.e., α = 0,01) will be found t_j = 11,345. Therefore, it seems reasonable to assume that there is "bad" measurement present.

Using y_i and σ_{y_i} normalized residual for each measurement can be calculated. Measurements having the largest absolute normalized residual are labeled as prime suspect. These prime suspects are removed from the state estimator calculation one at a time, starting with the measurement having the largest normalized residual. After a measurement has been removed, the state estimation calculation is rerun. The measurement with the largest absolute y_i^{norm} is the again removed and the entire procedure repeated successively until J(x) is less than t_j.[2][3][4][5]

4. CONCLUSIONS

The ability to detect and identify bad measurement is extremely valuable to a power system's operation department. Measurement devices may have been wired incorrectly or the measurement device itself may be malfunctioning so that it simply no longer gives accurate readings. The statistical theory required to understand and analyze bad measurement detection and identification is straightforward but lengthy.

The ability to detect (using the chi-squared statistic) and identify (using normalized residuals) are extremely useful features of a state estimator. Without the state estimator calculation using the system measurement data, those measurement whose values are not obviously wrong have little chance of being detected and identified. With the state estimator, the operations personnel have a greater assurance that quantities being display are not grossly in error.

IMPACT OF RFID TO RETAIL SUPPLY CHAIN COLLABORATION

Agus Purnomo
Industrial Engineering Department
Engineering Faculty – Pasundan University Bandung 40153
e-mail : nrpsga@yahoo.com ; aguspurnomo@unpas.ac.id

ABSTRACT

The retail industry is experiencing problems in the supply chain because there is no formal collaboration between the retailer and supplier. Retailers need innovative ways to differentiate themselves in highly saturated and cluttered markets. Demand uncertainty in the supply chain, known as the "bullwhip effect," results in excess inventory and inefficiencies in the supply chain. Demand forecasts and orders are often distorted unless they are developed jointly by the partners. These factors create a need for supply-chain integration and a way to provide supporting collaborative forecasting and replenishing processes, with the goal of increasing sales and reducing inventory investments and cycle time. Collaboration can reduce waste in the supply chain, but it can also increase market responsiveness, customer satisfaction, and competitiveness among all of the members of the partnership. Radio Frequency Identification (RFID) provides a major advantage to supply chain management. Implementing supply chain collaboration along with RFID can enable retailers to achieve the best level of business performance. Retailers can expect extensive inventory and labor-cost savings. RFID has the most potential to offer in streamlining the value-chain management, but handling the amount of data by RFID in the retail industry limits the potential of RFID benefits. In this paper, we explore RFID and propose a research agenda to address a series of broad research questions related to how RFID technology: 1) is developed, adopted, and implemented by retail; 2) is used, supported, and evolved within organizations and alliances; and 3) impacts individuals, business processes, organizations, and markets.

Keywords : business value, supply chain collaboration, diffusion of innovations, radio frequency identification, technology adoption.

1. INTRODUCTION

The traditional retail supply chain consists of all the parties involved directly or indirectly in fulfilling a customer request, including manufacturers, suppliers, transporters, warehouses, retailers, and the customers themselves [9]. Each retail supply-chain entity includes functions like product development, marketing, operations, distribution, finance, and customer service. The only information that is available to the supplier is the purchase order issued by the retailer. Because there is no overall picture of the external demand that is placed by customers, inventory can increase at every level of the supply chain. The main goal of each member of the supply chain is to reduce unwanted inventory levels and increase ROI [13].

Since the early 1990s, there has been a growing understanding that supply chain management should be built around the integration of trading partners [6], the sharing of information and benefits [15] and the collaboration of organizations [16]. Supply chain collaboration as understood today has begun to take form since the mid-1990s, when the forms of collaboration multiplied [17] and new forms of information sharing extended their focus to include not only a passive exchange of information between partners, but also a more proactive approach through common planning and synchronisation of activities and business processes [21], taking advantage of innovative technologies. Anthony [3] suggests that supply chain collaboration occurs when two or more companies share the responsibility of exchanging common planning, management, execution, and performance measurement information. Bowersox et al. [8] state that firms collaborate in the sense of leveraging benefits to achieve common goals.

Supply chain collaboration in retailing and Fast Moving Consumer Goods industry (FMCG) has mainly been expressed in the form of practices such as Vendor Managed Inventory (VMI), Continuous Replenishment Program (CRP), and Collaborative Planning, Forecasting and Replenishment (CPFR). VMI is probably the first trust-based business link between suppliers and customers [6], whereby the manufacturer (supplier) has the sole responsibility for managing the customer's inventory policy, including the replenishment process, based on the variation of stock level in the customer's main warehouse or distribution center [11]. CRP moves one step ahead of VMI and handles the inventory policy not only with the variations of inventory levels at the customers' main stock-holding facility but also with sales forecasting, based on point-of-sales (POS) data from the retailer's stores [1]. Collaborative Planning, Forecasting and Replenishment (CPFR) can be seen as an evolution from VMI and CRP, addressing not only replenishment but also joint demand forecasting and promotions planning, focusing on promotions and special-line items [12]. CPFR is based on extended information sharing between retailer and supplier, including POS data, forecasts and promotion plans. Pramatari et al. [18] further suggest a new form of CPFR, named Process of Collaborative Store Ordering (PCSO), addressing the daily store replenishment process. This process is supported by special IT infrastructure (a web collaborative platform) allowing: the daily online sharing of store-level information (e.g. POS data, store assortments, stock level in the store, promotion activities, out-of-shelf alerts, etc), the sales forecasting and order generation, the online collaboration of the trading partners,

and finally the order exchange and order status tracking. Based on these short descriptions, VMI and CRP are more about efficient replenishment and supply, whereas CPFR puts more emphasis on the demand side.

There is a clear evolution path in the capabilities and sophistication of the Information Technology (IT) infrastructure supporting all these collaboration practices, in the amount of information exchanged between the trading partners and in the process(es) enabled by this information sharing supporting former versus later forms of collaboration. Compared to the traditional ordering process, VMI/CRP and CPFR highly increase the total volume of information transmitted between retailers and suppliers on a daily basis. The volume of information exchanged and the intensity of interaction are expected to further increase dramatically when the advanced data capture capabilities of Radio Frequency Identification (RFID) technology coupled with unique product identification and real-time information gathering are employed. The emergence of RFID is expected to revolutionize many of the supply chain processes, especially those involving collaborating partners (Prater et al., 2005). Figure 1 [17] below summarizes the evolving path of supply chain collaboration practices in retail and the underlying information technologies that have enabled this collaboration over time.

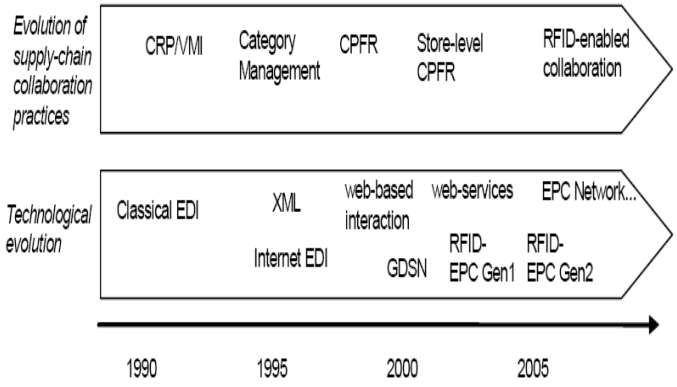

Figure 1: Evolution of supply chain collaboration practices and enabling technologies in retail industry

In this context, this paper proposes eight RFID-enabled supply chain collaboration services (e.g. dynamic pricing, smart recall, in-store promotion management, outof-shelf response) in a networked retail business environment. The services are characterized, on a high-level, by the information shared between retailers and suppliers, the level of tagging (pallet/case/item level) and the location of the tag readers. However, this paper presents the first findings of a research-in-progress with the ultimate purpose to assess and categorize the RFID-enabled supply chain collaboration scenarios according to four dimensions: the extent of collaboration required between retailers and suppliers, the RFID technology requirements, the transformation of existing (or the introduction of new) processes and the business performance impact of the RFID-enabled collaborative service.

2. SUPPLY CHAIN COLLABORATION

Collaboration is defined as two or more companies sharing the responsibility of exchanging common planning, management, execution, and performance-measurement information [3]. The critical step that many companies have not been able to take so far is to incorporate customer-demand information into their production and inventory-control processes. Companies that collaborate typically exchange information on a high level, but the production planning process remains unchanged, which eliminates the opportunity for a radical improvement of the dynamics in the supply chain. In our view, the critical feature is not only to exchange information, but to alter the replenishment and planning decision structure. The demand at the retailer drives the combined inventory and production control process, together with feedback on complete supply-chain inventory, rather than at individual tiers in the supply chain [13].

Manufacturers must secure and emulate the cooperation and dedication of relevant supply-chain partners to adapt in the most cost-effective way. Effective adaptation requires nearly real-time access to reliable, dispersed information to make quick, accurate, proactive decisions that can dramatically improve supplychain performance. True collaboration goes far beyond sharing forecasts and automating the purchase order (PO) process. It requires sharing data regarding sales orders, manufacturing runs, inventory levels, and purchasing activities, see figure 2 [13]. One solution for this particular task is called the Collaborative Planning, Forecasting, and Replenishment (CPFR) process. CPFR is defined as “an initiative among all participants in the supply chain intended to improve the relationship among them through jointly managed planning processes and shared information” [12].

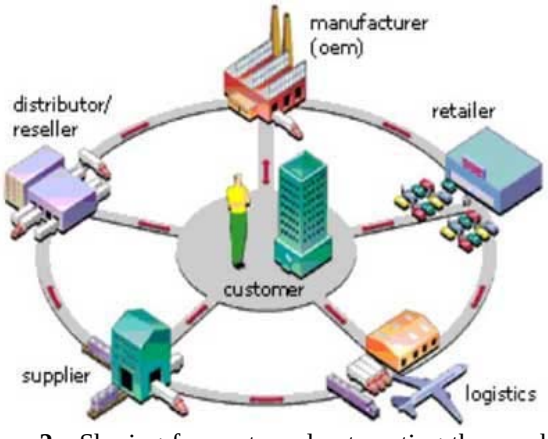

Figure 2 : Sharing forecasts and automating the purchase order (PO) process

The Strategy & Planning cycle establishes the ground rules for the collaborative relationship, determines product mix and placement, and develops event plans for the period (Figure 3). The Demand & Supply Management cycle projects consumer (point-of-sale) demand, as well as

order and shipment requirements over the planning horizon. The Execution cycle places orders, prepares and delivers shipments, receives and stocks products on retail shelves, records sales transactions, and makes payments. The Analysis phase monitors planning and execution activities for exception conditions, aggregates results, calculates key performance metrics, shares insights, and adjusts plans for continuously improved results. While these collaboration activities are presented in logical order, most companies are involved in all of them at any moment in time.

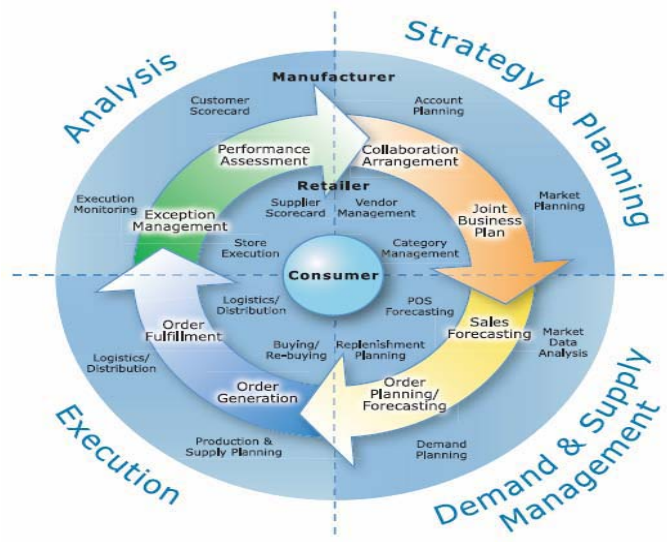

Figure 3 : The Strategy & Planning cycle establishes the ground rules for the collaborative relationship

There is no predefined sequence of steps. Execution issues can impact strategy, and analysis can lead to adjustments in forecasts. This clearly illustrates that CPFR complies with the supply-chain collaboration principles, yet there are issues that hinder the development of true supply-chain collaboration. There is a gap between the true customer demand and the inventory at any time. There is still no visibility of the product through the supply chain; the retailer still experiences out-of-stock conditions; and customers are unsatisfied [22].

3. ADOPTING RFID IN SUPPLY CHAIN

Radio Frequency Identification (RFID) is a generic technology concept that refers to the use of radio waves to identify objects (Auto-ID Center, 2002). The core of RFID technology is the RFID transponder (tag) – a tiny computer chip with an antenna. Consumer good suppliers attach these tags to logistic units (palettes, cases, cartons and hanger-good shipments) and, in some cases, to individual items. Logistic units and individual items are identified by the Electronic Product Code (EPC). An RFID reader is used to identify the EPC stored on the RFID tag (Loebbecke, 2007). The antenna enables the microchip to transmit the object information to the reader, which transforms it to a format understandable by computers (Angelles, 2005). Finkenzeller (1999) provides a general overview of RFID technology while Sarma (2002) describes the specific technology for supply chain management.

Nowadays, many in the retail sector are already looking to the business case of RFID as the "next generation of barcode" through its capabilities to uniquely identify, track and trace consumer products along the entire supply chain requiring neither direct human contact nor line of sight, to store much more information and to enable a broad spectrum of supply chain applications ranging from upstream warehouse and distribution management down to retail-outlet operations, including efficient inventory management, shelf management, promotions management and innovative consumer services, as well as applications spanning the whole supply chain, such as product traceability (Sarma et al., 2002, Loebbecke, 2007). Although RFID technology is still emerging, RFID adoption is pushed by major retailers (RFID journal, 2003) which are already executing a number of pilot applications.

The benefits of RFID adoption in various application areas can be sought across the following axes (Pramatari, 2006): 1) the automation of existing processes, leading to time/cost savings and more efficient operations; 2) the enablement of new or transformed business processes and innovative consumer services, such as monitoring of product shelf availability or consumer self check-out; 3) the improvement of different dimensions of information quality, such as integrity, accuracy, timeliness etc. (Ballou et al., 1998) and 4) the formation of new types of information, leading to a more precise representation of the physical environment, e.g. a product's exact position in the store, a specific product's sales history etc. For the full benefits to be ripped, the information needs to be shared among the supply chain partners in a complex network of relationships and decision making. The internal exploitation of RFID technology by a network leader-retailer looking solely at its own benefits is expected to have a negative impact on RFID market acceptance and adoption rates since suppliers will confront RFID as another unfortunate strategic necessity (Barua et al., 1997).

4. RFID-ENABLED SUPPLY CHAIN COLLABORATION SERVICES

The proposed system, categorized as a distributed Web-based decision support system, with participating user companies being European grocery retailers and suppliers from the fast-moving consumer goods sector [23]. Companies in the sector already have a more-than-ten-years collaboration history and some collaboration processes havebecome standard business practice across Europe, such as CRP/VMI employed in retail warehouse replenishment or Category Management dealing with the marketing aspects of managing product categories in the store [17].

The proposed architecture is a generic distributed architecture that can potentially support various supply chain collaboration and decision support scenarios, whether these are enabled by RFID technology or not [23] :

1) Backroom Visibility
In this scenario, both retailer and suppliers have a clear picture of the products' stock level in the store, as well as of the products' sales and collaborate on order placement for store replenishment. The store personnel receive from the system real time information about the backroom inventory level of each product. If a product is out-of-shelf, but there is available stock in the backroom, the store personnel is informed to refill the shelf; otherwise, if there is no stock (out-ofstock), a new store order is placed and sent to the distribution center. The salesmen of direct-store-delivery suppliers have also direct access to this information through their PDAs. The system updates the backroom inventory records automatically and sends the information to the PDA of the suppliers' salesmen. The salesmen inform the store staff to refill the shelf, but if there is no backroom stock, they prepare an order based on the inventory information provided by the system. At the retailer's headquarters, they can monitor the orders that the suppliers' salesmen have placed. The salesmen leave the store satisfied, since they succeeded in moving their products to the shelves and they also took efficient ordering decisions to avoid out-of-stock & out-of-shelf. The tags are applied on case and item level. The tag readers are fixed on the backroom entrance and the backroom to sales floor entrance.
2) Out-of-shelf Response
The last 50 yard problem of product shortages on the shelf is a crucial issue in retail operations, both for the supplier and the retailer. On one hand the retailer should be aware of the time to move items from the backroom to the shelf, and on the other hand the supplier should be able to monitor the level of out-of-shelf in the stores, in order to identify problems and take corrective actions about the service level of new products to the end customer. The system monitors the stock in the backroom and on the shelves and when there are out-of-shelf cases it generates an out-of-shelf alert and sends specific instructions on the PDA of backroom personnel about which goods to move from the backroom to the shelf. This collaborative scenario enables the store personnel to better manage the shelf replenishment process, which is currently one of the major causes behind the outof-shelf problem.
3) Remote Shelf management
Retailers and suppliers are provided with real time information about the actual shelf layout and have the opportunity to collaboratively manage the shelves allocation and appearance. RFID readers "scan" and "read" the shelves and provide their "digital image", including information about the size, specific products' position and layout, as well as information about the shelves' performance. By using the system, the suppliers are now able to check if the products get the room they deserve on the shelf and are neatly positioned according to the store's planogram. If the suppliers notice that some of the products have fewer facings on the shelf, than what has been agreed with the retailer, or that some shelf space has been left empty, they informs the retailer, as well as the merchandiser to visit the store and take care of the shelf.
4) Dynamic Pricing
Retailers and suppliers have the opportunity to identify products that are close to their expiration date, or are standing still on the shelves for a long time. For these reasons they can dynamically reduce the products' price, in order to boost consumer demand and reduce waste. This collaborative service is very useful for fresh products, such as dairy products, bread, meat, etc. When consumers visit the store with their shopping list, they usually purchase products with the longest expiration date, since they cost the same. Thus, in order to avoid big on-hand stock of expired products, the system does periodic checks of on-hand stock to identify products approaching expiration date and then informs the suppliers. The suppliers, based on the system's recommendations, suggest to the retailer to decrease the price of these products. The retailer approves the suppliers' proposal for price change. In this case, the customers face a dilemma, if they should sacrifice the longest expiration date for a better price. But there are economic difficulties, so they usually choose the cheaper one. As a result, the customers leave the store happy that they managed to save money and both the retailer and the supplier are also satisfied because they managed to sell products that would otherwise be trashed. The tags are applied on case and item level. The tag readers are fixed on the shelves, on the backroom entrance, and on the backroom to the sales floor entrance.
5) In-store Promotion management and Promotion evaluation
Customers get direct information about special offers and promotions relevant to the product they just picked up from the shelf. When the consumer picks up the product, the fixed tag reader scans it and the customer gets a promotion message on a special information screen or even its mobile phone. The system distinguishes between shelf sales and promotion stands sales. The suppliers use the system to monitor the sales of products in every store and get assistance in the design of new in-store promotion events. The system even provides them with statistics, evaluation reports, recommendations and specific locations in the store to use, based on their performance and cost. The tags are applied on item level. The tag readers are fixed on the shelves, on the promotion stands and near the special information screens.
6) Demand management
According to this scenario, retailers and suppliers are capable of monitoring the inventory and the sales of products in every store and relocate them, if needed, (e.g. in case of a special promotion event) in order to eliminate lost sales opportunities. Using the system, they receive, on real time, from every retail outlet the on-hand inventory level in the backroom, on the shelves, and even on the promotion stands. They also get sales data from the Point-Of-Sales system. For example, if the supplier runs a promotion campaign for product A and notices that product A is almost out-of-stock in store Y, where it has high sale rates, but in store X there is a lot of product inventory that is not sold then he issues an order "Move product A from store X to store Y". The tags are applied

on case and item level. The tag readers are fixed on the backroom entrance, on the backroom entrance to the sales entrance, on the shelves and on the promotion stands.

7) Traceability information

According to this scenario, the consumer at the end-point-of-sales (retail store) has a clear view of the products' history and origin. When the consumer reaches the shelf, he cannot be sure for the product's quality and safety. So, he picks up the product, the fixed tag reader scans it and, by special information screens, the customer gets details about production date and origin, expiration dates and other unique product's information that can ensure product authenticity and safety. The tags are applied on item level. The tag readers are fixed near the special information screens. The traceability information that belongs to the suppliers is shared with the retailers, in order to enable this collaboration service.

8) Smart Recall

Retailers and suppliers have the capability to identify the location of products with specific characteristics and recall them fast and at minimum cost from the market, e.g. in case there is a risk with consumer safety. When a crisis happens and the products of a specific production lot are found defective, the suppliers' quality managers issue an order "Recall the defective production lot from the market". The system identifies the products and provides with all the locations in the retailer's stores where the products of the specific production lot have been sent. The store personnel is informed to withdraw the products from the specific shelves, promotion stands and the backroom and prepare them to be sent back to the suppliers. As a result, the retailer has avoided the customers' dissatisfaction and for the suppliers it was not necessary to recall all the products of the kind. The tags are applied on case and item level. The tag readers are fixed on the backroom entrance and shelves, on the backroom to the sales floor entrance, on the shelves and on the promotion stands.

Table 1 summarizes the above RFID-enabled supply chain collaboration services. Each scenario is presented according to the information shared between the collaborating retailers and suppliers, the tag readers location, and the tagging level.

Table 1: Characteristics of the eight RFID-enabled Supply Chain Collaboration Services

RFID-enabled Collaboration service	Information shared	Tag Readers Location	Tagging Level
Backroom visibility	Backroom on-hand stock Orders POS data	Backroom entrance Backroom to sales floor entrance	Case, Item
Out-of-shelf response	Backroom on-hand stock Shelves on-hand stock Out-of-shelf alerts	Backroom entrance Backroom to sales floor entrance Sales floor shelves	Case, Item
Remote shelf management	Number of products' facings Products' position Shelf layout Shelf sales	Sales floor shelves	Item
Dynamic Pricing	Products expiration date Backroom on-hand stock Shelves on-hand stock	Backroom entrance Backroom to sales floor entrance Sales floor shelves	Case, Item
In-store Promotion management and Promotion evaluation	Shelf sales Promotion stands sales POS data	Sales floor shelves Promotion stands near the special information screens	Item
Demand management	POS data Backroom on-hand stock Shelves on-hand stock Promotion stands on-hand stock	Backroom entrance Backroom to sales floor entrance Sales floor shelves Promotion stands	Case, Item
Traceability information	Product traceability information (production date and origin, expiration date, product history, etc.)	near the special information screens	Item
Smart Recall	Product information Product location information	Backroom entrance Backroom to sales floor entrance Backroom shelves Sales floor shelves Promotion stands	Case, Item

5. CONCLUSIONS

Supply chain collaboration in retailing and Fast Moving Consumer Goods industry (FMCG) has mainly been

expressed in the form of practices such as Vendor Managed Inventory (VMI), Continuous Replenishment Program (CRP), and Collaborative Planning, Forecasting and Replenishment (CPFR). The emergence of RFID is expected to revolutionize many of the collaborative supply chain processes and to empower new collaboration scenarios, such as anticounterfeiting, product recall and reverse logistics, collaborative in-store promotion management and total inventory management. This paper proposes eight RFID-enabled supply chain collaboration services (e.g. dynamic pricing, smart recall, in-store promotion management, out-of-shelf response) in a networked retail business environment. The services are characterized, on a high-level, by the information shared between retailers and suppliers, the level of tagging (pallet/case/item level) and the location of the tag readers. However, these RFID-enabled supply chain collaboration scenarios will be further assessed according to four dimensions : the extent of collaboration required between retailers and suppliers; the RFID technology requirements the transformation of existing (or the introduction of new) processes and the business case contribution of the service.

ABSTRACT

Micro Wind Turbine (MWT) is a small scale wind turbine of Micro Wind Power (MWP) with major application for buildings. The power range is varied, however, it's defined that MWP has power until 1,000 W. According to its axis, MWP can be divided into 2 parts; horizontal axis WT and vertical axis WT.

Sebesi island is located at 5o 55' 37,43" - 5o 58'44,48" SL and 105o 27' 30,50" - 105o 30' 47,54" WL, at Lampung gulf, close to Krakatau archipelagos. The island has area of 2,620 ha and is inhabited by approximately 2,500 people. Main occupation of the people is fishing and farming. Loads at Sibesi Island are supplied by 2 diesel power plants with existing capacities of 40 kW and 50 kW. The fuel used is high speed diesel (HSD). Due to economical reason, everyday the power plant can only operate for 8 hours taking at 4.00 pm to 12.00 am of which the peak load usually happens at 8.00 pm as much as 49 kW.

This study is aimed for conducting simulation if the current power supply is integrated or even eliminated with the application of MWP. We demonstrated the reliability and continuity supply of that integration so that the power can be delivered along day. Pessimistic scenario we used in simulation resulted in the application of MWT may save energy for about 21.02 – 840.96 kWh per year.

Keywords : *Micro Wind Power (MWP), Wind Turbine, Reliability and Continuity Supply, Sibesi Island*

1. INTRODUCTION

Wind is air flowing from which higher pressure to lower pressure. Due to this movement, kinetic energy can be driven, and it depends on mass and velocity. Equation 1 expresses the kinetic energy formula :

$$E = \tfrac{1}{2} m V^2 \quad (1)$$

If $m = A.V.q$ and thus

$$P = \tfrac{1}{2} q A V^3 \quad (2)$$

Betz describes Wind Turbine (WT) can only convert wind kinetic energy not more than 59.3 %. This boundary is then called Betz limit which is 0.592593. According to this limit, the power resulted by WT can be obtained by equation 3 below :

$$P = 0.592593 \left(\tfrac{1}{2} q A V^3\right) \quad (3)$$

Notes :
m = mass of air block [kg],
A= surface area of air block [m2],
q = air density [kg/m3]
V = air velocity [m/sec],
E=energy [Joule],
P=power[Watt].

The wind velocity depends on at what height the measurement is conducted. Besides, it also depends on roughness of earth surface which is represented by equation 4 below :

$$\frac{V}{V_r} = \left[\frac{H}{H_r}\right]^{\alpha} \quad (4)$$

Where $\alpha = \dfrac{0.37 - 0.088 \ln(V_r)}{1 - 0.088 \ln\left[\dfrac{H}{10}\right]}$

The graph below represents α :

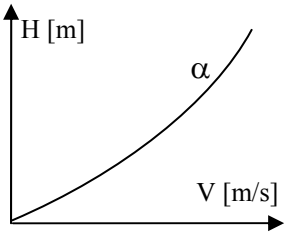

Figure 1. Friction coefficient of earth surface

Notes :

V = wind velocity at height H [m/sec],
Vr = wind velocity at referenced height Hr [m/sec],
H = height at which measurement conducted [m],
Hr = referenced height [m]
α = Earth surface friction coefficient

2. THEORETICAL OVERVIEW

Micro wind power (MWP) is the systems of wind power having micro power. The power range is varied, however, it's defined that MWP has the power until 1,000 W. According to its axis, MWP can be divided into 2 parts; horizontal axis WT and vertical axis WT. Figure 2 and 3 describe those kinds of WT.

Figure 2. Wind Turbine with Horizontal Axis

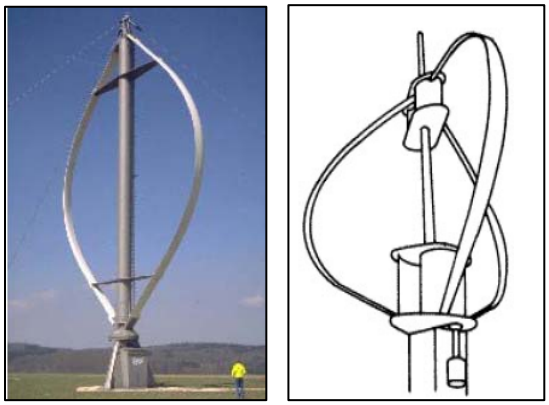

Figure 3. Wind Turbine with Vertical Axis

Micro horizontal axis WT is usually used on the roof building or beside the building. Figure 4 shows the application of horizontal axis WT.

Figure 4. Application of Horizontal Axis Wind Turbine

For the areas with low wind velocity, the MWP is equipped with batteries and electronic control equipment. Figure 5 shows the application of vertical axis wind turbine.

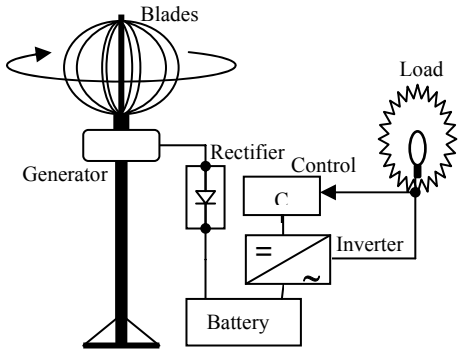

Figure 5. Wind Power Systems

Nowadays some of WT are using permanent magnet induction generator as for electricity generation. The rotor is composed by strong-permanent magnet made by Neodymium (NdFeB). The flux resulted by this material can achieve 10 times higher than that of conventional magnet (Ferrite). Besides, the rotor and stator have also simple shapes, in the plate-form. Figure 6 shows the rotor and stator of MWT.

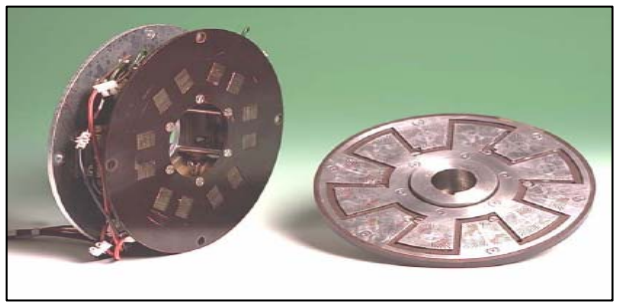

Figure 6. Stator and Rotor of Micro Wind Turbine

3. METHODOLOGY

3.1 Study Area

Sebesi island is located at 5o 55' 37,43" - 5o 58'44,48" SL and 105o 27' 30,50" - 105o 30' 47,54" WL, at Lampung province gulf, close to Krakatau archipelagos. The island has area of 2,620 ha and is inhabited by approximately 2,500 people. Main occupation of the people is fishing and farming. Figure 7 shows the location of Sibesi Island captured by Google Earth Map :

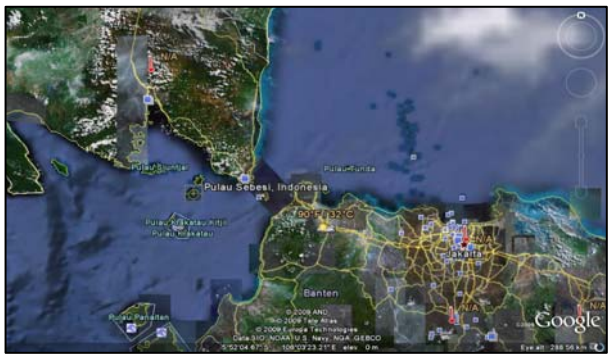

Figure 7. Location of Sibesi Island

3.2 Data Gathering

In this simulation, we did not measure the wind velocity at the proposed area. We are utilizing the data obtained from the website of www.weatherbase.com. The website informs that the average wind velocity in Sibesi Island measured at height of 10 m is 4.17 m/s. The annual wind velocity of Sibesi Island can be seen at Figure 8 below :

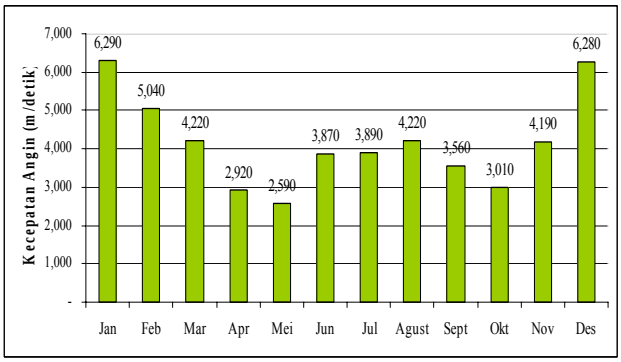

Figure 8. Average Wind Velocity in Sibesi Island

According to Apriansyah, reporting daily load for Sibesi Island to PT. PLN (Persero) branch Lampung in 2009, the loads are supplied by 2 diesel power plants with existing capacities of 40 kW and 50 kW. The fuel used is high speed diesel (HSD). Due to economical reason, everyday the power plant can only operate for 8 hours taking at 4.00 pm to 12.00 am. The peak load usually happens at 8.00 pm as much as 49 kW. The daily curve load of Sibesi Island may be seen in Figure 9 below.

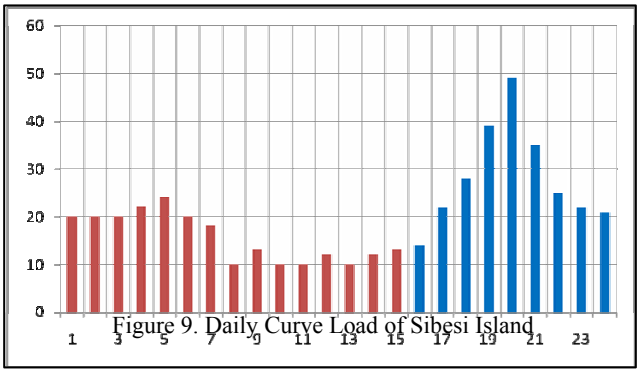

Figure 9. Daily Curve Load of Sibesi Island

Notes :
The blue bar shows the real load. The red bar presents the daily curve load if the load's supplied by full 24 hours a day.

4. RESULT AND ANALYSIS

The study is then conducted be assessing the systems if the loads are supplied by a continued power, 24 hours a day. For this case, we apply the HOMER software, a micropower optimization software developed by National Renewable Energy Laboratory USA. The result shows the daily loads profile of Sibesi Island as can be seen in Figure 10.

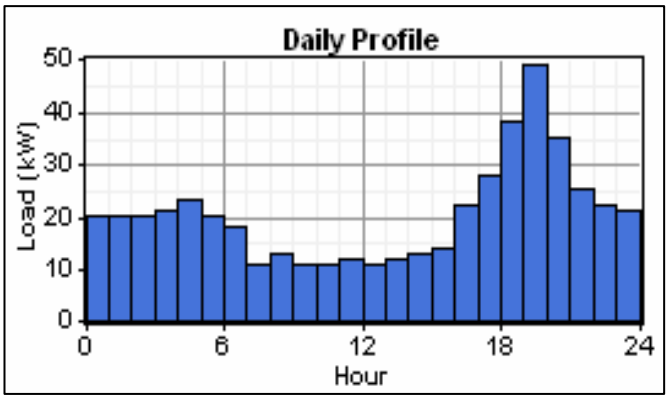

Figure 10. Daily Curve Load of Sibesi Island with Continued Supply (Simulated by HOMER software)

The simulation used pessimistic scenario, suited with the location. We assumed the loads are buildings at Sibesi Island. The number of user and usage period can be predicted as below :

- Number of User : 0.8 x 1/5 building/people x 2000 people = 400 users.
  The value of 0.8 is the user factor.
- Usage time for 1 year : 0.6 x 8760 jam = 5260 jam
- WT height is approximated 4 m.

The MWT used in this simulation is with capacity of 400 W. Wind velocity is ranged at 2.8 – 6.29 m/s. The simulation resulted in the annual energy production of MWT as table 1 below :

Table 1. Annual energy production of MWT

% User	Energy [MWh]			
	25%	50%	75%	100%
10	21.02	42.05	63.07	84.10
20	42.05	84.10	126.14	168.19
30	63.07	126.14	189.22	252.29
40	84.10	168.19	252.29	336.38
50	105.12	210.24	315.36	420.48
60	126.14	252.29	378.43	504.58
70	147.17	294.34	441.50	588.67
80	168.19	336.38	504.58	672.77
90	189.22	378.43	567.65	756.86
100	210.24	420.48	630.72	840.96

Or it's more convinience by showing it through Figure 11 below :

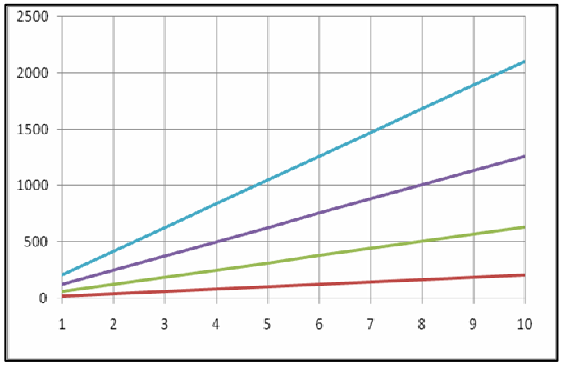

Figure 11. Annual energy production of MWT

The above table informs by using the lowest wind velocity and the less users, the MWT may save the energy as much as 21.02 kWh per year. Meanwhile, by using highest approach, the MWT may produce energy as much as 840.96 kWh. The pessimistic scenario was taken sonce the power purchse of the people living at Sibesi Island is still low. By applying MWT, the peak load not only will be suppled by diesel power plant, but also by MWT. As the matter of fact, the system will more reliable and the dependance to fossil fuel can be decreased, even may be eliminated from the grids.

5. CONCLUSION

The investigation of continuity and reliability supply of MWT at Sibesi Island has been studied. The simulation shows the application of MWT results in the higher reliable of the systems. Consequently, the use of high speed diesel as the fuel can be decreased. Pessimistic scenario delivers the application of MWT may save energy for about 21.02 – 840.96 kWh per year.

ABSTRACT

Web based automated essay grading system using Latent Semantic Analysis (LSA) method for Indonesian language has been developed in Electrical Engineering Department, University of Indonesia. The system which is called SIMPLE-O is developed using PHP and MATLAB for essay grading process. SIMPLE-O has some weaknesses based on previous research. First: consumed maximum of processor time (resource) to process essay grading; second: does not support multisession.

Improvement of SIMPLE-O is designed by replacing MATLAB with Java Matrix (JAMA). JAMA is a basic linear algebra package for Java and compatible with PHP language. Performance analysis is executed by benchmarking and perflogs tools. Benchmarking result shows the summary of throughput and percentage of running system while perflogs tools show the percentage of processor time.

The analysis results of implementation SIMPLE-O with JAMA have shows an improvement on its performance which is enhancement in time of request approximately two times faster for single user and also for multiple user. An improvement on processor performance is shown by its efficient and effective time to handle single and multiple users. The testing result shows that request failure is decrease compare to the SIMPLE-O before the implementation of improvement design.

1. INTRODUCTION

Assessment is very important component in every education system to evaluate student understanding of the whole study materials. There are two main forms of assessment questions [1]: objective form and essay form. Objective type of question is multiple choices with several answers available to choose. While essay form, do not provide answers. Student must answers the question with their own thought, therefore answers will vary.

Assessment with essay form is more preferable for lecturer to evaluate student's ability because it provides an opportunity for student to demonstrate wide range of skill and knowledge including higher-order thinking skills such as synthesis and analysis [2]. Although assessing student's writing is the most expensive and time consuming, and also hard to give objective judgment.

On e-learning concept, assessment made online start from answer the question until grading with numbers. This evaluation system uses computers to give faster and accurate grading and also handle large scale of assessment.

Next problem is how to make effective grading process in the system. The idea of automated essay grading is based on this problem. Several automated essay grading methods on computer based system already being developed. Each method has its own grading system.

One of the developed automated essays grading method is Latent Semantic Analysis (LSA). In its grading process, LSA method only considers the word contexts does and does not appear without consider its linguistic characteristic [3]. This method is based on linier algebra computation, Singular Value Decomposition (SVD), which is a mathematical matrix decomposition technique. Matrix is representation of the text, where each row stands for a unique word and each column stands for a text passage. In SVD, a rectangular matrix is decomposed into the product of three other matrices. These matrices are reconstructed after one of the matrix, which is diagonal matrix containing scaling value being simplified. Reconstructed matrix has shown strong correlation between topic and text. This method is relatively simple but quiet accurate compare to human raters. Because of it simplicity and accurate, this method is interesting to be developed as essay grading on web-based distance learning system.

Doctoral research at Electrical Engineering Department, University of Indonesia, has developed an automated essay grading using LSA [4]. This system was originally given the name SIMPLE, and then become SIMPLE-O (SIsteM PeniLaian Esei Otomatic) which can be accessed from the intranet/internet through a web browser. This system process students' answers with LSA method to calculate the final mark. This web-based system developed with PHP programming language and MATLAB as a computing device to perform the SVD on the matrix of LSA.

The results of performance analysis [5], SIMPLE-O has some weaknesses, namely:

1. SIMPLE-O using the processor (resource) to 100% for the process essay grading.

2. SIMPLE-O does not support multisession. There was some process failure in the entire request that not successfully perform.

On this paper, the weaknesses above are fixed to improve the system performance, where it can be more effective and efficient. Therefore, the improvement of SIMPLE-O is designed by replacing MATLAB with other applications that are expected to process the SVD calculation faster and do not burdensome processor work, which is JAMA (Java Matrix). Code optimization is also need to carry out by using ZEND compiler and afterward convert the PHP 4 into PHP 5.

2. AUTOMATED ESSAY GRADING

Conventional essay grading is generally done by human raters. Now, many automated essay grading has been developed. Automatic in this context means that the essay grading is done by the tool, which is computer.

Some methods of automatic essays grading by computers have been developed which are *Project Essay Grade* (PEG), *Intelligent Essay Assessor* (IEA), *Electronic Essay Rater* (E-Rater), *Conceptual Rater* (C-Rater), *Bayesian Essay Test Scoring System* (BETSY), and *Automark, Scema Extrack Analyse Report* (SEAR) [6]. Every method has its own way to grade. One of the automated essays grading that being developed on Bahasa Indonesia based exam is SIMPLE-O.

2.1 SIMPLE-O

SIMPLE-O using the Latent Semantic Analysis (LSA) method to evaluate the students' essay exam answers. Basically, an LSA compare a text with the words chosen as a reference. LSA represents the words in a text in a semantics matrix. A relationship between each word is obtained by matrix algebra technique known as singular Value Decomposition (SVD).

2.1.1 Latent Semantic Analysis (LSA)

LSA is a technique to extract and represent sentences with mathematical or statistical calculation. The strength of the LSA technique lies in the syntax structure insensitive, thus the words processed are words from a bag of words ignoring the sequence of the sentences. LSA express the ideas about the meaning of the word, where words are occupying a position in semantic space and the meaning is the relationship between one sentences to another [7].

Assumptions that underlie LSA are that the similarities and differences in the meaning of words can be influenced by the similarities and differences in the overall context in which the word is there or not. Conversely, in the meaning of the sentence can be verbal outline of the combination (in the form of mathematics) from the words within it. This assumption implies that usually the dominant verbal meaning is based on the selection and combination of words in the speech. And for various purposes, the order in a text can be ignored in the sense to estimate similarity with only slight loss of accuracy. Thus the assessment of any text with the LSA more emphasis on the words contained in any text without notice a linguistic characteristics, such as grammar, how to write, and order of words in a sentence, therefore a sentence does not require a good rhetoric.

To apply to the basic assumption in computing systems will require a model where the word is a representation of mathematics function as a set of the observed linguistic context, and representation of linguistic context is a mathematical function of the words that are in it. In LSA, the linier function between word and meaning of text and linier factorization are used to construct text into the form of high dimension vectors. In LSA, the text is a combination of the vectors containing the words, and words are the meaning of the vectors from the observed text. Computation form that is used in the LSA is an algebra method of Singular Value Decomposition (SVD) matrix, continued with the dimensional reduction.

2.1.2 Singular Value Decomposition

Singular Value Decomposition (SVD) is a mathematical matrix decomposition technique. Matrix formed from whether there is or there isn't a specific word appears in a text (usually already defined as keywords). This matrix by Singular Value Decomposition divided into 3 (three) matrices [3]. In reconstructed matrix from decomposed matrix using SVD will be seen strong correlation between topics or sentences joined in a specific group.

After the 3 matrices are obtained, the next process is reducing matrix dimension by reducing the second matrix dimension, a diagonal matrix. Reducing the dimension of a diagonal matrix is performed by setting all diagonal values of the second matrix into zero (0) except for certain chosen dimension. And if the three matrices components are multiplied, it will produce other reconstruction matrix for desired correlation value purpose.

Mathematically, a matrix can be well decomposed if it has small factor value compared to smallest dimension of the original matrix. Thus, the best matrix reconstruction will be obtained when the factor value is smaller than the sum of factor used

2.1.3 JAMA: JAVA MATRIX

JAMA: Java Matrix is a basic linear algebra package for Java [8]. It provides user-level classes for constructing and manipulating real, dense matrices. JAMA is comprised of six Java classes: *Matrix, CholeskyDecomposition, LUDecomposition, QRDecomposition, Singular Value Decomposition* and *Eigenvalue Decomposition.*

The Matrix class provides the fundamental operations of numerical linear algebra. Five fundamental matrix decompositions, which consist of pairs or triples of matrices, permutation vectors, and the like, produce results in five decomposition classes. These decompositions are accessed by the Matrix class to compute solutions of simultaneous linear equations, determinants, inverses and other matrix functions. The five decompositions are

1. Cholesky Decomposition of symmetric, positive definite matrices
2. LU Decomposition (Gaussian elimination) of rectangular matrices
3. QR Decomposition of rectangular matrices
4. Eigenvalue Decomposition of both symmetric and nonsymmetric square matrices
5. Singular Value Decomposition of rectangular matrices

Currently, there are six classes JAMA on the programming language PHP. Class has been converted into the PHP language that can be used on systems with the function call.

2.1.4 Benchmarking

In computing, a benchmark is the act of running a computer program, a set of programs, or other operations, in order to assess the relative performance of an object, normally by running a number of standard tests and trials against it.

An effective way to test and design a system to detect the bottleneck is with the benchmarking of traffic simulation [14]. Benchmarking is a method to measure the ability and speed of a computer program. Tools that can be used to perform benchmarking is Apache Bench.

One of the benchmarking tools is ab, Apache benchmarking. This tool is one package with Apache web server and is usually already installed on systems that run Apache. Ab's working concept is by sending a number of client requests to simulate a web server with a certain delay to access the same URL.

3. DESIGN OF IMPROVED SIMPLE-O

3.1 System Specification:

- Software: PHP 5.3.11, MySQL 5.0.45, Apache 2.0.49, JAMA 1.0.1 and Windows XP
- Hardware: minimum requirements are Pentium 4 with 2 GHz and Memory 512

3.2 Architecture

Figure 1 below shows the architecture of Automated Essay Grading by using LSA method (SIMPLE-O) with JAMA. The block component of JAMA has replaced MATLAB.

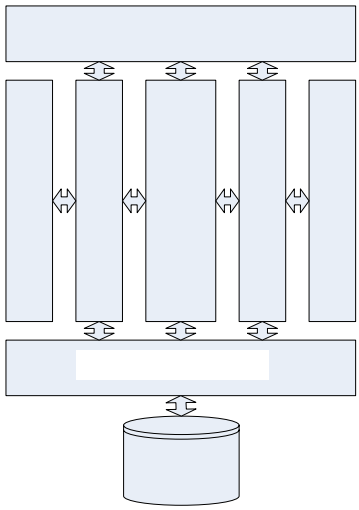

Figure 1 Architecture of improved SIMPLE-O

At the server side, web server program is installed with MySQL and JAMA. MySQL has a function as structure process while JAMA program has a function as a center of grading computation, where the singular value decomposition function on JAMA is utilized to do the computation based on Latent Semantic Analysis system. Library of singular value decomposition function on JAMA being connected or called from PHP program on client web browser.

JAMA used in this architecture is JAMA API that has been ported or compile into PHP. Thus the evaluation process on essay exams is expected to be faster.

3.3 Optimize Code

Code optimization to improve performance of SIMPLE-O is done using the software Zend Studio. With Zend Studio, scripting SIMPLE-O, who was originally using PHP 4, converted to PHP 5. This is done because there are some limitations on PHP 4. A limitation in the PHP 4 is located on the object oriented model, where

duplication of a semantic object type as its native. This is clearly visible at the time to send a variable (that point to another variable), then a copy of the object will be created. Developers assume that the two variables refer to the same object, although in reality the two variables are different duplicate objects. Changes in the value of an object will not change the value of the duplicates object. These limitations

affect performance even trigger the emergence of strange bugs.

4. IMPLEMENTATION AND TESTING OF IMPROVED SIMPLE-O

The performance improvement design of SIMPLE-O is implemented in a notebook computer that functions as a client while the server software with the support that has been previously installed.

Implementation on optimization is done by changing the method in the iteration algorithm of the search word in the database with the method of internal searching in PHP, which is array_search. This method is the method dichotomy search, the search process so much faster than the search method sequential. In addition, this method is a method of internal PHP functions that speed up the process of search and iteration.

JAMA on the implementation of the SIMPLE-O is done by placing the folder containing the six classes JAMA on same the folder with SIMPLE-O. If not placed in the same folder then needed include ¬ _path in php.ini file, so that PHP can call JAMA.

To analyze the performance of SIMPLE-O, testing is made with 2 types. Trial conducted with the purpose to know the performance of SIMPLE-O with the number of:

1. Only one user (single user).
2. Many users (multiple users).

4.1 Single user testing

Testing is done when user's type a URL in a browser to access SIMPLE-O http://localhost/bobotsama. After that the login page will appear before login to the system, where the user must enter userid and password. Userid and password has been registered before by the administrator. Userid used for the testing has a role as student that can only access 'Pilih Ujian' (take exam) and 'Lihat Nilai' (grade/mark). When student clicks the 'Pilih Ujian', the page will looks as seen in Figure 2.

Figure 2 List of Exam

After student clicks the 'Submit' button, the SIMPLE-O will process student's answers with LSA method. Processes are

1. Form answers matrix where there are:
   - the separation of each word in the student answers
   - the process of keyword searches and similar word of each word answers from students
2. compare the reference matrix and the answers matrix
   - computing the matrix SVD
   - Frobenius normalization and alpha Cosinus

To get the test data as much as 10 times, testing is done by using the ApacheBench to simulate the functioning of sequential communication. This method is used to see the performance of SVD in to calculate a LSA method.

4.2 Multiple user testing

Testing aims to analyze the performance of SIMPLE-O at the same time accessed by many users. With only one computer, then the testing is done using the ApacheBench which is able to simulate the user traffic. To test this, ApacheBench configured with 50 concurrent users and client as 5. So SIMPLE-O runs through ApacheBench send a request to calculate the simulated value of 50 students from the user, where the calculation is done for 5 users at one time simultaneously.

5. ANALYSIS OF TESTING RESULT

5.1 Result of single user testing

At this testing, the one of tools in Administrative Tools, the Performance Logs and Alerts being used to capture *%Processor Time* on the Apache and MySQL. *% Processor Time* is percentage of time that is used by the processor to execute a thread. *Counter* is the main indicator of processor activity and displays average percentage of processor work. The results is shown in Table 1 below

Table 1: Single user testing result (% Processor Time)

Time	Apache %	MySQL%
7:44:23 PM	21	0
7:44:24 PM	99	0
7:44:25 PM	98	0
7:44:26 PM	100	0
7:44:27 PM	99	0
7:44:28 PM	99	0
7:44:29 PM	96	0
7:44:30 PM	99	0
7:44:31 PM	100	0
7:44:32 PM	97	0
7:44:33 PM	98	0
7:44:34 PM	99	0
7:44:35 PM	100	0
7:44:36 PM	99	0
7:44:37 PM	99	0
7:44:38 PM	99	0
7:44:39 PM	99	0
7:44:40 PM	99	0
7:44:41 PM	37	0
Average	**90.28571**	**0**
Max	**100**	**0**
Min	**37**	**0**
Std Deviation	**23.49975**	**0**

Figure 3 shows the results of SIMPLE-O simulation with JAMA for 10 alternate user with the Concurrency Level = 1. The average time per request was 1.761 seconds. Data in Figure 3 also shows the throughput of requests per second = 0.57 and time per request = 1.761533 seconds. Percentage indicates the end of that time to the maximum of a request is 1.812 seconds.

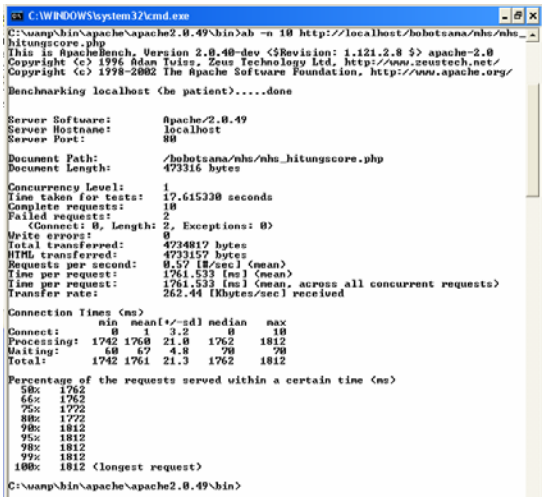

Figure 3 Simulation result of SIMPLE-O with JAMA from *ApacheBench* with 10 requests.

Figure 3 also shows 2 requests fails from 10 requests that run through the simulation ApacheBench, the SIMPLE-O with JAMA and the B-Tree indexing the failure of 20%.

Compare to previous research [5], the average time per request is 78, 854 seconds. The throughput of requests per second = 0.01 and time per request = 78.854 seconds. The last percentage indicates the maximum time of a request is 82.949 seconds. 10 request from the 2 runs that have failed the request. Thus SIMPLE-O experienced failures of 20%.

5.2 Result of multiple user testing

Table 2 is the result of the testing with 50 users of the Performance Logs and Alerts tool. ApacheBench run for 50 users and 5 Concurrent clients by using the option-n and-c.

Table 2: Multiple user testing result (% Processor Time)

Time	Apache	MySQL%
Average	98.18852	0
Max	100	0
Min	53	0
Std Deviation	4.41884	0

Figure 4 Simulation result of SIMPLE-O with JAMA from *ApacheBench* with 50 requests and 5 concurrent clients.

Figure 4 is summary result of SIMPLE-O with JAMA for 50 users with 5 concurrent clients. The results showed the failure of a request is 4 out of 50 requests. The percentage request failure has reach 8%. The average time per request was 2.431 seconds, where the average is taken of the overall concurrent request. Data in Figure 4 also shows the throughput of requests per second = 0.41 and time per request = 12.1575 seconds. The last percentage indicates the maximum time of a request is 23.163 seconds.

The result of a simulation SIMPLE-O with 50 users on the previous research [5] is the average time per request is 114, 671 seconds. This simulation test results shows 8 request fail out of 50 requests. Number of concurrent, which should be processed, is 5 requests. This means that each group of 5 Concurrent with any request that fails to request 0.8 Percentage with 16%. The result also shows the throughput of requests per second = 0.01 and time per request = 215.121 seconds. The last percentage indicates the maximum time of a request is 781.083 seconds.

5.3 Analysis of testing

5.3.1. Analysis of single user testing

The monitor results in Table 1 further analyzed with emphasis on the distribution of the appearance of significant numbers shows improvement of SIMPLE-O. Data processed with the frequency of all numbers that also appear to use the normal distribution function for the distribution of data. A result of processing data as a graph is shown in Figure 5 for % processor time. This result will be compared with the results of previous research, where the SIMPLE-O is still using MATLAB. Figure 6 shows the result graph of previous research.

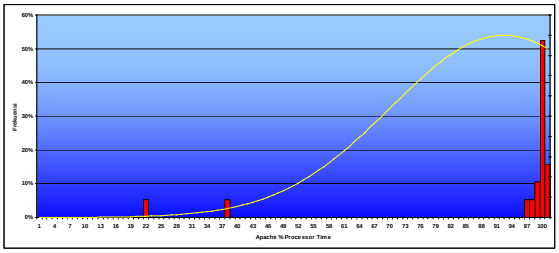

Figure 5 the graph of percentage distribution of the processor Apache on SIMPLE-O with JAMA

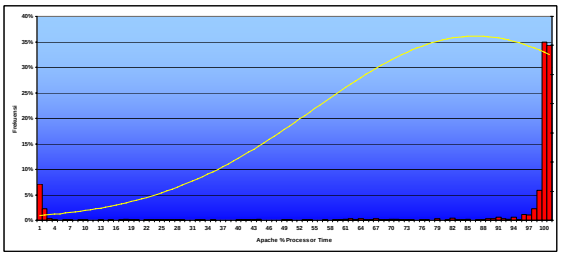

Figure 6 the graph of percentage distribution of the processor Apache on SIMPLE-O

From the graph in Figure 5 shows that the performance of processor becomes more efficient in processing system, with less idle time compare to the previous research. The idle time on the SIMPLE-O system is due to waiting on the results of computing MATLAB.

In Figure 3, the average request was 1.761 seconds. Compared to the results of previous research that reaches the time 78.854 seconds. Thus, SIMPLE-O with JAMA has speed up the process of assessment of the essay grading 44 times faster.

5.3.2. Analysis of multiple user testing

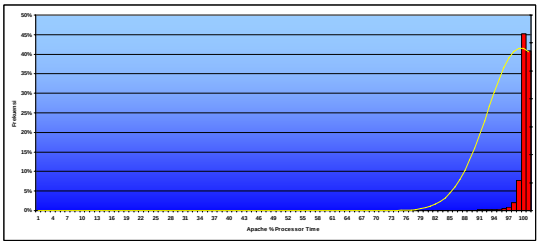

Figure 7 the graph of percentage distribution of the processor Apache on SIMPLE-O

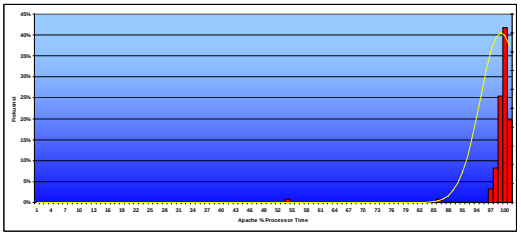

Figure 8 the graph of percentage distribution of processor Apache on SIMPLE-O with JAMA

From the graphs in Figure 7 and Figure 9, visible changes in the chart with wide differences in the distribution of standard deviation from the previous 6.848932 SIMPLE-O 4.41884 on a SIMPLE-O with JAMA and the B-Tree indexing. This change is in line with expectations from previous research that is SIMPLE-O after the improvements will have a standard deviation that is smaller and the distribution of the graph becomes smaller.

In Figure 4, the average request was 2.431 seconds. Compared to the results of previous research that reaches the 114.671 seconds, thus SIMPLE-O JAMA has speed up the process of essay grading into 47 times faster. And also the percentage request failure has reach 8%, decrease by 8% compare to previous research.

6. CONCLUSION

Implementation and analysis of system's testing result on a SIMPLE-O with JAMA have produced the following conclusions:

1. Multisession, reduce the request failure into 8% for multiple users
2. Improvement algorithm is become efficient as evidenced from the time of the request (time to process a request), which increased 44 times faster for single user and 47 times faster for multiple users

ABSTRACT

Providing uninterrupted power to a remote telecommunication site has been a problem for industry for many years This paper discussed about the way to design the aspects of a hybrid power system that will target for Base Transceiver Station (BTS) in Pecatu Bali. The main power system is emphasizes on the photovoltaic panels, wind turbine and combine generator as backup units to obtain a reliable autonomous system with the optimization of the component sizes and the improvement of the capital cost. The optimization software used for this paper is Hybrid Optimization Model for Energy Renewable (HOMER). HOMER is a design models that determines the optimal architecture and control strategy of the hybrid system. It can also determine the sensitivity of the outputs to changes in the inputs. It performs an hourly time series analysis on each of different configurations. The results of HOMER simulation for electrical BTS shows that annual production consists of Photovoltaic (12,330 kWh/yr), wind turbine (9,423 kWh/yr), and generator (6,032 kWh/yr), AC primary load consumption 14,308 kWh/yr, and DC primary load 11,480kWh/yr. Besides the results shows unmet load (electrical load that the power system is unable to serve) in system 0.07% or 17.5kWh, it is indicates that the power system from hybrid energy is reliable within supply BTS power load.

Keyword
Hybrid energy, BTS(Base Transceiver System), Telecommunication, Photovoltaic, Wind Turbine, Generator.

1. INTRODUCTION

The fuel price in Indonesia country always changed overtime, the effect of fuel price makes the inflation rate going into fluctuation. This uncertainty condition influenced telecommunication sector which is the cost of network load system increased expensively. For example, to generate electrical power BTS (Base Transceiver Station) in remote area can not reliable only from Government, so we can used renewable energy and generator to back up power and can support the available electricity energy system and provide the continuity of supply demand for whole year.

Renewable energy designs depending on the nature resources in that area [1]. This paper is concern about the configuration of hybrid power system planning for BTS in Pecatu Bali. Pecatu located in South of Bali Island, with the coordinate 8° 49' 50" South and 115° 07' 37" East. Pecatu have global solar radiation 4,82kWh/m2/d [2] and annual wind speed 4,37 m/s [3]. BTS needs power load AC 39kWh/d and power load DC 31kWh/d [4]. With utilize aught natural resources, therefore renewable energy concept that is utilized namely combine the sun energy and the wind energy, and diesel generator for meeting energy requisition while system experiences trouble, so network will make a abode stable. Acquired gain of BTS renewable energy among those is increase electricity, more electric reserve long-lasting, penny wise its preserve, and doesn't result perilous waste. The electricity of wind turbine and solar cell will keep in battery. On normal condition, battery will meet the need electricity. In designs of BTS alternative energy, can be helped by named software Homer. Homer, the micro optimization model, simplifies the task of evaluating designs of both off-grid and grid-connected power system for a variety of applications [5].

2. RENEWABLE RESOURCE DATA

2.1 Wind Resources Information

The preliminary study was done using data obtained from Kuta wind report (www.windfinder.com). The report data observations taken between 12/2002 - 2/2009 daily from 7am to 7pm local time with annual wind speed average 4.37 m/s. Based on the available data, the average wind speed at 10m height for each month in Pecatu is plotted in fig. 1.

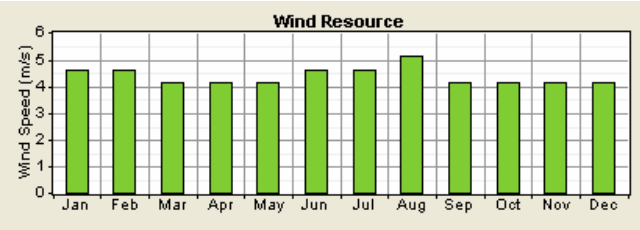

Figure 1. Pecatu average monthly wind speed

2.2 Solar Resources Information

The solar resources for this study are obtained from NREL and NASA data. The monthly average solar irradiance is summarized in Figure 2.

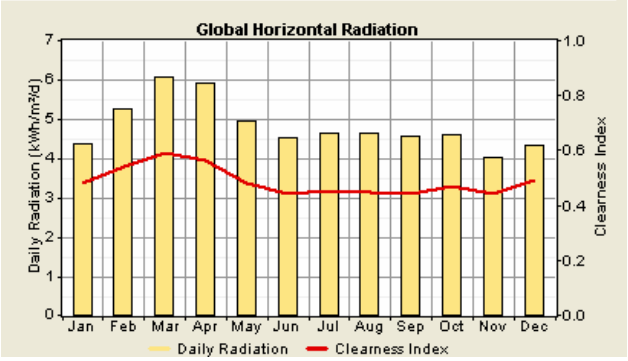

Figure 2. Pecatu average monthly solar irradiance

3. ELECTRICAL LOAD DATA

Pecatu load data collected over three days (March 1-3 2008) which represents weekday and weekend load. Based on Indosat telecommunication operator, the BTS load consists of AC and DC load. The daily AC load power consumed 39kWh/d, and DC power load consumed 31kWh/d. Minimum load occurring betweens midnight until 6 am, due to the reduction of telephone calls during this period. Figure 3, and figure 4 is an annual graph of the site loading as produced by HOMER software.

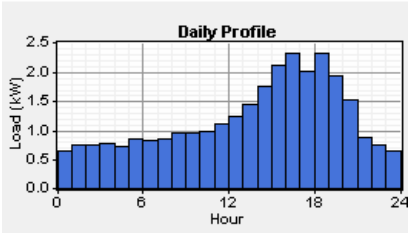

Figure 3. The annual DC Power load

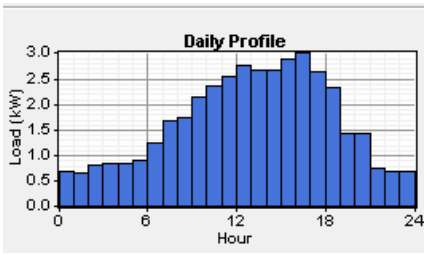

Figure 4. The annual AC Power load

4. HYBRID SYSTEM COMPONENT

The main components of an isolated grid connected PV-Wind-diesel hybrid system are solar cell, wind turbines, and diesel generator. A typical PV-Wind-diesel system used in HOMER software is shown in Figure 5. The system consists of solar cell, wind turbine, diesel generator, converter, battery bank, AC-DC bus and primary load. The cost of each component, the number of units used in simulation, the economical and control parameters required by software are discussed in the forthcoming paragraphs.

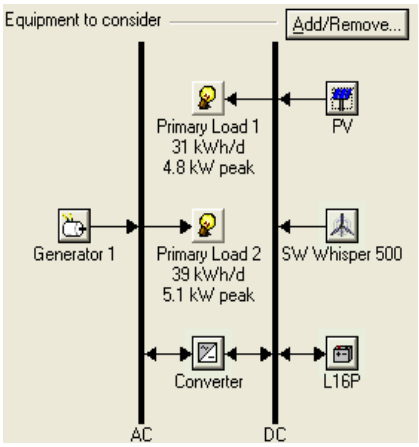

Figure 5. PV-Wind-Diesel system

4.1 Photovoltaic

Solar cell panel utilized MA100. One solar cell panel gets capacity 100W at the price $875.00. That cost included ordering cost via online, shipping, installation charge. In a general way, solar cell module marketed by capacity 100 peak's Watts (Wp) and its multiple. Solar unit Watt peak is power unit (Watt) one that gets to be generates by photovoltaic module in Standard Test Condition (STC) [6]. In one system, this solar panel can be arranged and is strung up as many panels, according to energy which is needed. This solar panel have excess which is film coat structure photovoltaic that weatherproof, stable regular under tall temperature up to summer. Lifetime of the modules has been taken as 25 years.

4.2 Wind Turbine

HOMER models a wind turbine as device that converts the kinetic energy of the wind into AC or DC electricity. Wind turbine type used SW Whisper 500, between another wind turbine data one provided by HOMER, this turbine has best performance for wind speed quality average 4m/s. Wind turbine have energy of 3kW at the price $6,300, and warranty up to 5 years [7].

4.3 Generator

Generator consumes fuel to produce electricity, and possibly heat as a by-product. Generator is designed not for supply peak load entirely, because largely load charges serviced by solar and wind energy. The capital costs of the diesel generator are set to $2110, replacement costs $2110, and operation & maintenance costs $0.2/hr [8].

4.4 Converter

Converter is device that converts electric power from AC to DC in a process called rectification, and from DC to AC in a

process called inversion. HOMER can model the two common types of converters: solid state and rotary. The converter type that is used in this system is Xantrex 4kW 12V 50A Inverter Charger [9]. The converter supporting component consists of inverter and rectifier. Converters have efficiency of 95.9% and 95.9%. Cost for converter buy as big as $3130, warranty up to 15 years.

4.5 Battery Bank

HOMER uses the kinetic battery model and represents batteries as a "two tank" system. One tank provides immediately available capacity while the second can only be discharged at a limited rate. Trojan L16P 2x6V nominal capacity 420Ah was chosen because they are a popular and inexpensive option [10]. HOMER considered up to 50 of these batteries.

5. SUPPORTING FACTOR SYSTEM

Fuel Price

In this system uses diesel as a fuel of generator. Fuel price data gets based on Pertamina corporation, diesel price per liter as big as 6,000 IDR [11] or $0.6 (1USD = 10.000 IDR, June 2009).

Economical parameters

Annual interest rate is the discount rate used to convert between one-time costs and annualized costs. The project lifetime was taken as 20 years and the annual real interest rate as 7% [12].

System Control

The system control input define, how HOMER models the operation of battery bank and generators. The dispatch strategy determines how systems charge the battery. This system used dispatch strategy load following, the load following strategy is a dispatch strategy whereby whenever a generator operates, it produces only enough power to meet the primary load. Lower-priority objectives such as charging the battery bank or serving the deferrable load are left to the renewable power sources.

Emissions Inputs

Issue penalty factor is fine one be put on to firm, to draw the line resulting issue systems if exceed specified bounds. Base Energy Information Administration's data (EIA), done by CO2 issue penalty of $100 / ton, NO_2 of $5000/t and SO_2 of $2000/t [13].

System Constraints

Constraints are conditions which systems must satisfy. HOMER discards systems that do not satisfy the specified constraints, so they do not appear in the optimization results or sensitivity results. Maximum annual capacity shortage is the maximum allowable value of the capacity shortage fraction, which is the total capacity shortage divided by the total annual electric load, assumed by its point of 0.5 %. Minimum renewable fraction is he minimum allowable value of the annual renewable fraction, on renewable fraction was done to sensitivity analysis of 75%, 80%, 90%.

HOMER adds this percentage of the hourly average primary load (AC and DC separately) to the required operating reserve for each hour. A value of 10% means that the system must keep enough spare capacity operating to serve a sudden 10% increase in the load.

6. RESULT AND DISCUSSION

6.1 Optimization Result

The simulation software provides the results in terms of optimal systems and the sensitivity analysis. In this software the optimized results are presented categorically for a particular set of sensitivity parameters like wind speed, solar radiation, and fuel price.

Homer groups 5 systems configurations that variably to each component. The results of optimization for wind speed of 4.37 m/s, solar radiation of 4.82kWh/m^2/d, and diesel price of $0.6.

In this BTS case gotten by system configurations as, 8 kW PV panel, 2 wind turbines (6kW), 5kW generator, 50 battery bank, 4kW converter. This configuration is chosen on row first Figure 9, based on the lowest total Net Present Cost (NPC) of $265,317, with Initial Capital Cost of $122,960, and Cost of Energy (COE) of $0.883/kWh. Homer got 78.3% for simulation renewable fraction results. During project lifetime, generator working up to 2,421 hours, with fueled consumption as much 2,476 Liters.

HOMER calculates all of total electrical energy production from hybrid energy and total electrical energy consumption that consists of AC primary load (14.308kWh/yr) and DC primary load (11.490kWh/yr). In this system, PV array generates 12.330kWh/yr, wind turbine of 9.423 kWh/yr, and generator of 6.032kWh/yr. The unmet load of the system is 0.07% or 17.5kWh/yr, capacity shortage is 43.6 kWh/yr, and excess electricity as big 562 kWh/yr. The electrical simulation result is shown in Figure 11. The equation of total production PV and wind turbine shows in below.

Total Production PV = Mean output x 8760 h
= 1.41 kW x 8760 h
= 12,330kWh/yr

Total Production Wind = Mean output x 8760 h
= 1.08 x 8760h
= 9,423kWh/yr

Figure 6 shows the daily contribution of PV, wind turbine, Generator, Batteries on March 1st.

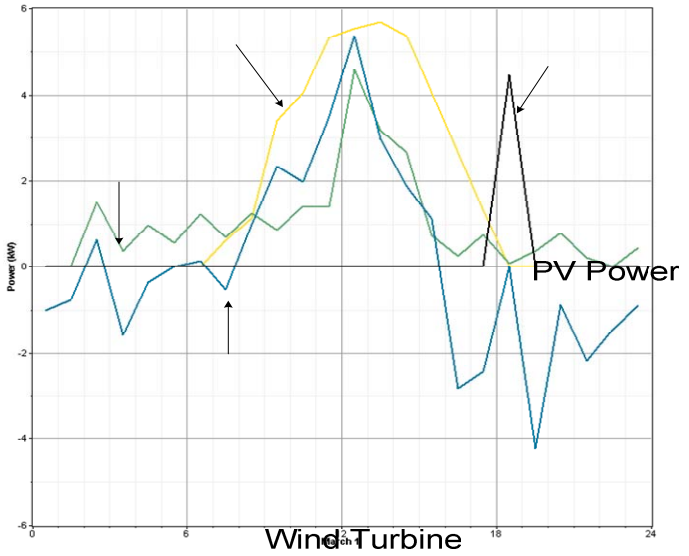

Figure 6. Daily simulation results: contribution of PV/Wind turbine/Generator/Battery on March 1st.

Renewable fraction designed of 75%, it because of wants to maximize energy resource potencies that exist at that region, after simulates, HOMER results renewable fraction of 78%. It means that system was supplied by energy of PV array and wind turbine of 78%, and diesel generator generates energy of 22% to service during a year. The function of generator is only for back up energy when energy from solar cell and wind turbine decrease. Figure 6 shows monthly average electric production by diesel generator, PV, wind turbine, with 78% renewable fraction.

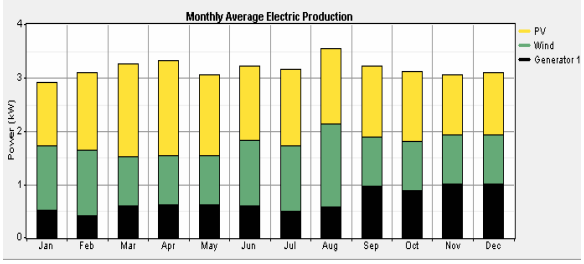

Figure 7. Monthly average electric production with 78% renewable fraction

Renewable fraction influence total NPC and COE. The greater renewable fraction, makes total NPC and COE will greater too (Table 3). It is caused because more system used a lot of hybrid energy where purchasing wind turbine and solar cell more expensive if as compared to generator.

The equation of COE is shown in below :

$$\text{COE 75\%} = \frac{\text{total annualized cost}}{\text{Total consumption energy}} = \frac{\$22{,}767}{25{,}788\text{kWh/yr}} = 0.883$$

$$\text{COE 80\%} = \frac{\text{total annualized cost}}{\text{Total consumption energy}} = \frac{\$22{,}912}{25{,}787\text{kWh/yr}} = 0.888$$

$$\text{COE 90\%} = \frac{\text{total annualized cost}}{\text{Total consumption energy}} = \frac{\$25{,}162}{25{,}797\text{kWh/yr}} = 0.975$$

Table1. Comparison of renewable fraction to output parameter

Renewable fraction (%)	Initial Capital ($)	NPC ($)	COE ($/kWh)	Excess Electricity (%)	Emmision (kg/yr)
78	**122,960**	**265,317**	**0.883**	**2.02**	**6,521**
80	144,525	267,003	0.888	3.55	5,591
90	159,525	293,222	0.975	10.7	5,968

When renewable fraction of 78%, excess electricity that resulting system is seen very small as compared to renewable fraction of 80 and 90%. Excess electricity is surplus electrical energy that must be dumped because it cannot be used to serve a load or charge the batteries. Total excess electricity can be reduced by adds total battery bank, because battery bank function as DC energy storage, but if battery bank increases, it will make systems expensively and changed system configuration entirely. Hybrid power systems have disadvantages in cost sector. To build BTS hybrid energy power system needs fund approximately $122,960**.**

The advantages of BTS hybrid energy systems is increases electricity, durable electrical reserve, economical maintenance, can reduce pollution, and do not depends on government.

6.2 Sensitivity Analysis

Each category was done sensitivity analysis to anticipate uncertainty condition if the value changed on some years, and each changing will determine configurations of systems. Renewable energy system for this BTS will be done for 3 categories sensitivity analysis which is wind speed (3, 4.37, 5, 6m/s), solar radiation (4.82, 5, 6kwh/m2/d), and diesel fuel price (0.3, 0.45, 0.6, 0.8 $/L). So as a whole configuration result is 120 possible configuration systems of 48 sensitivity cases, with simulated time up to 58 minute 32 seconds. The result of sensitivity analysis shows with OST Graph (Optimal System Type).

6.2.1 Condition 1 (Fuel price $0.6/L and $0.8/L)

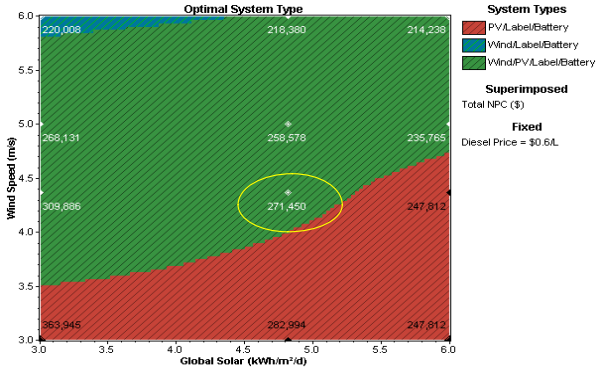

Figure 8. OST graph wind speed and solar radiation: Diesel price $0.6/L

The large of wind speed and solar radiation influenced the result of optimization systems, meanwhile diesel price does not influenced the configuration. It is caused because system utilize hybrid energy of 78%, and generator only 22%, so the system does not consumed a lot of diesel fuel. The most optimal results configurations are PV/Wind/Generator /Battery, with PV and wind turbine as main electrical source. Total NPC and COE cost rise up when the diesel fuel price increase become $0.6/L to $0.8/L.

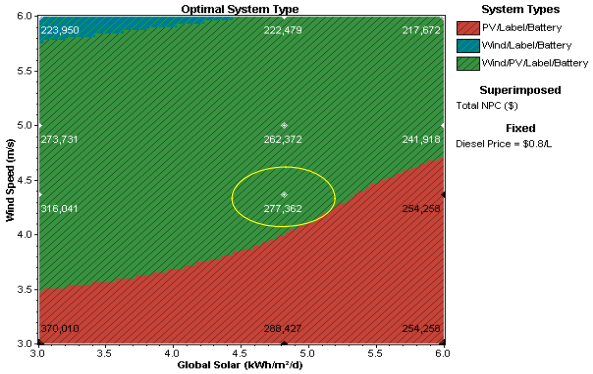

Figure 9. OST graph wind speed and solar radiation: Diesel price $0.8/L

Figure 13 shows graph diesel price $0.6/L, and Figure 14 shows graph diesel price $0.8/L. The different of both figures indicates that total NPC cost changed from $271,450 to $277,362, and total COE changed from $0.903 to $0.923.

6.2.2 Condition 2 (Solar radiation 3 kWh/m^2/d and 6 kWh/m2/d)

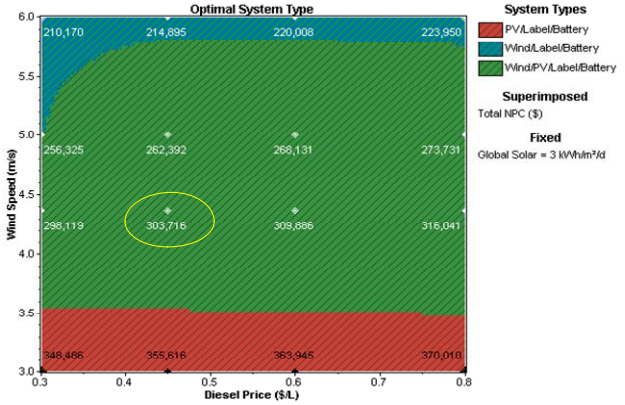

Figure 10. OST graph wind speed and diesel price: Solar radiation 3 kWh/m^2/d

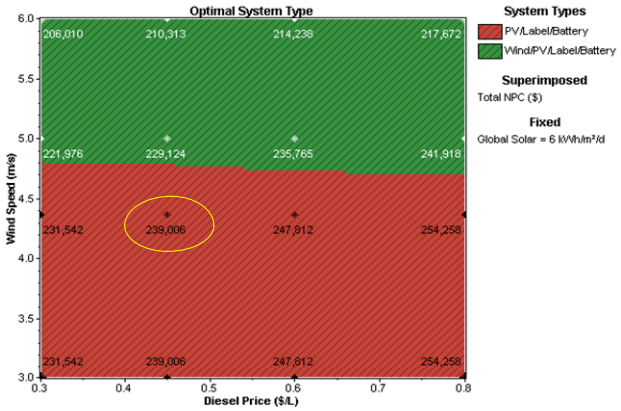

Figure 11. OST graph wind speed and diesel price: Solar radiation 6 kWh/m^2/d

Figure 15 and Figure 16 shows that solar radiation changed from 3kWh/m^2/d to 6 kWh/m^2/d. Alternating solar radiation, influence system configuration and total cost production system. If solar radiation is bigger, hence the configuration system will more rely on solar cell as main hybrid source. Total NPC changes from $300,716 to $233,009.

6.2.3 Condition 3 (Wind Speed 3 m/s and 6 m/s)

HOMER optimization results produce configurations system when the wind speed of 3m/s, consists of PV 16kW, 50 Battery bank, 4kW converter, 5kW Generator. Total NPC system NPC of $275,055, and total COE of $0.915/kWh. Figure 17 shows OST graph when wind speed of 3m/s.

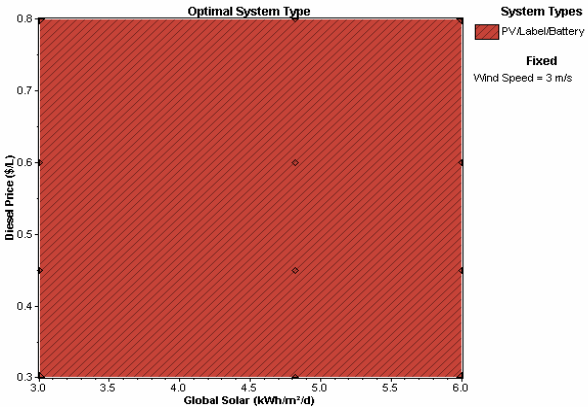

Figure 12. OST graph and diesel price and solar radiation: Wind speed 3m/s

When wind speed increase become 6m/s, configuration system does not change, but total cost production system decrease, total NPC of $213,920, total COE of $0.712/kWh, Initial Capital $87,960.

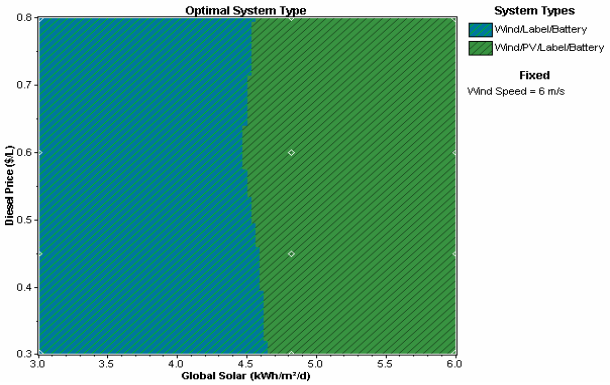

Figure 13. OST graph and diesel price and solar radiation: Wind speed 6m/s

7. CONCLUSION

Providing uninterruptible power for a BTS remote telecommunication in Pecatu Bali is possible using hybrid renewable energy. Pecatu Bali have good annual wind speed (4.37m/s), and solar radiation (4.82kWh/m^2/d). HOMER optimization result has shown configuration system most optimal as 8kW PV array, 6kW wind turbine, 5kW diesel generator, 50 battery bank of 108kWh, and 4kW converter. Total NPC system of $265,317, and COE system of $ 0.883.

Total COE system very expensively, it is caused by renewable fraction system BTS of 78%. However, the greater renewable fraction makes generator carbon issue can be reduced. If wants to economize fuel, reducing pollution, preventing global instillation, and creating environmental clearly, and do not depend on government, and then renewable energy solar cell and wind turbine can be considered, but with expensive cost consequence.

ABSTRACT

MIMO OFDM technology have ability to minimizing BER, increasing channel capacity and efficiently of bandwidth used. In this paper, simulation and analysis of spatial multiplexing MIMO OFDM technique with SVD channel model for Mobile WiMAX is proposed. Channel modeling that used in this simulation based on Singular Value Decomposition (SVD). The evaluation of system performance is proposed to Bit Error Rate (BER), Channel Capacity and Throughput parameter toward Eb/No value. System performances are simulated with three type of modulation, they are QPSK, 16-QAM and 64-QAM. In addition, three type of Error Control Coding is used in this simulation with different code-rate value. Beside that, there are two user condition in this simulation, that are idle user (v = 0 m/s) and mobile user (v = 10 m/s). The simulation results show that the system performance with high Eb/No value is most better. This condition is shown for BER, channel capacity, throughput and signal space graph. In addition, we can see the performance with code rate 1/3 is also better than other code rate values.

MIMO, OFDM, Spatial multiplexing, SVD, Mobile WiMAX

1. INTRODUCTION

The development of wireless telecommunication technology leads to fulfilled high capacity needs, using efficiently of bandwidth and ability to protect data from noise and minimizing error.

OFDM is multicarrier modulation that have ability to work in multipath fading condition and give a solution of real time high speed access needs[1]. Combination of MIMO OFDM have ability to support high speed communication access, reliable, flexible and also using efficiently of bandwidth[2]-[5], but the complexity of the system with conventional channel modelling is high with poor performance.

In this paper, simulation and analysis of spatial multiplexing MIMO OFDM technique with SVD channel model for Mobile WiMAX is proposed. Channel modeling that used in this simulation based on Singular Value Decomposition (SVD). The evaluation of system performance is proposed to Bit Error Rate (BER), Channel Capacity and Throughput parameter toward Eb/No value. System performances are simulated with three type of modulation, they are QPSK, 16-QAM and 64-QAM. In addition, three type of Error Control Coding is used in this simulation with different code-rate value. Beside that, there are two user condition in this simulation, that are idle user (v = 0 m/s) and mobile user (v = 10 m/s). The simulation results show that the system performance with high Eb/No value is most better. This condition is shown for BER, channel capacity, throughput and signal space graph. In addition, we can see the performance with code rate 1/3 is also better than other code rate values.

2. MIMO and OFDM SYSTEM

2.1. Multiple Input Multiple Output (MIMO)

Multiple Input Multiple Output (MIMO) antenna system consist of some transmitter and receiver antenna. MIMO system use multipath condition to create some equivalent channel as though separate one to others, that in normal condition, multipath will introduce fading that affect data transmission. There are two type MIMO technique that used in mobile wireless communication, that are spatial multiplexing and spatial diversity. Spatial multiplexing technique transmits different parallel data and coded for each transmitter antenna. The purpose of using this technique is to gain high channel capacity with dividing high stream data into low stream parallel data depends on number of transmitter antenna. Low stream datas are flow over certain matrices that this matrices have function to combine signals from all parallel stream datas with certain combination. This proses is multiplex that happen in spatial dimension because each combination of parallel data guided to one of transmitter antenna. Singular value decomposition (SVD) matrices operation used here to diagonalizing channel matrices and get eigen value from that matrices in purpose to estimate channel matrices response. Channel matrices respon result is shown as follow:

$$H = U_H \Sigma_H V_H^* \quad \text{.....(1.1)}$$

Channel capacity of MIMO system is calculated based on Shannon formula:

$$C_{1x1} = E\left[\log_2\left(1+\frac{P|h_{11}|^2}{\sigma_n^2}\right)\right] \; bps/Hz \quad \text{…(1.2)}$$

With SVD operation, Shannon capacity channel representated by:

$$C_{RxT} = E\left[\log_2\left(\det\left(I_{R_o}+\frac{P}{T\sigma_n^2}HH^h\right)\right)\right]$$

$$= E\left[\sum_{i=1}^{rank(H)}\log_2\left(1+\frac{P}{T\sigma_n^2}\delta_i^2\right)\right] \; bps/Hz \quad (1.3)$$

With C is channel capacity in bps/Hz, E is expectation of all channel realisation, P is avarage power that transmited in channel, H is gain of random complex channel, σ_n^2 is noise variant, I_{R_o} is identity matrices with *rank(H)* dimension depends on number receive antenna, T is number spatial channel, H^h is hermitian matrices, *rank(H)* $\leq$ min{R,T}, δ_i^2 is singular value square that related with power from each channel decomposition matrices HH^h results, and P/σ_n^2 is *signal-to-noise* (SNR) average ratio in each receiver side.[4]

2.2 OFDM

OFDM is multicarrier transmition scheme that combine modulation technique and multiplexing. The basic idea from OFDM is separation data transmition into an amount subcarriers and modulated with low rate . In the other word, a OFDM signal consist of a number *narrowband carrier* that transmitted from same source and different frequency.
Each subcarriers are orthogonal. Orthogonality introduce overlapping spectral between subcarriers, that spectrum from each subcarriers have null value on center frequency other subcarriers with the result interference between subcarrier will not happen. This is the point of differences between OFDM and FDM, where channel separation in FDM only based on frequency with guard interval between channel to avoid interference. From this point, clearly show that OFDM more efficient in using bandwidth compared with FDM.

3. SYSTEM MODELLING

Transmiter scheme is shown in figure 4.1.

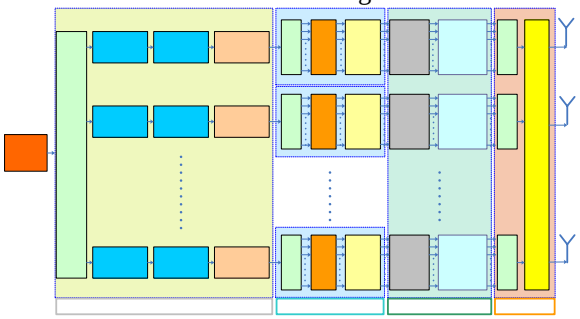

Figure 1 *Transmitter*

Data is to be transmited are generated by data generator. With serial to parallel algortihm, data divided into some data stream (depends on number transmit antenna), where in this simulation, data divided into 2 stream data. Convolutional encoder used here as channel encoder to minimizing error rate while transmit data. Coderate values that used for convolutional encoder in this simulation are 2/3, ½, 1/3. To minimizing burst error in transimition data, interleaver is used. Next, mapping data into complex symbol through data modulator, that three type of modulation used here, that are QPSK, 16-QAM and 64-QAM.
IFFT and also FFT in receiver side, are main component in OFDM system. OFDM subchannel parameter using ULTRA WIDEBAND COMMNICATION SYSTEM parameter. Width of each bandwidth channel is 10 MHz. 256 subcarrier will become subchannel with carrier frequency between 3400-3600 MHz or lecated in band frequency 3.5 GHz. Every subchannel modulated by IFFT, in order to representate data in time domain. Then, OFDM symbol complex resulted from IFFT combined into serial data and added cyclic prefix to avoid ISI and ICI. Next, upsampling data with factor 4 and upconversion data into passband to facilitate transmision of complex signal.

Before transmission signal, matrices V that have function as prefilter, multiply with signal in purpose to get symbols that will transitted from transmit antenna. The using of prefilter with matrices V because of Singular Value Decomposition that used in MIMO channel.

In receiver side, process that happen to signal are inverse from process in the transmitter side, as shown in figure 4.2. Because of using SVD operation in matrices channel, symbol that received by receive antenna multiply with demultiplex matrices U^h, that act as postfilter. Then, signal will process with downconversion, downsample, cyclic prefix removal, FFT, Demodulator, Deinterleaver and Channel decoder.

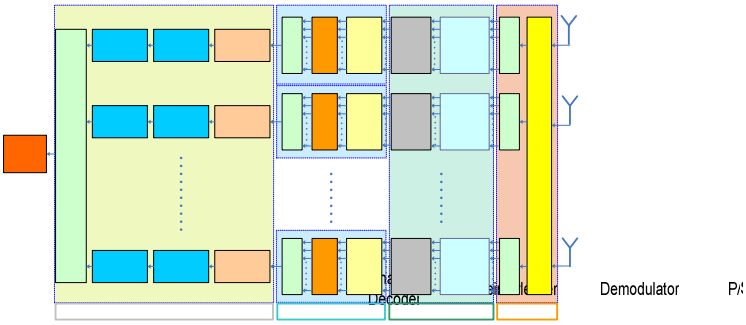

Figure 2 *Receiver*

4. SIMULATION RESULTS

Generally, the results of the simulation can be divided into 2 part, that are system performance graph, consists of BER, channel capacity , throughput toward EbNo and signal space graph. System performance, analyzed with system without ECC and system with ECC. Beside that, there are two other condition that used in this simulatioan to see system performance, that are idle user (v = 0 m/s) and mobile user (v = 10 m/s).

The analysis of throughput parameter, same with other parameter, as shown in Figure 3, where high throuhput is reach with system that using ECC. This thing caused of BER value affect throughput system. Maximum throughput is reached when BER = 0. Thus, because of system with ECC reach BER = 0 at EbNo value that smaller than system without ECC, then maksimum throughput for system with ECC also reached faster.

System performance for mobile and idel user aer shown in Figure 4, 5, and 6. Generally, BER for idle user have smaller value compared with mobile user. BER value for QPSK and 16-QAM modulation type, are close and reach zero value at EbNo = 5 dB and 9 dB for QPSK and 16 QAM sequently. For 64 QAM modulation, zero value of BER for idle user is reached at EbNo = 17 db (higher than other modulation type), and for mobile user, high BER value still exist.

Channel capacity performance shown in figure 4. From figure 4 we ca see that the channel capacity for both idle and mobile user doesn't have sigificant difference. Next figure shows throughput performance. From graph 5 we ca see that the maksimum throughput for both system condition are close / same. Throughput system affected by BER value. So, when BER value is zero, throughput system will reach maximum state. As seen at figure 5, for idle user and 16-QAM modulation, reach

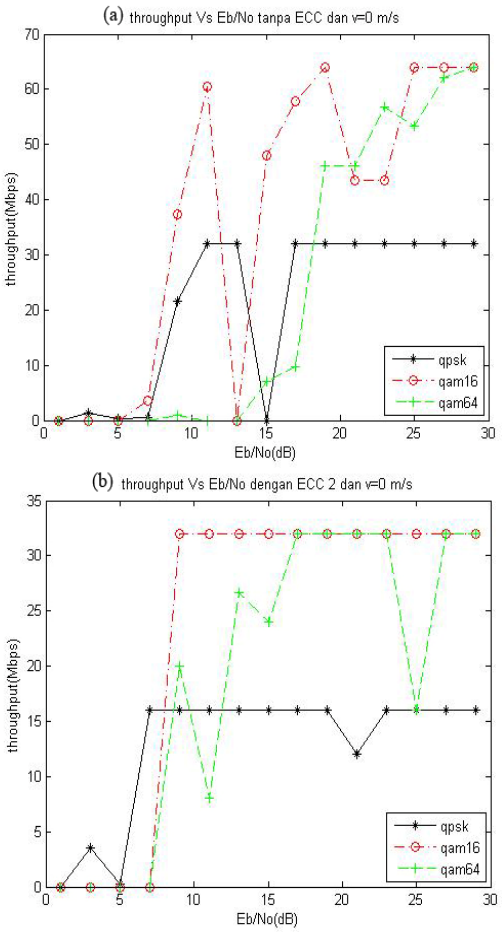

Figure 3 Throughput vs Eb/No V = 0 m/s

maximum state at EbNo = 9 dB, and also occur for mobile user with same modulation type. In the end, generally system performance between idle user and mobile user in this simulation doesn't have significant difference. But, for whole parameter, system performance with idle user a little better than system with mobile user.

Channel capacity performance are shown in figure 4. From figure 6 seen channel capacity for both idle and mobile user doesn't have sigificant difference. Next figure shows throughput performance. From graph 7we can see that maksimum throughput for both system condition are close / same. Throughput system affected by BER value. So, when BER value is zero, throughput system will reach maximum state. As shown in Figure 5, for idle user and 16-QAM modulation, reach maximum state at EbNo = 9 dB, and also occur for mobile user with same modulation type. In the end, generally system performance between idle user and mobile user in this simulation doesn't have significant difference.

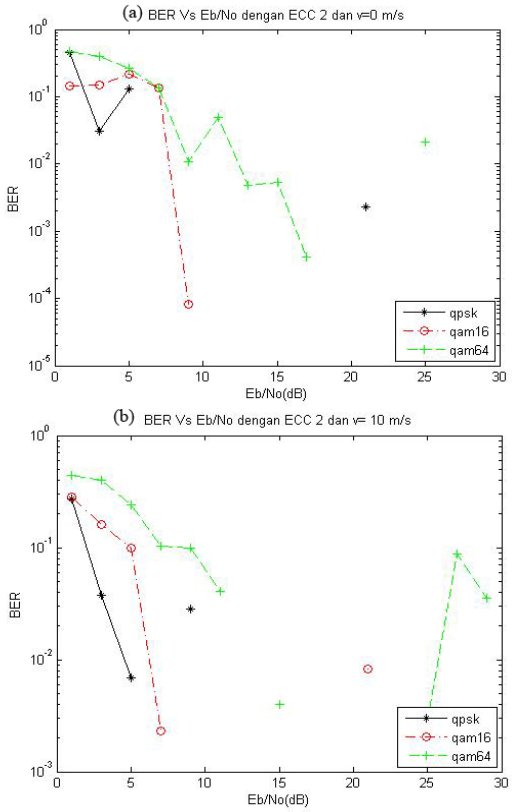

Figure 4 BER vs Eb/No ECC = 2

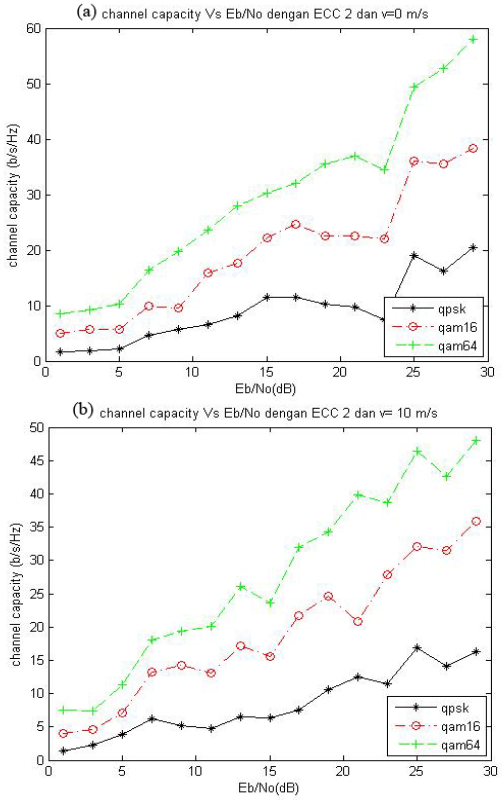

Figure 5. Channel capacity vs Eb/No ECC = 2

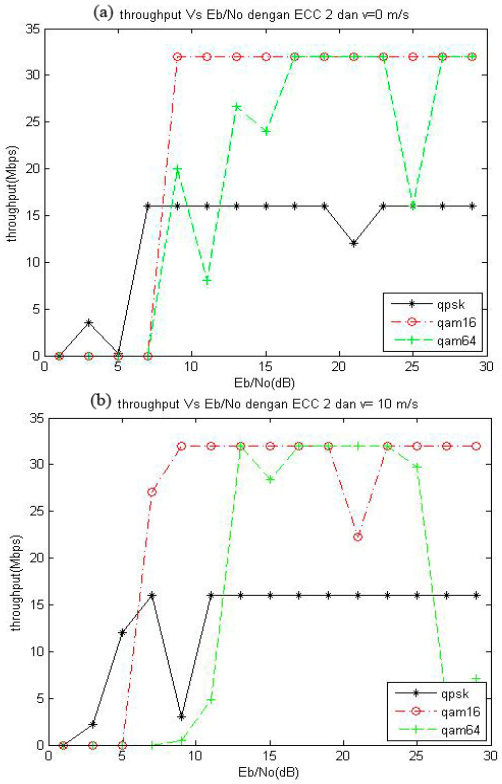

Figure 6. *Throughput* vs Eb/No ECC = 2

5. CONCLUSION

From spatial multiplexing MIMO OFDM based on SVD simulation, can be concluded in following sentences.

1. MIMO OFDM systems with spatial multiplexing technique have advantage at high speed data transfer side.
2. Performance for system with ECC is better than system without ECC, that is shown from BER, channel capacity and throughput graph.
3. Performance of system with idle user is better than system with mobile user, eventough in this simulation, the differences is not significant.
4. The better perforamnce can be achieved in channel coding with high code rate.

ABSTRACT

Broadband Power Line Communication (PLC) network is more possible to be implementation at low voltage powerline network. However, utilization of electric powerline as access network is still very limited, in spite of a currently some of the approaches are Multi-Carrier Modulation, Multi-Carrier Spread Spectrum, OFDM-FDMA, MC-CDMA, and some coding method is already applied at physical layer. Those coding techniques are supposed to handle bandwidth limited and error data transmission due to disturbance of noise problem in a shared transmission medium[2].
Normally, users are connected into broadband PLC network in form of a bus topology. Base stations as a central network has responsibility to manage of communication link for inter- subscribers and subscribers to telecommunication backbone network. At the transmission media, in addition to information traffic, impulse noise which appear in broadband PLC network. This additional noise will there fore decrease the performance of broadband PLC from a satisfying QoS requirement and hence must be compensated. In this paper, we propose a state equation to describe a dynamic model of broadband PLC network. This model is used to expose of broadband PLC network behavior, included the impacts of environment condition to the system. Knowing the behavior of broadband PLC network, we can turn in the performance of the system to an expected level.

Keywords: *Broadband PLC, dynamic model, QoS, state equation, .*

1. INTRODUCTION

At the beginning, powerline is designed only for electricity power distribution in interval of frequency (50-60) Hz. Theoretically, electricity power transmision possible to pass frequency signal over 60 Hz until order of 100 MHz (In practical point of view, current technology can support frequency up to 30 MHz). PLC's technology has been used in electrical power system for long time ago in (125 Hz-1500 kHz) frequency using medium and high voltage for electricity power system management.
During 1990 decade, researchers and developers started to realize the possibility of broadband PLC using powerline. This possibility, thus, can provide broadband communication to rural area or residence area which has less or no telecommunication infrastructure. In fact, powerline network has wider coverage area than PTSN network in most countries, include Indonesia[1,2].
Main problem in broadband data communication using powerline network is impulse noise from internal network. This impulse noise, for examples, originates from the electrical load and electricity power system itself. Somes technical approach have been applied, e.g Multi Carrier Spread Spectrum Modultion scheme, Orthogonal Frequency Division Multiplexing (OFDM), and CDMA in transmission PLC system. These modulation schemes are aimed to produce efficient and wider bandwith capacity. In addition, these modulation schemes can also increase the robustness of broadband PLC network against impulse noise interference[2,5].
Researches on PLC network at physical layer (such as modulation, coding, etc) had done extensively. However, research on network level and higher level of implementation, unfortunately, is very less. Thus, despite of promising future, mayority of powerline network capacity are still useless, as depicted in Figure. 1. below.

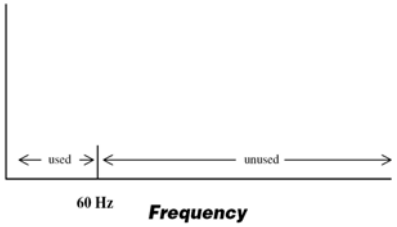

Figure 1. Frequency occupancy area of *powerline* [7]

ISSN 114-1284

At Network Layer, for example, mostly MAC protocol layer that apply for PLC broadband, such as CSMA/CA and TDMA, are coming from IEEE 802.11 which originally used for wireless technology. Since wire and wireless technology certainly have difference characteristics and environments, therefore applying wireless protocol for wire communication is not appropriate.

Technically, to increases the performance of broadband PLC network one should choose an appropriate medium access control (MAC) protocol layer. This MAC protocol should take in to account the condition of Physical Layer, the Dynamic characteristic of Network, and the QoS of the Network. For that reason, we need to model these three aspects into broadband PLC network modeling. The development for access control mechanism in MAC protocol layer then will be based on this model. In this paper we propose a state equation to describe a dynamic model for broadband PLC network.

2. BROADBAND POWERLINE COMMUNICATION (PLC) NETWORK

Broadband PLC is a wide band communication technology through the electricity power transmission channel in frequency over 1 MHz. Interfacing between communication systems to electricity power using a coupling. Broadband PLC network is built on the powerline distribution network at low voltage which is inherently forms of bus network topology. For this topology, one line bus is shared as transmission medium for all users. Therefore, it is an obligation, in such situation, to introduce a fair access control mechanism for all users. Therefore, OFDM-FDMA scheme have been applied to handle multiple access control.

2.1. Powerline network

Electrical powerline network consists of three levels:

- level : 110-380 kV, from generator to huge user area (distance up to 100 km).
- level : 10-30 kV, wide area powerline network (city, industries or commercial users, distance up to 10 km).
- level : 230-400 V or 110 V, is a powerline network to user, individual user (distance within several meters).

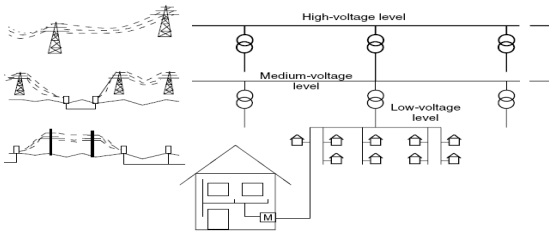

Figure 2. Power electric network level

2.2. Broadband PLC channel model

Broadband PLC channel is described using two approaches. *First*, physical channel approach. In this approach, the main focuses are *attenuation* and *transmission in frequency domain*. In physical view, impulse response of channel causes echo signal. This echo is mainly due to the variation of impedance of Broadband PLC channel within frequency in orde (1-1000) Ohm. Wire impedance characteristic, network topology and electric load all accumulate to produce echo at receiver side. Network multipath has caused discontinued-impedance that causing reflection and multipath signal transmission, as Figure 3.

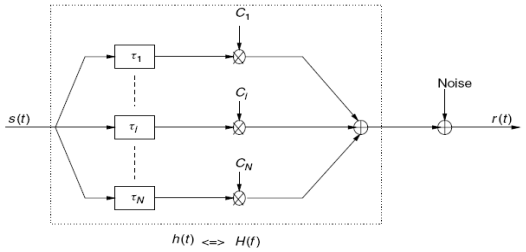

Figure. 3. Multipath channel model[2]

In Figure 3, echo from multipath channel powerline model is describes as transmitted in PLC channel will break through several N branches. Each i branch has delay (τ_i) and attenuation factor (C_i). PLC channel in frequency domain[2,5] therefore can be expressed as:

$$H(f) = \sum_{i=1}^{N} g_i . e^{(a_0 + a_1 . f^k) l_i} . e^{-j2\pi f \tau_i} \quad \ldots(2.1)$$

Second, logically model approach. A number transmission channel is used by a number subscribers which have dynamic behavior with four probability conditions: (1) busy, (2) idle, free (3) error, dan (4) reserve. Figure 4, describes these conditions and the possible change of each condition.

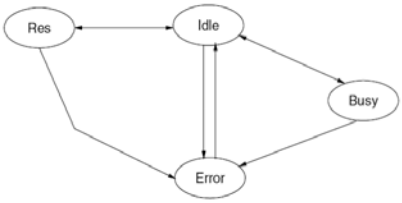

Figure.4. Diagram model state channel [3]

2.3 Noise in broadband PLC network.

As previous explained that in broadband PLC channel, besides Additive White Gaussian Noise (AWGN) also appear some impulse noise disturbance with power greater than AWGN power. The whole of disturbances are classified into five types based on four categories: disturbances based on duration, spectrum, occupancy, and intensity, as depicted in Figure 5.

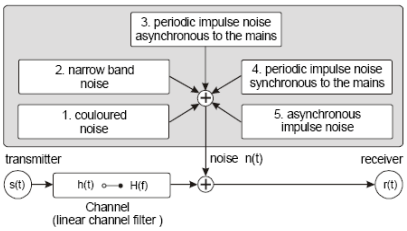

Figure 5 : *noises* in PLC[6],

Broadband PLC noise environment is a superposition of background noise with some narrowband noise interference.

$$n_{imp}(t) = \sum_{i=-\infty}^{\infty} A_i . p(\frac{t - t_{a.i}}{t_{w.i}}) \text{ .....(2.2)}$$

Impulsive noise is formed from synchronous and asynchronous periodic impulse noise within electrical power frequency itself. Impulse is modeled with *train pulse* (wide: t_w, amplitude : A; inter-arrival time : t_a), *function pulse* $p(t/t_w)$, where *i* random variable.

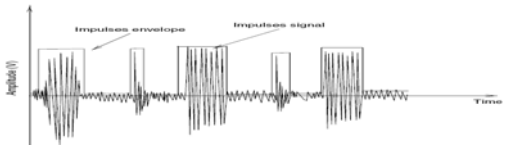

Figure 6 : *Impulse noise* in time domain [3]

2.4. Broadband PLC Access Network.

Broadband PLC access network is realized in low voltage distribution network, as depicted in Figure 7, below.

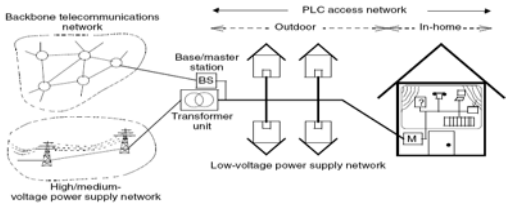

Figure 7: Access network *PLC*[2]

As previously explained that broadband PLC is a bus topology network. Base station as central network acts as communication interface from users to WAN, and from user to user in centralized network structure.

Figure 8 : Logical bus structure PLC network [2] ;

3. DYNAMIC MODEL BROADBAND PLC NETWORK

Mathematical model is used to show network dynamic in accordance to *traffic information, noise,* and *channel characteristics* of electricity power system.

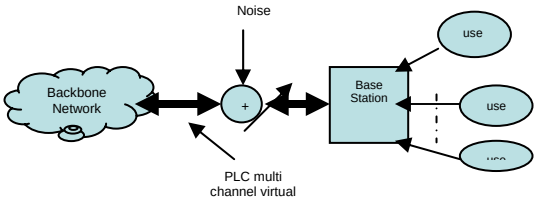

Figure 9: Broadband PLC's network environment

Mechanism processes that take place in broadband PLC access network, is described in Figure 10.

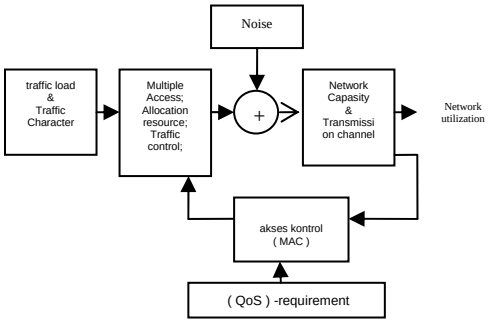

Figure. 10. Block Diagram of dynamic network process

Diagram above can be explained as follows, broadband PLC network, especially the Base Station node and link toward backbone network, will change every time due to traffic load and noise disturbance from the electricity system. These changes will influence the network utilization indicator. MAC protocol as an agent in regulating access control, actively regulate and manage resources in accessing the shared transmission channel, MAC protocol is responsible in accessing the number of free available channels. Every resources or users, who are currently accessing the shared media, utilized the multiplexing techniques based on OFDMA. This multiplexing technique also responsibles in suppressing the transmission error due to impulse noise.

Since the traffic and noise are stochastic process, then changes of network state is also a dynamic process. Dynamic transition of network is modeled as a state equation which mathematically expressed in (3.1)

$Q(t+1) = Q(t) + AQ(t) + BU(t)$ .....…...(3.1)

where :

Q(t+1): Vector of network next state

Q(t) : Vector of network current state

A : Matrix of network state

B : Matrix of control

U(t) : Vector of control

4. CONCLUSION

Equation (3.1) describes the probability of broadband PLC's network state transition from *Q(t)* to *Q(t +1)* state as function of *information traffic*, *impulse noise* from the electricity power network, and *control process by MAC protocol* layer scheme.
How probability of state transition occurs, that to be works in our future research.

ABSTRACT

The increasing of non-linear loads causes the increasing of harmonic distortion level on the electric grids. Harmonic distortion is the change of waveform of both current and voltage from the ideal sinusoidal waveform. This phenomena result in several disadvantages to the power quality such as increasing losses on the transmission, derating of transformers and other stuffs.

The household loads are the main cause for harmonic phenomena. This is because the household loads are generally using non-linear loads such as refrigerator, air conditioner, water pump, electronic ballast lamp, and computer. The study investigate the design of harmonic filter to reduce harmonic level to be applied for those kinds of loads for household with power of 1300 VA. The surveys of electricity equipments broadly used in the household are then conducted and the data are simulated to view the load characteristics. The harmonic filter developed in this study is the single-tuned filter which has harmonic distortion of current and voltage of order 3. The result shows that the filter plays important role in decreasing the harmonic distortion level, lowering the active power consumed by equipments, and increasing power factor which will in turn upgrade the power quality of the grids.
.

Keywords : *single-tuned filter, non-linear loads, harmonic distortion, power quality.*

1. INTRODUCTION

Power quality has 3 main parameter : voltage, current, and frequency. The deviation of the three-parameters will degrade the quality of power supplied for the loads. The degrading in power quality will cause failure or wrong in operation at the consumer side. The stated-owned electric company (PLN) is still trying to overcome the problems arising due to this issue started on transmission and distribution systems until the costumers receive the power. However, the power quality problems are also coming from the load side which will in turn affect the systems.

One of power quality related problems coming from load side are harmonic distortion. Harmonic distortion is the change of waveform of both current and voltage from the ideal sinusoidal waveform. This phenomena result in several disadvantages to the power quality such as increasing losses on the transmission, derating of transformers and other stuffs.

Indonesia is the fast-growth populated country which is demanding huge electric energy needs especially household loads. In line with the huge household loads, the harmonic distortion may also be huge when it's accumulated. Thus, The study investigate the design of harmonic filter to reduce harmonic level to be applied for those kinds of loads for household with power of 1300 VA

2. THEORETICAL OVERVIEW

Harmonic is the phenomena of sinusoidal wave forming in which the new frequency is the multiply of rational number with its base frequency. If there is superposition between base frequency and harmonic frequency, it therefore will form distorted sinusoidal wave, meaning the wave is not sinusoidal anymore. The phenomena is then called as harmonic distortion.

The sum of non-sinusoidal wave can be analyzed by using Fourier series as below :

$$Y(t) = Y_0 + \sum_{n=1}^{n=\infty} Y_n \sqrt{2} \sin(n 2\pi f t - \varphi_n) \qquad (1)$$

Notes :

- Y_0 amplitude of DC components in distribution systems , usually zero valued.
- Y_n: root mean square (rms) value of harmonic component -n
- f base frequency (50 *Hz*)
- φ_n Phase angle od harmonic component -n

The equation (1) represented the distorted sinusoidal wave. It may be seen at Figure 1 as below :

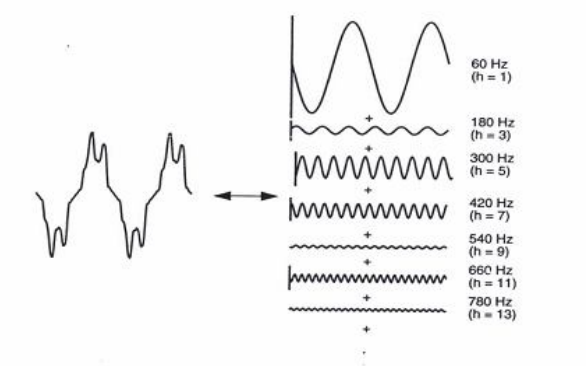

Figure 1. Fourier Series of Distorted Sinusoidal Wave

Total Harmonic Distortion (THD) express the amount of distortion arised by all harmonic components which can be stated as :

$$THD = \frac{\sqrt{\sum_{n=2}^{n=\infty} M_n^2}}{M_1} \quad (2)$$

Notes:
THD Total Harmonic Distortion
M_n RMS of harmonic current and voltage –n
M_1 RMS of base current and voltage

THD may also represent as a potential heating as the result of relative harmonic against its base frequency.

Harmonic current and voltage can cause the different effects to the electric stuffs, depending on its load characteristics. However, generally the effect may be divided into three main parts :

1) RMS value of current and voltage will be higher
2) Peak value of voltage and current will rise
3) The frequency systems will decrease

Each element in electrical load systems generates specific distortion. The higher RMS value may cause heating in the conductor. The current and voltage which are higher than the peak value will cause the failure in measurement. And the increase of frequency will affect the conductor impedance. If the conductor often receives the peak value of voltage, it will result in high of drop voltage. The resonance phenomena will appear at certain frequency which cause the increasing current.

3. METHODOLOGY

The methodology of this study is divided into 3 main works :

1) Identification of general electric equipments widely used by households with power of 1,300 VA
2) Measurement of harmonic loads
3) Designing of harmonic single-tuned filter

3.1 Identification of general electric equipments

According to survey we conducted, the general household electric equipments with power of 1,300 VA are as follow :

Table 1. Specification of Measured Loads

No.	Electric Stuffs	Unit	Power (W)	Voltage (V)	Frequency (Hz)
1	LHE				
	A	4	8	170-250	50/60

	Monitor	1	240	100-240	50/60
	Speaker	1	10	220	50
5	Refrigerator	1	77	220	50/60
6	Dispenser	1	300	220	50

Notes :
LHE : *Lampu Hemat Energi* (Energy-Saved Light)

3.2 Measurement of Harmonic Loads

After considering the general electric stuffs widely used by households, we then conducted the measurement of each harmonic loads by using power quality analyzer. The results are shown in Table 2.

3.3 Designing of Harmonic Single-Tuned Filter

In order to design the filter, it is necessary to obtain the highest voltage harmonic (THD V) and current harmonic (THD I) in the loads systems. The data may be seen in table 2 and 3. The highest THD V is used for determining at what order the current harmonic will be filtered.

According to the experiment, we found the highest THD V is on the third order. This leaves the passive filter will be designed on the order 3.

After determining the filter's order, the next step is to fix the reactive power should be supplied to the systems. This effort is aimed at improving the power factor of the systems. For this reason, we calculated the total power of the systems which can be seen in Table 4.

Table 4. Power Loads Characteristic in Household

Power	Average	Maximum	Minimum

Tabel 3. Harmonik Arus Pada Beban Total

Order	THD I (%)	Order	THD I (%)	Order	THD I(%)
1	100	11	1.28	21	1.41
2	8.29	12	5.30	22	0.47
3	12.92	13	1.73	23	0.52
4	3.34	14	0.89	24	0.49
5	3.17	15	2.84	25	0.71
6	1.93	16	0.58	26	0.43
7	4.72	17	1.71	27	0.45
8	1.71	18	0.56	28	0.41
9	5.06	19	0.80	29	0.86
10	1.34	20	0.51	30	0.37

The power factor may be found by applying the equation 2 below :

$$PF = \frac{P}{S} \quad (2)$$

From the above equation, maximum power factor are obtained as much as 0.9576. The maximum approach was taken to anticipate reactive power in the systems. If the filter is designed for improving power factor until 0.98, the reactive power needed can be calculated by using equation 3 as below :

$$Q_{VAR} = \sqrt{\left[\frac{P_1}{PF_0}\right]^2 - P_1^2} - \sqrt{\left[\frac{P_1}{PF}\right]^2 - P_1^2} \quad (3)$$

The calculation shows that the reactive power as much as 166.5 VAR should be injected to the systems in order to improve power factor from 0.9576 to 0.98. Reactive power obtained through equation 3 are then used to determine capacitor impedance by applying the equation below :

$$X_C = \frac{kV_{rated}^2}{M\ \mathrm{var}_{rated}} \quad (4)$$

With rating voltage of 220 V and rating VAR of 166.5 VAR, it is obtained that the capacitor impedance as much as 290.7 Ω. The capacitor capacitance is then calculated by equation 5 below :

$$C = \frac{1}{2\pi f X_C} \quad (5)$$

The calculation result in capacitor capacitance as much as 11 µF. After that, we quantify the filter impedance by applying the equation 6 as below :

$$X_L = \frac{X_C}{n^2} \quad (6)$$

Note : n = voltage harmonic order after filtered

In this experiment we decrease the order a little bit into 2.9. This is as tolerance of filter component to prevent resonance in the systems. The calculation gives the filter impedance would be 34.57 Ω. The inductance of inductor can be obtained by applying equation 7 below:

$$L = \frac{X_L}{2\pi f} \quad (7)$$

From the calculation we got inductance as much as 110 mH.

To evaluate the designed systems, we then assessed the systems by implementing the other system (model) which was quite different with the proposed system. The specification of the proposed systems and the model may be seen in the Table 5 below :

Table 5. Filter inductance and capacitance

	Desain	Model
L	110 mH	100 mH
X_L	34.5	31.4
C	11 µF	12 µF
X_C	289.5	265.4

4. RESULT AND ANALYSIS

The result shows that the filter works efficiently when the systems are on full loads mode. This is because the filter compensate the reactive power and reduce filter when all loads are operated. However, because in the experiment we couldnot operate the full loads, therefore, the manual calculation were conducted by considering all currents, both fundamental and harmonic, taking into account its phases. Figure 2 is the graph of current harmonic at full loads :

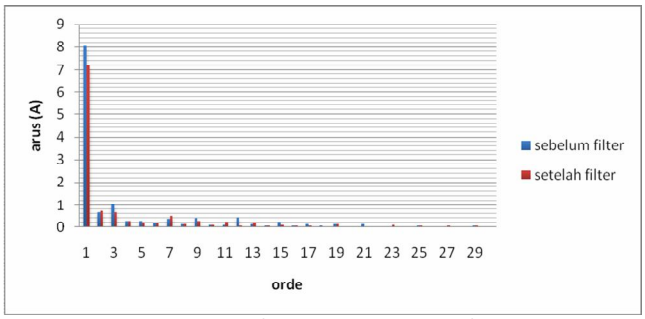

Figure 2 Graph of current harmonic at full loads

Before the filter was applied, the amount of THD I was 19.07 % with RMS current was 8.1913 A. After it's applied, the THD I decreased into 17.79 % with RMS current of 7.3120 A. Table 6 shows the comparison of RMS current between the systems prior filtered and after filtered below:

Table 6. RMS current of each load

Loads	Before Filtered	After Filtered
LHE 18 W	0.4985	1.2569
LHE 14 W	0.3761	1.1697
LHE 8 W	0.2156	1.1086
TV	0.5202	1.1229
PC	1.2903	1.5067
AC	4.2626	4.4361
Refrigerator	0.6762	0.6215
Dispenser	1.8556	0.7422
Total	**8.1913**	**7.3120**

The above comparison shows the filter can reduce the current harmonic on the total loads and compensate the reactive power to the systems. The total load currents

which are inductive are then injected to the filter loads which are capacitive. This, if it's added can weaken each other. As the result, the fundamental and harmonic current will decrease.

The experiment also shows most of odd-order of harmonic currents decrease. Contrary, the even-order of harmonic currents rises. Though the odd-order harmonic current affect THD, it is not significant enough to change the wave produced by the systems. The Fourier transformation informs that the even-order of harmonic current has mutual disappear each other, so that this order may be neglected.

The filter design qualifies to reduce harmonic current at order 3. At this order, the harmonic current decreases from 12.95 % at 1.0397 A into 9.45 % at 0.68 A.

5. CONCLUSION

The study to design the single-tuned filter has been conducted. The conclusion of this study are :

1) For each household load, the highest THD V can be found at the order 3 with varied percentages compared to base voltage ranging from 1.23 % to 2.67 % . This gives the filter's designed at the order 3 to reduce the harmonic current.
2) To prevent resonance of frequency, the single-tuned filter is set to be work at order 2.9 or at frequency of 145 Hz.
3) Inductive and capacitive impedance are synchronized so that it's obtained the minimum impedance at order 2.9.
4) The designed filter has RMS current of 1.4 A, peak voltage of 341.5 V, RMS voltage of 265.9 and total VAR of 372.3 VAR.
5) The maximum active power decreases from 1,702.5 W into 1,390.9 W after the systems apply the filter.

Abstract

Nowadays, RISC (Reduced Instruction Set Computer) architecture processor is used rapidly in multimedia, telecommunication, and household application. In order to support those application, RISC processor have to be integrated as system-on-chip (SoC) with some peripherals. This level of design requires bus systems which have high performance and low power consumption. In order to solve that problem, AMBA (Advanced Microcontroller Bus Architecture) is used to support interface system between processor and another component or peripheral in SoC level design.
The objective of this research is to design an interfacing system based on AMBA and to design RTC as peripheral which support RISC Processor. Proposed design used SIEGE32 processor which is based on RISC Architecture which is integrated with RTC (Real Time Clock) as peripheral for this processor. The design process started by designing AHB system, Bridge system, and APB system. After that the design continued by RTC (Real Time Clock).
This system is design and simulated using ModelSim 6.0, The simulation result show that this system is work at 180MHz and enable to operate in single transfer mode, where one cycle of AHB or APB could only acces one data packet of one address.

Keywords
SoC, RISC, SIEGE32, RTC, ModelSim

1. INTRODUCTION

Within the development of *System-On-Chip* technology, processor with RISC (*Reduced Instruction Set Computer*) architecture is used commonly in multimedia, telecommunication, and household appliance. To support those applications, RISC processor has to be integrated as system-on-chip (SoC) with some peripherals. This level of design requires bus systems which have high performance and low power consumption. In order to solve that problem, AMBA (*Advanced Microcontroller Bus Architecture)* is used to support interface system between processor and another component or peripheral in SoC level design transfer, which both of them have different specification.

This paper will describe how to design an interfacing system based on AMBA and peripherals which support RISC Processor. SIEGE32 is a processor that based on RISC architecture. In this research, SIEGE32 will be connected with RTC (*Real Time Clock*) as peripheral for SIEGE32 Processor.

2. BASIC THEORY

Host processor on system *on-chip* need bus interface system that optimize to connect processor with other modules which have different specification in bandwidth, power consumption and architecture complexity. Making specification boundary when design that interface system will inhibits the reuse of peripheral macro cells. To solve that problem, AMBA (*Advanced Microcontroller Bus Architecture*) can be used to solve that interface connection problem . Three buses are defined within the AMBA specification [2]:

- AHB (*Advanced High performance Bus*)
- ASB (*Advanced System Bus*)
- APB (*Advanced Peripheral Bus*)

Figure 1 shows a typical AMBA system:

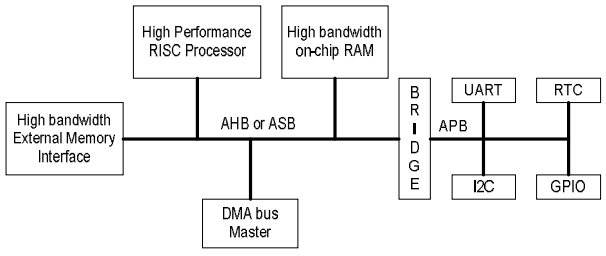

Figure.1. A typical AMBA-Based System, consist of AHB/ASB, Bridge and APB [8]

The AHB dan ASB is used to connect high performance system modules (ex. CPU, *on-chip* memory, and DMA (*Direct Memory Acces*)), APB is used for low performance peripheral, optimized for lower power consumption and to support interface system with low bandwidth. Bridge system is used to connect AHB and APB to support the compatibility of AHB to APB.

2.1. AHB (*Advanced High performance Bus*)

AHB is a part of AMBA bus which is intended to address the requirements of high-performance synthesizable designs. It is a high-performance system bus that supports multiple bus masters and provides high-bandwidth operation. AMBA AHB implements the features required for high-performance, high clock frequency systems including:

• burst transfers
• split transactions
• single-cycle bus master handover
• single-clock edge operation
• non-tristate implementation
• wider data bus configurations (64/128 bits).

An AMBA AHB design may contain one or more bus masters, typically a system would contain at least the processor. Bus Master is a system bus that initiated transfer operated, including read and write process. The external memory interface, APB Bridge and any internal memory are the most common AHB slaves.

2.2. APB (*Advanced Peripheral Bus*)

The APB is part of the AMBA hierarchy of buses and is optimized for minimal power consumption and reduced interface complexity. The AMBA APB appears as a local secondary bus that is encapsulated as a single AHB slave device. The AMBA APB should be used to interface to any peripherals which are low bandwidth and do not require the high performance of a pipelined bus interface.

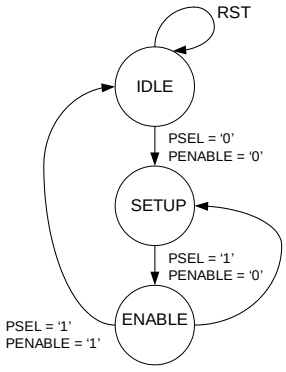

Figure .2. APB *State Diagram* [8]

Operation of the state machine is through the three states described below:

- IDLE: APB default state.
- SETUP: When a transfer is required the bus moves into the SETUP state, where the appropriate select signal, **PSELx**, is asserted. The bus only remains in the SETUP state for one clock cycle and will always move to the ENABLE state on the next rising edge of the clock
- ENABLE: In the ENABLE state the enable signal, **PENABLE** is asserted. The address, write and select signals all remain stable during the transition from the SETUP to ENABLE state. The ENABLE state also only lasts for a single clock cycle and after this state the bus will return to the IDLE state if no further transfers are required. Alternatively, if another transfer is to follow then the bus will move directly to the SETUP state. It is acceptable for the address, write and select signals to glitch during a transition from the ENABLE to SETUP states.

2.3. Bridge AHB-APB

The APB Bridge is the only bus master on the AMBA APB. In addition, the APB Bridge is also a slave on the higher-level system bus. The bridge unit converts system bus transfers into APB transfers and performs the following functions:

- Latches the address and holds it valid throughout the transfer.
- Decodes the address and generates a peripheral select, **PSELx**. Only one select signal can be active during a transfer.
- Drives the data onto the APB for a write transfer.
- Drives the APB data onto the system bus for a read transfer.
- Generates a timing strobe, **PENABLE**, for the transfer.

Bridge consist of:

- AHB Interface
- APB Interface
- Control Block
- Address Decoder

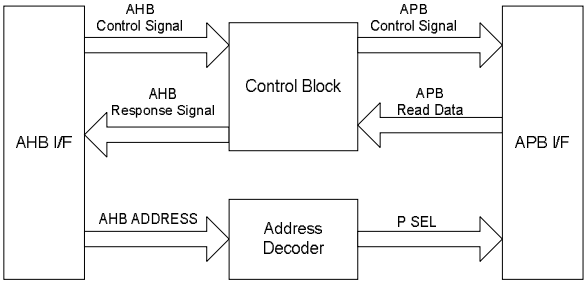

Fig 3. Architecture Bridge AHB-APB.

AHB Control Signal: HWRITE, HTRANS, HSIZE, HBURST

APB Control Signal: PWRITE
AHB Response Signal: HREADY, HRESP

Communication between AHB master and APB slave could be done by select the appropriate slave and drive the address, data and control information to selected slave and then show all the receiving data in AHB data bus

2.4. AHB Master and Slave

AHB *Maste*r is a bus system which initiated read and write process by giving appropriate address and control signal information. In this design SIEGE 32 processor [5] acts as AHB Master. *Bridge* AHB-APB is AHB Slave, which respond read or write operation that giving by AHB master.

2.5. RTC (*Real Time Clock*)

Real Time Clock (RTC) is a *peripheral* in AMBA bus system which use as timer, basic alarm, and long time base counter. In AMBA bus system, RTC is connected to APB as peripheral for RISC processor. Interface connection between AMBA APB with RTC is shown figure bellow.

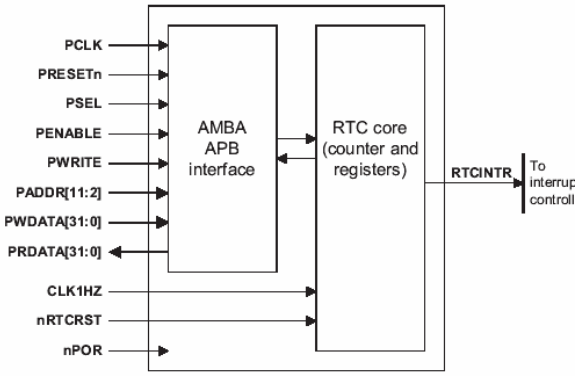

Figure. 4 Interface connection AMBA APB to RTC [8]

Parts of RTC are :

- AMBA APB *Interface* : produce read and write information for RTC
- Register Block : register to store data being read or write via AMBA APB
- Control Block : to control interrupt of RTC. If the value of counter match with the value of . RTC Match Register (RTCMR) inside, interrupt will generated (RTCINTR = '1')
- Counter Block : 32 bit up counter that work base on RTC clock.

Pin configuration of RTC is show in figure 5 below

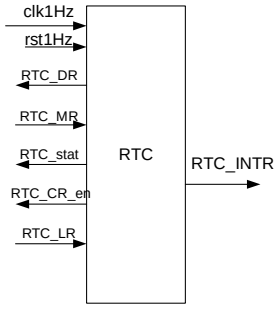

Figure 5. RTC Pin Configuration.

Function of each pins is explained in table 1.

Table 1. Pin Configuration of RTC.

Port	I/O	Wide (bit)	Function	Synch
clk1Hz	I	1	system Clock RTC	-
rst1Hz	I	1	system Reset RTC	
RTC_DR	O	32	RTC *Data* Register.	Clk 1Hz
RTC_MR	I	32	*Match Register*,	Clk 1 Hz
RTC_Stat	O	32	RTC *Status* Register,	Clk 1hz
RTC_CR _en	O	1	RTC *Clear Enable*.	Clk 1 Hz
RTC_LR	I	32	RTC *Load Register*.	Clk 1 Hz
RTCINT R	O	1	Interrupt Condition	Clk 1 Hz

Counter 32 bit is incremented in rising edge of clock RTC. Counting in one second interval is achieved by use of a 1Hz clock input in RTC. The counter is loaded with a start value by writing to load register RTCLR(RTC *Load Register*). If counter has reached the maksimum value 0Xffffffff, it wraps to 0X00000000 and continues incrementing. The value of incrementing can be read anytime via register RTCDR (RTC *Data Register*).

Interrupt signal is produced by comparing the value from register RTCMR (RTC *Match Compare Register*) and the value from counter incrementing. If the value is same, the interrupt signal will be generated. RTC Timing Diagram can be shown in Figure 6 :

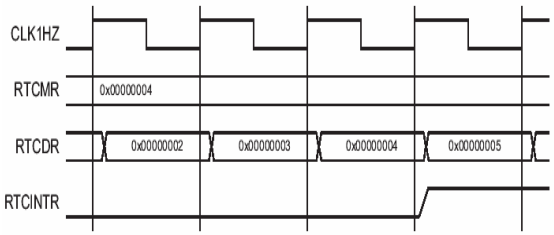

Figure.6 RTC Timing Diagaram.

Masking interrupt is controlled by register RTCCR (RTC *Control Register*. Interrupt status can be read vai register RTCstat.

2.6. Clock Divider

Each components on this system have different frequency value. SIEGE32 processor work at 27 MHz, meanwhile RTC work at 1 Hz. Figure 7 show the clock divider diagram block.

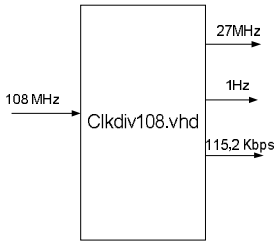

Figure. 7 Clock Divider Block Diagram

Frequency input for clock divider is 108Mhz, and then divide to produce 27MH and 1Hz frequency value.

3. SYSTEM DESIGN

This section will discussed steps of designing interface system of RTC as peripheral for SIEGR32 with AMBA bus system as interface protocol.

3.1. AHB Master dan Slave Design

AHB *Master* is a bus system which initiated read and write process by giving appropriate address and control signal information. In this design SIEGE 32 processor act as AHB Master. *Bridge* AHB-APB is AHB Slave, which respond read or write operation that giving by AHB master. Figure 8 show the connection of SIEGE32 processor to AHB as bus master to Bridge system.

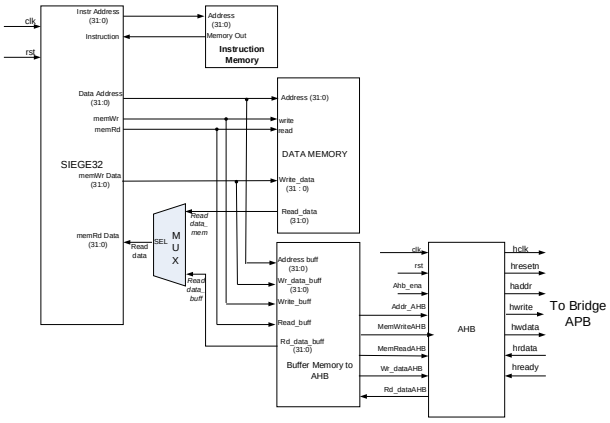

Figure 8. System Connection SIEGE32 processor to AHB bus system [5]

When operated as AHB Master, addressing system must be used to connect processor with peripheral as a slave module. In this design address 0x2F0 – 0x300 is used to RTC access.

Modificiation in instruction memory module must be doing support transfer between processor and bus system. The example of modification in HDL programming is :

```
architecture behave of inst_memory is
  begin
  inst_out <=
  --put your program here--

X"E3B0000A" when address = conv_std_logic_vector
(0,32) else -- move(MOV) data 0Ah to register R0

X"E58E02F4" when address = conv_std_logic_vector
(4,32) else -- store (STR) data from register R0 to
address 2F4

       X"E59E42F0"       when       address       =
conv_std_logic_vector (40,32) else --  load (LDR)
data from address  2F0 and store it to register 3
```

3.2. RTC design and integration with AMBA bus

RTC is designed to have 32 bit data wide, and have 1second time reference. Diagram block of interfacing system RTC with AMBA bus is shown in figure 9.

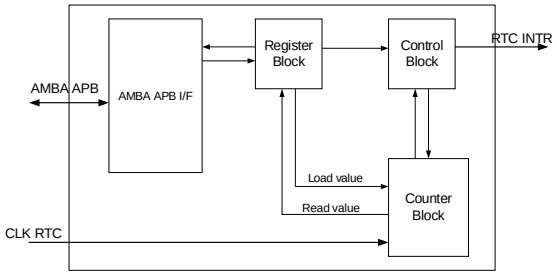

Figure 9. RTC Functional Diagram Block [8]

Parts of RTC are :

- Register Block : including RTCDR (RTC *Data register*) and RTCLR (RTC *Load Register*). RTCDR is a register which store the incremental value from *Counter Block*, RTCLR is a register which load by the first value of incremental value.
- Control Block : including RTCMR (RTC Match Register), which the output of RTCINTR will be '1' if he value of counter is same as the value of RTCMR (see the state diagram of RTC in figure 10) RTCINTR will disable if RTCCR (RTC Clear Register) is '1' . The condition of RTC interrupt can be read in register RTCstat (RTC status)

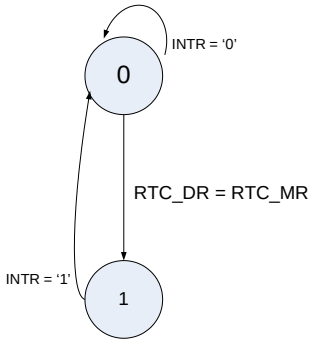

Figure. 10. State diagram RTC

- Counter Block : is a 32 bit counter increments by one of rising edge of RTC clock.

Connection of AMBA bus with RTC can be shown in figure 11.

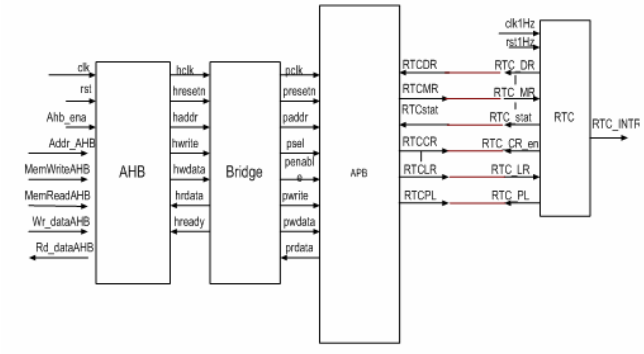

Figure.11 Connection of AMBA bus with RTC

Interface connection in figure 8 can be described in HDL programming below.

```
entity apb_periph is
port(

    -- APB Port --
    ------------ RTC REG'S BLOCK -----
RTCDR : in std_logic_vector (31 downto 0);
RTCMR : out std_logic_vector (31 downto 0);
RTCSTAT: in  std_logic_vector (31 downto 0);
RTCLR  : out std_logic_vector (31 downto 0);
RTCCR  : out std_logic_vector (31 downto 0);
req_RTC   : out std_logic;
busy_RTC  : in std_logic;
```

If APB bus wants to read RTC data, it will send request signal (req_rtc) to RTC. First the condition of write enable (write_en) is set to '0'.

```
req_rtc <= '1' when write_en = '0' else '0';
```

Meanwhile, to transfer data from APB bus to RTC can be described in HDL programming below :

```
if (paddr = X"000002f0" ) then
  if (write_en ='1') then
   case state is
     when IDLE_st =>
       data_buff <= (others => 'Z');
     when SETUP_st =>
       data_buff <= (others => 'Z');
     when ENABLE_st =>
       data_buff <= pwdata;
     when others =>
       data_buff <= (others => 'Z');
     end case;
     elsif (read_en = '1')then --

    case state is
      when IDLE_st =>
       if (busy_RTC = '1') then
         prdata <= (others => 'Z');
       else
         prdata <= (others => 'Z');
        end if;
      when SETUP_st =>
         if (busy_RTC = '1') then
          prdata <= (others => 'Z');
         else
          prdata <= (others => 'Z');
         end if;
      when ENABLE_st =>
         if (busy_RTC = '1') then
           prdata <= (others => 'Z');
         else
           prdata <= RTCDR;
         end if;
      when others =>
           prdata <= (others => 'Z');
      end case;
      end if;
      end if;
    if (paddr = X"000002f4" ) then  -- RTCMR
     if (write_en ='1') then
```

```
      case state is
       when IDLE_st =>
         RTCMR <= (others => 'Z');
       when SETUP_st =>
         RTCMR <= (others => 'Z');
       when ENABLE_st =>
         RTCMR <= pwdata;
       when others =>
         RTCMR <= (others => 'Z');
       end case;

elsif (read_en = '1') then
  case state is
    when IDLE_st =>
      prdata <= (others => 'Z');
    when SETUP_st =>
      prdata <= (others => 'Z');
    when ENABLE_st =>
      prdata <= (others => 'Z');
    when others =>
      prdata <= (others => 'Z');
    end case;
  end if;
end if;
          -- etc
```

RTC addressing system is :

- Address 0x2F0 : read data from RTCDR
- Address 0x2F4 : send data for RTCMR
- Address 0x2F8 : read RTCSTAT condition
- Address 0x2FC : send data for RTCLR
- Address 0x300 : send RTCCR condition

VHDL Coding above show assignment port for register blok RTC in every state condition (IDLE, SETUP, and ENABLE) and in every address for each port (0x2F0 – 0x300). On write process (write_en = '1') data from pwdata will be send to register RTCMR and RTCLR as 32 bit data , , and to RTCCR as 1 bit data . On read process (read_en = '1'), APB bus will read data which send by RTC on ENABLE state, and if busy condition of RTC (busy_rtc) = '0' which means RTC is ready to send data trough APB bus.

4. EXPERIMENTAL RESULT

Testing is doing by using *ModelSim* Simulation. First, each modules is tested by stand alone system, and then tested as integrated system with AMBA bus. Result of ModelSim Simulation for the integrated system is shown in figure below.

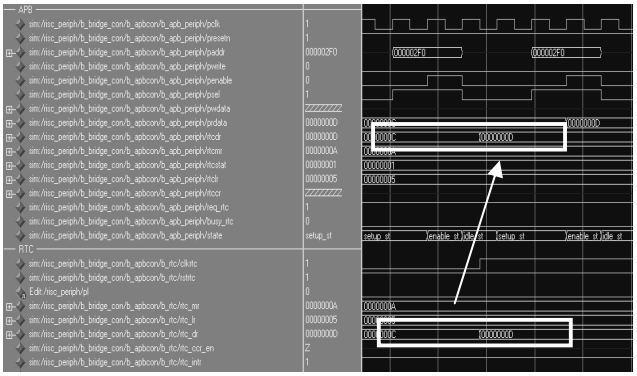

Figure 12. Read data RTC to APB bus

Figure 12, shown one example of the transfer data process from RTC to APB. In this simulation RTC is doing data counting which value is store in RTCMR (0Ah). RTCDR count the data and the incrementing counter value from RTCDR is read by APB bus through register prdata, when pwrite = '0'. APB read data on address 2F0 (read data from RTCDR), and using the instruction :

```
X"E59E42F0"       when       address       =
conv_std_logic_vector (40,32) else -- LDR
2F0
```

Figure 13 show when the value of RTCDR is same as RTCMR (0Ah). The interrupt condition is high (RTCINTR ='1'), and RTCstat = '1'. This condition is read by APB as 01h.

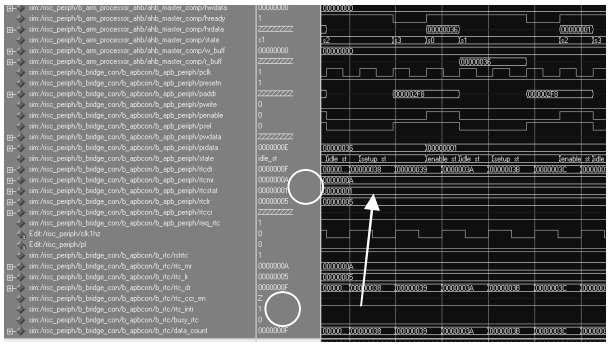

Figure 13. Read data RTCINTR to APB

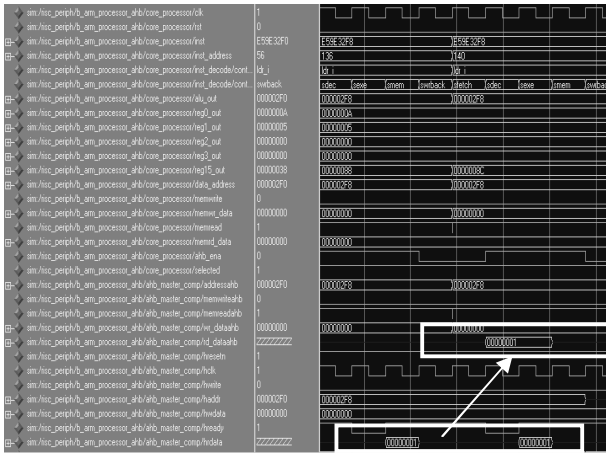

Figure 14. Read data RTC_DR to AHB

After read by APB, the interrupt value of RTC (01h) is read in register hrdata of AHB when there is LDR instruction and address show 2f8 (figure 14). This condition will make the data is sent to processor and can be read in register rd_dataahb of processor.

5. CONCLUSIONS

The result of simulation and synthesis show that system works at 180MHz and able to operate in single transfer mode, where one cycle of AHB or APB could only acces one data packet of one address.

Each bus AHB and APB capable to work in their specification, and *Bridge* is used to converts system transfer AHB to APB by controling state machine condition for each bus.

Data transfer process from processor to RTC can work properly. RTC able to do it function as counter and timer in processor SIEGE32 system.

ABSTRACT

To measure the performance of an antenna, the measurement system which is usually used is the far field method. However, if the antenna has a large size, a problem occurs concerning the large distance needed for the far field method to measure the radiation pattern of the antenna. For an antenna measurement conducted in an anechoic chamber with limited space, this cannot be achieved.
One solution to overcome this problem is to use near field method. There are three near field methods known which are the planar, cylindrical and spherical surfaces. In this paper, the design of the near field method with planar surface is proposed due to the advantages of the formula and computation process simplicity compared with the other near field surface methods.
The data is transformed from near field to far field data using the fast Fourier transform (FFT) method. This FFT method is more efficient for the computer process compared to other method. The transformed data can show the far field radiation pattern of the antenna.

Keywords: *near field, planar, radiation pattern*

1. INTRODUCTION

Antenna measurement is needed to ensure that the design of an antenna in accordance with the expected performance. Measurement antenna is usually done using the far field method. In the far field method, when the antenna has a large size, a problem occurs concerning the large distance needed for the far field method to measure the radiation pattern of the antenna [1]. However, the measurement of the antenna can only be done with near field method [1].

There are three near field methods known which are: the planar, cylindrical and spherical surfaces [1]-[3]. The design of the near field method with planar surface is proposed due to the advantages of the formula and computation process simplicity compared with the other near field surface methods. Although this planar surface method is not an accurate method, this planar surface method can be used well to predict measurement of the antenna's radiation pattern.
In this paper, the measurement design is developed to transform near field data to far field data. It uses the fast Fourier Transform (FFT) method for the computation process. This FFT method is more efficient for the computer process compared to other method.

2. THE PLANAR NEAR FIELD MEASUREMENT SYSTEM

The design of the near field measurement system will provide significant flexibility to increase the measurement capability. Figure 1 shows the planar nearfield measurement system. The design of this system can be divided into 3 parts; they are the scanner with the scanning area, measuring equipment and management system [4].

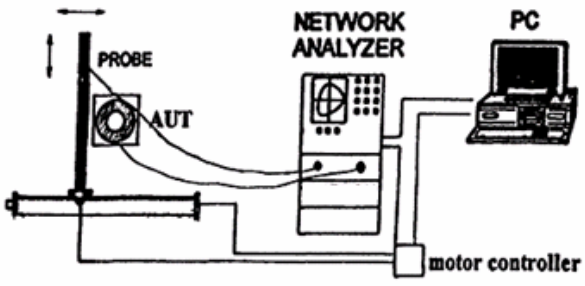

Figure 1: Planar Near Field Measurement System [4]

The scanner has a probe antenna that moves in certain points of the planar surface. The scanning area is designed

to cover the planar surface in the near field region of the antenna under test (AUT). Furthermore, the probe also can be rotated to get the variable component in the vertical and horizontal polarization. This design will be very appropriate to be placed in an anechoic chamber with limited dimension.

The scanner has a pair of stepper motor which is controlled by a computer to determine the probe position on the planar surface scanning area. It is also needed to change the polarization of the probe.

The scanning area was designed to 2 x 2 meters that consist of 128 x 128 data, the distance between the sampling points of measurement is 15.62 mm. The distance of the sampling point must be correctly calculated because it concerns with the accuracy in the evaluation of the Fourier integral. The Fourier integral requires grid spacing Δy and Δz on the measurement surface to be less than or equal to $\lambda/2$ [7].

Figure 2 shows the distribution of the measurement locations on the surface of the planar scanning area[1]. Therefore the distance between the AUT and probe antenna is 38 cm. For the planar surface method, if the distance between AUT and scanning area is defined for 0.38 meter, the measurement system designed can reach the point of θ in the range of 20.80^o to 158.89^o and φ in the range of -69.19^o to 68.89^o.

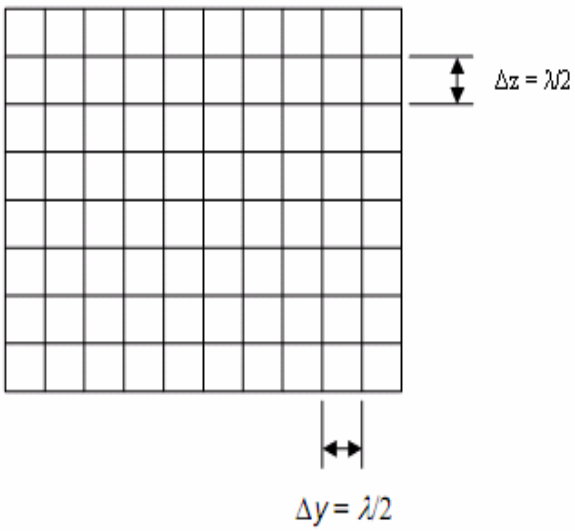

Figure 2: The Sample of Scanning Surface [7]

The measurement equipment is the Vector Network Analyzer (VNA), provided in the anechoic chamber, Electrical Engineering Department, Faculty of Engineering, University of Indonesia. At the same time, a computer as management and communication system is used to control the movement of the stepper motor. This is to obtain data from the VNA and the data transferred from the VNA to the computer. This computer will than calculate near field to far field transformation.

The probe movement in the planar measurements is described in Figure 3. From the measurement data pattern of each measurement point, it will appear as the data is on a line with few points. Furthermore, the measured data will be obtained only in the form of (m x n, 1) matrix data, with m and n respectively are the amount of sampling points in each vertical and horizontal line. The dimensional measurement data will be arranged to the matrix of (m x n), and there has to be a procedure to convert the early data measured. The design of the system can be developed into the cylindrical measurement system by adding the rotating feature on the AUT [4].

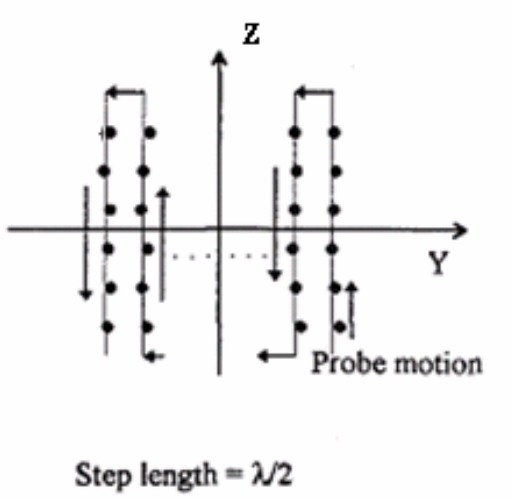

Figure 3: The pattern of the Probe Motion [4]

After the design of planar near field measurement is completed as implemented in Fig. 1, the process of planar near field measurement can be carried out. The processes are generally divided into two parts, consists of data acquisition and data transformation. At the first stage, the process takes place on the hardware system. The main objective is to obtain data from the near field antenna under test that consists of several phases which are [5]:

1. The computer will determine the measurement position on the measurement area
2. The probe moves into the position which was determined
3. The measurement is done in that position and than save the measurement result
4. Repeat step 1 until all position measured for both polarizations: horizontal and vertical.

Data transformation is used to process the near field measured data which is obtained from the previous process. The near field data is used for transformation into far field data to see the antenna performance. These processes can be divided into two steps, they are the transformations of near field measurements to far field data and plot the results of the transformation [5].

3. Near Field to Far Field Transformation

Following is the general far field equation, where θ is the elevation angle while φ is the azimuth angle from the point of the far field observation [2].

$$E(\theta,\varphi) = E_\theta(\theta,\varphi)\hat{\theta} + E_\varphi(\theta,\varphi)\hat{\varphi} \quad (1)$$

$$H(\theta,\varphi) = \frac{1}{\eta}[E_\theta(\theta,\varphi)\hat{\theta} - E_\varphi(\theta,\varphi)\hat{\varphi}] \quad (2)$$

The above mentioned equation can be obtained from the near field data. To transform the near field to far field data, the E-field from the probe antenna has to be determined. The determined E-field from the probe antenna is used to define the determinant of the system (Δ(θ, φ)), as follow [2]:

$$E_\theta(\theta,\varphi) = \frac{\sin\theta\cos\varphi}{\Delta(\theta,\varphi)}[I_H(\theta,\varphi)E_\varphi{}^V(\pi-\theta,\varphi) - I_V(\theta,\varphi)E_\varphi{}^H(\pi-\theta,\varphi)] \quad (3)$$

$$E_\varphi(\theta,\varphi) = \frac{\sin\theta\cos\varphi}{\Delta(\theta,\varphi)}[I_H(\theta,\varphi)E_\theta{}^v(\pi-\theta,\varphi) - I_V(\theta,\varphi)E_\theta{}^H(\pi-\theta,\varphi)] \quad (4)$$

Where,

$$\Delta(\theta,\varphi) = E_\theta{}^H(\pi-\theta,\varphi)E_\varphi{}^V(\pi-\theta,\varphi) - E_\theta{}^V(\pi-\theta,\varphi)E_\varphi{}^H(\pi-\theta,\varphi) \quad (5)$$

From the determinat of the system and from the probe response (I_v and I_H), the far field of the AUT can be obtained.The probe response is obtained from the complex voltage of AUT [2].

$$I_V(k_y,k_z) = \exp(jk_x x_0). \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} v_V(x_0,y,z)\exp(jk_y.y + jk_z.z)dydz \quad (6)$$

$$I_H(k_y,k_z) = \exp(jk_x x_0) \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} v_H(x_0,y,z)\exp(jk_y.y + jk_z.z)dydz \quad (7)$$

where $k = \frac{2\pi}{\lambda}$, $k_y = k\sin\theta\sin\varphi$, $k_z = k\cos\theta$ and $k_x = k\sin\theta\cos\varphi$

The equation (6) and (7) can be solved using FFT, while $v_H(x_o,y,z)$ and $v_v(x_o,y,z)$ are the near field complex voltages of the AUT.

From all of the equations above, it can be organized into a flow chart that describes the measurement process such as depicted in Figure 4.

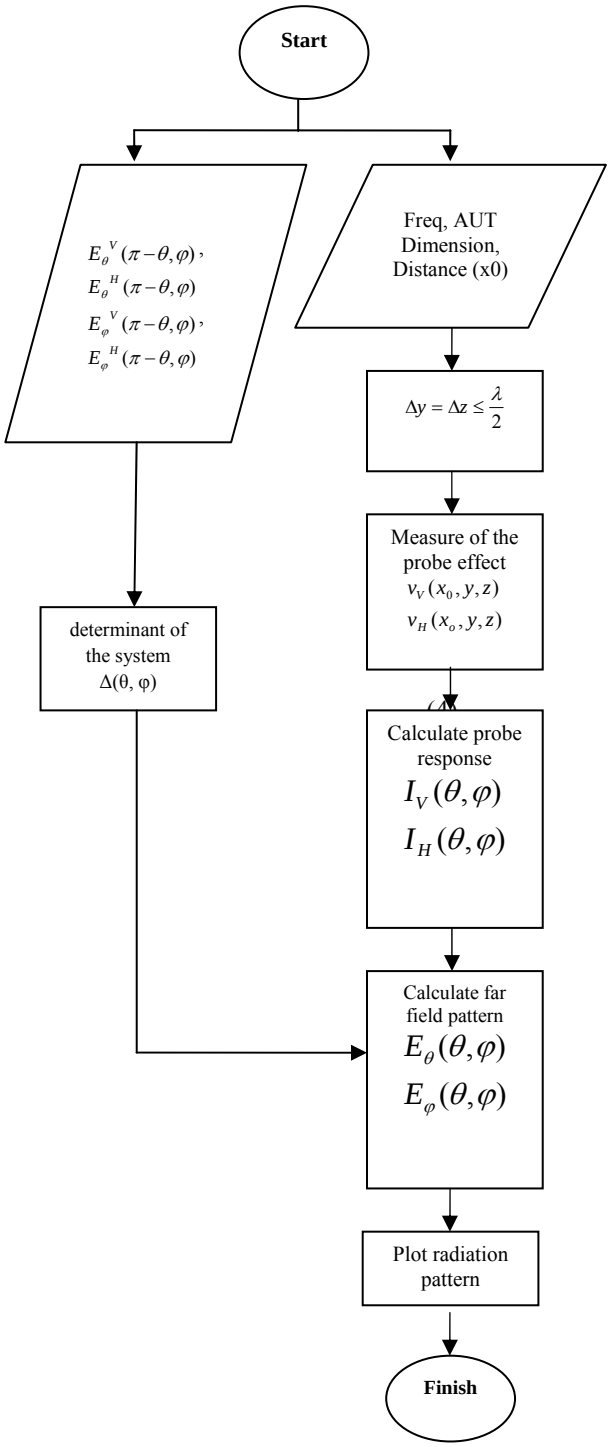

Figure 4: Flow Chart Measurement and Transformation

The measurement and visualization can be easily defined by assuming the position of the data which is taken from the sampling points. The sampling points show the position to be measured and this is the component of the matrix data as described in Figure 5. In Fig. 5 shows 9x11 data but the actual data is extended to 128 x 128 data as aforementioned in previous chapter.

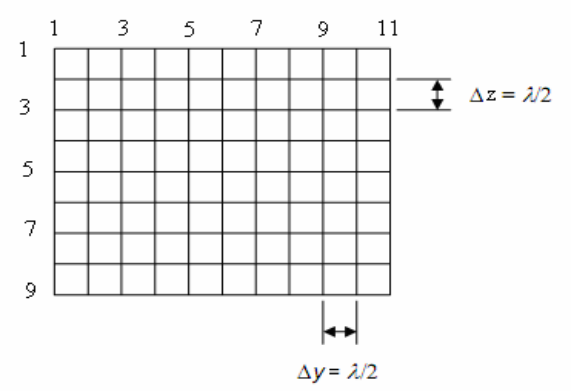

Figure 5: the position of data

Future development of this work is to implement the simulation program into the hardware of the near field measurement system.

4. Conclusions

By knowing the steps of the data transformation from planar near field to far field data, the program can be designed to obtain the process of transformation. The result of the transformation process may represent the far field performance of the antenna.

Performance Analysis of Delta-zigzag (Dz) Connection Transformer With Secondary symmetrical Cross-winding Minimized Harmonics Based on the Rating of Volt-Ampere Output Power

Chairul Gagarin Irianto
[1]Electrical Engineering Departement, FTI – Trisakti University, Jakarta
Email: chairul_irianto@trisakti.ac.id

ABSTRACT

An investigative and comparative test of the performance of secondary Dz connection transformer with 2 windings and secondary Dz with Symmetrical 3 Cross-winding on symmetrical and non-symmetrical load operations due to the harmonics distortion of the non-linear load, executed through mathematical modelling and laboratory testing approaches. The wave-form approaching the pure sinusoidal form without any non-sinusoidal wave distortions is the ideal description of the characteristics of transformer loading with attention to the influence of load imbalance. Mathematic modelling and operational testing of imbalanced phase-3 loading showed that the THD current value of secondary Dz with 2 windings and secondary Dz with Symmetrical 3 Cross-winding are different, even though they are loaded with the same amount of Volt-Ampere output power. Because the connection scheme of the secondary Dz with 2 windings has an imbalanced structure, the imbalance limiting performance of the phase-3 is worse than that of the 3-windings secondary zigzag delta connection scheme, the latter which is expected to be able to change the 3-phase-3 power into 2-phase and 1-phase power more effectively.

This paper is explaining to reduce the harmonics, especially 3rd order of harmonics and its multiplication, using transformer technology. In this paper, Dz transformer with 3 coils on the secondary part is used to reduce harmonic pollution. This paper also explaining about how the transformer handles unbalanced load because of the 3rd order (and its multiplication) of harmonics distortion that are produced by non linear loads in distribution system. This paper proposes solution to reduce harmonics problems direct from their source. Based on mathematics analysis and experiment on its parameter, the transformer is engineered to have: (1) Configuration of primary and secondary coil design, (2) Separation of interconnection in secondary coil part, (3) Magnetized coupling within secondary coil part, (4) Magnetized coupling between primary and secondary coil part, (5) Coupling between coil and core, and (6) Series connection with polarity sequence in secondary coil part.

The Dz transformer with crossed connection in its secondary part is purposed to isolating and reducing harmonics distortion in distribution system. The Dz transformer damps harmonic distortion load current. The transformer would damps high frequency band effectively. The principal of Dz transformer is resists the phase by doubling the series inductance in secondary part. The phase is resisted by dividing the secondary coil part by 3 symmetrically, which each part is connected to 3 different phase. By arranging series connection on each 1/3 part of coil in one phase, the MMF induction polarity can be enforcing or the opposite. So, there is one coil part in the same phase which has opposite phase angle until 180o. Therefore because of the 180 o opposition, the MMF induction in 2 groups of coil will resist each other, so the crossing of harmonic frequency signal would never happen. The transformer acts as low frequency filter. Hopefully, the specially designed transformer connection wild reduce harmonics distortion 1.3 – 1.4 times as compared to the conventional one therefore the transformer will be able to increase the system power capacity up to 10 %. The calculation results of the simulations show that the form of the current waveforms on the primary or source side is became near pure sinusoidal form because the THD current value is reduced.

Keywords: total harmonics distortion, non linear loads, unbalanced loads, 3rd order harmonics current, delta zigzag transformer.

1. Introduction

The problem of harmonics distortion is an important issue in the efforts to supply electrical power, in line with the higher attention the people is giving to the issue of the quality of electrical power. Harmonics distortion is the deviation of the power or current wave from the ideal sinusoidal wave. The problems of harmonics distortion is getting more difficult, because there is increasing use of power electronic-based devices that give additional benefits due to their efficiency and effectiveness. According to Prabhakara [1], in 2020 more than 50% of the electrical power capacity generated serves phase-1 non-linear loads, which have imbalanced distribution and

thus even bigger power rating. This means that the impact of current harmonics and load that it causes to the distribution system of the electrical power and to the load becomes more serious. Some of the negative impacts of harmonics distortion are overheating of transformers and motors, operational malfunctions of electronic components, excessive currents in neutral areas, operational problems on computer and telecommunications equipments, etc.

The latest technological developments have given many solutions for electrical power quality problems caused by harmonics distortion due to the imbalanced loading of one-phase linear load. Examples of these are filters, K-rated transformers, Dy transformers, zigzag transformer and phase-shifter combos, Scott transformers, Le Blanc transformer and filter combos, etc. Limiting the impacts of imbalanced loading of one-phase non-linear loading requires special connection transformers. The research done by Cheng-Ping Huang et al. [2] on the Vee/vee, Scott and Le Blanc models for resolving load imbalance on the performance of special connection transformers has not given maximum results.

The analysis results state that the Vee/vee connection scheme causes a more serious imbalance disturbance on three-phase sources than the Scott and Le Blanc connection scheme [2]. The Scott connection does not provide delta windings for circulating 3rd harmonic currents, so the triplene harmonic currents remain on the primary and secondary circuits of the transformer. With the delta connection of the primary side of the three-phase Le Blanc connection, the excess of the connection in these windings are able to limit the triplene harmonic voltages. However, if the secondary windings of a Le Blanc transformer are given a large capacity load between the phase lines to the neutral, then the loading becomes imbalanced.

For that purpose, tertiary delta-connected windings or a filter on the secondary side is needed [4]. From the above explanation of transformer technology, we know that the primary delta winding design is not yet optimum for resisting the currents of distorted harmonics from the secondary side caused by imbalanced load. So the first thing to do is to reduce the level of load imbalance by balancing the resultant mmf induced by load currents. This is done by balancing the resultant mmf induction of load currents by distributing mmf induction symmetrically to the three core legs. In this way, the resultant mmf induction of the load harmonics component does not become excessive, and it can be limited by circulating the harmonics currents through the primary delta windings. Limiting the circulation of harmonic currents will reduce the lost heat of transformer windings, as well as reduce the current of the electromagnetic field current to the supply line side.

This text discusses symmetrical cross-winding secondary Dz special connection transformers as a solution to the harmonics distortion problem caused by non-linear load on balanced and imbalanced loading conditions based on three principles: first is the principle of minimising the quantity and balancing the induction of mmf load currents on the secondary side. The second is the principle of phase-resisting method, which is resisting the electromagnetic energy caused by harmonics currents from the secondary side to the primary side by increasing the leak inductance in secondary windings. Last is the isolator principle, which is isolating the remnants of induction mmf of load currents by circulating them in the connection circuit of the primary delta.

The first principle is executed by dividing each number of secondary phase winding coils into three symmetrical parts, then place each 1/3, *n* part of these windings on three different legs. The second principle serially connects each *n* part of the windings between the three core legs in a symmetrical cross that forms one phase winding. The third principle is executed by connecting the primary windings in the delta to eliminate the 3rd harmonics current induction by circulating the triplene harmonics induction currents generated by non-linear load on the secondary side of the transformer.

The 2nd part of this text presents the ideas for the methods and the study of the mathematical models of the Dz special connection transformer. The 3rd part investigates the minimising of harmonics in balanced and imbalanced loading conditions of the phase-1 non-linear loads. Part 4 represents the results of the investigation and discussion. Part 5 contains the conclusion of this research.

2. Dz Connection Transformer with Symmetrical Secondary Cross-windings in order to Minimise Harmonics Distortion

   a. *Symmetrical Secondary Two Cross-windings Dz Special Connection Transformer*

      On the secondary side of each number low-voltage phase winding, N_2 is divided into two equal parts: $n = N_2/2$. Each n of the phase winding part is placed in a symmetrical cross on three different core legs, as shown in Figure 1 (b). The two n parts of the winding are serially placed to form one phase winding. The result is that the resultant magnetic motive force (*mmf*) of the phase winding is √3 x n, or each half part of the mmf.

      The advantage of this configuration is that it is able to limit the triplene harmonics current between the lines of the load and neutral phases by counter-positioning the phase of each n voltage in the serial winding part.

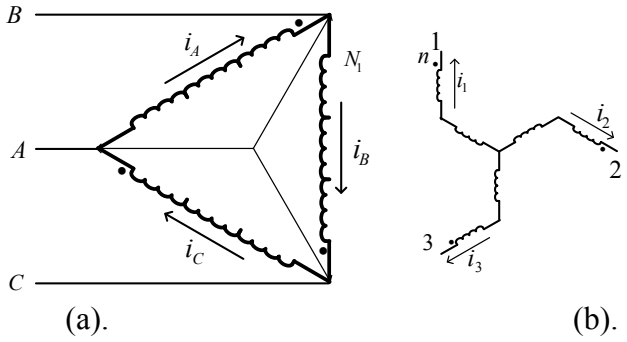

Figure 1 The Secondary 2-winding Dz Transformer Connection

As we can see in Figure 2, the diagram shows that the Dz transformer scheme supplies equal non-linear one-phase loads. Each non-linear one-phase load generates equal 3rd harmonic currents I_3 in each phase conductor. From the diagram, we know that the ampere-winding mmf on the same core leg on the secondary side cancel out (eliminate) each other. This results in the lack of 3rd harmonic currents circulating in the primary delta side.

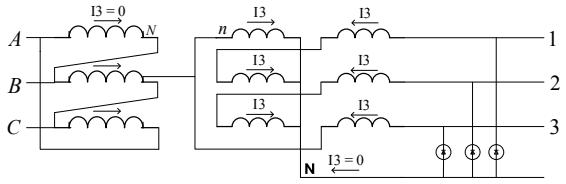

Figure 2 3rd Harmonics Current on Secondary 2-winding Dz Transformer

However, in practice, the 3rd harmonic current components are not always equal on the phase currents, so the resultant mmf ampere-winding on the same leg on the secondary side do

not minimise each other totally [14]. As a result, 3rd harmonic currents remain circulating in the primary winding and in the power supply line.

b. Symmetrical Secondary Three Cross-windings Dz Special Connection Transformer

The idea of the zigzag three winding connection on the secondary side is based on the transpositional theory of phase-3 power transmission line wires for resolving non-symmetry due to the geometrical position of the zigzag windings [11]. On the secondary winding side of each low-voltage phase winding number, N_2 is divided into three equal parts: $n = N_2/3$. Each n of the winding part of the phase is placed cross-symmetrically on three different core legs. The three parts of the n windings are then placed serially to compose one phase winding (see Figure 3). The resultant mmf phase winding is ½ for each n, or 1/3 of the mmf part.

The advantage of this configuration is that it is able to limit the harmonics triplene current between the load and neutral phase lines by counter-positioning the phase of each n voltage of the serial winding. With this zigzag secondary side configuration, the impedance of the secondary 3-winding Dz transformer is bigger than that of standard transformers.

The diagram of the Symmetrical Cross-winding Secondary Dz transformer is as follows:

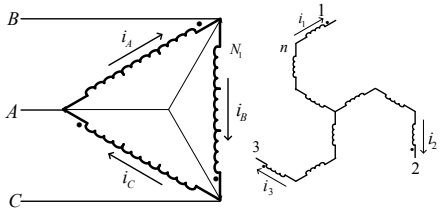

Figure 3 The Secondary 3-winding Dz Transformer Connection

Because the above mmf vector connection of secondary phase windings is formed of zigzag winding connections, then the currents at the zigzag windings minimised at the delta windings are:

$$i_A = (n/N_1)(-i_1 - i_2 + i_3) \quad (1)$$

$$i_B = (n/N_1)(i_1 - i_2 + i_3) \quad (2)$$

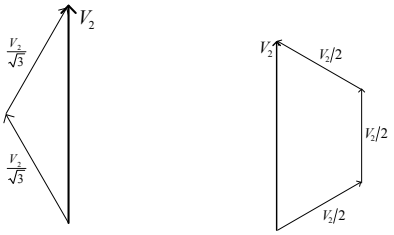
$$i_C = (n/N_1)(i_1 + i_2 - i_3) \quad (3)$$

Three parts of secondary windings build up the magnetic flux in the transformer's core, where the phase angle has a 180 electrical degree difference. This way, the magnetic flux from the three winding parts reduces each other and the signals of harmonic frequencies are eliminated. Afterwards, there is no electromagnetic energy transfer from the core to secondary windings. This means that the currents of the transformer's primary delta winding phases are expected to contain little 3rd harmonic component, as this component is expected not to show in the source line currents.

c. Comparison of the Inductance Values of Dz Special Connection Transformers

As stated in sections *a* and *b*, the mmf (ampere-winding) requirements for generating V_2 effective output value of equal size between two divisions of windings per phase and three divisions of windings per phase are different (see **Figure 4**).

ISSN 114-1284



(a). **(b).**

Figure 4 Scheme of Effective Output Voltage Phasor of the Secondary Side
(a) Zigzag with 2 winding parts (b) Zigzag with 3 winding parts

From **Figure 4** we see that the total mmf amount for generating equal effective secondary output voltages on 2 parts and 3 parts winding per phase are respectively $2V_2/\sqrt{3}$ and $3V_2/2$. So the ratio of mmf requirement between 3-winding and 2-winding secondary Dz transformer is:

$$\frac{E_{z3}}{E_{z2}} = \frac{3V_2/2}{2V_2/\sqrt{3}} = 1{,}3 \quad (4)$$

Based on the fact that the 3-winding parts secondary Dz transformer requires 1.3 times mmf than the 2-winding parts secondary Dz transformer to create the same effective voltage output. The same phase winding current means that the number of *N* winding in the secondary 3-winding parts is 1.3 times bigger than the 2-winding parts, as we can see in equation (4). For the same winding conductor cross-section, the number of the secondary 3-part zigzag winding is bigger and longer. This results in a larger resistive impedance value in the 3-part secondary zigzag winding coil than the resistive impedance value of 2-part secondary zigzag winding coil, as we can see in equation (5),

$$R = \rho \frac{l}{A} \quad (5)$$

Where R = the value of resistive impedance [Ohm], ρ = the conductive capability of the material, l = the length of the conductor [m], and A = the cross-section size of the conductor [m^2].

Large L inductive impedance when the harmonic frequency is increased is expected to be able to resist 3rd harmonic currents and triplene harmonics on the secondary windings of the transformer. This resistance can prevent the flow of electromagnetic energy distorted 3rd harmonic current from circulating in the primary windings. The performance of the transformer becomes more efficient, and energy can be saved because the lost electric power is reduced and because obstructing 3rd harmonics can improve the impacts of secondary voltage distortion. These filter-capability transformers are expected to generate cleaner, more economical power quality.

3. Testing Scheme

Laboratory testing on the 380/220V 4-wire phase-3 electrical power distribution system was connected to non-linear loads. The loads were comprised of fluorescent lamps with electronic return. AC sources from the laboratory were used as distribution points. A 1250 VA, 380 V/6 x 55 V, 50 Hz symmetrical cross-winding secondary Dz transformer was used as the mitigation/obstruction harmonic distortion device, and 3 x 40 electronic return fluorescent lamps of 10 Watts each were the non-linear phase-1 harmonic generator loads. For balancing the load of Dz transformers, each secondary phase voltage output terminal supplied a 450 Volt-Ampere power. Imbalanced loading of Dz transformers uses secondary phase voltage output terminals which supplied 360, 270, and 270 Volt-Amperes. The scheme of the simulation was as shown in Figure 4:

ISSN 114-1284

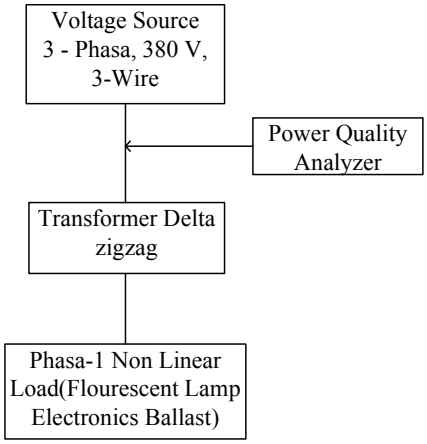


Figure 4 Measurement Test Flow chart

Measurements were taken under the following conditions:

a. Balanced and imbalanced direct connection to panel points of distribution through a Symmetrical Two Cross-winding Secondary Dz Transformer.
b. Balanced and imbalanced direct connection to panel points of distribution through a Symmetrical Three Cross-winding Secondary Dz Transformer.

4. Results and Discussion

Table 1 and Table 2 show harmonics reading when the load is connected to the source panel through a Symmetrical 2 Cross-winding Secondary Dz Transformer. As expected, the non-linear phase-1 load of LHE lamps with half-wave director creates 3rd, 5th, 7th, and triplene harmonic frequencies that can be lowered 40%-44% using the Symmetrical 2 Cross-winding Secondary Dz Transformer, both on balanced and imbalanced load conditions.

(a) Balanced Loads, and (b) Imbalanced Loads

Figures 4 (a) and 4 (b) show the spectrum of harmonic currents on balanced and imbalanced loads. Harmonic currents are the largest part of the current flowing through the conductor.

Tables 3 and 4 show the influence of special connection Dz transformers on electrical systems. We can see in Tables 3 and 4 that a special connection Dz transformer placed between the load and the source panel of a phase-3 voltage highly influences the harmonic content. Using transformers with large inductive impedance values will make the transformer able to filter and eliminate triplene harmonics, and reduce other sequential harmonic contents. Current THD is reduced from 39% to 28% in balanced load conditions, and from 44% to 34% in imbalanced condition. This means a 10% increase in the power capacity of the system.

5. Conclusion

Laboratory tests show that symmetrical cross-winding secondary Dz transformers can limit harmonics in the phase-3 electrical power distribution system. Symmetrical 3 cross-winding secondary special connection Dz transformers are able to limit the harmonic distortion of currents in the utility side better than the symmetrical 2 cross-winding secondary Dz in balanced loading condition. The level of harmonic distortion in the utility side is reduced more when using the symmetrical 3 cross-winding secondary special connection Dz transformer than when using the symmetrical 2 cross-winding secondary Dz. Placing a number of small-capacity Dz transformers on the distribution panel may improve the overall performance of the system and reduce power quality problems due to harmonics.

ABSTRACT

Frequency Hopping (FH) technique is one of data transmission method in the telecommunication system. FH can help system to resolve transmission problems, i.e. jamming, noise, interference, and multipath fading. The goal or this research is developing AM broadcast radio communication system with frequency hopping. Transmitter and receiver are not synchronized.

System that has been designed is using PLL (Phase Lock Loop) as a carrier signal oscillator. There are two carrier signal oscillators to be set to perform FH technique, which are at frequency of 1000 kHz and 1050 kHz. The change in frequency is controlled by programmable divider.

This research produces AM broadcast radio communication system with frequency hopping. After some tests were performed, it turns out that the prototype can work well. Information signal that was transmitted by AM transmitter can be well received at the receiver. Frequency hopping has been well performed with hopping period of one carrier signal is 0.5 second. The system can be further developed by adding the number of carrier frequency for hopping technique and synchronization between transmitter and receiver.

Keywords
Frequency hopping, AM broadcast, radio communication

1. INTRODUCTION

Information signal should be put on the radio signal that has higher frequency as a carrier. The method to add the two signals is called modulation [1]. Modulate means change the parameter of carrier signal that has higher frequency with information signal that has lower frequency.

Analog signal modulation that is used in this research is amplitude modulation (AM). The amplitude of carrier signal is changed according to the change of information signal amplitude.

Information signal often suffer from distortion during transmission due to fading, delay, attenuation, interference, jamming, and noise. Information signal will be corrupted and the received signal quality will be decreased [2]. Jamming is a transmission of interferer signal deliberately in the same channel and disturbs the existing service channel [3].

Interference and jamming will appear as the number of transmitter increase in a fix allocation of frequency spectra. If the transmitter operates in moderate quality factor, then the bandwidth will disturb other transmitter on the adjacent channel.

Above mention problem does not occur in the AM radio frequency spectrum due to the number of broadcast AM radio transmitter that is getting smaller. Jakarta has only 13 transmitters [4–6], whereas the frequency allocation for AM radio transmitter is very wide. This trend happens because there is much interference experienced inherently by information signal that is transmitted with AM technique. Nowadays, most of AM radio broadcast transmitters settled into FM technique. FM technique is more interesting due to the ability to suppress interference problem [1].

One of the techniques to solve this problem is spread spectrum that has antijam capability, interference suppression, ability to combat multipath fading, and security features [7]. One of the well-known spread spectrum techniques is Frequency Hopping Spread Spectrum (FHSS). The use of random channel can resolve jamming problem, especially when jamming target is only a particular frequency. FHSS can suppress interference, especially when interference hits a particular frequency. FHSS can also combat multipath fading, especially frequency selective fading. This technique will increase the channel capacity, so that more transmitters can use the same frequency spectrum with different hopping sequence [8].

This research produces AM broadcast radio communication system with frequency hopping. The equipment that has been designed is laboratory scale system prototypes that can be develop as commercial equipment. The system consists of AM radio transmitter and receiver with two carrier frequencies, 1000 kHz and 1050 kHz that hopped every 0.5 second. Transmitter and receiver are independent, not synchronize, and will be tested separately.

The result of this research can be considered as a starting point and reference of further development of the application of FH in broadcast communication system. Proper development will increase the quality of communication service and efficiency of spectrum utilization. The number of broadcast AM radio transmitter will rapidly increase without worrying about service quality decrement. AM radio spectrum potentially become an interesting alternative for

broadcast radio transmitter to grow like the old time.

2. THEORETICAL BACKGROUND

2.1. Amplitude Modulation

Amplitude modulation (AM) is a modulation process that changes the carrier signal amplitude according to the amplitude of information signal with fix carrier frequency. The instantaneous carrier frequency can be expressed as [1]

$$e_c(t) = E_{c\max}\cos(\omega_c t + \phi_c) \quad (1)$$

where $E_{c\max}$ is carrier signal amplitude, ω_c is carrier angle frequency, and ϕ_c is carrier phase. The wave shape of carrier signal is depicted in Figure 1.

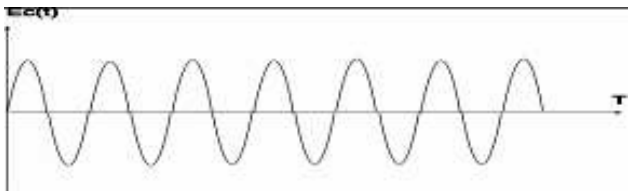

Figure 1: Carrier wave shape [1]

Modulating signal can be expressed as [1]

$$e_m(t) = E_{m\max}\cos(\omega_m t + \phi_m) \quad (2)$$

where $E_{m\max}$ is modulating signal amplitude, ω_m is modulating signal angle frequency, dan ϕ_m is modulating signal phase. The wave shape of modulating signal is depicted in Figure 2.

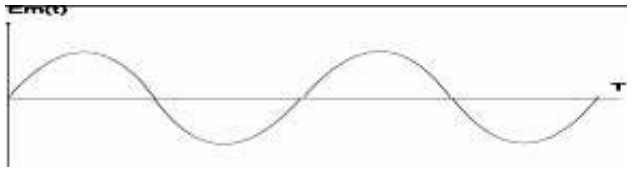

Figure 2. Modulating wave shape [1]

Modulation process produce modulated signal, which can be expressed as [1]

$$e(t) = [E_{c\max} + e_m(t)]\cos(\omega t + \phi) \quad (3)$$

The wave shape of modulated signal is depicted in Figure 3.

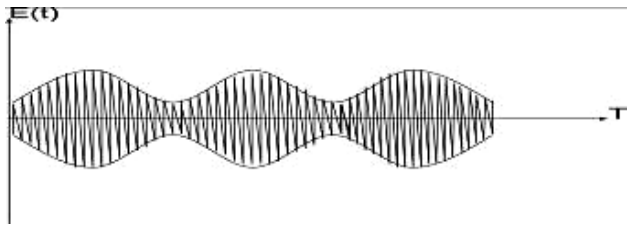

Figure 3. Modulated wave shape [1]

2.2. Frequency Hopping

Frequency hopping (FH) is a change of carrier frequency periodically that is controlled by certain algorithm [8]. The particular frequency will carry the information signal in a certain period and then the carrier frequency will change to other frequency as it is depicted in Figure 4.

The bended arrow in Figure 4 shows the hopping sequence that is from $f_1 \rightarrow f_3 \rightarrow f_7 \rightarrow f_2 \rightarrow f_5 \rightarrow f_4 \rightarrow f_6$, and repeated continuously. The change of carrier frequency can be done hundreds times per second. The receiver should be able to tune the change of frequency, so that the information can be well received.

FH is one of the spread spectrum technique and the bandwidth is wider than minimum bandwidth that is needed for sending the same information if using single carrier. System that use spread spectrum technique will have advantages such as antijam ability, interference suppression, combat multipath fading, low probability of intercept, secure communication, and increase spectral efficiency [7]

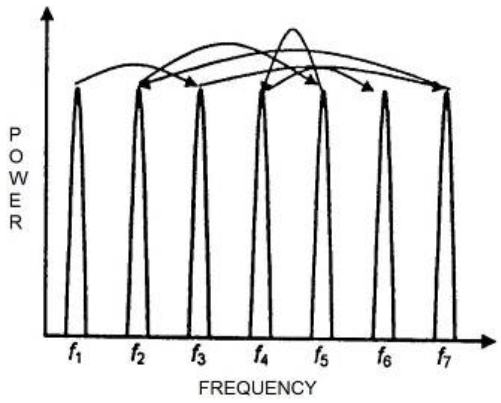

Figure 4: FH technique [8]

The hop process, from one frequency to another, is usually controlled sequentially or randomly using pseudorandom code. If interference appear and disturb one of the channels, e.g. f_2, then this frequency will always suffer the disturbance, but only when its turn to carry the information signal. This mechanism is shown in Figure 5.

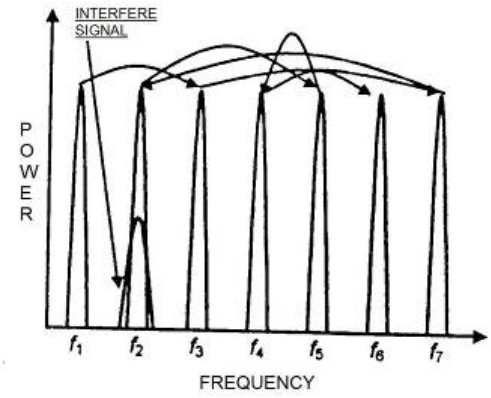

Figure 5: Interference on FH transmission [8]

3. RESEARCH METHODOLOGY

3.1. System Model

System model can be depicted in Figure 6 (transmitter) and Figure 7 (receiver). Two carrier signals with different frequency (f_1 and f_2) will work consecutively. Carrier signal changes was done by switching device. Oscillator was designed using PLL (Phase Locked Loop) with programmable counter to generate two frequencies. Modulated signal will be amplified prior to trasmitting from antenna.

In the receiver side, radio signal will be amplified prior to demodulation process. In the AM demodulator, modulated signal will be combined with signal from local oscillator that was designed using PLL. This PLL has the same configuration with the one in the transmitter.

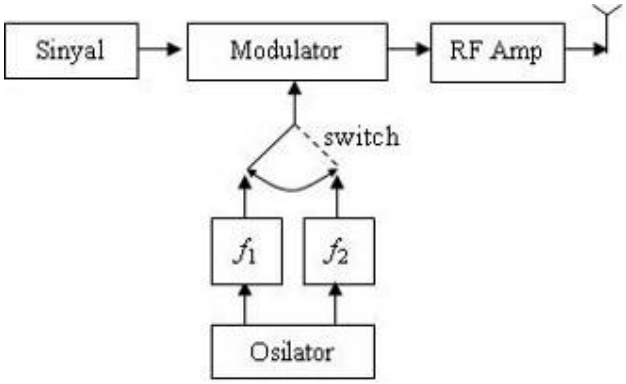

Figure 6: Transmitter model

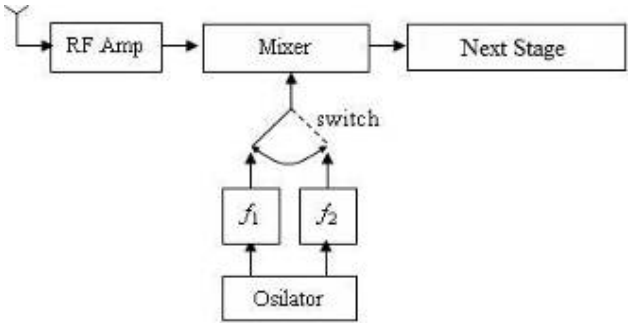

Figure 7: Receiver model

3.2. System Design

Figure 8 shows the block diagram of AM transmitter with FH. ORF is a reference oscillator, PD is a phase detector, LPF is a Low Phase Filter, VCO is a Voltage Controlled Oscillator, and PT is programmable divider. PLL operation is established by PD, LPF, and VCO.

Programmable divider is controlled by electronic switch. The output of programmable divider will be compared with reference frequency in the phase detector. The phase detector will produce DC voltage level to control the VCO and generate the carrier frequency.

The circuit of AM receiver with FH is depicted in Figure 9. Figure 9 shows that radio signals come from the antenna and will be driven to RF amplifier. Signal is then passed through the mixer, mixed with signal from local oscillator as a reference signal, so that generate an Intermediate Frequency (IF). Signal amplitude is amplified in IF amplifier and then passed through the detector for information and carrier signal separation. After separation, signal is processed in the LPF to suppressed the noise prior to be processed in volume control and speaker. The function of mixer, IF amplifier and detector is replaced by IC ZN414.

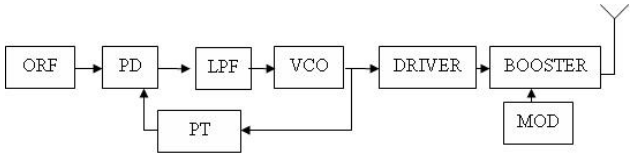

Figure 8. Block diagram of AM transmitter with FH

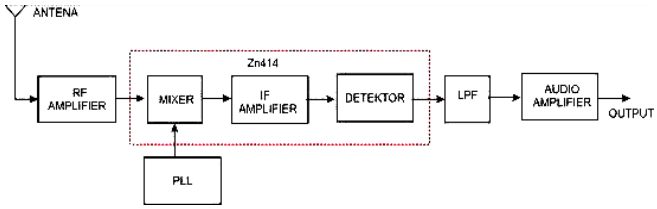

Figure 9. Block diagram of AM receiver with FH

4. DISCUSSION

4.1. AM Transmitter with FH

4.1.1. Transmitter Transmission Testing

The test was performed using system model that is illustrated in Figure 10. Transmitter block sends information signal using two carrier frequencies, i.e. 1000 kHz and 1050 kHz. Signal that is sent from the transmitter is received by two AM receivers, each of them are tuned at 1000 kHz and 1050 kHz.

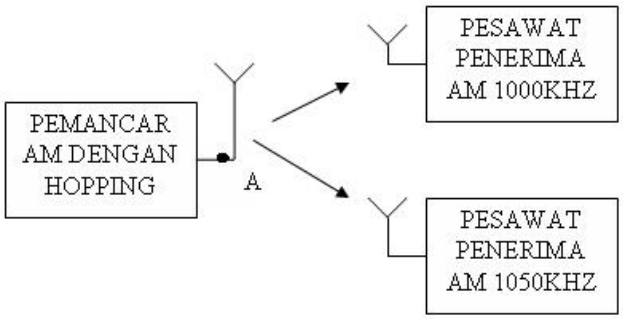

Figure 10. System model for transmitter transmission testing

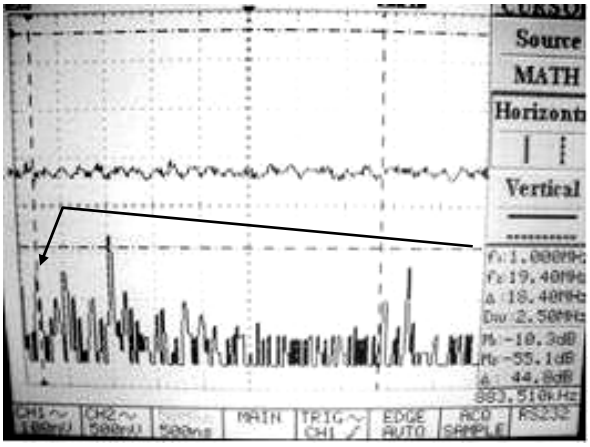
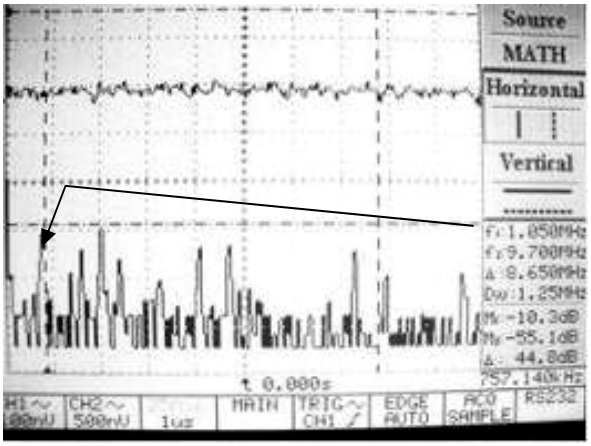
Figure 11 shows the display of frequency spectrum of transmitter that was taken in point A of Figure 10. It is shown that transmitter has a good and stable carrier frequency at 1000 kHz and 1050 kHz.

ISSN 114-1284



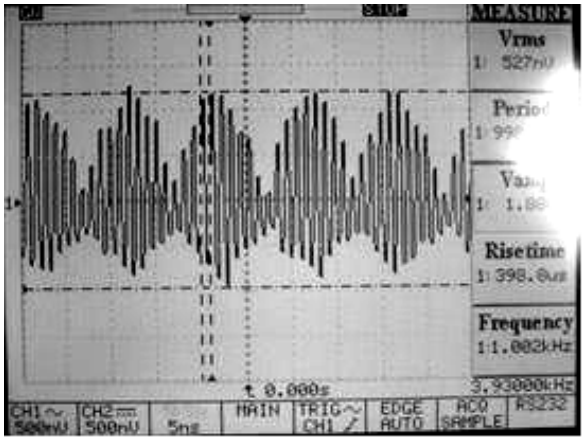
(a)



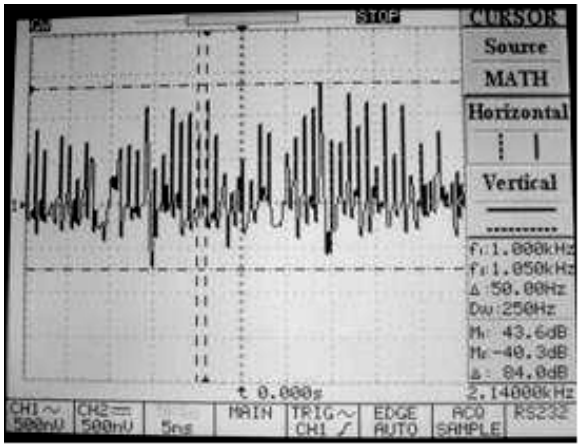
(b)

Figure 11. Carrier frequency spectrum of transmitter at (a) 1000 kHz (b) 1050 kHz

Transmitter is also tested to prove that it works on AM technique. Sinusoidal information signal with frequency 4 kHz is sent with both carriers. The wave shape of the modulated signal as the result of modulation process is shown in Figure 12. Figure 12 shows that the transmitter works on AM technique.



(a)

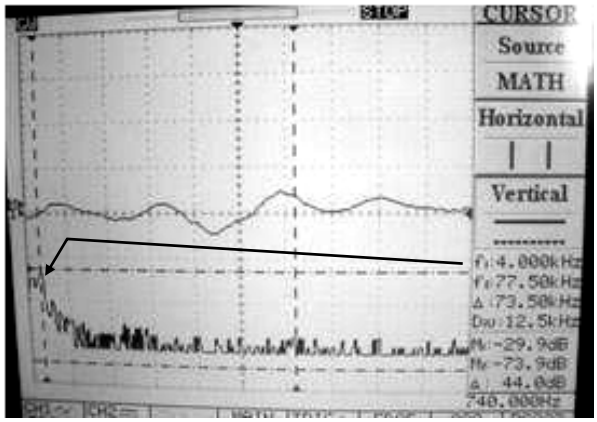


(b)

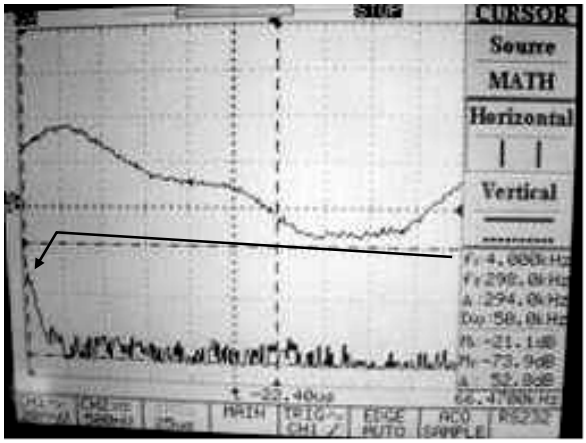
Figure 12. AM technique with carrier frequency (a) 1000 kHz (b) 1050 kHz

Figure 12. (cont'd) AM technique with carrier frequency (a) 1000 kHz (b) 1050 kHz

Observation is also done by listen the tone sound quality at AM receiver speaker. The higher the information signal frequency, the higher the tone sound. Figure 13 shows the frequency spectrum of audio signal from the speaker in the AM receiver. The spectrum at the receiver has the same fundamental frequency with the signal transmitted.



(a)



(b)

Figure 13. Audio frequency spectrum at the AM receiver with carrier frequency (a) 1000 kHz. (b) 1050 kHz

4.1.2. Carrier Frequency Stability Testing when Hopping

The test was performed using system model that is illustrated in Figure 14. Output signal of transmitter block is measured using frequency counter for 300 seconds. Table 1 shows the data when hopping. Data were taken every 50 seconds.

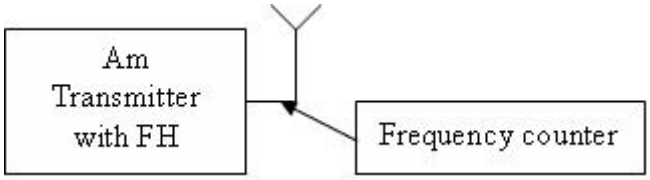


Figure 14. Transmitter stability testing when hopping

Table 1. Data of transmitter stability testing when hopping

Time (s)	Carrier Frequency 1 (KHz)	Carrier Frequency 2 (KHz)
50	1000,0	1050,0
100	1000,2	1050,6
150	1000,4	1050,2
200	1000,0	1050,1
250	1000,0	1050,3
300	1000,1	1050,8
Average	1000,1	1050,3
Error (%)	0,01	0,28

Table 1 show that average error percentage of carrier frequency is very small, that is 0.01 % for carrier frequency 1000 MHz and 0.28 % for carrier frequency 1050 MHz. The error percentage shows that transmitter has stable carrier frequency when hopping.

4.2. AM Receiver with FH

The test was performed using system model that is illustrated in Figure 15 at point 1 and point 2. RF Generator send 50% modulated signal over carrier signal with frequency 1000 kHz and 1050 kHz.

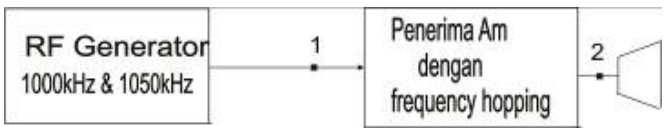

Figure 15. AM receiver testing

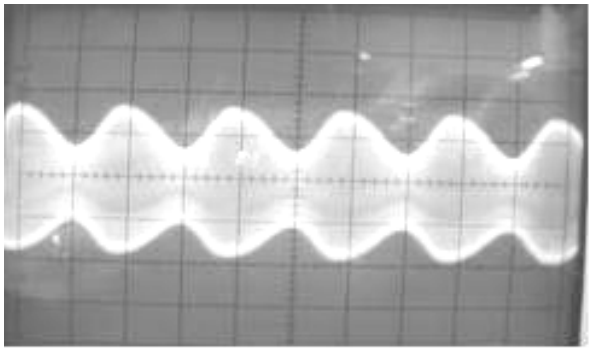
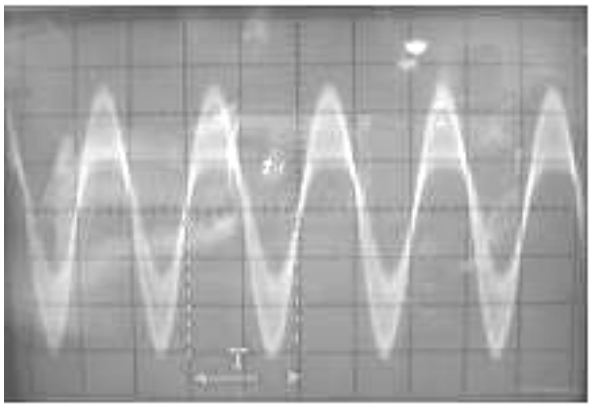
Figure 16 (a) shows the input signal of AM receiver that was observed at point 1. Calculation of carrier frequency refers to Figure 16 (b) that is the enlarge version of Figure 16 (a) with time/division on the oscilloscope is set at $T = 2x0{,}5x10^{-6} = 1x10^{-6}\,s$. So that carrier frequency received by receiver can be defined as

$$f = \frac{1}{T} = \frac{1}{1x10^{-6}} = 1000kHz \qquad (4)$$



(a)

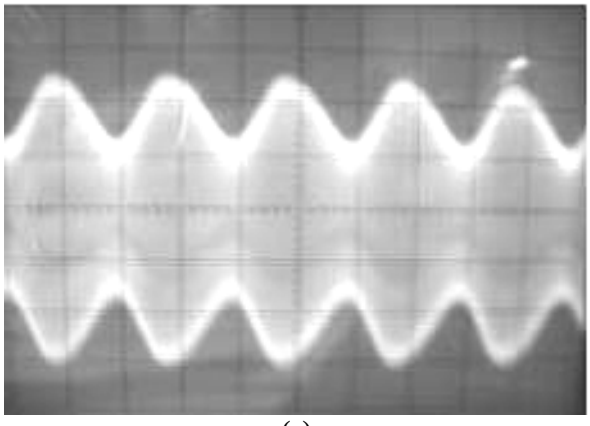


(b)

Figure 16. (a) Input signal of AM receiver at 1000 kHz
(b) Enlarge version of (a)

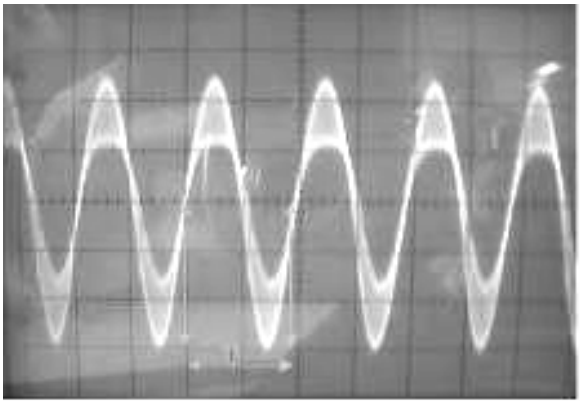
Figure 17 (a) shows the input signal of AM receiver that was observed at point 1. Calculation of carrier frequency refers to Figure 17 (b) that is the enlarge version of Figure 17 (a) with time/division on the oscilloscope is set at $T = 1{,}9x0{,}5x10^{-6} = 9{,}5x10^{-7}\,s$. So that carrier frequency received by receiver can be defined as

$$f = \frac{1}{T} = \frac{1}{9{,}5x10^{-7}} = 1052kHz \qquad (5)$$



(a)

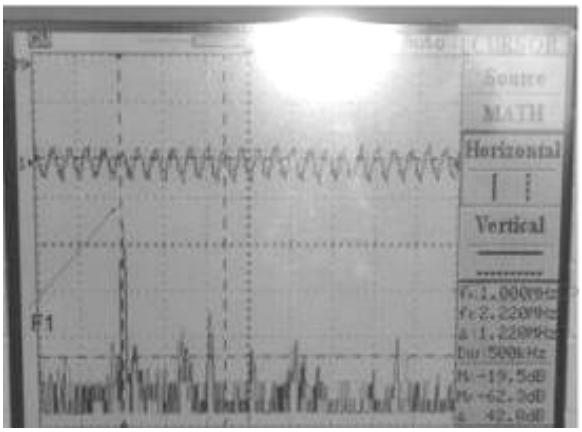
Figure 17. (a) Input signal of AM receiver at 1050 kHz (b) Enlarge version of (a)



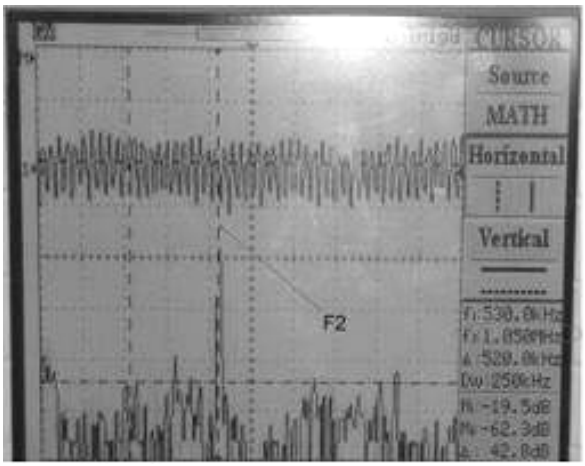
(b)

Figure 17. (cont'd) (a) Input signal of AM receiver at 1050 kHz (b) Enlarge version of (a)

Figure 16 and Figure 17 shows that AM receiver can receive signal correctly. Frequency spectrum also shows that frequency transmitted is correct. Carrier frequency spectrum at 1000 kHz and 1050 kHz is depicted in Figure 18.



(a)

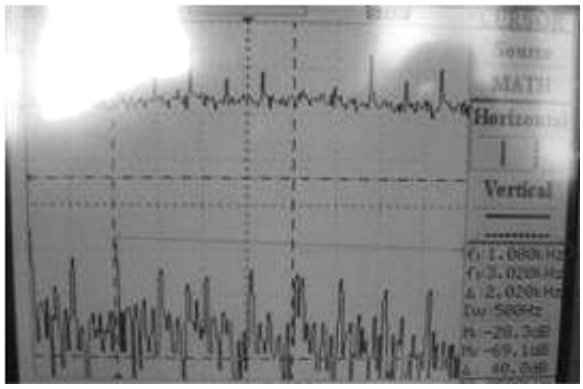


(b)

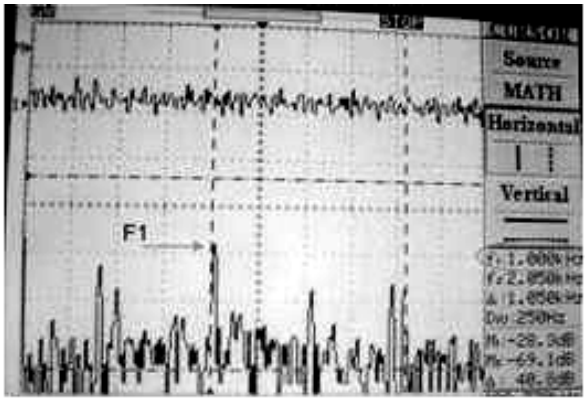
Figure 18. Carrier frequency spectrum (a) 1000 kHz, (b) 1050 kHz

F1 in Figure 18 (a) shows the highest signal peak at 1000 kHz. F1 in Figure 18 (b) shows the highest signal peak at 1050 kHz. Test was performed for each carrier frequency consecutively. For each carrier frequency, only one tone with particular frequency can be listened.

Test for defining the audio frequency that is produced by AM receiver is done at point 1 and point 2 simultaneously. Modulated signal carries audio signal with frequency 1 kHz. When point 1 receives carrier frequency of 1000 kHz, point 2 is measured and the result is depicted in Figure 19 (a). When point 1 receives carrier frequency of 1050 kHz, point 2 is measured and the result is depicted in Figure 19 (b).



(a)



(b)

Figure 19. Audio signal with frequency 1kHz on carrier frequency (a) 1000kHz (b) 1050kHz

F1 shows the fundamental frequency with many harmonics. The harmonics signal does not affect system performance. It seems that fundamental frequency shows the difference between frequency received and frequency transmitted. Pointer can not be placed in the middle of the signal peak, so that the measurement that is shown in Figure 19 is the best measurement that can be taken. However, the performance of AM receiver is already met the design specification.

Frequency hopping process can not be clearly observed as the time domain of the output of timer is too tight comparing the output of VCO as PLL output. Figure 20 shows the hopping process when carrier frequency 1000 kHz change to 1050

kHz. Measurement is done at timer output and VCO output simultaneously.

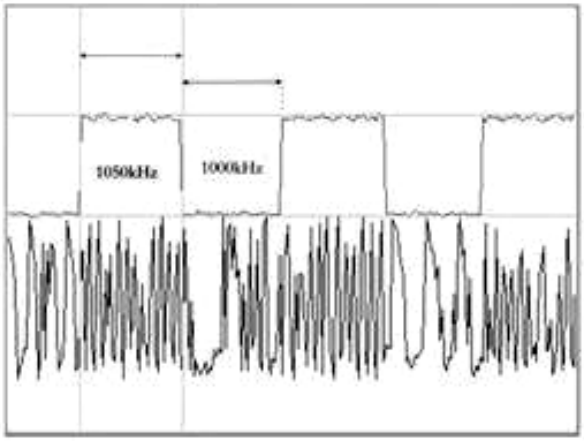


Figure 20. Hopping process of two carrier frequencies.

Carrier signal with frequency 1050 kHz looks tighter than carrier signal with frequency 1000 kHz. When timer is ON, it generates carrier frequency 1050 kHz. When timer is OFF, it generates carrier frequency 1000 kHz. The test result shows that hopping process is agreeing with the design.

5. CONCLUSION AND SUGGESTION

5.1. Conclusion

a. The prototype that has been made can work well according to the design.
b. AM receiver can tune the signal from transmitter with carrier frequency 1000 kHz and 1050 kHz consecutively.
c. Hopping period for one carrier frequency is 0.5 seconds.

5.2. Suggestion

a. The system can still be developed with synchronization mechanism for transmitter and receiver.
b. The number of carrier frequency can be improved for better FH technique.

ABSTRACT

Frequency Hopping (FH) technique is one of data transmission method in the telecommunication system. FH can help system to resolve transmission problems, i.e. jamming, noise, interference, and multipath fading. The goal or this research is developing FM broadcast radio communication system with frequency hopping. Transmitter and receiver are not synchronized.

System that has been designed is using PLL (*Phase Lock Loop*) as a carrier signal oscillator. There are two carrier signal oscillators to be set to perform FH technique, which are at frequency of 90 MHz and 100 MHz. The change in frequency is controlled by programmable divider.

This research produces FM broadcast radio communication system with frequency hopping. After some tests were performed, it turns out that the prototype can work well. Information signal that was transmitted by FM transmitter can be well received at the receiver. FM receiver can tunes two carrier frequencies, 90 MHZ and 100 MHz. Hopping period of one carrier signal is 0.5 second. The system can be further developed by adding the number of carrier frequency for hopping technique and synchronization between transmitter and receiver.

Keywords
Frequency hopping, FM broadcast, radio communication

1. INTRODUCTION

Information signal should be put on the radio signal that has higher frequency as a carrier. The method to add the two signals is called modulation [1]. Modulate means change the parameter of carrier signal that has higher frequency with information signal that has lower frequency.

Analog signal modulation that is used in this research is frequency modulation (FM). The frequency of carrier signal is changed according to the change of information signal amplitude.

Information signal often suffer from distortion during transmission due to fading, delay, attenuation, interference, jamming, and noise. Information signal will be corrupted and the received signal quality will be decreased [2]. Jamming is a transmission of interferer signal deliberately in the same channel and disturbs the existing service channel [3].

Interference and jamming will appear as the number of transmitter increase in a fix allocation of frequency spectra. If the transmitter operates in moderate quality factor, then the bandwidth will disturb other transmitter on the adjacent channel.

For example, there are 47 broadcast FM radio transmitters in Jakarta with allocation of frequency spectra between 87.6 MHz up to 107.8 MHz [4]. Surabaya has 37 transmitters [5] and Yogyakarta has 43 transmitters [6]. The frequency band for each transmitter is about 300 kHz, so Jakarta is already saturated. If there were an additional transmitter operated, there will be interference and jamming occurs among transmitters. Surabaya and Yogyakarta still can be expanded in limited number. One day, the spectrum will full up and there is no space to expand.

One of the techniques to solve this problem is spread spectrum that has antijam capability, interference suppression, ability to combat multipath fading, and security features [7]. One of the well-known spread spectrum techniques is Frequency Hopping Spread Spectrum (FHSS). The use of random channel can resolve jamming problem, especially when jamming target is only a particular frequency. FHSS can suppress interference, especially when interference hits a particular frequency. FHSS can also combat multipath fading, especially frequency selective fading. This technique will increase the channel capacity, so that more transmitters can use the same frequency spectrum with different hopping sequence [8].

This research produces FM broadcast radio communication system with frequency hopping. The equipment that has been designed is a laboratory scale system prototype that can be develop as commercial equipment. The system consists of FM radio transmitter and receiver with two carrier frequencies, 90 MHz and 100 MHz that hopped every 0.5 second. Transmitter and receiver are independent, not synchronize, and will be tested separately.

The result of this research can be considered as a starting point and reference of further development of the application of FH in broadcast communication system. Proper development will increase the quality of communication service and efficiency of spectrum utilization. The number of broadcast radio transmitter will rapidly increase without worrying about service quality decrement.

2. THEORETICAL BACKGROUND

2.1. Frequency Modulation

Frequency modulation (FM) is a modulation process that changes the carrier frequency according to the amplitude of information signal with fix carrier amplitude [9]. Figure 1 shows that when information signal amplitude is positive, carrier frequency is deviated by Δf and become f_1. When information signal amplitude is negative, carrier frequency is deviated by Δf and become $-f_1$. As information signal amplitude increase, the frequency deviation is also increase and potentially capable of disturbing other transmitter [1]. The instantaneous carrier frequency can be expressed as

$$f_i(t) = f_c(t) + ke_m(t) \quad (1)$$

Information signal as modulating signal, e_m, is used to change the carrier frequency. The change in frequency is ke_m, with k is a frequency deviation constant, and f_c is an unmodulated carrier frequency.

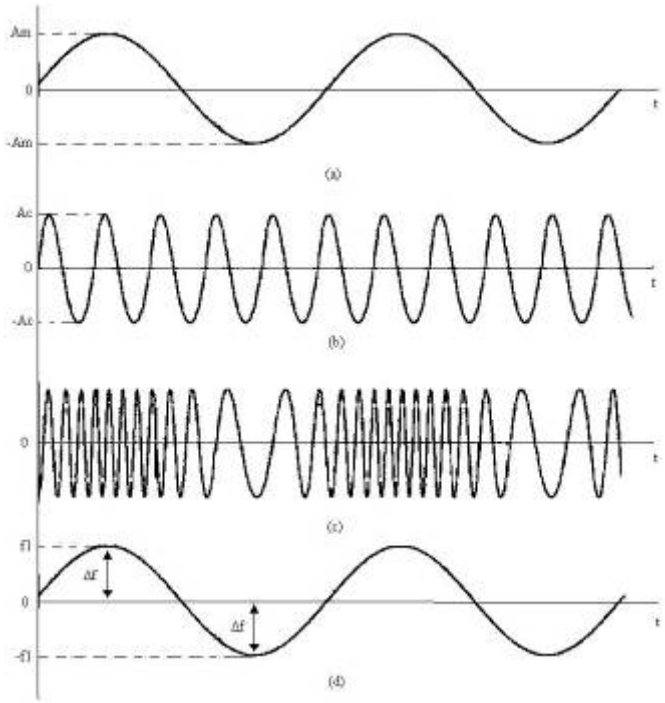

Figure 1: FM [9] (a) Information signal (b) *Carrier* signal. (c) Amplitude vs. time (d) Frequency vs. time

2.2. Frequency Hopping

Frequency hopping (FH) is a change of carrier frequency periodically that is controlled by certain algorithm [8]. The particular frequency will carry the information signal in a certain period and then the carrier frequency will change to other frequency as it is depicted in Figure 2.

The bended arrow in Figure 2 shows the hopping sequence that is from $f_1 \rightarrow f_3 \rightarrow f_7 \rightarrow f_2 \rightarrow f_5 \rightarrow f_4 \rightarrow f_6$, and repeated continuously. The change of carrier frequency can be done hundreds times per second. The receiver should be able to tune the change of frequency, so that the information can be well received.

FH is one of the spread spectrum technique and the bandwidth is wider than minimum bandwidth that is needed for sending the same information if using single carrier. System that use spread spectrum technique will have advantages such as antijam ability, interference suppression, combat multipath fading, low probability of intercept, secure communication, and increase spectral efficiency [7]

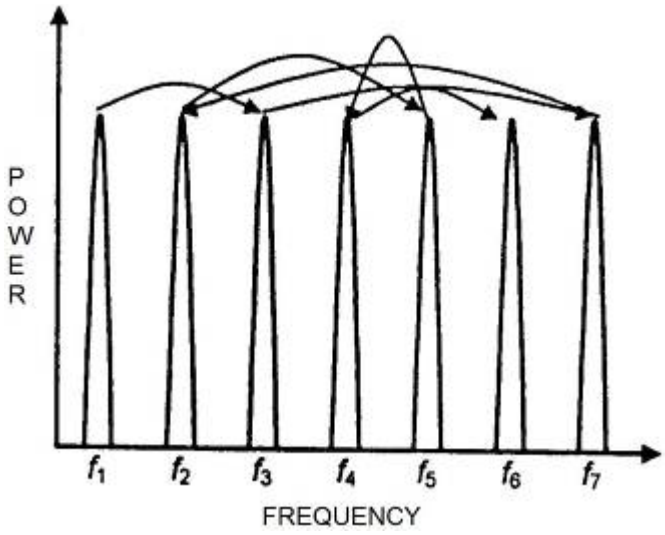

Figure 2: FH technique [8]

The hop process, from one frequency to another, is usually controlled sequentially or randomly using pseudorandom code. If interference appear and disturb one of the channels, e.g. f_2, then this frequency will always suffer the disturbance, but only when its turn to carry the information signal. This mechanism is shown in Figure 3.

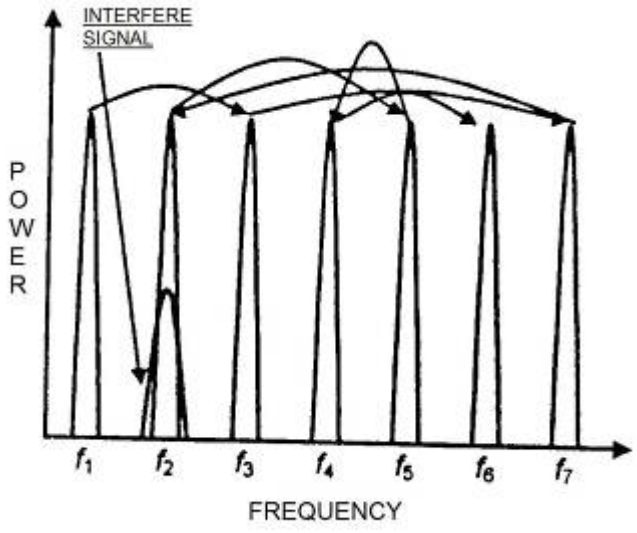

Figure 3: Interference on FH transmission [8]

3. RESEARCH METHODOLOGY

3.1. System Model

System model can be depicted in Figure 4 (transmitter) and Figure 5 (receiver). Two carrier signals with different frequency (f_1 and f_2) will work consecutively. Carrier signal changes was done by switching device. Oscillator was designed using PLL (Phase Locked Loop) with programmable counter to generate two frequencies. Modulated signal will be amplified prior to trasmitting from antenna.

In the receiver side, radio signal will be amplified prior to demodulation process. In the FM demodulator, modulated signal will be combined with signal from local oscillator that was designed using PLL. This PLL has the same configuration with the one in the transmitter.

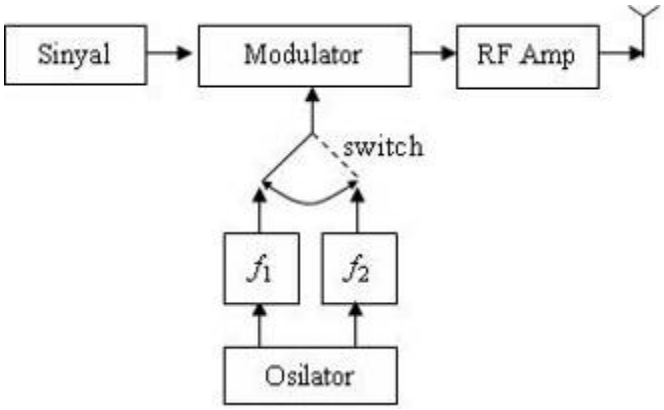

Figure 4: Transmitter model

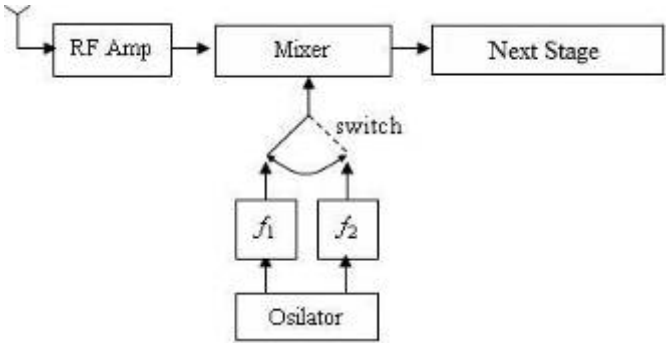

Figure 5: Receiver model

3.2. System Design

Figure 6 shows the block diagram of FM transmitter with FH. The function of prescaler block is as preliminary divider for output signal frequency of VCO (Voltage Controlled Oscillator) block, because this frequency is still too high to be divided in the programmable divider.

Programmable divider is controlled by electronic switch (switch 1 and switch 2). The output of programmable divider will be compared with reference frequency in the phase detector. The phase detector will produce DC voltage level to control the VCO and generate the carrier frequency.

The circuit of FM receiver with FH is depicted in Figure 7. The circuit consists of nine parts. These nine parts is classified in two main groups. The first groups is radio signal processing group that consist of RF (Radio Frequency) amplifier, mixer, IF (Intermediate Frequency) amplifier, Q.D. (Quadrature Detector), AF (Audio Frequency) amplifier. The second group is FH controlling group that consist of crystal oscillator, PLL, VCO and programmable counter/divider.

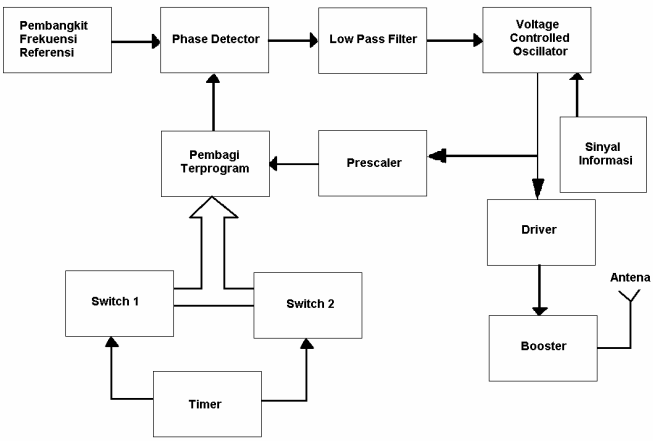

Figure 6. Block diagram of FM transmitter with FH

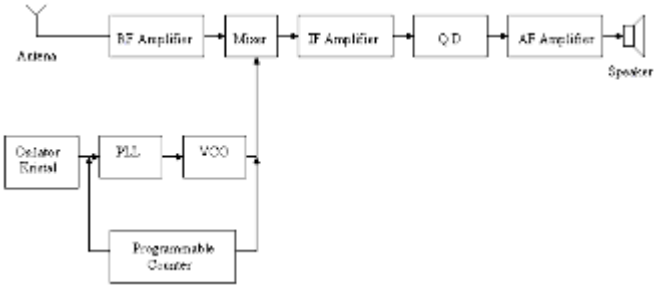

Figure 7. Block diagram of FM receiver with FH

Antenna receives all radio signals that exist. RF amplifier together with mixer will select a particular FM signal and amplify it. FM signal will be combined with local oscillator signal. Local oscillator is built from PLL and VCO circuit that has been set by programmable counter in the mixer. The output of mixer is an IF signal. IF signal will be amplified by IF amplifier. QD is used to separate audio signal from carrier signal. The audio signal will be amplified so that the power of the signal can drive the speaker.

4. DISCUSSION

4.1. FM Transmitter with FH

4.1.1. Transmitter Transmission Testing

The test was performed using system model that is illustrated in Figure 8. Transmitter block sends information signal using two carrier frequencies, i.e. 90 MHz and 100 MHz. Signal that is sent from the transmitter is received by two FM

receivers, each of them are tuned at 90 MHz and 100 MHz.

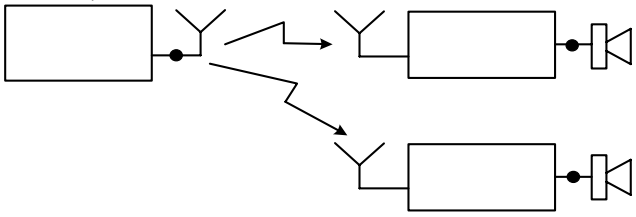

Figure 8. System model for transmitter transmission testing

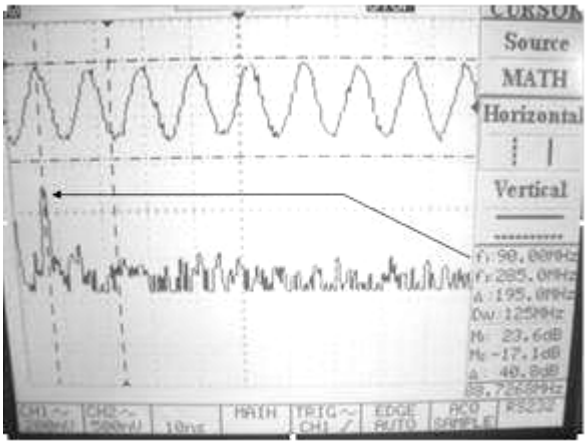
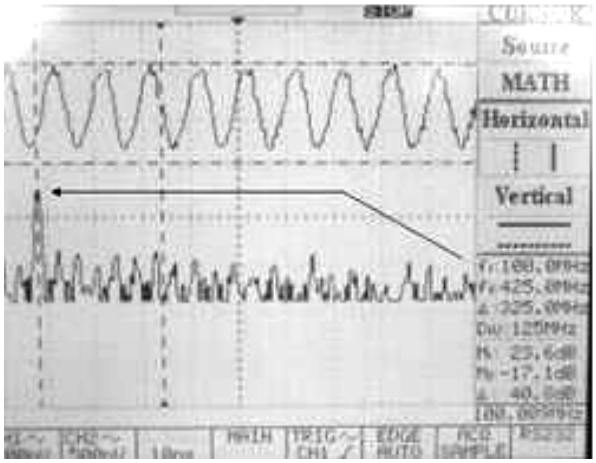
Figure 9 shows the display of frequency spectrum of transmitter that was taken in point a of Figure 8. It is shown that transmitter has a good and stable carrier frequency at 90 MHz and 100 MHz.



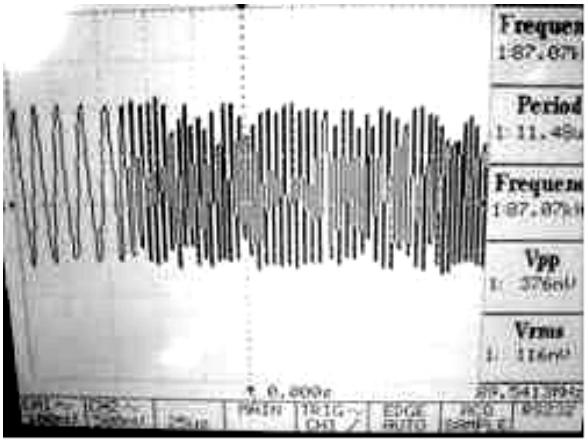
(a)



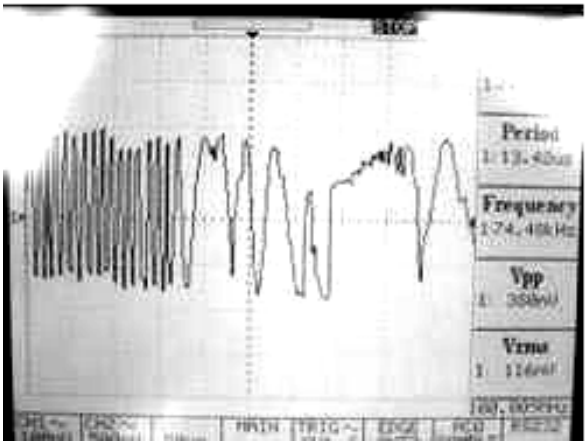
(b)

Figure 9. Carrier frequency spectrum of transmitter at (a) 90 MHz (b) 100 MHz

Transmitter is also tested to prove that it works on FM technique. Sinusoidal information signal with frequency 4 kHz 10 Vpp is sent with both carriers. The wave shape of the modulated signal as the result of modulation process is shown in Figure 10. Figure 10 shows that the transmitter works on FM technique.



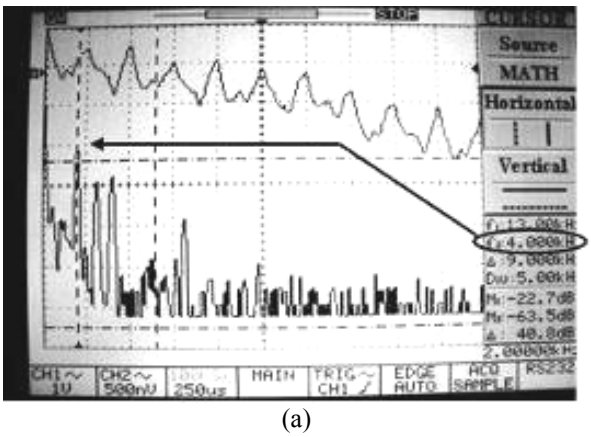
(a)



(b)

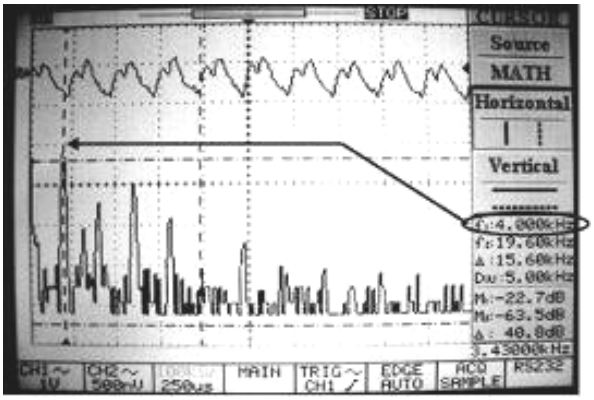
Figure 10. FM technique with carrier frequency (a) 90 MHz (b) 100 MHz

Point b and point c in Figure 8 is testing points of information signal that is received by FM receiver. Figure 11 shows the frequency spectrum of audio signal from the speaker in the FM receiver. It shows that the received signal is the same of the transmitted signal. The spectrum at the receiver has the same fundamental frequency with the signal transmitted.



(a)

Figure 11. Audio frequency spectrum at the FM receiver with carrier frequency (a) 100 MHz. (b) 90 MHz



(b)

Figure 11. (cont'd) Audio frequency spectrum at the FM receiver with carrier frequency (a) 100 MHz. (b) 90 MHz

4.1.2. Carrier Frequency Stability Testing when Hopping

The test was performed using system model that is illustrated in Figure 12. Output signal of transmitter block is measured using frequency counter for 500 seconds. Table 1 shows the data when hopping. Data were taken every 50 seconds.

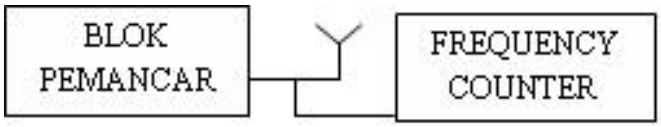


Figure 12. Transmitter stability testing when hopping

Table 1. Data of transmitter stability testing when hopping

Time (s)	Frequency *Carrier* 1 (MHz)	Frequency *Carrier* 2 (MHz)
50	90,0	99,8
100	89,9	99,9
150	89,8	99,9
200	90,0	100,0
250	89,9	100,0
300	90,0	99,9
350	90,0	100,0
400	90,0	99,9
450	90,0	100,0
500	89,9	99,9
Average($\overline{X}$)	89,95	99,93
Persen *error* (%)	0,001	0,0007

Table 1 show that average error percentage of carrier frequency is very small, that is 0.001 % for *carrier* frequency 90 MHz and 0.0007 % for *carrier* frequency 100 MHz. The error percentage shows that transmitter has stable carrier frequency when hopping.

4.2. FM Receiver with FH

4.2.1. Receiving Quality Testing

The test was performed using system model that is illustrated in Figure 13. Two of FM transmitter blocks are set to send carrier signal with frequency 90 MHz and 100 MHz. Signal is received by FM receiver with FH.

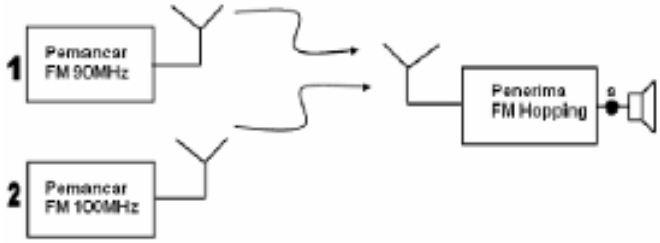

Figure 13. Receiving Quality Testing

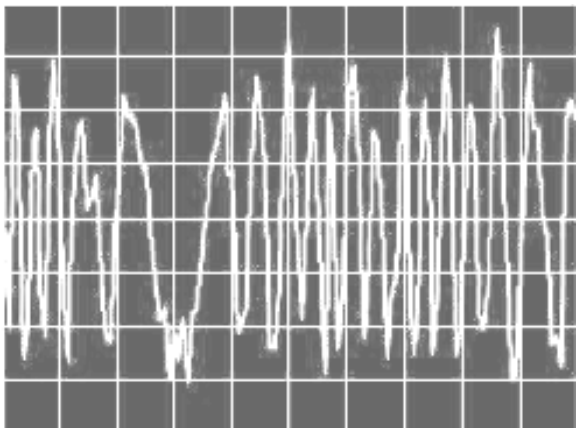
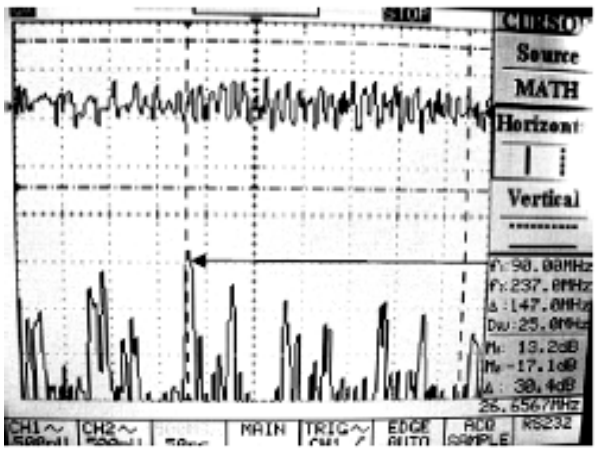
The RF output testing was performed when transmitter sends modulated signal with frequency of information signal is 2 kHz and amplitude 2.5V. It is proven that RF amplifier can tune frequency 90 MHz and 100 MHz as it is shown in Figure 13.

Figure 13 also shows that received signal at RF amplifier is FM signal. Figure 13 (a) is received signal shape when 90 MHz transmitter is activated and Figure 13 (b) is the signal spectrum. Figure 14 (a) is received signal shape when 100 MHz transmitter is activated and Figure 14 (b) is the signal spectrum.

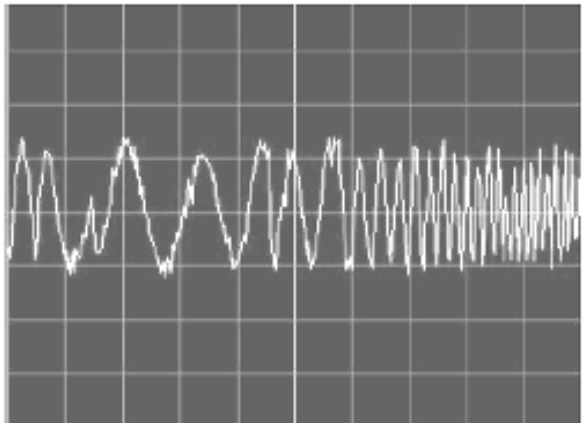


(a)

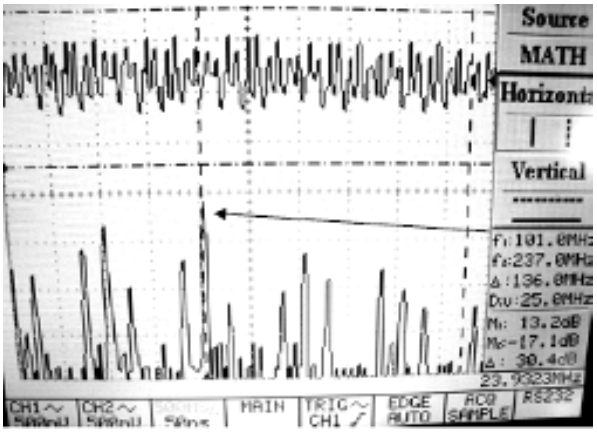


(b)

Figure 13. RF amplifier output signal at frequency 90 MHz
(a) RF amplifier output signal
(b) RF amplifier output spectrum



(a)



(b)

Figure 14. RF amplifier output signal at frequency 100 MHz
(a) RF amplifier output signal
(b) RF amplifier output spectrum

After some test at RF amplifier, it is also known that the gain of the amplifier is very small. However, overall performance is not so affected and system still can work well according to design. Output signal amplitude of RF amplifier at frequency 90 MHz is 616 mVpp. Measured transmit signal amplitude at the antenna is 8 Vpp, for frequency 90 MHz and 100 Mhz. Therefore, the gain of RF amplifier is 0,077 for frequency 90 MHz and 0,074 for frequency 100 MHz. Although, the test result can not be compared with the design, but it is obvious that the gain of RF amplifier is very small.

Test was also performed by observing and listening the information signal quality that has been received by receiver. Figure 15 shows transmitted information signal that is sinusoidal signal form AFG (*Audio Function Generator*). Information signal is a tone that has 5 Vpp amplitude and frequency 2 kHz. Point a in Figure 13 is a test point of received information signal at FM receiver.

Figure 16 shows the audio output spectrum at FM receiver. It is also shown that frequency spectrum of audio signal from the speaker in the FM receiver is the same of the transmitted signal. The spectrum at the receiver has the same fundamental frequency with the signal transmitted.

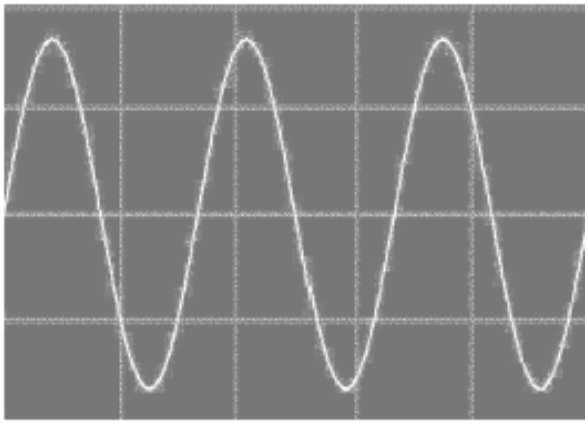


Figure 15. Information signal with frequency 2 kHz.

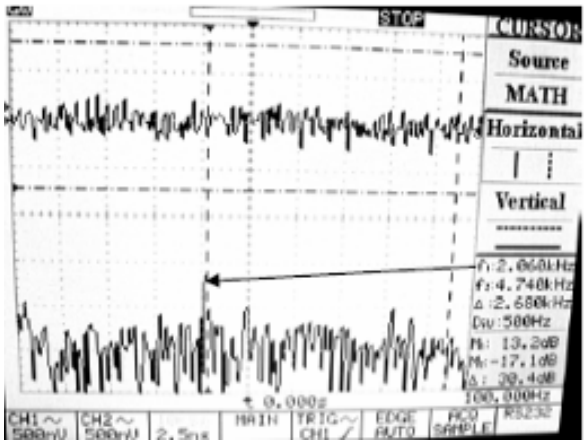
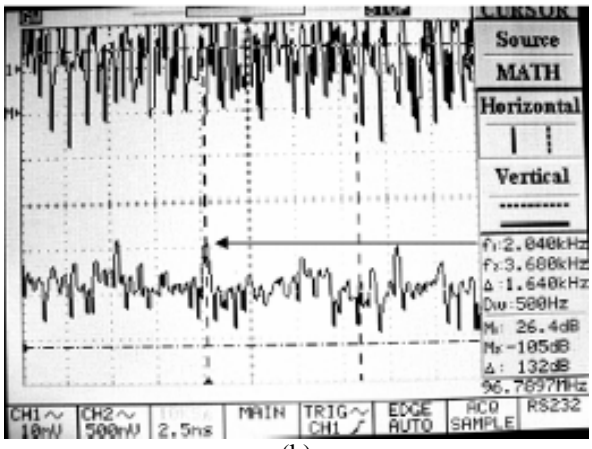


(a)



(b)

Figure 16. Audio frequency spectrum at FM receiver and carrier frequency (a). 90 MHz. (b) 100 MHz.

5. CONCLUSION AND SUGGESTION

5.1. Conclusion

a. The prototype that has been made can work well according to the design.
b. FM receiver can tune the signal from transmitter with carrier frequency 90 MHz and 100 MHz consecutively.
c. Hopping period for one carrier frequency is 0.5 seconds.

5.2. Suggestion

a. The system can still be developed with synchronization mechanism for transmitter and receiver.
b. The number of carrier frequency can be improved for better FH technique.
c. Clock should be set accurately so that the change in carrier frequency more stable.

ABSTRACT

Delay has been a problem in electronic system that can't be removed completely. Many efforts has been done in order to compensate for delay occured in a system, e.g. in PID control system, the derivative element is used to increase its dynamic response performance by predicting the system behavior. Negative delay is thought to be one of the ways to compensate for delay. The main purpose of this work is to get a better insight about negative delay occurred in electronic circuit. The circuit which we observed, comprised of 3 main parts, i.e. a pulse generator, a 4th - order low-pass filter, and a negative delay circuit. In this work, we observed the input and output signals of the negative delay circuit using an oscilloscope. The waveform obtained by the oscilloscope is captured and analyzed using own-made MATLAB code. There are several parameters that we investigated in relevance with the negative delay, such as delay length, signal correlation, and delay circuit's resistor R value. The result shows that increasing value of R will increase the length of the negative delay but in the same time decrease the correlation between input and output signal.

Keywords

Negative delay, low-pass filter, correlation

1. INTRODUCTION

Negative delay is already implemented in various application implicitly, e.g in a hot-wire anemometer, the signals from the slow sensors are compensated using a differentiator. In PID control system, the derivative element is used to predict the system behaviour and to improve its dynamic response. A feedback loop with a derivative element is needed, when a capacitive load connected to the output of an op-amp, which is known as the lead compensations. All these efforts are performed to compensate delays in a system [1]. Negative delay in electronic circuit is also helpful in gaining a better insight about superluminal group velocity [2]. Superluminal group velocity has been proved experimentally in various systems [3], but there are still some question left unanswered. Hopefully, by observing the negative delay in electronic circuit, some of those questions can be answered. Negative delay experiment using electronic cicruit is far simpler and easier to do than in other system, while the insight gained can help to understand negative delay in a more complicated system.

2. NEGATIVE DELAY

A band-limited input signal $E_{in}(t)$ can be expressed as a product of the carrier $\exp(i\omega_0 t)$ and the envelope $\varepsilon_{in}(t)$: $E_{in}(t) = \varepsilon_{in}(t)e^{i\omega 0t} + c.c$, where $c.c$ represent the complex conjugate. By expanding in terms of Fourier component $\tilde{\varepsilon}_{in}(u)$ of the envelope $\varepsilon_{in}(t)$, the signal becomes

$$E_{in}(t) = \int_{-\Omega/2}^{\Omega/2} du\tilde{\varepsilon}_{in}(u)e^{i(\omega_0+u)t} + c.c \qquad (1)$$

where Ω is the bandwidth and u is the offset frequency from ω_0. The transfer function $H(\omega)$ is defined for each frequency $\omega=\omega_0+u$, and the output can be written as

$$E_{out}(t) = \int_{-\Omega/2}^{\Omega/2} du\tilde{\varepsilon}_{in}(u)H(\omega)e^{i(\omega_0+u)t} + c.c$$

$$E_{out}(t) = \int_{-\Omega/2}^{\Omega/2} du\tilde{\varepsilon}_{in}(u)A(\omega)e^{i(\omega_0+u)t}e^{i\phi(\omega)} + c.c \qquad (2)$$

We assumed that within the bandwith $(|u|<\Omega/2)$, the amplitude $A(\omega)$ is nearly unity and the phase $\phi(\omega)$ can be approximated by a linear function that is,

$$A(\omega) \sim 1, \qquad \Phi(\omega) \sim \Phi(\omega_0) - u.t_d. \tag{3}$$

The group delay t_d is defined as

$$t_d = -\left.\frac{d\phi}{d\omega}\right|_{\omega_0}. \tag{4}$$

The envelope of the output is obtained from (2) and (3) as

$$\varepsilon_{out}(t)=\varepsilon_{in}(t-t_d)e^{i\Phi(\omega 0)}. \tag{5}$$

From Eq. (5), we can say that the envelope of the output is shifted by the group delay t_d, while maintaining its shape. Negative delay happens for $t_d < 0$ so that the output precedes the input [1], [4].

3. THE CIRCUITS

The circuit that will be tested comprised of three parts, i.e pulse generator, low-pass filter, and negative delay circuits. The system's schematic is shown in Figure 1. The system was made based on the work of Nakanishi *et al* [1], [4].

3.1 Pulse Generator

For generating pulse, we are using a monostable multivibrator circuit utilizing the 555 timer IC. This circuit will create a pulse when triggered as seen in Figure 2.

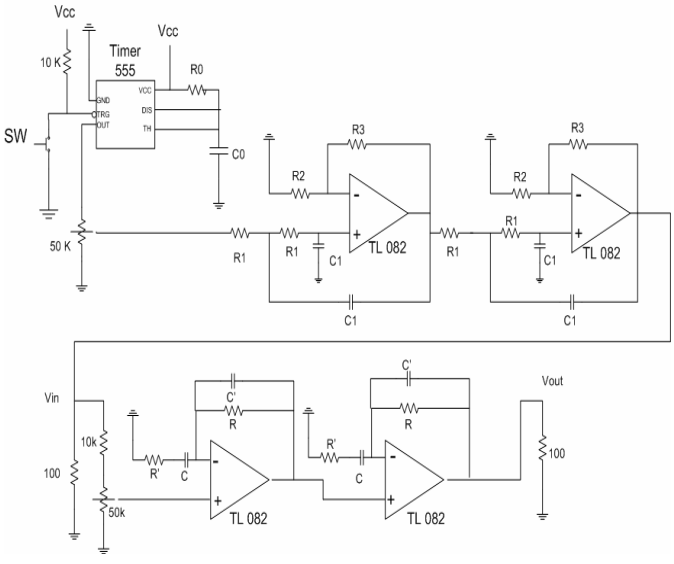

Figure 1. Schematics of the tested system

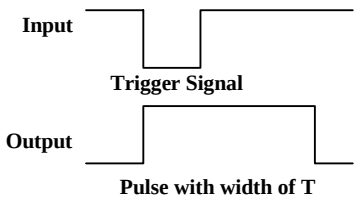

Figure 2. Monostable Multivibrator timing diagram

The width of the pulse depends on the value of the resistor R and capacitor C employed in the circuit. For this work, we used a 6.8 MΩ resistor and a 0.22 μF capacitor. The pulse width produced by the circuit is 1.5 s.

3.2 Low-Pass Filter

To prepare a band-limited pulse we introduce low-pass filters. The rectangular pulse produced by the pulse generator has high-frequency components. Because of these components, the negative delay circuit does not work properly [4]. We must eliminate the high frequency components with low-pass filters. As seen in Figure 1, we used a two-stage low-pass filter. We used Bessel filter for this system, since it has a smoother response and small overshoot for rectangular waves. The transfer function for Bessel filter is

$$H_B^{(m)}(\omega) = \frac{y_m(0)}{y_m(i\omega\alpha_m T_L)} \tag{6}$$

where $y_m(x)$ is m^{th} order of Bessel Polynomial, T_L is the inverse of cut-off frequency, and α_m is a parameter chosen such that

$$H_B^{(m)}(T_L^{-1}) = 1/\sqrt{2}\,. \tag{7}$$

The total order of the filter being used is $m = 4$, where each filter is a 2^{nd} order filter with transfer function

$$H_B^{(2)} = \frac{1}{1 + i\omega\alpha_2 T_L + \frac{(i\omega\alpha_2 T_L)^2}{3}} \tag{8}$$

where $T_L = 1.272R_1C_1$, and $\alpha_2 = 1+R_3/R_2 = 1.268$. All these parameters are chosen so that

$$\omega_c = \frac{0.35}{T} \tag{9}$$

Where $T = RC$ is the time constant of the negative delay circuit [1], [4]. With Eq. (9) satisfied, the $A(\omega)$ and $\Phi(\omega)$ can be assumed to be constant and linear.

3.3 Negative Delay Circuit

The negative delay circuit is basically a non-inverting differentiator as shown in Figure 3. The transfer function for this circuit is

$$H(\omega)=A(\omega)e^{i\Phi(\omega)}=1+i\omega T \tag{10}$$

where $T=RC$. In time domain, the corresponding input and output relation is

$$v_{out}(t)=\left(1+T\frac{d}{dt}\right)v_{in}(t)=v_{in}(t)+T\frac{dv_{in}(t)}{dt} \quad (11)$$

From Eq. (11) we can say that for the rising edge, which has a positive slope, the two terms interfere constructively, while for the falling edge, which has a negative slope, the two terms interfere destructively such that the pulse peak advance [1], [4].

$H(\omega)$, in the low frequency region $(|\omega|<<1/T)$, can be approximated by

$$A(\omega)=1+O(\omega^2T^2) \quad (12)$$

$$\Phi(\omega)=\omega T+O(\omega^3T^3) \quad (13)$$

From (12) and (13), we can say that the amplitude is nearly constant and the phase increases linearly with the frequency. The group delay also becomes negative

$$t_d=-\left.\frac{d\phi}{d\omega}\right|_{\omega_0}=-T<0 \quad (14)$$

The higher order terms in Eqs. (12) and (13) induce distortion of the waveform of the output [1], [4].

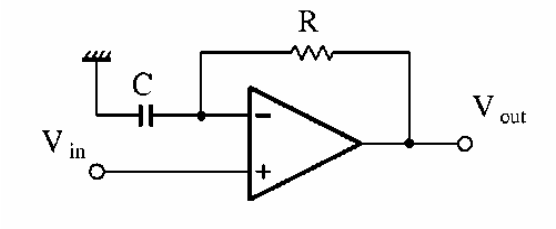

Figure 3. The negative delay circuit

The actual negative delay circuit in Figure 1 differs from that shown in Figure 3. In the actual the resistor R' and capacitor C' are added to suppress high-frequency noises. The parameters are chosen to satisfy $R'C$, $C'R << T$. Thus, the phase $\Phi(\omega)$ for $|\omega|T<1$ is not affected.

4. EXPERIMENTAL RESULT

4.1 Negative Delay

Figure 4 shows the observation result of the system shown in Figure 1. As seen in Figure 4 the peak of the output signal precedes the peak of the input signal as consequence of the resulted negative group delay. The waveform in Figure 4 is obtained using an oscilloscope and then extracted using an own-made MATLAB code. The extracted curve were then fitted to a 4th order Gaussian curve using MATLAB. The result is as shown in Figure 4. The time difference between the input and output peak in Figure 4 is 0.41 s. This delay quantitatively agrees with the expected negative delay derived using Eq. (14). The expected negative delay is $2T$ = 0.44 s. The delay is multiply by 2 because we connected two circuits in series for larger effect. The pulse width also increases from 1.5 s to about 6 s. It is because of the delay caused by the low-pass filter. The steep edge of the rectangular pulse, is smoothened by the low-pass filter which results in the pulse widening

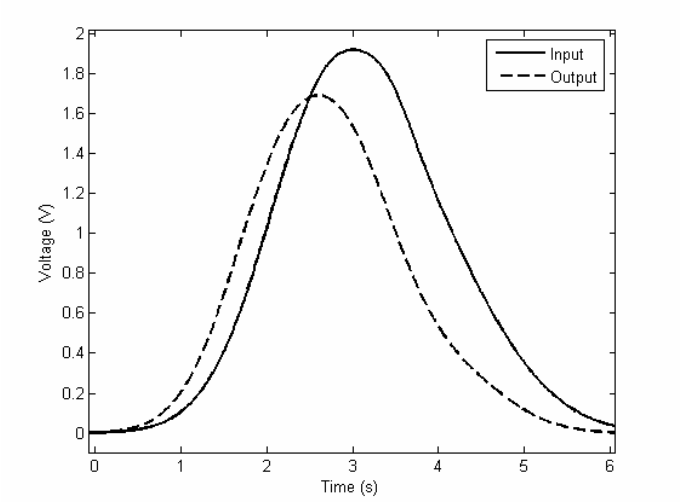

Figure 4. Negative delay circuit observation result

4.2 The Effect of Increasing the Value of Resistor R to the Negative Delay

In this stage of experiment, we observed the effect of increasing the value of resistor R to the negative delay. The increase in R will increase the time constant T so that the length of the negative delay will increase as well according to Eq. (14). In this experiment, the resistor value range from 1 MΩ to 2 MΩ with increment of 0.1 MΩ for each observation. Figure 5 shows the input and output signal for all resistor value, while Table 2 shows the delay produced by each resistor value.

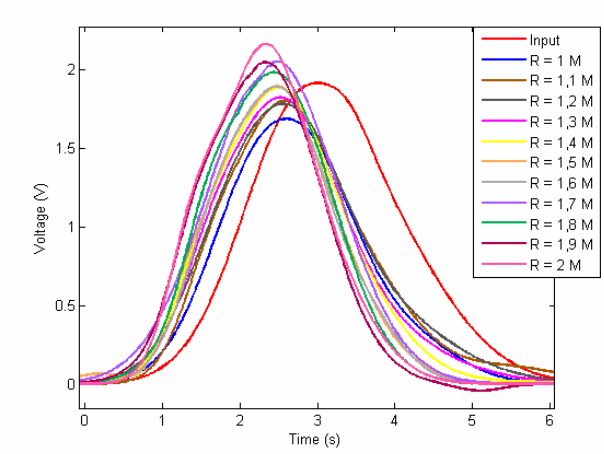

Figure 5. Input and output signals for all resistor value.

There are several things that we can learn from Figure 5 and Table 2. First, generally the increase in resistor value, resulting in increasing the length of the negative delay. However, the increment is different from the expectation based on Eq. (14). As shown in Table 2, for several resistor values, the negative delay produced is the same. We assumed that it is because Eq. (14) is based on approximation. Besides, the curve extraction and delay measurement were performed manually.

Table 2. Observation result for various R values.

R Value (MΩ)	Delay Observed (s)	Delay Expected (s)	Difference (%)
1	0.41	0.440	6.82
1.1	0.43	0.484	11.16
1.2	0.45	0.528	14.77
1.3	0.52	0.572	9.09
1.4	0.52	0.616	15.58
1.5	0.53	0.660	19.70
1.6	0.53	0.704	24.72
1.7	0.53	0.748	29.14
1.8	0.57	0.792	28.03
1.9	0.66	0.836	21.05
2	0.66	0.880	25.00

4.3 The Effect of Increasing the Value of Resistor R to the Correlation Between The Input and Output Signals.

Using the data obtained from previous measurement, we calculated the correlation between the input and output signals. The correlation is computed using MATLAB. There are two method, in the first method, before calculating the correlation, we shift the data so that the peak of both input and output signals coincide. Then, we calculate the correlation. The result is shown in Table 3 and Figure 6. In the second method, we use the cross-correlation function. The cross-correlation method will produce an x,y pair, where x is the shift in x axis and y is the intersection between the curve. The highest y value shows the time when the intersection area between the two curve is the biggest, it represents the highest correlation between the curve and the corresponding x value shows the shift need to be made to produce such result. We assumed that the highest y value will be produced when the x value equal to the negative delay, and this y value will equal to the correlation calculated with the first method. Table 4 shows the cross correlation result. The delay and correlation calculated using the cross correlation are different from the one calculated before. Despite the difference, Table 3, Table 4, and Figure 6 show a decreasing trend of the correlation for increasing R value. However, there are some inaccuracy. We speculate that it happens because of error due manual extraction of the data. But the decreasing trend tells us that with increasing R value, which implies increasing length of the negative delay, the correlation decreases, which mean more information are lost. This lost is a consequence of causality. Also, as discussed in Section 3, the higher order terms in Eqs. (12) and (13) induce distortion of the wave form of the output [1], [4]. These terms are dependent to the time constant $T = RC$, so that increasing R value will cause the distortion to increase as well.

Table 3. Correlation between input and shifted output signals for various R values

R Value (MΩ)	Delay (s)	Correlation
1	0.41	0.9894
1.1	0.43	0.9982
1.2	0.45	0.9983
1.3	0.52	0.9938
1.4	0.52	0.9941
1.5	0.53	0.9888
1.6	0.53	0.9796
1.7	0.53	0.9897
1.8	0.57	0.9792
1.9	0.66	0.9792
2	0.66	0.9755

Tabel 4. Cross correlation between input and output signals.

R Value (MΩ)	Delay (s)	Correlation
1	0.42	0.9959
1.1	0.42	0.9984
1.2	0.54	0.9999
1.3	0.54	0.9952
1.4	0.6	0.9955
1.5	0.66	0.9910
1.6	0.66	0.9873
1.7	0.72	0.9917
1.8	0.78	0.9844
1.9	0.78	0.9884
2	0.78	0.9834

We assumed that the difference in delay and correlation is caused by the difference in determining the reference point to calculate the negative delay. The negative delay calculated in Section 4.1 uses the peak of the signal as the reference point, while the cross-correlation method is uses the highest correlation as the reference point. It means that the highest correlation doesn't always happen when the signal's peaks coincide. The reference point being used to determine the negative delay, depends on the application of the negative delay. In application that only needs a small portion of the signal, e.g the peak for triggering, we use the signal's peak as the reference point. Otherwise, in application that needs the whole information contained in the signal, we use the highest correlation as the reference point.

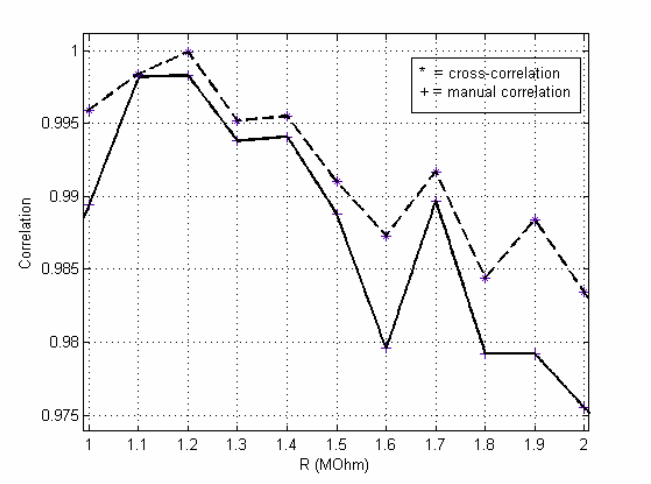

Figure 6. Correlation vs R value

5. CONCLUSION

From the observations and experiments of the negative delay circuit, we conclude that:

1. The system under study can create a negative delay.
2. The negative delay circuit works by increasing the slope of the rising and falling edges of input signal so that the pulse peak is advanced.
3. The increment in resistor R value results in the increment of the negative delay length. However, this increment is different from the expected increment due to distortion that depends to the time constant T and frequency ω.
4. The increment in resistor R value also results in the decrement of the correlation between input and output signal. It means that the longer the negative delay, more information is lost.
5. In calculating the negative delay, there are two reference points that can be used i.e, the signal's peak and the correlation between the signal. The reference point depends on the application of the negative delay.

ABSTRACT

The paper "The effectiveness E' Government either using mobile phone Technologies (SMS) or computer (Internet), seeks to find the best technology for narrowing the digital gap, and to develop a model for implementing e-government. The main reason for this is to ascertain the appropriate services that will maximise access for the citizen. In most developing countries the technology that can be most easily afforded by the society is mobile phone technology. So, it is important to look at the e-government and m-government benefits and disadvantages, and at the models and services available in developed countries and to see what developing countries can learn from that.

Keywords

e-government, m-government, digital divide, SMS, internet

1. INTRODUCTION

Electronic government or e-government can be defined as office automation and internal management and expert systems, as well as client-facing web sites and the use of Information and Communication Technology (ICT) to promote efficient, convenient, and cost-effective government services. In the beginning the e-Government project involves using information technologies, particularly web-based Internet applications. However, these functions are now spreading with the use of mobile and wireless technologies and creating a new direction: mobile government (m-government). As a result, it can be seen that m-government and e-government are not in fact two separate entities. M-government extends e-government availability to those confined to the use of mobile technologies such as mobile phones. The benefits for the governments are things such as, a reduction in response time, a reduction in paper work and the provision of new and improved services to the customer. For citizens, E-government offers a huge range of information and services, including information for research, the provision of government forms and other services, public policy information, employment and business opportunities, voting, tax filing, license registration or renewal, payment of fines and submission of comments to government officials. Moreover, the users of governmental information services will be benefited by the fact that many services previously available only during explicit office hours can now be accessed twenty-four hours a day, seven days a week.

The paper, "The Effectiveness E' Government services by mobile phone Technologies (SMS) and computer (Internet), seeks to find the best technology for narrowing the digital gap, and to develop a model for implementing e-government. The main reason for this is to ascertain the appropriate services that will maximise access for the citizen. In most developing countries the technology that can be most easily afforded by the society is mobile phone technology. So, it is important to look at the e-government and m-government benefits and disadvantages, and at the models and services available in developed countries and to see what developing countries can learn from that.

2. E- GOVERNMENT AND M- GOVERNMENT

The meaning of the term, e-government, is quite nebulous in that it means different things to different users. E-government is sometimes defined to included office automation and internal management and expert systems, as well as client-facing web sites and using ICT to promote efficient, convenient, and cost-effective government services. Such internal factors are seen as critical to the provision of greater public access to information and to make government more accessible to citizens [25]. Furthermore the OECD (2006) defines e-government as a tool to achieve better government services by using information and communication technologies

2.1 The e- government relationships

E-government relationships are categorized as government to citizen (G2C), government to employee (G2E), government to business (G2B) and government to government (G2G) [17].

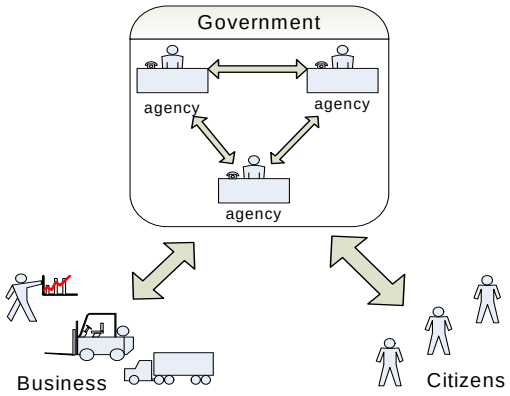

Figure 1: E-Government relationship[17]

2.1.1 The benefit and disadvantages of e-government

From the citizens' point of view, e- government can give many benefits, such as:

- More and easier access to services.

It is obvious that people do not like having to wait in a line for an hour or more to access a service that takes only five minutes at a counter to transact. In addition, they do not want to have to take time off from their work or business in order to conduct a transaction with the government that is only provided during their work hours. This becomes a problem because usually the "government hours" are the same as the general business and working hours of the society [16]. E-government is a good solution for these problems. Using e-government gives citizens 24-hour access to government information and services. For example, citizens will know that they can use the Internet to find out about such things as contact and service availability.

- Citizens can find their own information.

Citizens often need help with routine transactions and often ask similar questions about them, therefore e-government sites can use facilities such as Frequently Asked Questions pages (FAQs) to avoid wasting time answering common questions that have standard answers. This means that more time can be spent dealing with those issues that are specific to a particular client or situation and require responses that are difficult to standardise. This can make service delivery much faster and smoother for citizens as well as for the government agency providing the service. These standardised procedure pages can provide information dealing with quite complex policies and can provide up-to-date news and information, and even standardised responses to common situations via automatic emails [17].

- Transparency of government service (to reduce the scope for corruption).

For instance, there was a case in Gujarat in India, which adopted an e- government service for controlling border checks. The result was a reduction in corruption and a significant increase in Gujarat State's tax base. The new e-government system gave a three-fold increase in tax revenue in two years; increasing from $12m to $35m and subsequently repaying the cost for implementing the e-government system, $4m, in just six months [15].

- Better communication with rural and remote communities

For countries that have a widely dispersed population, an e-government service allows the citizens who live in remote areas to have an equal opportunity to access services as those citizens who live in cities. In developed countries Canada is an example of a country with a widely dispersed population; Canada has ranked first in the Accenture's global e-government survey for the past five years [68]. Canadian GOL (Government On-line) provides 30 percent of government transactions in Canada. Wireless infrastructure improves the possibility for regional and rural communities to have the same levels of access to information and government transactions, and their service expectations are aligned with the enhanced capability of the technology.

- Reduce the cost of operations.

Using e- government can reduce the operational cost of providing services and information. Because, it changes a paper based system to an electronic system, e-Government allows the service process to be handled by fewer employees. It is important to note that it is not only individuals who need to interact with the government; businesses and government agencies also need to do so. There is interaction between different sections of one department, or between different government agencies. These types of intergovernmental transactions have been investigated by the Australian government Department of Finance and Administration, and they found that the use of e-government is achieving cost reductions through a combination of direct savings, lower cost of delivery, and improved internal or business processes. The report also suggested that "participating agencies were expecting reductions in costs of about $100 million from 24 e-government programs" [66].

2.1.2 The weaknesses of E-government

Despite the many facts that show that e-government can provide many benefits not only for the society but also for the government itself, e- government still has disadvantages for some citizens, such as:

- Not everyone can access e-government.

Many countries are made up of economically, educationally and ethically diverse populations. Therefore introducing a service that relies on Internet technology creates an inherent problem. In order to use the service a person must firstly have a computer with connection to the Internet and secondly the user must have adequate technical knowledge to use the

facilities provided on e-government service web pages. This means that e-government services are only be available to the citizens within a country that are of a certain financial and educational standing. Consequently, implementing an e-government service can potentially isolate large numbers of citizens who have no, or only limited access to the online service.

- E-government segmenting the society

Many countries are made up of various ethnic groups. Therefore consideration has to be given to the selection of languages provided within the e-government service. For example, in Canada, the country is dived into French and English speaking regions, and this fact has to be dealt with by making on-line services available in both French and English [68].

- E-government creates ways in which government officials could use technology to avoid taking responsibility for their duties.

As anything available on an e-government site can be taken down or altered with little evidence that corrections or changes have been made, it is possible that there may be a reduced effort by government officials to perform duties correctly. Furthermore, the technology of e-government has the potential to become a standard excuse for government officials as an explanation for all problems regardless of their true nature [46].

- With technology-based services it is often too easy to avoid real issues by make an excuse that problems with the service provided are because of the technology.

It is often a lot easier to ignore an email than to ignore a person or to make the excuse that a person's account was not updated because of a 'server going down' and rather than because of an employee not doing their job properly [46].

For the concept of e-government to be true to its meaning, it has to be implemented in such a way that meets the following ideals: the majority of citizens have easy access to ICT at an affordable price; every citizen owns the technologies required for access; and everybody knows how to use those technologies.

2.2 M- Government

The efficiency and effectiveness of e-government using current information technologies, especially in the web based Internet is effectively proven. However, with the growth of mobiles technologies, the concept of e-government is spreading into this field. The use of mobile technologies for e-government drives it in a new direction, causing it to become m-government (mobile government). Eventually m-government may lead to even more intensive and wide spread government services than is possible using e-government forms, further evolving the relationship between government and citizens.

2.2.1 Definition of m-government

M-government is a strategy and an implementation that involves the utilization of mobile technology [40]. It includes services, applications and devices for improving and extending the benefits supplied by the use of e-government. A key task of government is supplying information to its citizens, and in many countries this is often not an easy job. Both e-government and m-government offer the potential for improving the delivery of information delivery to the public, but the mobile form would seem to offer greater benefits overall.

2.2.2 What is the reason for using m-government?

It is simply a fact that there are more people who can afford to cell phone or other similar wireless devices as compared to those who have access to PCs. This is supported by data from ITU (2006) that compares the rates of the usage in Information and Mobile Communication Technologies. Moreover this ITU data shows that the use of mobile phones is increasing rapidly, as can be seen in the figure below:

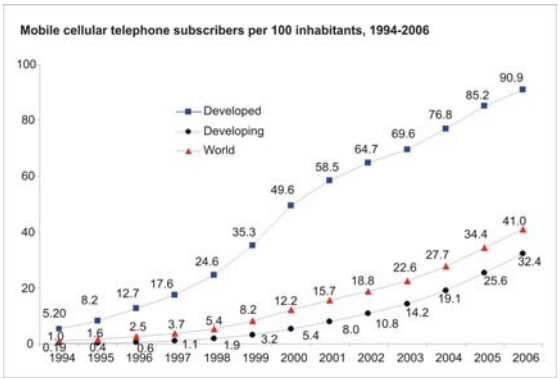

Figure 2: Mobile cellular telephone subscribers per 100 inhabitants, 1994-2006

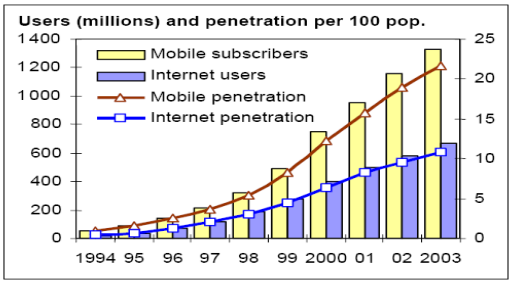
In addition, since 2000, Internet penetration has grown at a slower rate than the usage of mobile phones. This can be seen from the following figure.



Source: ITU World Telecommunication Indicators Database.

Figure 3: Graph of Internet penetration and Mobile Penetration

3. THE DIGITAL DIVIDES

A widely accessible and affordable communications infrastructure is one of the critical success factors for the delivery of government services online. However, the world can be divided into the information rich and the information poor. Therefore, ICT access and e-Government must be closely linked. Many of the most successful e-Government initiatives include, or are launched in combination with measures that are designed to expand access to more of the community. In addition, the availability of e-Government services that can save citizens and businesses time and money will, in turn, tend to drive demand for ICT access, further boosting infrastructure development and driving down the cost of access.

The digital divide exists not only between countries and regions but also within a country's borders, most commonly between rich and poor, between men and women, and between urban and rural areas. Urban areas tend to receive a disproportionately large share of public and private ICT investment in relation to the rest of the country. Usually, urban areas have at least a basic communications infrastructure and therefore are able to take advantage of ICTs, while rural areas tend to lack the infrastructure. Often ICT service providers do not have an incentive to invest in rural areas. The digital divide may correlate not only with income but also with cultural attitudes towards technology. Given the centrality of ICTs to both education and economic opportunity, those without access to ICTs are likely to fall further behind in a process that becomes a sort of vicious circle.

3.1 The major digital divide between develop and developing country

- The major reasons why the digital gap occurs between developed and developing countries are: The developing countries do not produce the technology, but they use the technology
- The major barrier limiting Internet access in both developed and developing counties is income level.
- Using a computer and the Internet is more complicated than sending a text messages by mobile phone or dialling a telephone. Meaningful use of the Internet requires computer, and cognitive skills for such things as seeking information, developing community networks, or participating in political activities.

4. ICT'S INFRASTRUCTURE APPROACHES FOR E-GOVERNMENT

There are five technologies that the government should consider for public access to e-government services. The importance of these approaches have been summarised in the table 1 below

Table 1: ICT's infrastructure approaches for e-government

User	Technology	Access	Hardware	Location	Accessibility
1st	Dial Up	Home Access	• Reliable electricity • Personal Computer • Modem dial up • Phone line	• Residential Access	• Pay their need for internet access.
2nd	Fixed Hot Spots	Easy access for commuter	• PDA • Laptop • Smart Mobile Phone • Wireless connections	• Post Office • Shopping centre • Community centre • University	• Free for accessing the internet, but they using their own work station for accessing the internet.
3rd	Kiosk	For public who want to access e-government and communication with email	• Reliable electricity • Share PC • Internet access (Dial up) • Share PC	• Post Office • Shopping centre • Community centre • Government office	• Access government web site • Open and reply email
4th	Mobile Kiosk	Rural and remote are society	• Share PC • Storage • Satellite • Vehicle (bus, boat or etc)	• Mobile library • Mobile Post office	• Mobile Kiosk which go to the rural area • access government web site • open and reply email
5th	SMS	Access for public who has a mobile phone	• Mobile Phone • Infrastructure for mobile phone	• Movable with the citizens	• Small text due to the limitation of the mobile phone screen

In the first approach, it is assumed that the phone line infrastructure exits in the area. Consequently, with the phone line, the user can access the Internet using a dial up modem and their PCs. The majority of these users are citizens that live in cities and urban areas. Therefore, there are no problems for this section of society in accessing government services through web sites.

The second alternative is for the consumers who have their own portable workstations such as PDAs, laptops or smart phones, but do not have internet access at home. They can use fixed wireless hot spots for accessing the Internet. This enables them to access government web sites in certain

places, for instance, post offices, public libraries, internet cafes and shopping centres.

The third alternative is for those members of the society who do not have Internet access or a portable work station. This section of the public can use shared PCs provided in kiosks only for accessing government web sites. So, the purpose of the kiosk is only to provide the means for the public to access government websites and email services.

The fourth alternative is for the government to use buses that provide shared PCs (bus kiosk). This facility is for people who live in the remote areas. The public can use shared PCs in the bus kiosk only for accessing government web sites and email services. The main purpose of this approach is that the kiosk goes to the rural area.

The fifth approach is using SMS services for delivering e-government. This approach would seem to provide the greatest scope for implementing e-government services quickly and widely, as most people in developing country already own mobile phones and the infrastructure to support this means of service delivery already exists in most places, as discussed in the previous sections. By providing e-government via the SMS service, the government can bypass many of the problems caused by limited access to infrastructure that are inherent in other technologies.

As for the use of mobile phones, it seems that SMS or mobile messaging is the most favoured of e-government activities in society. This can be seen from the number of e-government activities that are done by mobile messaging. Best practises from other countries are:

- Mobile Parking in Austria.

The M-parking system allows users to pay for parking via their mobile handsets. By day 7 of its inauguration in October 2003, a total of 20,604 m-parking applications had been received, a milestone which had not been expected to be reached until April 2004 [13].

- Malta launches "M-government" education initiative.

The government of Malta has launched an "M-government" initiative and is providing examination results by SMS. Other applications include notifications of court deferrals to clients and their lawyers, and sending renewal notifications for trade licences [53].

- More are paying bus fares in Finland by SMS.

During the summer months of 2002, sales of SMS tickets for Helsinki's public transport system (Finland) increased dramatically, by 30 percent SMS Tickets can be ordered by sending a text message and the user is billed through his or her regular mobile phone bill. The public transport ticket is also delivered to the commuter by SMS [9].

- Text messaging tests China's freedom.

Mobile users in China, the world's largest mobile market, can now send SMS to the 2,987 deputies of the National People's Congress. The new service lets people test the bounds of a new freedom of expression in China, where politically charged jokes have begun to spread like wildfire from the Internet onto cell phones [37].

- Hungarian SMS Elections.

In March 2002, two of the leading Hungarian portal operators invited Hungarian mobile subscribers to vote via SMS three weeks before the real parliamentary elections [44].

5. SMS proposed model for e-government

In order to make the use of SMS for e-government widespread , much strategic planning in developing SMS e-government services is required. The SMS applications can be classified with different methodologies, according to the parties involved, for example Government to Citizens (G2C), and according to the coverage (national or local).
In this research, both classifications will be used.

- Local Coverage

The local applications presented have significance in terms of their natural advantages. These applications are usually Government-to-Citizen applications that have a high chance of usage penetration in the near future. These applications are highly influenced by the high mobile penetration in Indonesia, the ease of use of mobile phones, and the mobile platform's ability to reach people anywhere/anytime. The penetration of these applications would increase the usage of the online governmental services they complement significantly; a factor that is of crucial importance. Also the anywhere/anytime nature of these services increase the convenience and the satisfaction levels of citizens extensively, with an incremental investment that is relatively low compared to other forms of e-Government investments.

- National Coverage

The national applications present general information for a national coverage. These applications are usually Government to Citizen applications that have a high chance of increasing citizens' participation in the Government's activities such as national elections etc.

Following is a set of recommendations or model based on our previous study of SMS applications in several countries:

- Stage 1: Alert information or an Announcement

In this stage of e-government SMS, the government is able to notify citizens about important public information. The information tends to be an alert or emergency notification. These services work when the public applies for this service.

- Stage 2: Pull information

This stage primarily involves the digitalising of available information and making it available and up-to-date. In this stage, the government provides two-way communications, where the citizen is able to access public or personal information by sending a request message and the citizen will get a feedback message from the government server or database. In this level, the type of SMS request must be in a certain format, so the SMS server recognises the keywords and can give an automatic response.

- Stage 3: Communicative Information (SMS based television or radio)

In the second stage, many interactions and services with a large of number of citizens are possible. This communicative information level provides the public with an opportunity to contribute and become apart of e-government services. The public can be involved in discussions or SMS voting systems in government shows on television or radio.

By giving public control over something meaningful, in government television or radio programs, SMS is a simple and pervasive technology for interactive e-government services. In this level, the SMS system is only designed for the sender to send a question or give input messages or participate in government' television or radio show. The replies for the public are by watching or listening to the radio or television show. In this stage the government could use Television or Radio networks that are already widespread in Indonesia for communicative information.

- Stage 4: Transactional presence

In the fourth stage, a wide variety of government transactions can be conducted by using SMS. These can include payment for donations, licences, fines, fees, bills and taxes. In addition, more sophisticated functions including passwords and encryption are also provided.

In this SMS model there is no dependency or correlation between each stage.

6. CONCLUSION

It is undeniable that there is a digital gap between the developed countries and the developing countries that has caused many of the implementations of e-government in developing countries to fail. One of the main factors in these failures is the fact that the services were imported without regard to local conditions. The digital gap takes many forms, it can be at the economic level, skill levels in English and IT proficiencies, and at the basic infrastructure level. In addition, the digital gap not only occurs between countries, but it also happens inside a country, such as the gap between the ICT facilities available in cities, compared to those in villages and remote areas. This gap also creates a different kind of user of ICT. There are users that use internet and mobile phone application (SMS).

Using SMS messages in mobile phone technologies can help to narrow the gap for people who want to use e-government services but who can't access the Internet. Moreover, the mobile phone network has developed surprisingly fast and it is one of the e-government tools applied in almost all of society. More precisely, using SMS messages from mobile phones for e-government applications is widespread in developed and developing countries. The use of SMS can be a significant factor in e-government in increasing the effectiveness of e-government relations between Governments and Citizens.

In order to make the use of SMS for e-government widespread, there needs to be a strategic plan involving a staged introduction of services. These stages can be loosely classified according to the parties involved, Government to Citizens (G2C), and according to the coverage (national or local).

Automatic Vehicle Identification and Inventory System using RFID Technology

Dodi Sudiana[1)], Arief Udhiarto[1)], Aji Nur Widyanto[1)]

[1)]Optics and Remote Sensing (OPRES) Research Group, Department of Electrical Engineering,
Faculty of Engineering Universitas Indonesia,
Kampus Baru UI Depok 16424, Indonesia
E-mail: dodi@ee.ui.ac.id

Abstract

*We developed an automatic vehicle identification and inventory system using RFID technology. RFID is a new identification technology which needs no direct contact between the object and the identifier. It is consisted of a transponder (tag) and a reader. The proposed system consists of automatic RFID reading, inventory, database, microcontroller and gate actuator subsystems for vehicles. According to the Ministry of Communication and Information, the reader works at 923-925 MHz frequency range. Middleware software has been developed using Borland Delphi 7. The experiment has been conducted to test the functionality and reliability of the system which consisted of vehicle identification, validation, inventory, opening/closing gates, and data recapitula*tion for reporting.

Keywords: RFID, tag, reader, vehicle identification, vehicle inventory, Delphi

1. Introduction

Universitas Indonesia as a big university has been flocked by cars and motorcycles every day and the number of vehicles entering and leaving the campus is increasing from time to time. Those vehicles (especially cars) are verified manually at the gate and if there is no license, the driver has to pay to the officer. To pay, and take an entrance card at the gate, each car has to spend about 10 seconds. In peak hours (morning), vehicles have to wait in a very long queue before entering the campus as shown in Fig. 1. Since there is no authorization for each vehicle in the campus vicinity, so the security risk is very high. When leaving the university exit gate, the driver just gave the entry card back to the officer. There is no record on vehicle identity such as license plate number, vehicle type, color, owner's name, address, etc. Therefore an automatic vehicle identification and inventory which could work fast with high accuracy urgently needed.

Fig. 1. Vehicles queueing in the UI entrance

In this research, we developed an automatic vehicle identification and inventory system based on Radio Frequency Identification (RFID) technology. RFID is a new identification technology which needs no direct contact between the tag attached to an object and the reader. The technology could automatically detect and identify an object, track and store the information of an object or part of it electronically.

RFID technology consists of tag, reader and collection, distribution and data management system which usually interfaced by a middleware as shown in Fig. 2. In practice, RFID tags could be implemented as labels, key chains, stickers, cards, coins, rings, or other forms. These tags could receive radio wave transmitted from the reader, convert it as an electric energy, feed the memory circuit inside it and transmit the ID content back to the reader.The distance between the tag and the reader, depends on the reader power and working frequency could range from several centimeters to tenth meters.

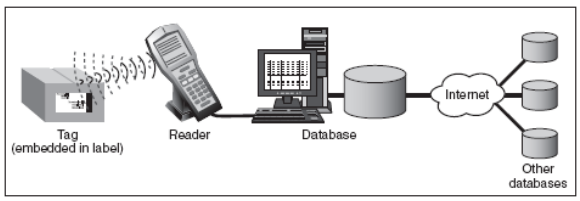

Fig. 2. RFID system and its components

The advantages of RFID are: needs no line-of-sight connection, dynamic information carrier, larger memory size, anti-collision (several tags could be read simultaneously), reliable and weather proof, affordable for long time investment, needs no human intervention

and maintenance-free. Therefore the system could be implemented to increase the effectivity and efficiency in parking and vehicle management system in the Universitas Indonesia.

1. Methods

Automatic vehicle identification and inventory system using RFID is implemented in the Universitas Indonesia. The system consists of tags and a reader which works at 923-925 MHz frequency range as recommended by the Ministry of Communication and Informatics. The reader is installed at the gate IN and OUT of the parking area. To control the gate opening and closing, a microcontroller is used as an interface between the PC and the gates. LED indicators are Fig. 2 showed the proposed system.

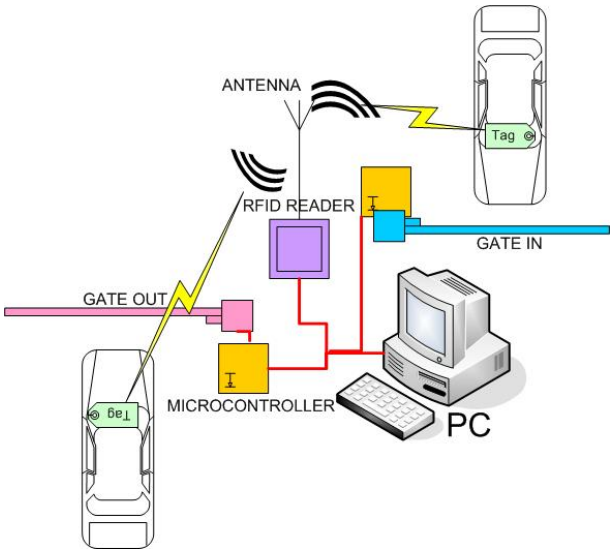

Fig. 3. Proposed vehicle identification and inventory system

As is generally the vehicle entrance gate, then there will be two routes, namely the entrance and exit. In design, this system uses only one RFID tag reader to detect the vehicles through this paths. Single RFID reader system itself can not distinguish directly enter the vehicle or the outside, but with the help of software. The software will run an algorithm to distinguish vehicles that enter or exit.

Vehicle that can go through the door of access into the parking area in the campus must have a tag that is registered on the database system. If the vehicle is detected by RFID reader, the software will match if the vehicle is registered in the database system or not. When the data obtained on the vehicle may not pass the gate access in the main program the software will provide information to the mikrokontroller action to set what should be done on the vehicle. If the data in the database have a vehicle then mikrokontroller will be ordered the doors to open access doors, if not then the door remains closed.

In general, the automatic parking system architecture consists of several parts. The first section is comprised of a RFID reader and tag. The second part is middleware or in the form of a computer system which contains the program and database. The third is microcontroller a function to set the exit and entrance gate, access entrance gate will be made by using the Servo motor. Figure 3 shows the system architecture of automatic vehicle inventory developed.

Read the data stored in the database system that is on the PC. Information read from the RFID reader to have a database on a PC using the software. The software used in the automatic parking system will be created using Delphi 7.

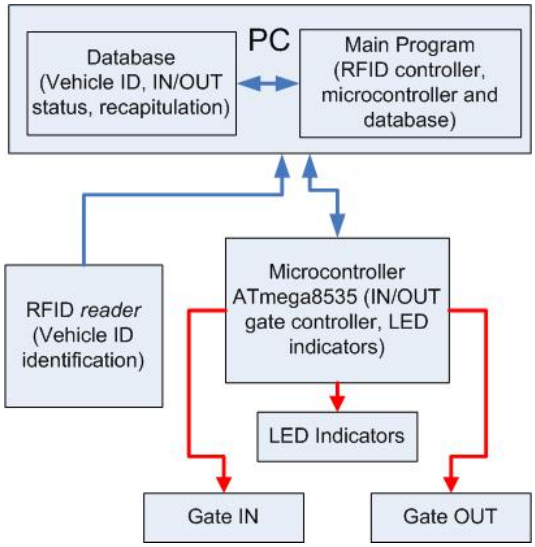

Fig. 4. System block diagram

Data communication between the RFID and the main program on the PC lasted only one direction, namely from RFID to the PC via RS232 serial port. And data communication between mikrokontroller with the main program on the PC also take direction from one PC to mikrokontroller through RS232 serial port. Communication from the PC to be used to run mikrokontroller Servo motor that serves as a parking lot gate. Servo Motor that will be used in this system amounted to 2 which functions as the entrance gate and gate to gate.

3.1. Flowchart Automatic Parking System

This flowchart describes the system-based automatic vehicle inventory RFID work, begining from RFID to be detected until stored in the database. Flowchart shown in Figure 4 with the following explanation:

1. System will continue detect by using RFID technology, if there are vehicles that pass the gate of access to parking or not.
2. If you have a vehicle that comes in, the system will detect whether the vehicle has entered the

appropriate code tags with the database system or not.

3. If it is not appropriate, the system will send commands to mikrokontroller to close the gate.
4. If the code tag in accordance with the database, the system will determine whether the vehicle entrance or exit by using the algorithms that run in the main program on the PC.
5. After that, information about the code tag will be entered into the database. Information is entered in the database, namely the identity of vehicles and their owners. In addition, the entry and exit times of vehicles will also be recorded on the database. Time of entry and exit this will be used to accumulate the cost of parking the vehicle owner listed in the database.
6. Then, the software will command the entrance or exit is opened or closed.
7. After the close the gate open, the system will return to the detection process vehicles as they are. This detection continues until the system is turned off manually.

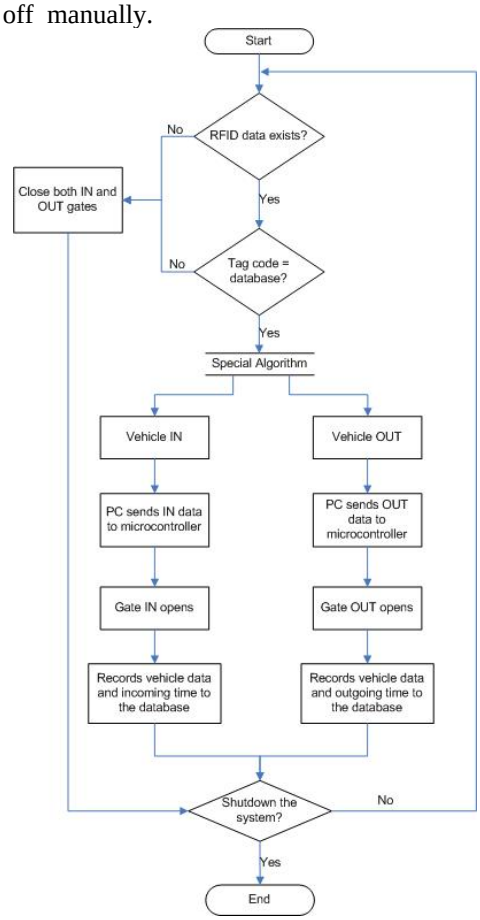

Fig. 5. Flow chart of the system

3.2. Automatic Vehicles Inventory System

In development, this system is gradually becoming some subsystem. In general, subsystems are responsible for certain functions, namely:

1. Subsystem with the vehicle identification RFID
2. Subsystem open-close gate
3. Subsystem software (the main program)
4. Subsystem database
5. Subsystem interfacing software with hardware

a. Vehicles Identification with RFID

The process of identification of vehicles with RFID is to place RFID tags on the vehicle and the RFID reader in a certain place in the parking lot near the gate. So if the vehicle through the gate of the identity of the vehicle will be directly recognized. This identification process will be based on the ability of the RFID reader is used.

Communication between the RFID reader with the PC itself can use some kind of communication, namely communication among parallel and serial communication. RFID communication depends on this component of the output is provided by the RFID reader is used. RFID tag data format is read by the reader as ASCII data with the following formats:

STX – MT – RT – 4 digits card number – 2 digits project number- EXT – LRC1 – LRC2 – CR – LF

Description:
STX = data prefix; MT = data type; RT = type RFID reader; 4 digits card number = 4-digit card number RFID tags in ASCII code; 2 digits project number = 2-digit project number in the RFID tag code ASCII; EXT = End of data; LCR1= first byte checksum; LCR2 = second byte checksum; CR = Carriage return (0x0D); LR = Line feed (0x0A)

b. Open – Close Parking Gate

In designing the system, opening and closing the gate using a Servo motor equipped with a latch. Latch to be used of the two: one for the entrance gate and one gate for exit.

The motor will be done by microcontroller that receive instructions from a computer to open or close the parking gate.

c. Software(Main Program)

Inventory control system for automatic vehicle uses software Delphi. Delphi itself is high-level language programming used in object-oriented Programs.

Software functions to the system and run the algorithm also connects with the database system so that the system is running well. To connect the database with Delphi components, are used in the Delphi ADO (Active Data Object).

In addition, this software also serves to connect the (interfacing) between the computer hardware that will be connected later as microcontroller and RFID. In communicating with the hardware, using a Delphi component called Com-Port.

d. Database

To save data vehicles in detail, required the database. MS Access is used in developing this system because it is a Microsoft Office database program so that easier for management. Database filled with data that are required such as RFID tag number, vehicle owner name, address, vehicle plate number, type and color of vehicle.

MS Access database will be accessible by the main program (in this case Delphi) using components found in the ADO (Active Data Object). With ADO, the distribution of the program only requires a program file (. Exe) and database (*. mdb) only. Database that are connected with the Delphi program shown in Figure 5.

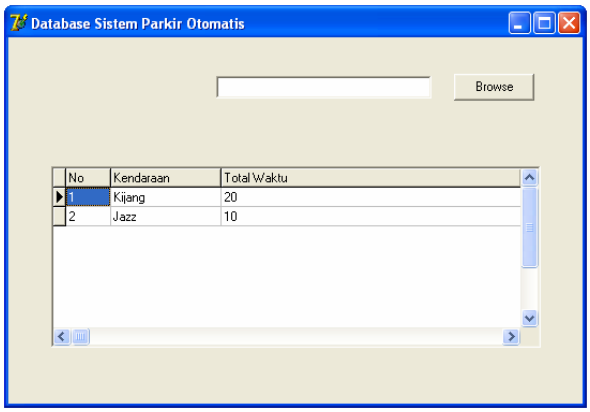

Fig. 5. Connection between DELPHI and *database*

e. Interfacing Software and Hardware

Inventory system has an automatic vehicle software and hardware devices which communicate with each other. Communication between software and hardware uses two communications, the serial communication and parallel communication.

But on this system later will use the serial communication as a means of communication between the hardware and software. In Delphi software itself is actually already available with the communication component of the hardware that is ComPort. ComPort akan disetting in accordance with the characteristics of the hardware. Figure 6 shows a description of the components ComPort is in Delphi.

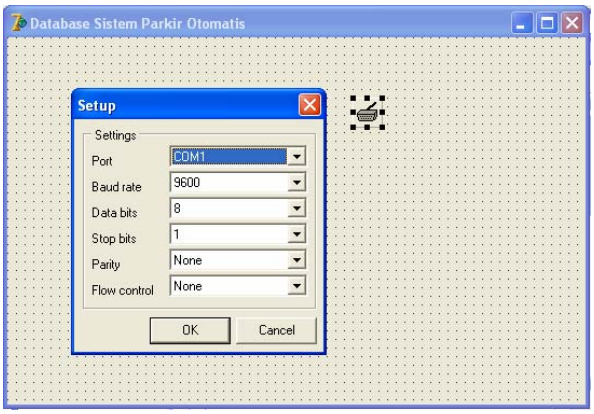

Fig. 6. The components ComPort in Delphi

Each of the hardware that is connected in the system will be configured first, starting from the port number to the parity is not used. Disettingnya with the hardware, the system will run properly and in accordance with the design.

2. Results and Discussion

The system was tested to verify the hardware and software functionalities of the system.

a. Hardware functionalities
b. Software functionalities
c. Overall system functionalities
d. Real-time functionalities

2.1. Hardware functionalities

The RFID reader (model DL910) has the reading distance capability up to 15 meters. The direction of readings are set as shown in Fig. 7.

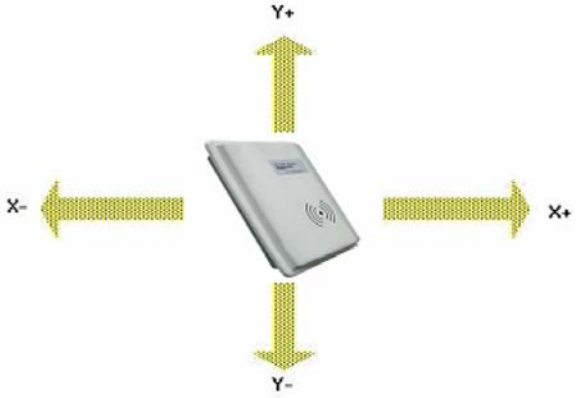

Fig. 7. The directionality of reading

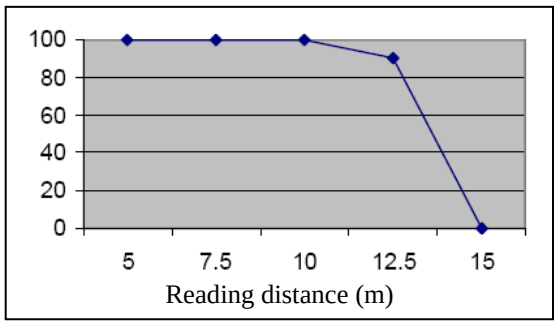
Reading capability (in % of output power) of the reader in 4 directions (no angle, -30°, +30 and) are shown in Fig. 8, 9, and 10, respectively. The data was taken for 10 times for each direction. The results showed a relative strong reading capability for distance less than



10 meters.

Fig. 8. Reading capability (in %) for -30° of X+ direction

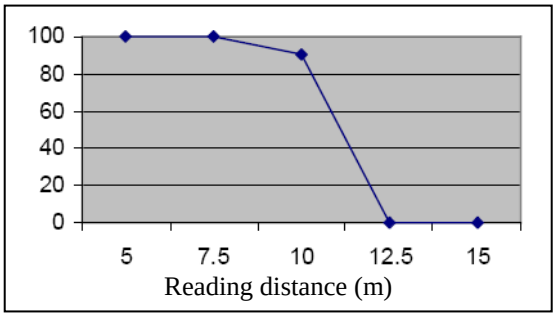


Fig. 9. Reading capability (in %) for +30° of X+ direction

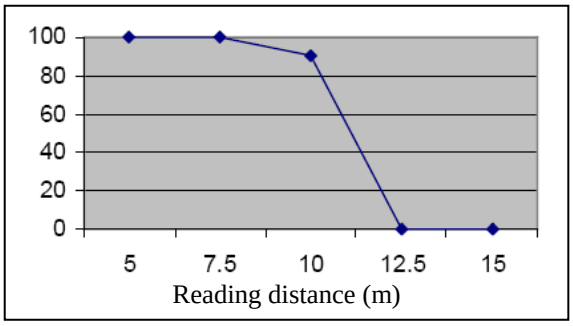

Fig. 10. Reading capability (in %) for -30° of X+ direction

2.2. Software functionalities

To test the software functionality, we checked the system durability for about 8 hours continously. The sample vehicles (for total 5 cars) with tag attached on its windshield are moved in and out and the test results showed a perfect recognition without any errors. The durability test of 5 tags is shown in Table 1.

Table 1. Durability of 5 tags for full performance

Tag distance	Tag1	Tag2	Tag3	Tag4	Tag5
5 m	×	×	×	×	×
4 m	×	×	×	×	×
3 m	✓	✓	✓	✓	✓
2 m	✓	✓	✓	✓	✓
1 m	✓	✓	✓	✓	✓

As shown in Table 1, the system could not recognize the tags attached in the cars for distance more than 3 meters. Therefore the system could be applied in real condition since there are only limited space near the parking gate.

4. Conclusion

Automatic parking system using RFID is designed and perform well for real application. Ideally the DL-910 could read up to 12.5 meters, but in real condition, the reading capability was decreased only to 3 meters. The durability of 5 tags tested was quite good for distance less than 3 meters.

ABSTRACT

A Speaker recognition system was created in this research by using discrete wavelet transform (DWT) and *k-Nearest Neighbor (k-NN). Evaluation of this research is using 45 data training database which represents 9 types of sound identity (3 speaker identities and 3 text identities). In summary, this system works by using the data sample of sound through the cutting stage, DWT, Dynamic Time Wrapping (DTW), and k-NN algorithm. The average success of this system in recognizing the sample of this speaker and text identity sound in the database is 98.33% with the average time recognition is 59.03 seconds. This result is achieved through level-2 wavelet decomposition and the usage of approximation coefficients (cA) along with detail coefficients (cD). The average success of this system in recognizing the sample of sound which the speaker and text identity is not available in the database is 72.33%.*

Keywords

Speaker Recognition, Discrete Wavelet Transform, k-Nearest Neighbors

1. INTRODUCTION

Speaker recognition was a digital signal processing technique for recognize, identification or speaker verification (speaker). Function of speaker recognition was classic example of problem in pattern recognition, which in general is useful to found kind of pattern from data got by the censor. Training process is needed for all of pattern recognition problem. For example in s*peaker authentication system*, user voice need to register. During that process, the system is "learn" the user voice that want to recognize. Speaker recognition can be text dependent or text independent. The word "text" in this context is a words is spoken by user [1]. In "*Speech Recognition for Controlling Movement of the Wheelchair*" using *Linear Predictive Coding* (*LPC*) and *Euclidean Squared Distance*, the maximum sucessful percentage that can be achieved is 78.57 % [2]. In this paper a speaker recognition system is developed by using Discrete Wavelet Transform (DWT) and k-Nearest Neighbors (k-NN). Evaluation of this system is using 45 data training database which represents 9 types of sound identity (3 speaker identities and 3 text identities).

2. THEORY

2.1 Discrete Wavelet Transform

Discrete Wavelet Transform (DWT) work by doing wavelet transform in discrete signal. The basic principle of *discrete wavelet transform* is how to get the representation of time and scale from a signal that using digital filter technique and sub-sampling operation or down-sampling operation. The signal first must be process in high pass filter and low pass filter, and then half of the output signal will be taken as sample with down-sampling operation. This process called the decomposition process one degree. The output from low-pass filter will be used as the input of the next decomposition process. This process will be repeated until the decomposition level that desire. Union of the signal output from high-pass filter and one output from the last low-pass filter is called wavelet coefficient, which contain the signal information in the form compressed signal. The explantion of two that process can be explain at Figure 1. Couple of *high-pass filter* and *low-pass filter* that used must be in the form *quadrature mirror filter* (QMF), which fulfill this equation:

$$h[n] = (-1)^n g[L+1-n] \qquad (1)$$

with $h[n]$ is *high-pass filter*, $g[n]$ is *low-pass filter* and L is length of *filter* [3].

2.2 Dynamic Time Warping

Dynamic Time Warping (DTW) is a method that used to calculate the distance between 2 data coefficient that may different in time and speed. The distance will represent how much the similiarity between that 2 data coefficient. As example, in the first recording process, the user speak with more fast, meanwhile in the second recording process, the user speak more slowly than the first recording process. Both the recording process, the user say same words with different in the speed, will produce the different length of distance. By using DTW method, the distance (similiarity) of between the two recording process can be known. This is the main advantage of DTW method. In general, *DTW* is a method that make a computer calculate the most optimal distance (similiarity) between the 2 coefficients given. The coefficients will be "warp" in non-linear in time domain to calculate the distance (similiarity) of the 2 coefficients [4].
Coefficient-coefficient can be arrange distance on the sides grid like at Figure 3. Figure 3 above is describe data coeffcient that want to identify (bottom side grid) and data coefficient reference that save in database (left side grid). Two data coefficient is begin from left side grid. Distance result is representative by blue grid. After that line had found will be get nearest distance between input data coefficient with data coefficient reference database. DTW algorithm is all distance in the grid. Because of that data coefficient will be result probability distance too much. DTW method will be result comparison process between 2 data coefficient.

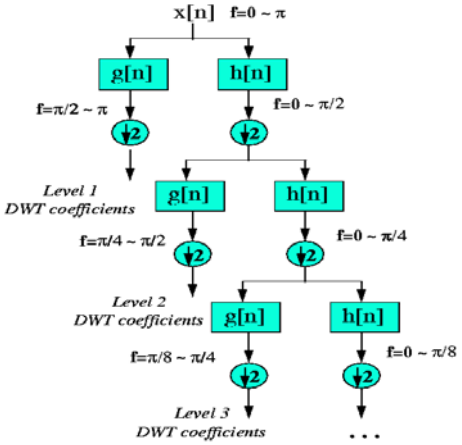

Figure 1: Decomposition Process in *Discrete Wavelet Transform*

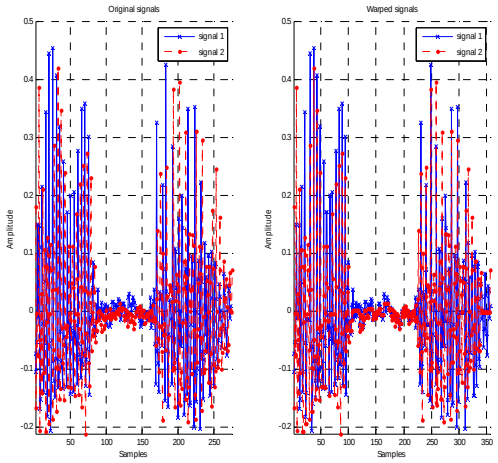

Figure 2 : Signal before (left) and after (right) *Dynamic Time Warping*

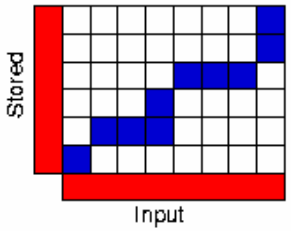

Figure 3 : *Dynamic Time Warping Grid*

2.3 k-Nearest Neighbors

k-Nearest Neighbors (k-NN) Method is method to do classification object by data that have nearest distance with object. Data will be projection to many dimension space, severally dimension representation feature from the data. That space consist many parts based on data learning. One point in the space will be sign c if c class have classification that the most in the k neraset neighbors [5]. Close or far neighbor usually computation based on euclidean distance that equation like: For $P = (p_1, p_2, ..., p_n)$ and $Q = (q_1, q_2, ..., q_n)$,then $\text{Distance} = \sqrt{\sum_{i=1}^{n} (p_i - q_i)^2}$ (2)
Figure 4 below explain about classification on k-NN method. Small green circle on the centre is a sample, the box symbols (blue) show the first class or speaker 1 and the triangle symbols (red) show the second class or speaker 2. If resolution value used is 3, then the result of k-NN algorithm will be second class classification or speaker 2 because there are 2 triangle symbols and only 1 box symbol in the resolution circle on Figure 4 below. And if the resolution

value changed be 5, this method will produce first class decision or speaker 1 because there are 3 box symbols and only 2 triangle symbols in the resolution circle on Figure 4 below.

3. IMPLEMENTATION

1. System recognition mode.
2. Recording process.
   On recording process, user say the words which it's identify has saved in database.
3. System run.
4. Program show the outputs.
   The output are sound signal on speaker and decision logic result showed on user interface display.
5. Fill the result experiment as table data.

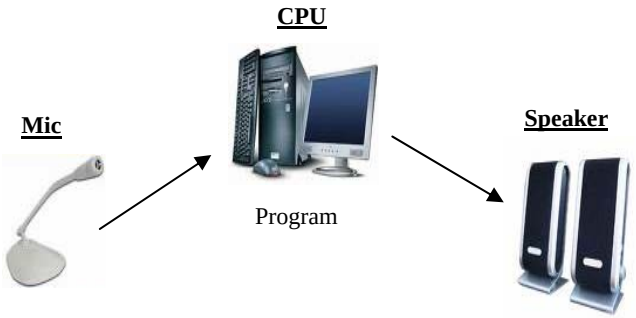

Figure 5 : System Block Diagram System

4. EVALUATION

Based on experiment data, the optimal result (success percentage or recognition time) got on experiment with sampling frequency 11,025 Hz, wavelet decomposition level-3, wavelet filter "db10", using Approximation Coefficients (cA) and Detail Coefficients (cD). By using that parameter configuration, the result sucessful percentage of the system is 91.11 % and average recognition time 20.64 second. Here's some results of the system with parameter above :

1. Speaker + Text : Bima + Open
   Sucessful percentage : 77.5 %
   Average Recognition Time : 22.90 second
2. *Speaker* + *Text* : Donny + Open
   Sucessful percentage : 95 %
   Average Recognition Time : 20.47 second
3. *Speaker* + *Text* : Rico + Open
   Sucessful percentage : 95 %
   Average Recognition Time : 20.84 second

For evaluation using 45 data training database which represents 9 types of sound identity (3 speaker identities and 3 text identities), the average success of this system in recognizing the sample of this speaker and text identity sound in the database is 98.33% with the average time recognition is 59.03 seconds. This result is achieved through level-2 wavelet decomposition and the usage of approximation coefficients (cA) along with detail coefficients (cD). However, on the testing system with level-3 wavelet decomposition, it is achieved that the average success is 91.11% with the average time recognition is 20.64 seconds, and on the testing system with level-4 wavelet decomposition, it is achieved that the average success is 50.28% with the average time recognizition is 8.20 seconds. The average success of this system in recognizing the sample of sound which the speaker and text identity is not available in the database is 72.33%. The average success of this system in recognizing the sample of the sound which the identity (Speaker and Text) is in the database with sampling frequency 44,100 Hz is 100% with the average time recognizition is 313.75 seconds. The research data shows a conclusion that the optimum result (both in the percentage of success and the time recognition) is achieved through testing with the sampling frequency 11,025 Hz, level-3 wavelet decomposition, type of wavelet filter "db 10", and the usage of approximation coefficients (cA) along with detail coefficients (cD).

5. CONCLUSION

From data implementation and evaluation system , got a conclusions like: first a success speaker recognition and

speaker recognition time turned comparison with level decomposition wavelet that use. Second a success speaker recognition straight comparison with speaker recognition time. Third, had got data result from optimal research (a success percentation and recogition time) got from system experiment with sampling frequency 11,025 Hz, decomposition *wavelet* level-3, *wavelet* filter 'db10' and *approximation coefficients* (cA) with *detail coefficients*.

ABSTRACT

In this paper, the effects of vertical scaling to the SiGe HBT with different lateral dimension are reported. The research methodology is as follows. First, the reference device structure is defined. And then physics parameters model and simulator control parameters are determined. The simulations were done with the help of Bipole3 devices simulator. The next step was lateral scaling. In this step the emitter finger width was scaled consistent to the minimum feature size lithographic developments i.e. from 0.25μm to 0.18μm, 0.12μm and 0.09μm. The last step was vertical scaling. In this step the base width of SiGe HBTs with different lateral dimension was reduced from 39nm to 32nm and their effects to the transistor performances were observed. The results show that vertical scaling has stronger effect to the SiGe HBT with larger lateral dimension than devices with smaller lateral dimension.

Keywords
SiGe, HBT, vertical scaling

1. INTRODUCTION

The concept of the HBT was patented by Shockley in 1951 [1] and the HBT theory was published by Kroemer in 1957 [2]. In 1987, the first SiGe HBT is reported [3] but world wide attention became focused on SiGe technology at 1990 with demonstration of SiGe HBT with peak cutoff frequency f_t of 75GHz [4]. Until about 1998, peak cutoff frequency remained in the 50 – 75GHz range. In this time period most research were focused on the vertical scaling and Ge profile optimization of the SiGe HBT [5-8]. Vertical scaling is the most efficient way to enhanced the cutoff frequency of SiGe HBT.

Since 2001 the SiGe HBTs frequency performances have been continue to increase and SiGe HBT with 350Ghz peak cutoff frequency was recorded in 2002 [9] while SiGe HBT with 350GHz peak maximum frequency of oscillation f_{max} was recorded in 2004 [10]. Higher frequency performances were achieved from SiGe HBT with smaller lateral dimension [11]. The ability to produce SiGe HBT with smaller lateral dimension depend on the minimum feature size of lithography technology. Reduction on feature size lithographic allows us to laterally scale down the SiGe HBT to enhance device performance.

In this paper, the effects of vertical scaling to the SiGe HBT with different lateral dimension are reported. The research methodology is as follows. First, the reference device structure is defined. Next, the physics parameters model and simulator control parameters are determined. The simulations were done with the help of Bipole3 devices simulator. The next step was lateral scaling. In this step the emitter finger width was scaled consistent to the minimum feature size lithographic developments i.e. from 0.25μm to 0.18μm, 0.12μm and 0.09μm. The last step was vertical scaling. In this step the base width of SiGe HBTs with different lateral dimension was reduced from 39nm to 32nm and their effects to the transistor performance were observed.

2. REFERENCE DEVICES

The lateral dimension of the reference device is shown in Fig. 1. The reference device has single emitter finger, two base contacts and single collector contact. The emitter finger area A_E = 0.25 μm × 10 μm. Each base contact has the same area as the emitter finger area. The collector contact area A_C = 0.50 μm × 12 μm.

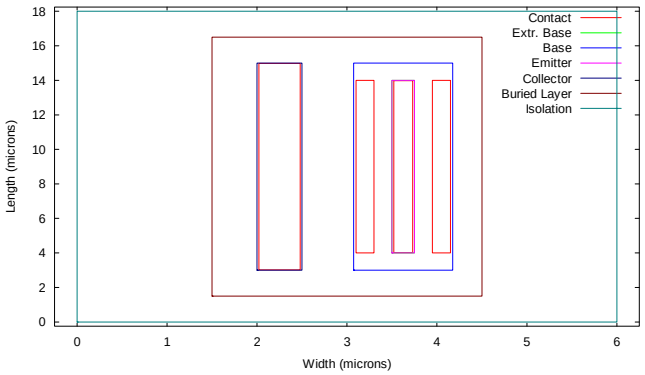

Figure 1: Lateral dimension of the reference device

The emitter, base and collector widths, doping profiles and Ge profile in the vertical direction are shown in Fig. 2. The emitter width W_E = 12 nm, base width W_B = 39 nm and collector width W_C = 650 nm. The Ge profile is rectangular with 5% Ge concentration. Peak doping concentrations in the emitter, base and collector are 10^{20} cm^{-3}, 10^{19} cm^{-3}, and 2×10^{18} cm^{-3}. The collector has selective implant collector (SIC) profiles.

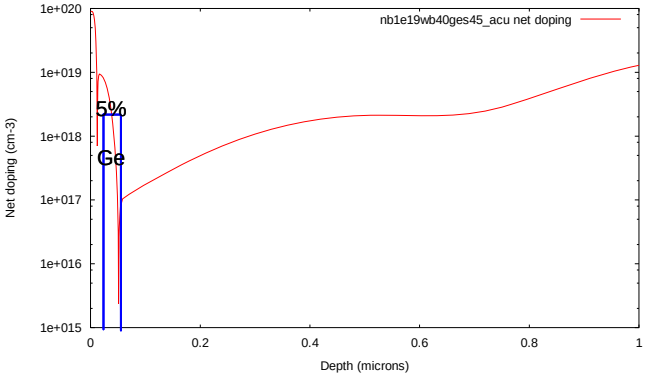

Figure 2: Vertical profile and dimension of the reference device

3. RESULTS AND DISCUSSIONS

3.1 Lateral Scaling

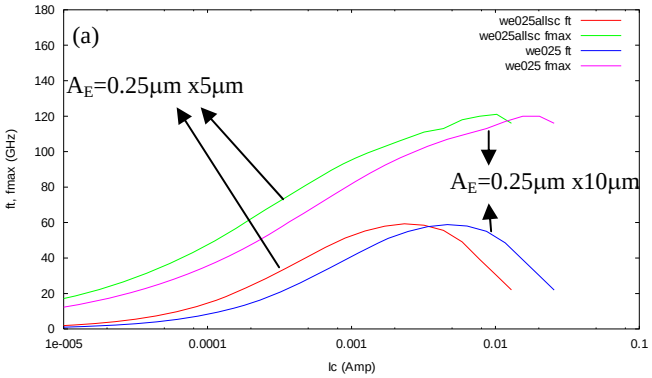
The lateral scaling process is divided into two steps. First, the emitter finger width of the reference SiGe HBT is scaled down from 0.25 µm to 0.18 µm, 0.12 µm and 0.09 µm. The simulation results shows that all SiGe HBTs have collector emitter breakdown voltage BV_{CEO} 2.8 V. The effects of emitter finger width to the SiGe HBT performances for collector base voltage V_{CB} = 0 V are shown in Table 1. The results show that scaling down the emitter finger width enhances the maximum frequency of oscillation significantly while its effect to the cutoff frequency is very small. Scaling down emitter finger width from 0.25 µm to 0.18 µm and from 0.18 µm to 0.12 µm enhances the peak f_{max} 16 GHz, while scaling down emitter finger width from 0.12 µm to 0.09 µm only enhances peak f_{max} 11 GHz. All of SiGe HBTs have peak cutoff frequency about 60 Ghz while the peak current gain vary from 160 to 150.

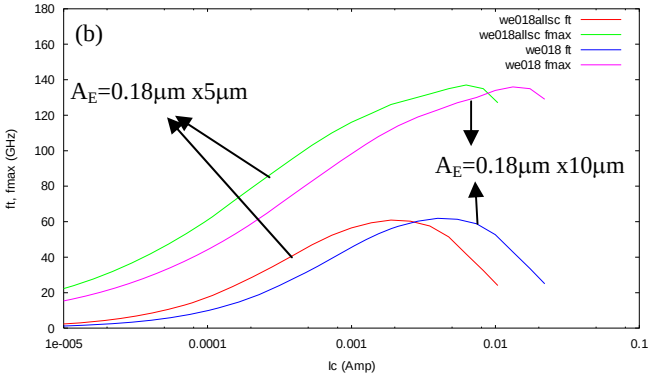
Tabel 1: The effects of emitter finger width to the SiGe HBT performances

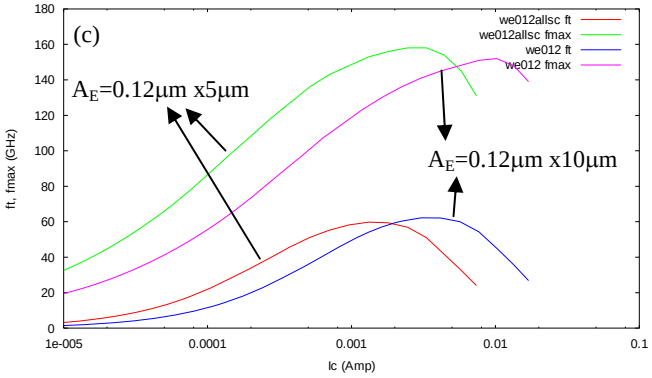
A_E (µm x µm)	Peak f_t (GHz)	Peak f_{max} (GHz)	Peak β_{dc}
0.25 × 10	59	120	162
0.18 × 10	62	136	169
0.12 × 10	62	152	159
0.09 × 10	63	163	153

After the emitter finger width is scaled down, the total area in the lateral direction of each SiGe HBT is scaled down by reducing base and collector contact width, space between emitter and base contact, space between base diffusion and collector, and the device length. In this work, the emitter finger length is scaled down from 10 µm to 5 µm. The simulation results are shown in Fig. 3. An example of SiGe HBT with 0.09 µm emitter finger width before and after the lateral area is scaled down is shown in Fig. 4.

Simulation results in Fig. 3 show that after the emitter finger width scaling, further scaling the lateral area doesn't affect the peak f_t and f_{max} values, however wider devices have peak f_t and f_{max} at higher collector current I_C. Lateral scaling does not affect the collector emitter breakdown voltage BV_{CEO}.







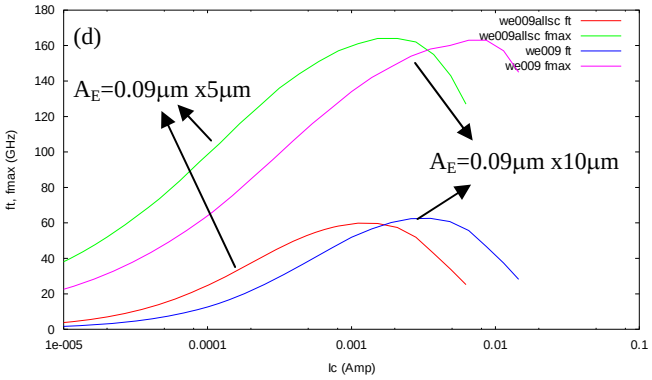


Figure 3: The f_t and f_{max} vs I_C curve of SiGe HBT with different lateral dimension

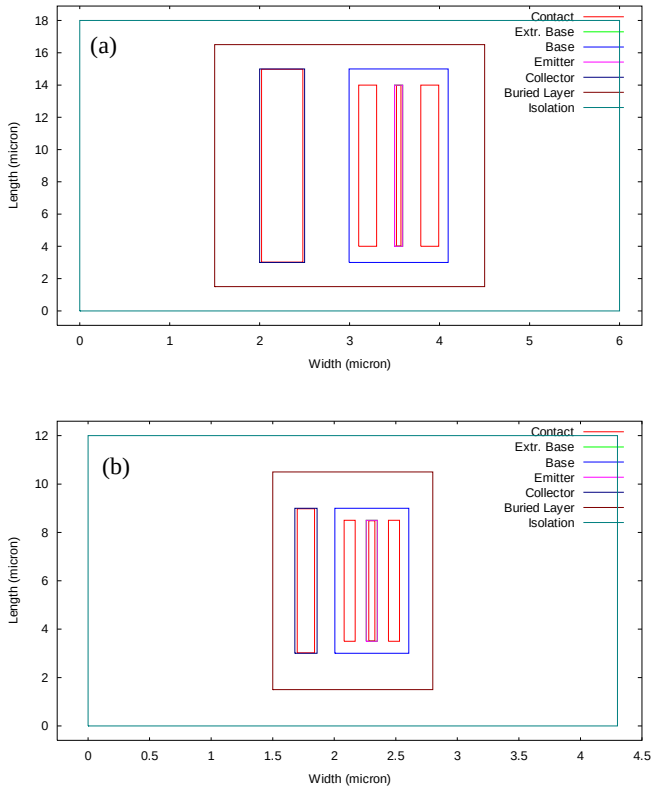

Figure 4: SiGe HBT with 0.09 μm emitter finger width (a) before and (b) after area scaling

3.2 Vertical Scaling

In this work, the vertical scaling is limited to the base width scaling because the base delay is the most dominant delay time in the reference device. As shown in Fig. 5, at the minimum total delay, the base delay component (TBASE) is about twice TRE (delay time due to $r_e \times (C_{je}+C_{jc})$ time constant) or TSCL (delay time due to collector space charge layer transit time). In this work, the base is scaled down from 39 nm to 32 nm which is about 80% from the original base width.

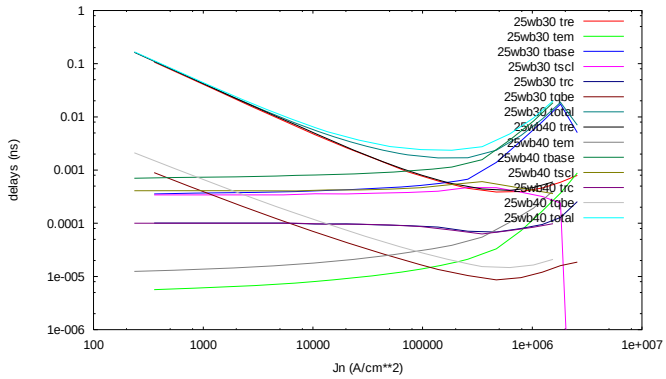

Figure 5: Delay time of SiGe HBTs with base width 39nm and 32nm, A_E=0.25 μm ×10μm.

For SiGe HBT with emitter area A_E = 0.25 μm × 10 μm, reducing base width from 39 nm to 32 nm decreases base delay from 0.76 ps to 0.39 ps and lowered the total delay about 0.6 ps. Simulation results for SiGe HBT with A_E = 0.18 μm × 10 μm, 0.25 μm × 10 μm and 0.25 μm × 10 μm are similar to the SiGe HBT with A_E = 0.25 μm × 10 μm because all of SiGe HBTs have the same the vertical profiles and dimensions. Devices with 32 nm base width have lower total delay time which mean higher cutoff frequencies. Relationship between total delay with cutoff frequency is:

$$f_t = \frac{1}{2\pi\tau_{ec}} \quad (1)$$

where τ_{ec} is the total delay.

The effects of base width scaling to SiGe HBTs performances are summarized in Table 2. All of SiGe HBTs with 32 nm base width have collector emitter breakdown voltage 2.5 V, lower than devices with 39 nm base width. This is happen because when the base width is reduced, the collector doping profile in the base-collector junction is affected.

SiGe HBTs with thinner base have higher current gain because they have higher collector current. This is consistent with the theory:

$$J_C = -\frac{qD_{nB}n_i^2}{N_B W_B}\left\{\exp\left(\frac{qV_{BE}}{kT}\right)-1\right\} \quad (2)$$

where q is the electron charge, D_{nB} is electron diffusion cofficient in the base, ni is intrinsic carrier concentration, N_B is base doping concentration, W_B is base width, V_{BE} is base emitter voltage, k is Boltzmann constant and T is temperature.

For SiGe HBTs with 0.25 μm and 0.18 μm emitter finger width, reducing base width enhance f_{max} about 10 GHz each but has no effect to SiGe HBTs with 0.12 μm and 0.09 μm emitter finger width. For all SiGe HBTs, reducing base width enhance f_t significantly. From Table 2 it is clear that the base width scaling affect wider SiGe HBT more than the narrower devices.

Tabel 2: The effects of base width scaling to SiGe HBTs performances

W_B (nm)	A_E (μm×μm)	Peak f_t (GHz) @ I_C (mA)	Peak f_{max} (GHz) @ I_C (mA)	Peak β_{dc}	BV_{ceo} (V)
39	0.25 × 10	59 @ 4,6	120 @ 15	162	2.8
32	0.25 × 10	80 @ 4.6	130 @ 20	234	2.5
39	0.18 × 10	62 @ 4	136 @ 13	169	2.8
32	0.18 × 10	80 @ 2.6	147 @ 8	217	2.5
39	0.12 × 10	62 @ 3	152 @ 10	159	2.8
32	0.12 × 10	72 @ 3.5	152 @ 10	179	2.5
39	0.09 × 10	63 @ 3.5	163 @ 6.5	153	2.8
32	0.09 × 10	70 @ 2.8	161 @ 6.7	163	2.5

4. CONCLUSIONS

The effects of vertical scaling to the SiGe HBTs with different lateral dimension are reported. The simulation results with Bipole3 show that scaling down the base width yields enhancement in f_t, f_{max} and β_{dc}. Base width scaling has stronger effect to the wider device compared to narrower SiGe HBT.

ABSTRACT

In the last few years WiMAX technology has become the main topic of discussion between vendor and world telecommunications operator. WiMAX have more capabilities compared with BWA (Broadband Wireless Access) technology and becomes one of challenger of the 3G (third generation cellular system) to fulfill the requirement high-speed access. WiMAX is a very promising technology. The main promises are the high throughput and the large coverage. It is necessary to provide Quality of Service (QoS) guaranteed with different characteristics, quite challenging, however, for Broadband Wireless Access (BWA) networks. Therefore, an effective scheduling is critical for the WiMAX system. Many traffic scheduling algorithms are available for wireless networks, e.g. Weighted Round Robin (WRR) and maximum Signal-to-Interference Ratio (mSIR). Among these conventional schemes, some cannot differentiate services, while some can fulfill the service differentiation with a high-complexity implementation. The focus of this paper is to compare the performance between those two scheduling algorithm, Weighted Round Robin (WRR) and maximum Signal-to-Interference Ratio (mSIR) on the real-time Polling Service (rtPS) QoS Class. WRR scheduling, is an extension of the RR scheduler, is designed to better handle servers with different processing capacities, based on static weights. mSIR is a new scheduler based on the allocation of radio resources to get efficient utilization. rtPS is designed to support real-time service flows that generate variable size of data packets on a periodic basis.

For all new technologies, performance studies are required. The network simulation is considered as a solution to test the performance of technologies and especially the wireless networks. Network Simulator 2 (NS-2) is a widely used tool to simulate wireless networks. To analyze the behavior both of WRR and mSIR scheduling algorithm, we use WiMAX module that run on NS-2. The simulations result in our scenario has figured the hypothesis that mSIR throughput is better than WRR. Some case might have different results, depend on the number of UGS, rtPS and BE users, traffic type and traffic load. Our scenario use propagation model of Two Ray Ground, Omni antenna model, transmits power of 0.025 and frame duration of 0,02s. The number of node is 14 which consists of 1 sink node, 1 Base Station, 9 UGS nodes, 9 rtPS nodes and 2 BE nodes. UDP traffic is used by UGS and rtPS. TCP traffic is used by BE. Performance metrics evaluated in this work is the number of delivered data packets compared with traffic load. Our work shows that using the same traffic load, the mSIR enables more data packets delivered compared with WRR.

1. INTRODUCTION

World Interoperability for Microwave Access (WiMAX) is intended to reduce the barriers to widespread broadband access deployment with standards-compliant wireless solutions engineered to deliver ubiquitous fixed and mobile services such as Voice over IP (VoIP), messaging, video, streaming media, and other IP traffic. WiMAX enables delivery of last-mile broadband access without the need for direct Line Of Sight (LOS). It's ease of installation, wide coverage, and flexibility make it suitable for a range of deployment over long-distance and regional networks, in addition to rural or underdeveloped areas where wired and other wireless solutions are not easily deployed and LOS coverage is not possible.

As a complement to the existing Wi-Fi installation base, WiMAX is expected to dramatically increase the availability of wireless connectivity by helping to fill in the broadband gaps between more than 127

million public hotspots and 223 million home-based Wi-Fi networks worldwide. Due to the increasing number of notebook computers, handhelds, and consumer electronics devices combined with WiMAX and Wi-Fi modules, customers will expect more seamless connectivity as they travel in and out of hotspots. Wi-Fi has become nearly a default feature in notebooks, with over 97 percent shipping with integrated Wi-Fi, and an increasing number of handhelds and consumer electronics devices adding Wi-Fi capabilities as well. WiMAX is designed to blanket large metropolitan, suburban, or rural areas with multimegabit per second mobile broadband Internet access. Although the wide-area Internet connectivity offered by 2.5G and 3G cellular data services has been mobile, these services do not provide the broadband speeds to which users have become accustomed to which can be delivered by WiMAX. Theoretically, the coverage range can reach 30 miles and the throughput can achieve 75 Mbit/s. Yet, in practice the maximum coverage range observed is about 20 km and the data throughput can reach 9 Mbit/s using User Datagram Protocol (UDP) and 5 Mbit/s using File Transfer
Protocol (FTP) over Transmission Control Protocol (TCP). The theoretical values do not always reflect the reality.

The WiMAX Forum Applications Working Group (AWG) has determined five initial application classes, listed in Tabel 1. Initial WiMax Forum Certified systems are capable of supporting these five classes simultaneously. The following is the classes:

- **Unsolicited Grant Service** (**UGS**) is used for real-time services like T1 and E1 lines, and for VOIP services with fixed packet sizes.
- **Real Time Polling Service (rtPS)** is used for real-time services such as streaming video. This offers a variable bit rate, but with a guaranteed minimum rate and guaranteed delay. Another example where this could be used is in enterprise access services. It is quite popular for fixed wireless operators (or WISPs) to guarantee E1/ T1-type data rates with wireline-equivalent SLAs, but to allow customers to burst higher if and when there is extra capacity on the network. This is quite a successful strategy for wireless operators competing against incumbent wireline providers.
- **Enhanced Real-Time Polling Service (erTPS)** is specified in 802.16e, and will be used for VOIP services with variable packet sizes as opposed to fixed packet sizes – typically, where silence sup- pression is used. This will include applications such as Skype – and partly explains why 802.16e equipment is not as good at supporting VOIP without vendor-specific tweaks to the standard MAC

Tabel 1. 802.16 QoS Classes [5]

Class	Description	Minimum rate	Maximum rate	Latency	Jitter	Priority
Unsolicited Grant Service	VOIP, E1; Fixed-size packets on periodic basis		x	x	x	
Real-Time Polling Sevice	Streaming audio/video	x	x	x		x
Enhanced Real Time Polling Service	VOIP with activity detection	x	x	x	x	x
Non-Real-Time Polling Service	FTP	x	x			x
Best-Effort	Data transfer, Web browsing, etc		x			x
X = QoS specified						

- **Non-Real-Time Polling Service (nrtPS)** is for services where a guaranteed bit rate is required, but guaranteed delay is not. This might be used for file transfer, for example.
- **Best-Effort** (**BE**) is the old standby for email and browsing and so forth, and is largely what people have on a DSL line at home today.

The objective of this paper is to provide differentiated services according to their QoS requirements, especially rtPS QoS class. Our extensive simulation showns that the proposed scheduling algorithm to enhance the throughput, and distinguishes the services in terms of the average delay. Therefore, we implemented the proposed scheduling used for rtPS QoS class by showing the simulation results.

2. THE WiMAX SCHEDULING ALGORITHMS

Scheduling algorithms serve as an important component in any communication network to satisfy the QoS requirements. The design is especially challenged by the limited capacity and dynamic channel status that are inherent in wireless communication systems. To design MAC layer protocol which can optimize the system performance, the following features and criteria should be concerned.

- Bandwidth utilization
  Efficient bandwidth utilization is the most important in the algorithm design. The algorithm must utilize the channel efficiently.
- QoS requirements

The proposed algorithm should support different applications to exploit better QoS. To support delay-sensitive applications, the algorithm provides the delay bound provisioning. The long-term throughput should be guaranteed for all connections when the sufficient bandwidth is provided.

- Fairness
  The algorithm should assign available resource fairly across connections. The fairness should be provided for both short term and long term.
- Implementation complexity
  In a high-speed network, the scheduling decision in making process must be completed very rapidly, and the reconfiguration process in response to any network state variation. Therefore, the amount of time available to the scheduler is limited. A low-complexity algorithm is necessary.
- Scalability
  The algorithm should operate efficiently as the number of connections or users sharing the channel increases.

In downlink operation, packets arrive from the network at the base station are placed in downlink user traffic queues. The scheduler decides which user traffic to map into a frame from the queues, and the appropriate burst is generated, together with the appropriate MAP information element. Users are scheduled according to their service classes (UGS, rtPS, ertPS, nrtPS, and BE). MAPs contain information on transmission to/from all users for each frame, including modulation and coding type, and size and position of allocation. The description of WRR scheduling and mSIR scheduling techniques that we use in this simulation is presented in the following.

2.1. Weighted Round Robin

Round-robin (RR) is one of the simplest scheduling algorithms for processes in an operating system, which assigns time slices to each process in equal portions and in circular order, handling all processes without priority. Round-robin scheduling is both simple and easy to implement, and starvation-free. Round-robin scheduling can also be applied to other scheduling problems, such as data packet scheduling in computer networks.

The **Weighted Round-robin** (WRR) scheduling, as an extension of the RR scheduler, is designed to better handle servers with different processing capacities. Each server can be assigned a weight, and an integer value that indicates the processing capacity. Servers with higher weights receive new connections before those with less weight, and servers with higher weights get more connections than those with less weights and servers with equal weights get equal connections. The weighted round-robin scheduling is better than the round-robin scheduling, when the processing capacity of real servers are different. However, dynamic load imbalance among the real servers if the loads of the requests vary highly. In short, there is the possibility that a majority of requests requiring large responses may be directed to the same real server. Actually, the round-robin scheduling is a special instance of the weighted round-robin scheduling, in which all the weights are equal.

2.2. Maximum Signal-to-Interference Ratio (mSIR)

A cellular network divides a region into cells (or zones) to process calls. Each cell has an antenna to receive and answer your call. The antenna is often on a pole with other communication equipment called a base station. The network determines which cell a mobile user is in, assigns a communication channel, and monitors the strength of the signal using the cell base station. When a user approach the boundary of the cell, the neighboring cell's base station, which has also been monitoring the signal, will switch the channel to one in that cell. This is sometimes called "handing off" the call. There are two base station antennas that are transmitting a signal of equal power to the phone; the primary base station of the cell in which the car is moving and a secondary base station in the neighboring cell the car is approaching. The signal from the secondary station causes interference with the signal from the primary station resulting a degradation of the cell phones capabilities. Thus the power of the signal received by the cell phone varies as the car moves along.

An uplink signal-to-interference ratio for each of multiple mobile radio terminal connections supported in a cell in a cellular communications system is estimated. A signal-to-interference ratio error is determined for selected ones of the estimated uplink signal-to-interference ratio. The **signal-to-interference ratio** (SIR) is the quotient between the average received modulated carrier power *S* or *C* and the average received co-channel interference power *I*, i.e. cross-talk, from other transmitters than the useful signal. From the explanation above we can make a definition :

 (1)

Where,
Pr = Power of the received signal
L = Distance from the phone
This formula applies to both the primary base station as well as the secondary base station.

$$SIR = \frac{Pr1}{Pr2} \quad (2)$$

Where,

SIR = Signal to interference ratio
Pr1 = Power of received signal from primary station
Pr1 = Power of received signal from primary station

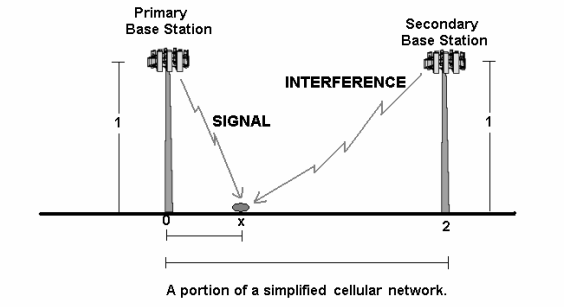

Figure 2. The simplified model for illustration [6]

The height of the antennas and the distance between base stations, both the power of the received signals and hence the signal-to-interference ratio can be computed. The goal is to determine the location x of the cell phone so that the signal-to-noise ratio is maximized.

In this project, we use the maximum Signal-to-Interface Ratio (mSIR) scheduler. This method work on radio allocation resources to subscriber stations which have the highest Signal-to-Interference Ratio (SIR). This scheduler also allows the highly efficient utilization of radio resources.

3. DESIGN AND IMPLEMENTATION SCHEDULING ALGORITHMS

In our work, we have compiled implemented WiMAX module *patch-QoS-WiMAX_prerelease-10-27-2008* and *QoS-includedWiMAX_27.10.2008.tar.gz* on NS-2 version 2.29 running on Linux Kernel 2.6. The module represents the scheduling algorithm that compared between WRR and mSIR. The mSIR scheduler is implemented the following scenario; one Sinknode via the BS sorts the SS according to their received SIR. The traffic that has the best SIR will be served first, until all the symbols are allocated.

WRR algorithm is implemented on a scenario on which according to the weights of the different SSs, the BS determines the SS that will be served. If there are still remaining symbols, the BS serves the next SS until all the symbols are allocated.

For the rtPS connections, the BS allocates periodic unicast request opportunities and then, according to these requests, the symbols needed for the rtPS connections. If the BS allocates unicast request opportunities and resource grants for rtPS connections in the same frame, the BS cannot immediately take into account the new length of the uplink data connection of the subscriber. The reason is that the BS allocates symbols for rtPS connections before receiving the latest unicast bandwidth request.

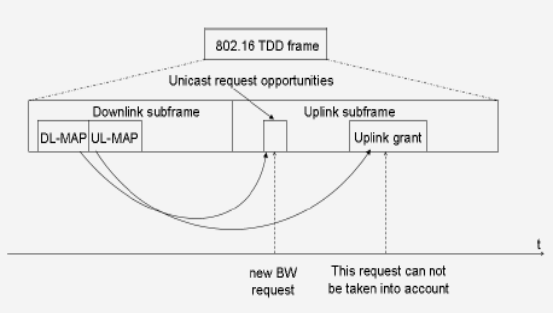

Figure 3.Allocation of symbol for rtPS connection [7]

Moreover, the mSIR scheduler serves those subscribers having the highest SIR at each frame. Therefore, subscribers with a slightly smaller SIR may not be served and then the mean delay to deliver data increases. The patch-QoS-WiMAX_prerelease-10-27-2008 module is modified the mSIR scheduler in order to decrease the mean time of sojourn. The mean sojourn time is the average time a data packet spends from its generation to its delivery at destination.

4. SIMULATION RESULT

4.1. Simulation Overview

As with many digital modulation schemes, the constellation diagram is a useful representation. In QAM, the constellation points are usually arranged in a square grid with equal vertical and horizontal spacing, although other configurations are possible (e.g. Cross-QAM). Since in digital telecommunications the data are usually binary, the number of points in the grid is usually a power of 2 (2, 4, 8 ...). Since QAM is usually square, some of these are rare—the most common forms are 16-QAM, 64-QAM, 128-QAM and 256-QAM. By moving to a higher-order constellation, it is possible to transmit more bits per symbol. However, if the

mean energy of the constellation is to remain the same (by way of making a fair comparison), the points must be closer together and are thus more susceptible to noise and other corruption; this results in a higher bit error rate and so higher-order QAM can deliver more data less reliably than lower-order QAM, for constant mean constellation energy.

64-QAM and 256-QAM are often used in digital cable television and cable modem applications. In the US, 64-QAM and 256-QAM are the mandated modulation schemes for digital cable (see QAM tuner) as standardized by the SCTE

Tabel 2. Main parameters of the simulation model [8]

Parameter	Values
Frame duration	20 ms
Propagation Model	Two Ray Ground
Antenna Model	Omni antenna
Antenna height	1.5 m
Transmit power	0.025
Receive power threshold	$2025e^{-12}$
Carrier sense power threshold	0.9*Receive power threshold

(Society of Cable Telecommunication Engineer) in the standard ANSI/SCTE 07 2000. It is also known as QAM-64 and QAM-256. In the UK, 16- QAM and 64-QAM are currently used for digital terrestrial television (Freeview and Top Up TV).

Communication systems designed to achieve very high levels of spectral efficiency usually employ very dense QAM constellations. One example is the ITU-T standard for networking over existing home wiring (coaxial cable, phone lines and power lines), which employs constellations up to 4096-QAM (12 bits/symbol).

For simulation purposes, we integrate not only both WRR and mSIR scheduler into NS-2 module but also QoS Parameter and rtPS services classes. The main parameter are given in Tabel 2. In our simulation, there are nine UGS, two BE, and nine
rtPS connections using 16QAM3/4. Since the mSIR scheduler provides high throughput with a good SIR then we assume that the rtPS connection can use 16QAM3/4.

4.2. Simulation NS-2

As mention in simulation overview, our scenario consists of 9 UGS nodes, 9 rtPS nodes and 2 BE nodes. The reason of simulating QAM is because according to the WiMAX module, mSIR scheduler provides high throughput, lot of nodes (create-god 22) only can be run in QAM modulation, not in QPSK. Based on that condition we choose 16QAM3/4 as option in our scenario. The Network Animator (NAM) shown in Figure 4.

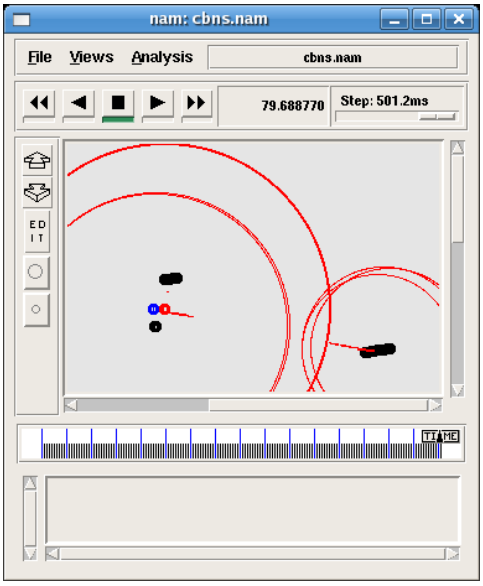

Figure 4. Network Animator (NAM) consists of nine UGS nodes, nine rtPS nodes and two BE nodes, one SinkNode and one Base Station

Tabel 3. Description of approach in NS-2 (WiMAX module) based on table 2

Characteristic	Values
Frame duration Mac/802_16 set frame_duration_ 0.020	20 ms
Propagation Model set opt(prop) Propagation/TwoRayGround ;# radio-propagation model	Two Ray Ground
Antenna Model set opt(ant) Antenna/OmniAntenna ;# antenna model	Omni antenna
Transmit power Phy/WirelessPhy set Pt_ 0.025 ;#transmit power	0.025
Receive power threshold Phy/WirelessPhy set RXThresh_ 2.025e-12 ;#500m radius	$2025e^{-12}$
Carrier sense power threshold Phy/WirelessPhy set CSThresh_ [expr 0.9*[Phy/WirelessPhy set RXThresh_]]	0.9*Receive power threshold

Throughout this simulation's throughput is computed as follows:

$$\text{Throughput} = \sum_{i=r_n}^{i=r_{n-1}} \text{Packet Size}; 0 \leq n \leq t \quad (3)$$

Throughput Graph Result (QAM Modulation, 9 UGS nodes, 9 rtPS nodes and 2 BE nodes) between mSIR – WRR can be seen in Figure 5.

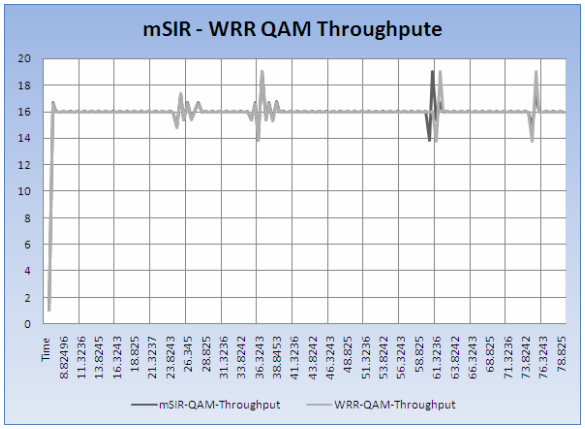

Figure 5. Throughput mSIR – WRR in XGraph

Jitter2 vs Received Time Graph Result mSIR-WRR can be seen in Figure 6.

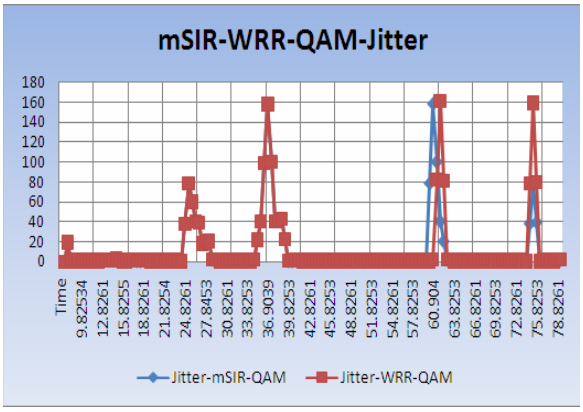

Figure 6. Jitter vs Received Time mSIR – WRR in XGraph

The graph shown in Figure 5 (according to our scenario, QAM Modulation, 9 UGS nodes, 8 rtPS nodes and 2 BE nodes) shows that (based on current time) mSIR deliver packets faster than WRR.

Throughput Graph Result (QPSK Modulation, 2 UGS nodes, 2 rtPS nodes and 2 BE nodes) between mSIR – WRR can be seen in Figure 7.

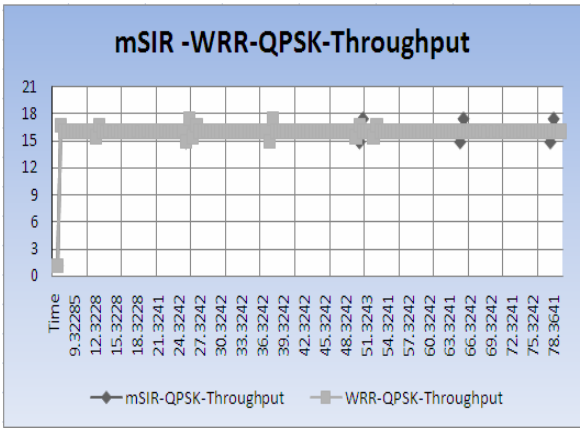

Figure 7. Throughput mSIR – WRR in XGraph

Jitter2 vs Received Time Graph Result mSIR-WRR can be seen in Figure 8.

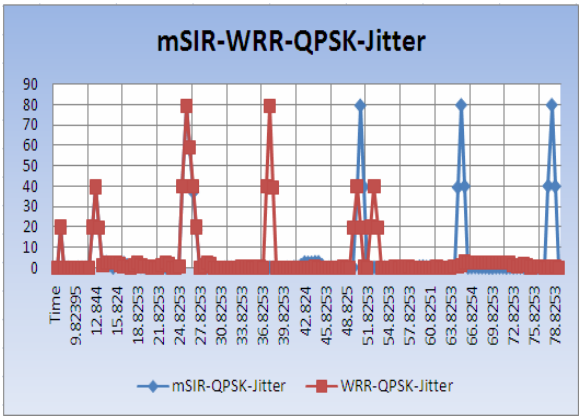

Figure 8. Jitter vs Received Time mSIR – WRR in XGraph

The graph shown in Figure 7 (according to our scenario, QPSK Modulation, 2 UGS nodes, 2 rtPS nodes and 2 BE nodes) shows that (based on current time) WRR deliver packets faster than WRR.

5. CONCLUSION

In this paper, we presented the behavior of WiMAX scheduling algorithms in rtPS schedulers. We based our work on the network simulation and implemented WiMAX module such as WRR and mSIR

scheduling, taking into account the QoS classes and its requirements. Algorithms compared are from different approaches so that all available approaches can be covered which can be useful guide for further research in this field. We have tabulated the different parameters on which QoS algorithms can be compared, which will be useful for developing new QoS algorithms. Our future work will be to implement an algorithm and suggestion for improving its performance in term of delay, throughput and other QoS.

According to throughput and jitter that we have from the simulation, to define what scheduler appropriate in certain case, we have to look amount of nodes, and some case depend on traffic load and traffic type.

ABSTRACT

Mining companies rely heavily on their fleets for their operation (production). However, unfortunately, many time they are facing difficult decisions whether to continue to use their old equipments or replace them with the new ones. Fleets in mining work at dynamic environment that changing with time. Several approaches have been used to determine the replacement age for the mining fleets. On this paper, we propose to utilize mean time between failure, MTBF. We argue that this measure is a good approach to represent the utilization of the fleets and the site. Thus, it will give a more realistic replacement age.

Keywords
replacement analysis, MTBF, mining, fleet

1. INTRODUCTION

There are basically two models of replacement analysis in industry. The first one is defender-challenger model. This model involves determining whether to continue to use the old asset (usually called as the defender) or to replace the existing asset with the new one (called as the challenger). This type of studies happen on situation when a company wants to install new facilities due to new technology advancement, or makes new products that require using new machines, or increases production lines which can be achieved by using bigger capacity equipments. The second model of replacement analysis involves determining in advance the economic life of an asset. This type of studies happens when setting up a new venture (with new facilities) or on a situation where there is no significant advancement of technology; meaning that there is no challenger on the analysis. Fleet replacement in mining industry belongs to this second line of study.

Mining is a kind of industry that requires high intensive capital. The industry uses many kinds of heavy equipments such as draglines, excavators, bulldozers, dump trucks, and so on to exploit the ore. Productivity of a miner depends on these assets.

Fleets in mining work at dynamic environment that changing with time. Not like their counterpart, non mining fleet which is utilized in almost similar environment during their useful life time, fleet in mining facing a more challenging environment as the time elapses. As the time goes by the workload increases (the environment changing; the mine getting deeper) till the miners move to a new place. At this point the work load is started normal and the pattern is repeated. The workload as a function of time resembles ripple pattern (Figure 1). This factor should be taken into consideration when analyzing replacing the fleet.

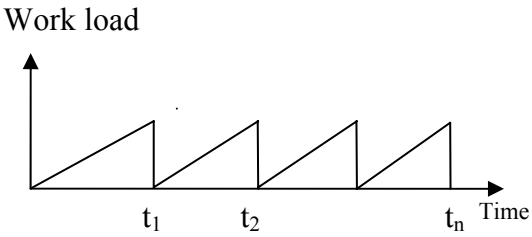

Figure 1: Work load vs time

The complex nature of the machineries and the environment where they are operated makes the management and maintenance of these assets a difficult task. In addition, the costs associated with running and maintaining these trackless fleets are substantial. However, effective management of the assets have not been fully understood or addressed by the miners. For instance the costs increases from older machines are not well understood (or quantified) thus accumulated to a big portion of hidden and/or known costs.

In this study, we proposed a new approach that uses mean time between failures as a measure to represent the pattern. We argue that this method is much better than using old one. The logic is as the work load increases the number of failures increases. As well the machines getting older the number of failures increases. Before we describe the approach, this paper will explain the methods that used in mining fleet replacement followed by the

challenge/difficulties surrounding the issue. The paper is closed by citing conclusions.

2. METHOD TO DETERMINE FLEET ECONOMIC OF LIFE

Several methods are utilized, four most common one are elaborated here:

1. Theory of Depreciation

Depreciation is the decrease in value of (physical) assets with the passage of time. Depending on the method of depreciation used the life of the assets is determined at the end of depreciation; meaning that replacement occurs when the book value of the asset is zero. This replacement method is easy, thus becomes a favorite one to be used albeit it has no solid ground and the replacement point can be unlimited. Depreciation is actually an accounting concept that mainly used to determine income tax instead of determining productive life of an asset.

2. Theory of vehicle replacement.

This method is basically based on the trade-off between decreasing capital cost and increasing running costs. As the age of the equipments increases the capital cost per unit time decreases. Considering only the capital cost, one will use the equipment as long as possible to minimize the capital cost. However, the older the machines the higher its running costs. The optimal time to replace the equipment, is then the point where the total cost is minimum.

3. Cost per ton trends

This approach uses the total machine costs divided by the number of tons a machine produces. It is based on the principle that as a machine ages, the running costs increase and as the availability of the machine decreases, the tons are reduced, hence increasing the cost per ton. The minimum cost per ton is the optimal replacement point. In a sense, this method uses a similar methodology of a cost-benefit or payback analysis. Cost per ton trends is very appropriate to use since the purpose of the machine is to produce tons, thereby, using this measure as a financial indicator. However information about the tons produced is required and often not available

4. Equivalent annuity Cost (EAC)

EAC methodology is commonly applied to replacement problems. This method looks at the cash flows associated with the machine and the times in which they are incurred. It uses the time value of money concept to compare different timing alternatives. This method is very powerful and is an accepted asset appraisal method, although it is commonly not easily understood and hence accepted

Theoretically, in any given year, total EAC has two components, i.e. EAC of capital and the EAC of operations and maintenance. The relationship is expressed as $EAC_t = EAC_{Cap,t} + EAC_{O\&M,t}$

$EAC_{Cap,t}$ is the component of cost associated with the capital in year t. The amount is based on the initial investment and subsequent depreciation of the asset, yielding a residual value at the end of year t. The $EAC_{Cap,t}$ curve is downward sloping, producing a lower value over time. In some instances, the curve decreases to a level which indicates that the salvage value of the underlying asset is equal to its scrap value.

$EAC_{O\&M,t}$ is the cost of operating and maintaining the vehicle in year t. Operational costs include labor, fuel, lubricants, electricity, supervision, insurance and so forth. Maintenance costs typically consist of labor, spares and costs associated with third parties – for example, subcontracted maintenance crews and service companies. Maintenance and operating costs can be divided into three parts: direct costs, indirect costs and administrative costs. As mentioned previously, the cost of operating and maintaining a vehicle tends to increase as it gets older.

The correct derivation EAC, which ultimately calculates the economic life of equipment, relies on the inclusion of all costs related to its replacement. However, the calculation should only include those costs which are related to the use of a particular machine or vehicle. Overhead costs such as administrative costs are irrelevant as they do not bear a direct or indirect correlation to the age of the vehicle.

The EAC methodology is a straightforward decision principle which is based on the shape of the total EAC curve: replace the equipment or machine whenever EAC_t reaches its minimum point. Figure 2 illustrates the likely shape of the $EAC_{Cap,t}$ and $EAC_{O\&M,t}$ curves as well as the resultant EAC_t

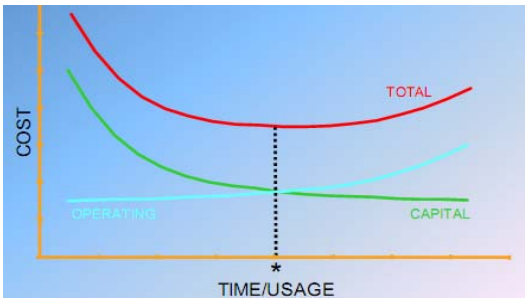

Figure 2: EAC against equipment life.

A policy which anticipates or delays equipment replacement decisions so that it diverges from the minimum value of the EAC_t curve is necessarily suboptimal and leads to a loss of value. In practice, of course, the decision is not often quite as direct. There are cases where the curvature of the EAC_t schedule rests only briefly at its minimum and other cases where the minimum point occurs over an interval. Here, the EAC decision principle is subject to an indifference zone; that is, the replacement of one vehicle for another can take place at any point during this interval. Where the decision to replace equipment is unclear, management may consider practical limitations such as budget restrictions to establish the optimal replacement time within this period of indifference.

3. THE CHALLENGE ON THE FIELD

Number of factors exist on the field that need to be included in the replacement decision. Some of which are relatively simple to calculate and others which prove somewhat more difficult. Some of the reasons include the fact that the parameters themselves can be difficult to quantify, over and above the lack of data, quality of these data or the format of the data available. A challenge in developing an appropriate model is to retrieve and use realistic and representative data in the absence of accurate quantitative information. The aim is to quantify the causes—factors influencing the replacement decision. This can be done by looking at the effects that are assumed to be representative of the causes, in this case the costs of running machines and the machine availability.

Another challenge with the mining replacement is difficulty to standardize the process since the operation environment is different and continuously evolved. For instance, the capacity and life-span of equipment differ significantly from those suggested by the supplier. Furthermore, it is reasonable to assume that two identical haulage trucks operating in different mines of varying characteristics have different economic lives. For instance dump trucks use at an open pit is different with dump trucks use at close pit. however, the to the equipments mobility, the number of fleets, and the environment complexity, it is almost impossible to manage such kind of asset.

The relevant indicator of economic life is not equipment availability, rather, it is equipment utilization – that is, the percentage of time in which the equipment remains operating. Idle time such as pauses, delays due to shift changes, temporary mine closure as a result of blasting and so forth, are deducted from the equipment's total available time. This reflects a clear shift from physical to economic life cycles. However, EAC theory refers to asset utilization which is not necessarily equal to calendar years.

4. PROPOSED APPROACH

Mean time between failures (MTBF) is the expected time of failure rate. The MTBF is for a repairable system. The model assumes the failed system is immediately repaired (zero elapsed time). Contrast to the mean time to failure (MTTF) which measures average time between failures with the modeling assumption that the failed system is not repaired. MTBF is calculated in term of its density function *f(t)* as:

$$MTBF = \int_0^\infty t\ f(t)\,dt \qquad (1)$$

with $$\int_0^\infty f(t)\,dt = 1 \qquad (2)$$

Assuming that all the failures have equal probability to occur, MTBF can be defined as the arithmetic mean (average) time between two consecutive failures and equation (1) can be calculated as:

$$MTBF = \sum_{i=1}^{n} \frac{(Downtime_{\ i+1} - Downtime_{\ i})}{n} \qquad (3)$$

Example: an equipment that can be repaired when there is a failure is used. The first failure (D_1) happens at 10 hours and it takes 2 hours to fix. The second failure (D_2) is at 19 hours and the repair duration is 3 hours. Then after working for 5 hours, the system fails at 27 hours (D_3). The repair lasts for 4 hours and the system is restored at 31 hours (see figure 3).

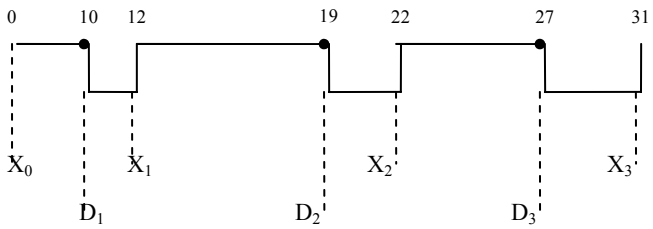

Figure 3: Failure and Repair Process for a Repairable System without Scheduled Replacements

Using equation (3), the MTBF = ½ (9 + 8) = 8.5 hours, if we use only the observations of 2 complete cycles. If we consider all the cycles, then the MTBF = ⅓ (9 + 8 + (D_1 - x_0) + (x_3 - D_3)) hours.

MTBF of a system usually depends on time, with the rate varying over the life cycle of the system. MTBF of a system, for instance an automobile, will be smaller as it grows older. MTBF in its fifth year of service may be many times smaller than its MTBF during its first year of service; one will not expect failure for a brand new automobile. This means as the equipment getting older, its operational period ($D_{i+1} - x_i$) will be shorter. On the contrary, as the equipment getting older, its repair time ($x_i - D_i$) getting longer. This condition due to more components need to be fixed as well the intensity of the failure is getting more serious resulting with more time to repair.

Reliability is defined as the probability that the product will perform its intended function, for a required period of time within a certain environment. Reliability is a function of MTBF with the relation:

$$R = 1 - F = 1 - \frac{1}{MTBF} \qquad (4)$$

Equation (4) indicates that MTBF is also environment

dependent. This property fits well to be used for mining industry since as mentioned earlier on the introduction, fleets in mining work at dynamic environment that changing with time. Figure 1 shows that as the time goes by the workload increases (the environment changing; the mine getting deeper) till the miners move to a new place.

Reliability Estimation Methods

MTBF can be estimated thru measuring the field data or using reliability information of similar equipments.

Similar Item Prediction Method

Similar item prediction method is based on historical reliability data of similar item to estimate an equipment. Its effectiveness mostly depends on how similar the new equipment is to the existing item which field data is available. Similarity should exist on the aspects of manufacturing processes, operating environments, product functions and designs. This method is especially useful for products that follow an evolutionary path, since it takes advantage of the past field experience. However, differences in new designs should be carefully investigated and accounted for in the final prediction. Since the method relies on the similarity of the two equipments, it can be used as a quick means for estimating reliability. This method is applicable on mining industry since mining fleet technology is very much the same.

Field Data Measurement Method

The field data measurement method is based on the actual field experience of products. This method, often referred to as Reliability Growth Management, is perhaps the most used method by manufacturers since it is an integral part of the manufacturers' quality control program. Because it is based on real field failures, this method accounts for failure modes that prediction methods sometimes miss. The method consists of tracking a sample population of new products and gathering the failure data. Once the data is gathered, the failure rate and MTBF are calculated. The failure rate is the percentage of a population of units that are expected to "fail" in a calendar year.

5. CONCLUSION

1. Methods have been developed for mining fleet replacement analysis do not take into consideration the ever-changing environment where the fleets are worked, even though this character is the one that differentiates mining industry with other industries. MTBF better fits for the purpose since the concept inherently includes the environment aspect.
2. One challenge in mining fleet replacement analysis is data collection. MTBF is relatively easier to use than methods explained on part 2. Data collected is simple as well the mechanism to record. Method such as similar item prediction and field data measurement can be used here.

ABSTRACT

The rapid expansion of science and technology has given a lot of effect in human life, including the information technology. However, it will bring some threats. One of those threats is there would be someone impersonates to get the illegal access. The authentication system can be a solution for this problem. The most popular authentication technique is the use of username and password. But that technique has a lot of weaknesses, for example, password can be forgotten, and compromised. Password chosen can also be weak so people can guess it easily. Therefore biometric can be a solution of problems related to the authentication technique using password.

Biometric authentication relies on any automatically measureable physical characteristic or personal trait that is distinctive to an individual. The biometric process consists of two features, the feature extraction and the feature matching. In this paper, the input system is a voice signal that will be processed with digital signal processing to get a real number that can represent an individual characteristic using the MFCC method. The real number is stored in the database. Someone who will try to get the access must give their voice as an input. The input will be extracted and compared with the values in database. If they are equal, then access will be granted, and if they are not, the access will be denied.

MFCC is used in feature extraction because it is the best known and most popular extraction method. MFCC is best on the known variation of the human ear's critical bandwidths with frequency. Hidden Markov Model is used in feature matching to compare the voice input and the values that have been stored in database. HMM is used so that the matching process can be optimized. The combination of both processes is expected to be the alternative solution in order to increase the quality of authentication system that using voice biometric.

Keywords

Biometric, voice authentication, MFCC, HMM.

1. INTRODUCTION

Authentication technique typically used by inputing a keyword or a password. Such a technique is very common in used because of its easy to use and process. But as many problems occurs become weakness of this technique, i.e, one can easily forget, lost or stolen the password. Other possibilities are the choosen of the passwod itself can be easily guess by other people, using the same password for diffrent systems or using the previous password which has been used before.

Speech is one of the natural forms of communication. Recent development has made it possible to use it in the security system. In speaker identification, the task is to use a speech sample to select the identity of the person that produced the speech from among a population of speakers. In speaker verification, the task is to use a speech sample to test whether a person who claims to have produced the speech has in fact done so [4].

This technique makes it possible to use the speaker's voice to verify their identity and control access to services such as voice dialing, banking by telephone, telephone shopping, database access services, information services, voice mail, security control for confidential information areas, and remote access to computers.

2. PRINCIPLES OF SPEAKER RECOGNITION

Speaker recognition methods can be divided into text-independent and text-dependent methods. In a text-independent system, speaker models capture the characteristics of somebody's speech which show up irrespective of what one is saying. In a text-dependent

system, on the other hand, the recognition of the speaker's identity is based on his or her speaking one or more specific phrases, like passwords, card numbers, PIN codes, etc. Every technology of speaker recognition, identification and verification, whether text-independent and text-dependent, each has its own advantages and disadvantages and may require different treatments and techniques. The choice of which technology to use is application-specific. At the highest level, all speaker recognition systems contain two main modules feature extraction and feature matching.

Speech processing has a wide use of its applications. Figure 1 shows part of the area and how the speaker recognition becomes part of it.

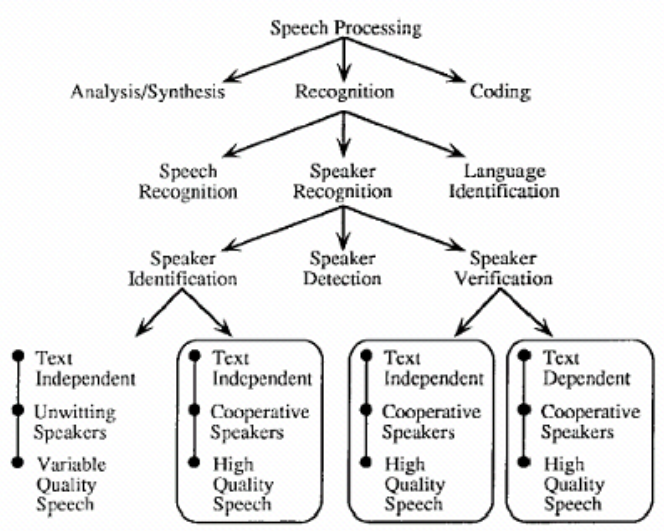

Figure 1: Signal Processing Tree to Speech Recognition

3. FEATURE EXTRACTION

The purpose of this part is to convert the speech waveform to some type of parametric representation (at a considerably lower information rate). The speech signal is a slowly time varying signal (it is called quasi-stationary). When examined over a sufficiently short period of time (between 5 and 100 ms), its characteristics are fairly stationary. However, over long periods of time (on the order of 0.2s or more) the signal characteristics change to reflect the different speech sounds being spoken. Therefore, short-time spectral analysis is the most common way to characterize the speech signal. A wide range of possibilities exist for parametrically representing the speech signal for the speaker recognition task, such as Linear Prediction Coding (LPC), Mel Frequency Cepstrum Coefficients (MFCC), and others. MFCC is perhaps the best known and most popular, and this feature has been used in this paper. MFCC's are based on the known variation of the human ear's critical bandwidths with frequency. The MFCC technique makes use of two types of filter, namely, linearly spaced filters and logarithmically spaced filters. To capture the phonetically important characteristics of speech, signal is expressed in the Mel frequency scale. Normal speech waveform may vary from time to time depending on the physical condition of speaker's vocal cord. Rather than the speech waveforms themselves, MFFCs are less susceptible to the said variations.

3.1 MFCC Processor

A block diagram of the structure of an MFCC processor is given in Figure 2. The speech input is recorded at a sampling rate of 22050Hz. This sampling frequency is chosen to minimize the effects of aliasing in the analog-to-digital conversion process. Figure 2 shows the block diagram of an MFCC processor and the sequensial process in it.

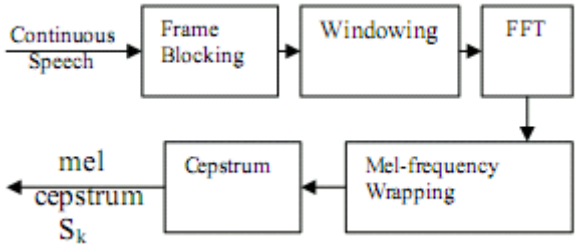

Figure 2: Block Diagram of a MFCC Processor

3.2 Mel-frequency Wrapping

The speech signal consists of tones with different frequencies. For each tone with an actual frequency, f, measured in Hz, a subjective pitch is measured on the 'Mel' scale. The Mel-frequency scale is linear frequency spacing below 1000 Hz and a logarithmic spacing above 1000 Hz. As a reference point, the pitch of a 1 kHz tone, 40 dB above the perceptual hearing threshold, is defined as 1000 mels. Therefore we can use the following formula to compute the mels for a given frequency f in Hz:

mel(f)= 2595*log10(1+f/700) …….. (1)

One approach to simulating the subjective spectrum is to use a filter bank, one filter for each desired mel-frequency component. The filter bank has a triangular bandpass frequency response, and the spacing as well as the bandwidth is determined by a constant mel-frequency interval.

3.3 Cepstrum

In the final step, the log mel spectrum has to be converted back to time. The result is called the mel frequency cepstrum coefficients (MFCCs). The cepstral representation of the speech spectrum provides a good representation of the local spectral properties of the signal for the given frame analysis. Because the mel spectrum coefficients are real numbers (and so are their logarithms), they may be converted to the time domain using the Discrete Cosine Transform (DCT). The MFCCs may be calculated using this equation [4]:

$$\tilde{c_n} = \sum_{k=1}^{K} (\log \tilde{S}_k) \left[n\left(k - \frac{1}{2}\right)\frac{\pi}{K} \right], \quad \text{where } n=1,2,\ldots K \qquad \ldots\ldots(2)$$

The number of mel cepstrum coefficients, K, is typically chosen as 20. The first component, c~0, is excluded from the DCT since it represents the mean value of the input signal which carries little speaker specific information. By applying the procedure described above, for each speech frame of about 30 ms with overlap, a set of mel-frequency cepstrum coefficients is computed. This set of coefficients is called an acoustic vector. These acoustic vectors can be used to represent and recognize the voice characteristic of the speaker. Therefore each input utterance is transformed into a sequence of acoustic vectors. The next section describes how these acoustic vectors can be used to represent and recognize the voice characteristic of a speaker.

4. FEATURE MATCHING

The state-of-the-art feature matching techniques used in speaker recognition include, Dynamic Time Warping (DTW), Hidden Markov Modeling (HMM), and Vector Quantization (VQ). HMM may be used to improve the efficiency and precision of the segmentation to deal with crosstalk, laughter and uncharacteristic speech sounds.
Deterministic approach is intuitive reason, but stochastic model has been developed recently which offer more flexibility and more probabilistic theoretically.

By stochastic model, pattern matching problem can be formulated as probabilistic of an observable event (A vector feature from unknown speaker vector) given as a speaker model. Observation means a random vector with conditional probability density functions (pdf) depend on the speaker. Conditional pdf for one speaker can be estimated from a set of training vector which then put in database as a value to compare. Estimated pdf can be a parameteric or non parametric model. From such model, for every frame of voice (or mean of frame series) probalility used to get unique information for everyone voice. Probabilistic is a match score. If using parametric model, a specific pdf can be assumed and exact parameter from pdf can be determined using the biggest probalilistic.

HMM is the most popular stochastic model. At Markov tradisional model, every state corresponds to every deterministic observable. In HMM, observation is a probabilistic function from state in the model, which is a stochastic process in double value. One value of it which is the prime value cannot be observable directly (means hidden) can only be seen through another set of stochastic process which gives an observable series. HMM is a limited state machine where a pdf (or stochastic model from feature vector) p(x|si) associated fro every state of si (base prime model). Every state connected by a transition net, where probability of transition state is aij = p(si|sj). As an example, HMM with 3 state hipotesis shown in Picture 3.

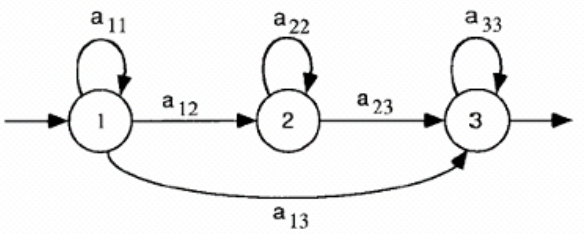

Figure 3: Example of 3 state of HMM

Probability of a frame voice series generalize by this model using Baum-Welch decoding. Probability here means score of frame L from voice input given by the model.

$$p = (x(1;L) \mid \text{model}) = \sum_{\text{semuaderetkemungkinan}} \prod_{i=1}^{L} p(x_i \mid s_i) p(s_i \mid s_{i-1}) \qquad \ldots(3)$$

5. RESULTS

The system has been implemented in Matlab 7.5.0 on windowsXP platform.The result of the study has been presented in Table 1 and Table 2. The probability database consists of 6 speakers, each person said letter "a" for 50 times. in this experiment, we obtained the probability of recognized speaker voice by the system for each spelling.

Table 1:
Probability of recognized speaker for each spelling (1-25.)

Experiment Number	Speaker

50	0.65	0.5	0.6	0.85	0.4875	0.575

5. ANALYSIS

By using Analysis of Variance (ANOVA), we can tested the hypotesis of average similarity from three or more population. The assumption in this ANOVA are:

1. The sample is been taken randomly and independently
2. Normal distribution of population
3. The population have variance similarity.

Next table, shows ANOVA table that must be calculate first to be able to do analysis.

Table 3 : ANOVA table for comparing means

Source	SS *(Sum of Squares, the numerator of the variance)*	DF *(the denominator)*	MS *(Mean Square, the variance)*	F
Treatment *(or Between or Model)*	$SST = \sum_{i=1}^{p} \sum_{j=1}^{n_i} (\bar{y}_i - \bar{y})^2$	$p-1$	$MST = \frac{SST}{p-1}$	$F = \frac{MST}{MSE}$
Error *(or Within)*	$SSE = \sum_{i=1}^{p} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2$	$n-p$	$MSE = \frac{SSE}{n-p}$	
Total	$TSS = \sum_{i=1}^{p} \sum_{j=1}^{n_i} (y_{ij} - \bar{y})^2$	$n-1$		

The solution using variance analysis in experimentation testing are:

- Hypothesis:

  H_o: $\mu_1 = \mu_2 = \mu_3 = \mu_4 = \mu_5 = \mu_6$

  H_1: there is an average value that is not equal
- Significancy level $\alpha = 0{,}01$
- Since df_1 = the denominator Treatment = 5 dan df_2 = the denominator Error = 294, so f(0,01; 5; 294) = 3,02)
- So, H_O rejected if F > 3,02)

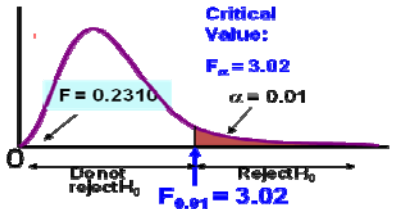

Figure 4: ANOVA Curve

Table 4: ANOVA Calculation Table

Source	DF (the denominator)	SS (Sum of Square, , the numerator of the variance	MS (Mean Square, the variance)	F
Treatment	5	0.1286	0.02572	0.2310222
Error	294	3.27314	0.11133129	
Total	299	3.40174		

Analysis :
Since F_{count}= 0.2310222 < 3,02, the H_0 approved.
So, $\mu_1 = \mu_2 = \mu_3 = \mu_4 = \mu_5 = \mu_6$ or in other words, there is similarity between mean of all person, with level of trust is *99% (α =0.01).*

From the experimentation, by using 99 % level of trust), we obtained approving profile as :

Table 5 : User acceptance profile

Acceptance Group	Range (%)	Speaker						Sum of Sampel	Acceptance (%)
		S*1	S*2	S*3	S*4	S*5	S*6		
Good Acceptance	81-100	2	0	0	4	8	3	17	5.666666667
Fair Acceptance	61-80	18	20	23	24	18	32	135	45
Loosy Acceptance	41-60	30	30	26	21	23	14	144	48
Bad Acceptance	21-40	0	0	1	1	1	1	4	1.333333333
Verry bad Acceptance	1-20	0	0	0	0	0	0	0	0
Total								300	100

6. CONCLUSION

With 99% level of trust (α=0.01), the system yields the similarity of means of each group of object. Thus, the system has a good level of accurateness. It means, MFCC and HMM is a good "method" to be implemented for voice authentication.

The Author has categorized the result into two groups, the first one is accepted group (*good dan fair acceptance*) and

the other one is unaccepted group (*loosy, bad, dan very bad*), with each presentation are 50,667% and 49,33%.

The present study is still ongoing, which may include following further works. We can reduce noise and "optimize" the feature extraction including "eliminating the zero voice (wait signal)" to increase the acceptance rate in this method.

ABSTRACT

This paper discusses the design of the GSM authentication simulation and the process of GSM authentication suitable for the mobile station. The design uses triplet's authentication to generate SRes using Microcontroller AT 89S52.
The result shows that the process of GSM authentication with A3 algorithm using microcontroller AT 89S52 as computation data could be displayed through LCD (Liquid Crystal Display).

Keywords
GSM Authentication, A3 Algorithm, Microcontroller

1. INTRODUCTION

Information security is a principle problem for cable or wireless communication network. Security information system includes the network security, security of information and the physical/equipments itself.

For mobile phone applications, high security system is needed because the transmission media via air can be tapped or cloned by unwanted person [1]. To counter serious information leakage the security system must be well developed.

Commonly, the security system consists of authentication, integrity of information and identification [2]. For Global System for Mobile Communication (GSM), the security among others can be in the form of the authentication SIM card GSM.

This paper proposes a design of user authentication. The user authentication design can prevent the illegal user to enter the network.

Authentication is a procedure which is used to check the validity identity of GSM subscribers to access GSM network and to use all of the facilities offered by GSM networks.

GSM Authentication uses certain algorithm [3]. The A3 Algorithm is an authentication algorithm for security and safety of GSM, functioning to generate response which is known well as SRes (Signal Response) and answer from random challenge recognized as Rand. The design uses triplet's authentication to generate SRes using Microcontroller AT 89S52.

2. GSM AUTHENTICATION

The main functions of authentication process conducted by GSM are:

1. Protection of GSM Network from accessing effort by illegal user and with no authority.
2. Protecting the privacy of customers from accessing effort by unwanted party/intruder.
3. Protecting data, this is transmitted at radio band, by sub-system radio during the pursuance of communications relation.

If the mobile subscriber (MS) will access the GSM system, the system will check the identity of the MS. The system delivers or transmits RAND (Random Number) to be accepted by the MS. The Mobile Equipment (ME) than delivers the RAND to Subscriber Identity Module (SIM) card, which will process the random number by using Authentication Key (Ki) in the SIM card so that it will result in a signal respond SRES (Signal Response) based on RAND, Ki and Algorithm A3.

The MS then delivers the SRES to the system, and the system will compare this SRES with its own calculation result (SRES from system) and if the same result occurs, this means that the authentication process succeeds. On the contrary, if the authentication process fails, than the system will stop the contact and sends indication at the MS that the authentication failed. This system is expressed in Fig.1.

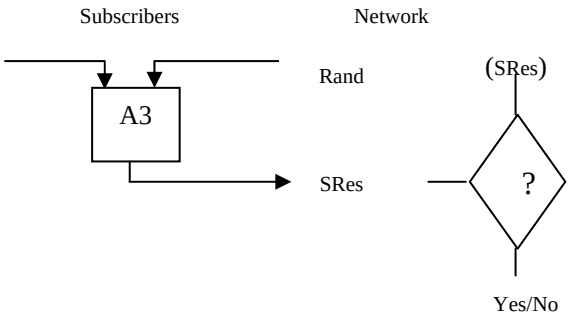

Figure 1: Elementary principle of authentication procedure at the GSM network.

During the execution of the authentication process, several procedures of signaling transfer occurs shown in Fig. 2 and explained as follow:

1. If MS accesses the GSM network by delivering signal (Request) to MSC (Mobile Service Switching Center) to be sent to VLR (Visitor Location Register), than the MS will be authenticated. The authentication process begins to be executed after the VLR accepts the MAP message from MSC.
2. If the MS is not recognized by VLR, than the VLR will ask the parameter authentication (triplets) from Home Location Register (HLR) or Authentication Center (AuC) or from previous VLR (from where the MS comes) by delivering message of authentication Information Request.
3. VLR then begins the execution of authentication procedure by delivering message authentication (Authentication Request) to MSC. This message contains the parameter of authentication RAND.

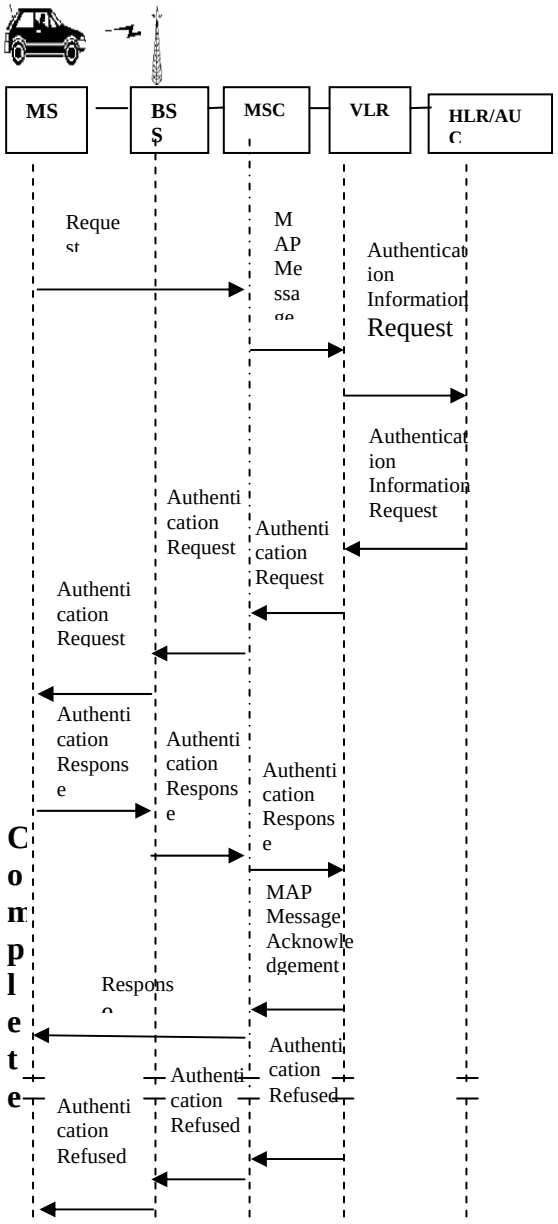

Figure 2: Signal transfer during authentication process [3]

4. The RAND authentication is sent to MS as message Authentication Request.
5. MS will respond by sending parameter SRes in the message Authentication Response. For the checking process of authentication SRes is sent to the message Authentication Response to VLR.
6. If the overall authentication process succeeds to be executed (complete), then the request (access) done by MS will be fulfilled, with the indication of the delivery signal (Response) from MSC to MS.
7. If the authentication process to MS failed to be executed, then the effort of accessing GSM network by the MS is refused/canceled (indicated with the message of Authentication Refused), followed with relation disconnection of communications

3. DESIGN OF GSM AUTHENTICATION SYSTEM

The design of GSM authentication system is shown in Fig. 3 and Fig. 4. Figure 3 represents the block diagram from the GSM authentication system.

Figure 3: Block diagram of GSM authentication system

The block diagram consists of Keypad, Power, Microcontroller and LCD. The system works as follow:

1. The power supply supplies the power for the microcontroller so that the microcontroller can operate properly. The communications between the power supply with the microcontroller is a one way communication. The microcontroller communicates with the simcard reader to take the Ki data, which will be read and computed with the rest of the data.
2. The Keypad with the microcontroller also has a one way communication relationship. The microcontroller receives instruction from the keypad such as the password and also the simulation of the data input. The Keypad also gives the command to be run by the microcontroller.
3. The LCD as the output from all of the process that happened receives all the input from the microcontroller. The LCD shows the data process processed by the microcontroller. Therefore, the communication between the LCD with microcontroller is also a one way communication.

Figure 4 shows the block diagram of the processing and transfer of data controlled by Microcontroller AT89S52.

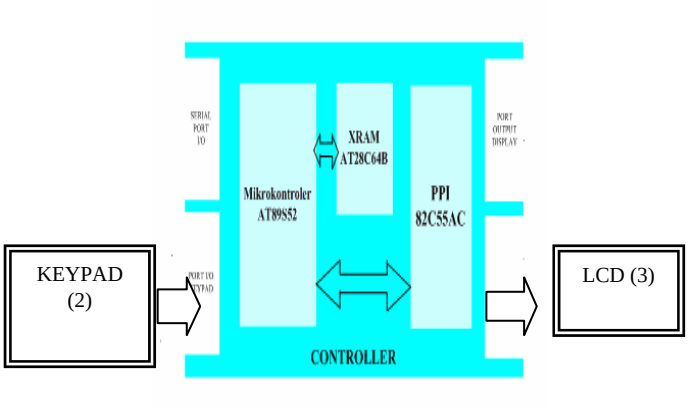

Figure 4: Block diagram system of processing and transfer of data Controlled by Microcontroller AT89S52

The block diagram works as follow:

1. The Keypad represents the part of I/O delivering signal pin to port PPI 82C55 and requires the address from the microcontroller to operate it. The PPI 82C55 address starts from 2000H to 3FFFH in the microcontroller.
2. The microcontroller delivers data to LCD as output display, and the LCD processes every input of command which is wanted to be shown from the microcontroller
3. The execution process can also be shown on the display monitor using the hyper terminal.

The main design of A3 algorithm is shown in Fig. 5. The input of the comparator is Rand which is a random number with maximal 128 bits and authentication key (Ki) which consists of maximal 128 bits. The input data will be compressed to 64 bits of Rand and 64 bits of Ki. Both input data will be XOR as a comparator function. This function is to prevent identical computational output.

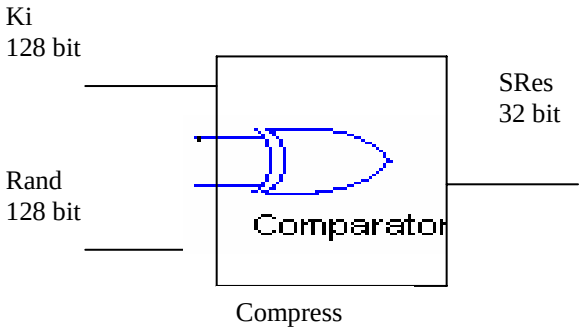

Fig 5 Design of A3 Algorithm

.

3.I Compress Data Value with Butterfly Structure

The input of the comparator which consists of 128 bits Ki and 128 bits Rand is compress using the butterfly structure. The butterfly structure is depicted in Fig.6.

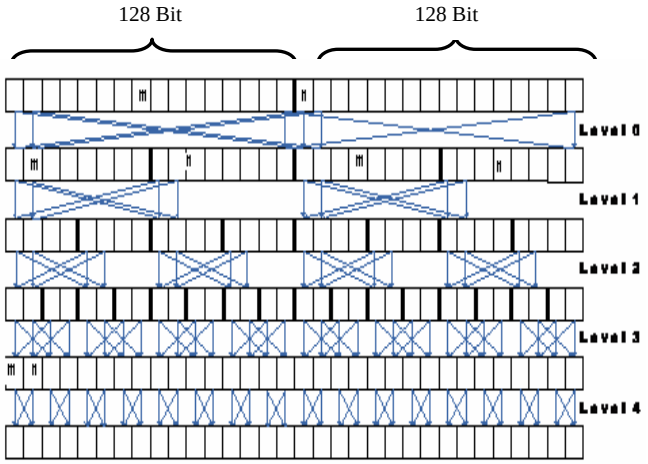

Figure 6: Compress data value using butterfly structure

The butterfly structure consists of 5 compression level. Each compression level produce bytes which is dependant of the previous input data bytes expressed as:

$$X=(Z[m]+2*Z[n])\bmod 2^{(9-j)} \quad (1)$$

$$Y=(2*Z[m]+Z[n])\bmod 2^{(9-j)} \quad (2)$$

Z [m] = T j [X] [m new result of look up table from element X]

Z [n] = T j [Y] [n new result of look up table from element Y]

Where:
Xn = Element X in level m
Yn = Element Y in level n
Z[m]/Z[n] = Matrix Z contains new value after Xm and Yn from previous computational result and substituted with the value from the authentication table.

This computational process is executed to five levels as shown in the butterfly structure.

3.2 Compress Data Capacities

The output of the data value compression process using the butterfly structure is changed into bit value per nibble. Therefore the output consists of 128 bits. The output compression data will be changed to bytes as shown in Fig. 7.

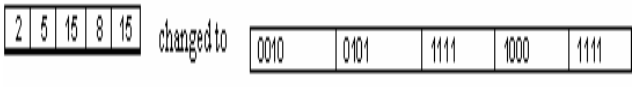

Fig. 7 Output value changed to Bytes

The butterfly which consists of 5 level compression changes bit to bytes (Data capacities compression 32 bytes becomes 8 byte) and than will form a matrix for permutation as shown in Fig.8.

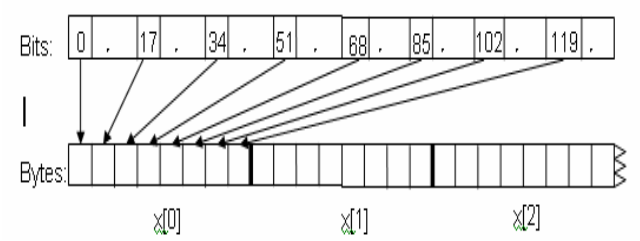

Figure 8: Change of bit to byte matrix permutation

Bits which are taken from Fig.8 goes to the final compression process (Data capacities compression 8 Byte becomes 4 Byte) with permutation process to create SRes as shown in Fig. 9.

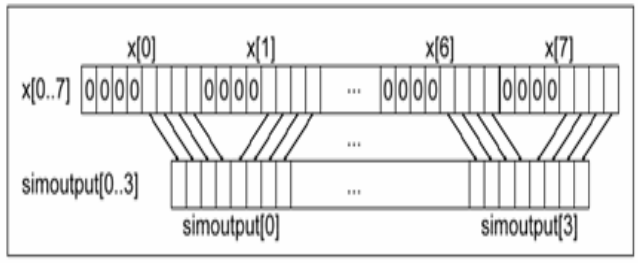

Figure 8: Change of matrix permutation to matrix value SRes

The output parameter of SRes matches the specification standard from ETSI.

4. SIMULATION RESULT AND ANALYISIS

The design of GSM authentication system is analyzed step by step in creating the SRes value.To verify the output value of SRes using A3 algorithm, the amount of SRes has to be 32 bit according to the ETSI specification standard.

Analyzing the important role of each step in the A3 algorithm to produce the SRes value of 32 bits, can be analyzed as follow:

- The data value 2^8 at the input is minimized to become 2^4 by using the butterfly structure
- The input capacities 32 bytes is compressed to become 8 byte
- The capacitiy of 8 bytes is compressed again to become 4 bytes.

The output released shows different byte values because the algorithm uses different inputs from previous level. If the output shows similar to the input that means the A3 algorithm does not work as preferred. This means that the A3 algorithm can not prevent illegal users to use the system because the authentication system does not work according to the A3 algorithm system.

Trial test was carried out to verify the design. The trial test shows if the output from customer's side is the same as the output from the network, the authentication process is achieved. In contrary, if the output from customer's side is not the same as the output from the network, then the authentication process is achieved.

5. CONCLUSION

Based on the simulation design of the authentication process, the design shows level of security and safety from the GSM authentication. The simulation design has worked based on A3 algorithm output as according to the ETSI specification standard.

ABSTRACT

This paper reports the computation of electro-osmotic flow (EOF) velocity using our own codes based on Matlab software by implementing finite element method (FEM) to solve the governing equations of EOF using an approach known as the Helmholtz-Smoluchowski (HS) approach. We also modify one equation of the approach so it takes into consideration the effects of electric field leakages through the channel walls using the differential form of Gauss's law and hence generalizing our method to include the cases of chips with inhomogeneous material composition. For simplicity, we only performed two-dimensional simulations with the assumption that our chip model consists of only a single and straight channel and the fluid material used to conduct the electroosmosis is salt (NaCl) solution. We then studied the relation between four physical parameters with the EOF velocity: (i) voltage difference across the channel, (ii) channel length, (iii) dielectric constant of the channel material, and (iv) salt concentration. The main conclusion of this paper is we managed to simulate the EOF using our own-built code based on Matlab software, which in this case is very cost-efficient (rather than using commercial software e.g. COMSOL).

Keywords:
Microfluidics, finite element method, electroosmosis, straight channels, simulation.

1. INTRODUCTION

Lab-on-a-chip (LOC) is new technology developed to enable the execution of the laboratory functions such as analyzing and controlling fluids, ions and other particles on a single chip of only millimeters to a few square centimeters in size.

LOC has a lot of advantages compared with the conventional laboratory:

1. Low consumption of fluid volumes, e.g. less than pico liters (10^{-12} liters).
2. Faster analysis and response times due to small volumes of the fluids and reagents required.
3. Massive parallelization due to compactness, which allows various processes to be executed simultaneously.
4. Portability of the chip, due to its size, which allows it to be carried out with ease.

Even though the LOC has many advantages, it also provides some difficulties and challenges:

1. It is a new technology and hence still need development in many areas.
2. Further study is required to investigate the physical effects in smaller scale, e.g. micro- and nano-scale, which are not the same as the physical effects in the larger scale, e.g. milli-scale.
3. As the scale of the channels becomes smaller, it becomes less practical to use hydrostatic pressure to control the flow, as it requires increasingly large pressure to control the flow in such a small scale.

This paper discusses one solution to the third problem, where electrodes (rather than pressure sources) are utilized to create electrostatic fields which are then used to direct and control the flow. The technique is called electroosmosis, while the resulting flow is named electro-osmotic flow (EOF).

In this paper, the EOF velocity is calculated by implementing a numerical technique called the finite element

method (FEM) to the governing equations of EOF using one approach known as the Helmholtz-Smoluchowski (HS) approach.

2. BASIC TERMS IN MICROFLUIDICS

Reynolds number is a dimensionless number which is used to differentiate between the laminar or turbulent flow. It is defined as *inertial forces/viscous forces* [1]. High and low Reynolds number, respectively, represent the turbulent flow and the laminar flow.

Electric double layer (EDL) is a layer formed when an electrolyte is brought in contact with a solid surface. It consists of two layers, i.e. Stern and Diffuse layers, and has a thickness defined by the so-called Debye length, λ_D. The Stern layer is a fixed layer, usually only one ion wide, whereas the diffuse layer is a mobile layer which can be set in motion upon the application of an external electric field. The Stern and diffuse layer are separated by the Shear Plane whose potential is called the ζ potential.

Electroosmosis is the movement of ionized fluid in a capillary tube or microchannel when an external electric field is applied parallel to the surface.

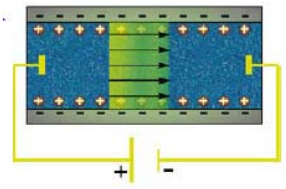

Fig. 1 The EOF in a microchannel [2]

3. THE HS APPROACH

The Helmholtz-Smoluchowski (HS) approach is an approach to calculate the EOF velocity based on the assumptions: (i) The EDLs thickness is very thin compared to the channel dimensions, e.g. channel height, and hence the EDLs do not overlap with each other, (ii) Low Reynolds number, i.e. steady flow, and (iii) no pressure gradient is applied across the channel [3].

The HS approach uses three equations, i.e. the differential form of Gauss's law (DFGL) defined by

$$\partial_x\left(\varepsilon_m\,\partial_x\phi(x,y)\right)+\partial_y\left(\varepsilon_m\,\partial_y\phi(x,y)\right)=0 \qquad (1)$$

to calculate the electric potential distribution, ϕ, and the HS equation defined by

$$\vec{u}_{eo}(x,y)=\left(-\frac{\varepsilon_S}{\mu}\zeta\right)\vec{E}(x,y)=\alpha_{eo}\vec{E}(x,y), \qquad (2)$$

to calculate the EOF velocity, $\vec{u}_{eo}$, where ε_m is the permittivity of the channel material, ε_s is the permittivity of the electrolyte solution, μ is the viscosity of the electrolyte solution, $\vec{E}$ is the electric field in the channel while the x and y coordinate, respectively, correspond to the 2-D channel geometrical coordinates. The electric field, $\vec{E}$, in Eq. (2) can be derived from the electric potential, ϕ, in Eq. (1) using the relation $\vec{E}=-\nabla\phi$, which is modified for the 2-dimensional case.

4. GEOMETRIC DESCRIPTION OF THE MICROFLUIDIC CHIP UNDER STUDY

The 2-dimensional geometry of the microfluidic chip is given below.

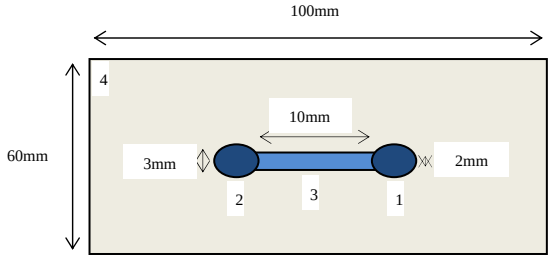

Fig. 2 The geometry of the microfluidic chip (see text for details on the number notations)

Details:

1. The chip consists of only a single and straight channel with two wells, i.e. the input and output wells, respectively, labeled as '1' and '2' in Fig. 2. Label '3' represents the channel while label '4' represents the other areas of the chip.
2. The chip is made of *polymethyl methacrylate* (PMMA), which is also known commonly as acrylic.
3. The channel is placed exactly in the middle of the chip both in the horizontal and vertical direction.

5. FEM IMPLEMENTATION OF THE DFGL

The FEM used is the Galerkin method [4], which is initiated by taking the weak formulation of the equation to be solved. The weak form of Eq. (1) is

$$\int_\Omega\left(\partial_x\left(\varepsilon_m\,\partial_x\phi\right)+\partial_y\left(\varepsilon_m\partial_y\phi\right)\right)w\,d\Omega=0, \qquad (3)$$

where Ω is the whole problem domain and w is a test function, i.e. an arbitrary chosen function whose values are not zero. As seen in Fig. 2, Ω can be divided to two sub-domains, i.e. sub-domain inside the channel, Ω_1, and sub-domain outside the channel, Ω_2, each having its own permittivity denoted respectively as ε_{m1} and ε_{m2}. The zero Neumann boundary condition (ZNBC), i.e. $\partial_n\phi=0$, is also imposed as the boundary condition for the outermost boundary in Fig. 2, i.e. all four sides of the rectangle. This means, physically, that the chip is insulated electrically, i.e.

no electric potential flux at the chip boundary [3]. Hence, Eq. (3) becomes

$$\int_{\Omega_1} \varepsilon_{m1} \left(\partial_x \phi \partial_x w + \partial_y \phi \partial_y w \right) d\Omega + \int_{\Omega_2} \varepsilon_{m2} \left(\partial_x \phi \partial_x w + \partial_y \phi \partial_y w \right) d\Omega = 0 \quad (4)$$

The next step is to replace ϕ with its two-dimensional finite elements approximation, where the three-node triangular elements are chosen. Using the derivation in [5], the discretized form of Eq. (4) is

$$[G]_{n \times n} [\phi]_{n \times 1} = [0]_{n \times 1}, \quad (5)$$

where $[G]$ is the global matrix defined as in [5], $[\phi]$ is the electric potential vector, $[0]$ is a zero vector, and n is the number of nodes in the domain discretization. The matrix system in Eq. (5) is then arranged using the method in [5], which then can be solved using the direct solver in Matlab.

6. DESCRIPTION OF THE SIMULATION PARAMETERS

There are 3 observation points in the simulation, i.e. a point near the channel's inlet, a point in the middle of the channel, and a point near the channel's outlet. The location of each point is shown in Fig. 3.

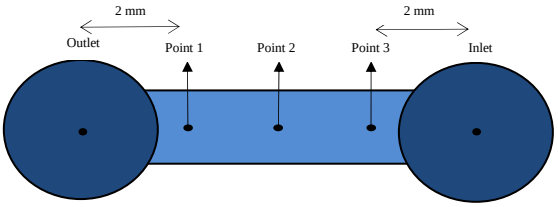

Fig. 3. Location of observation points in the channel geometry

6.1. Voltage Difference

The voltage difference across the channel is produced by the electrodes placed at the channel wells, i.e. circular-shaped electrodes with a diameter of 1mm is placed in the middle of each well. In the simulation, it is assumed that the electrode at the channel outlet connects to the electrical ground (0V) whereas the other electrode connects to positive electric potential. The variation of voltage difference ranges from 10V to 190 V with interval of 20 V.

6.2. Channel Length

The variation of channel length is as follows: 11 mm, 12 mm until 18 mm with the interval of 1.5 mm, 19 mm, and 20 mm until 95 mm with the interval of 5 mm.

6.3. Dielectric Constant

In addition to acrylic (PMMA), other polymer materials such as *poly dimethyl siloxane* (PDMS), *polycarbonate* (PC), *nylon* and *poly tetra fluoro ethylene* (PTFE or Teflon) are used in the simulation. Many of these materials are currently used for microchip fabrication [6]. The dielectric constant values for each polymer are as follows: (i) PTFE = 2.0, (ii) PDMS = 2.5, (iii) PC = 3.0, (iv) PMMA = 3.5, and (v) Nylon = 4.5.

6.4. Salt Concentration

Salt concentration, M, is a measure of the amount of NaCl molecules in water solution. In this paper, the concentration is replaced by the concentration variable defined by

$$pC = -\log M, \quad (6)$$

where M unit is in Molar. The pC serves as a useful normalization for the ζ potential on polymer substrates in contact with indifferent univalent counter-ions [6]. The relation of pC with the ζ potential can be approximately fitted to a linear relation, which can be found in [6]. The pC values from 1 until 4 with the interval of 0.5 are used in the simulation.

7. SIMULATION RESULTS

7.1 Electric Potential Distribution

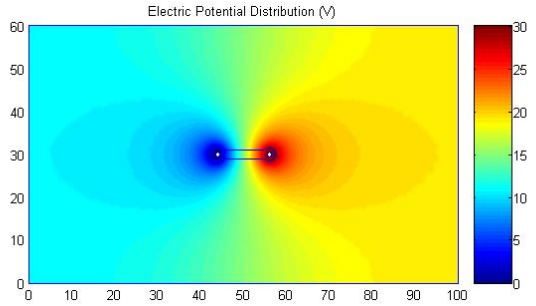

Fig. 4. Simulation result of electric potential distribution

Data for the simulation are as follows:

- Number of triangular elements = 75392
- Number of nodes = 37887
- Voltage difference = 30 V
- ε_s (NaCl solution) = 78.4 ε_0 (inside the channel)
- ε_m (PMMA) = 3.5 ε_0 (outside the channel)
- Boundary locations = 42.5 mm from the leftmost side and rightmost side of the channel and 28 mm from the uppermost side and lowermost side of the channel

Note: ε_0 is the permittivity of vacuum or free space.

In Fig. 4, it can be shown that the electric potential distribution in the chip model is symmetric vertically due to the symmetry of the chip geometry and the imposing of ZNBC.

7.2. Electric Field Distribution

Fig. 5 shows that the magnitude of electric field far away from the channel is zero. This phenomenon is a result of electric field confinement in the chip due to the imposing of ZNBC. Moreover, it can also be shown from Fig. 5 that there is electric field leakage through the channel. This electric field leakage is a result of the application of the DFGL as the governing equation for the electric potential distribution.

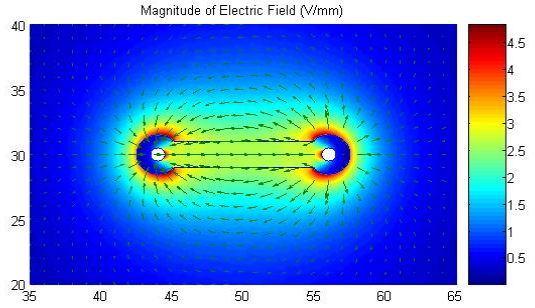

Fig. 5. Simulation result of electric field distribution

8. ANALYSIS AND DISCUSSIONS

In this section, the EOF velocity data in the simulation obtained from the points of interest mentioned previously are discussed. The EOF velocity is calculated using the parameters as follows, unless stated otherwise:

- ζ = -30 mV
- ε_0 = 8.854 × 10^{-12} kg^{-1} m^{-3} s^4 A^2
- μ = 8.9 ×10^{-4} kg m^{-1} s^{-1}

8.1. Variation of Voltage Difference

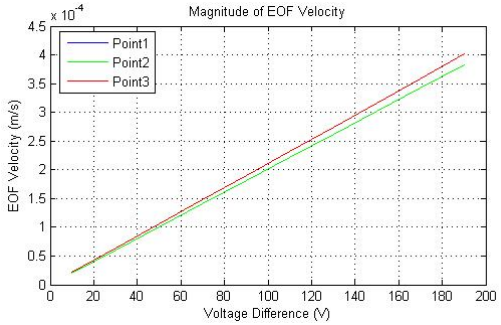

Fig. 6. Curves of magnitude of EOF velocity with variation of voltage difference

In Fig. 6, it can be shown that the magnitude of EOF velocity has a linear relationship with the variation of voltage difference. The order of EOF velocity in the figure ranges from □ 10^{-5} m/s to □ 10^{-4} m/s, which is in accordance to the order of velocity in [1]. This fact indicates that the data in the figure are quantitatively correct.

Another observation reveals that the EOF velocity at Point 1 (near the channel outlet) is equal to the velocity at Point 3 (near the channel inlet). This characteristic indicates that the distribution of magnitude of EOF velocity in the channel is symmetric horizontally due to the symmetry of the channel geometry.

Analyzing the curves quantitatively further shows that for a particular voltage difference, the magnitude of EOF velocity at Point 2 (in the middle of the channel) is a bit smaller than the velocity at Point 1 and Point 3. Thus it can be concluded that the trend of magnitude of EOF velocity observed from the channel inlet is as follows: it has the maximum value near the channel inlet and then continues to decrease until it reaches a minimum value in the middle of channel, and afterwards, it continues to increase until it reaches its maximum value again near the channel outlet.

The linear relation between the EOF velocity and the variation of voltage difference can be deduced from Eq. (2), where the magnitude of electric field can be approximated as

$$|E| \approx \frac{\Delta\phi}{\Delta d}, \qquad (7)$$

where $\Delta\phi$ is the change in the voltage difference across the channel and Δd is the change in the distance between the two electrodes in the channel.

8.2. Variation of Channel Length

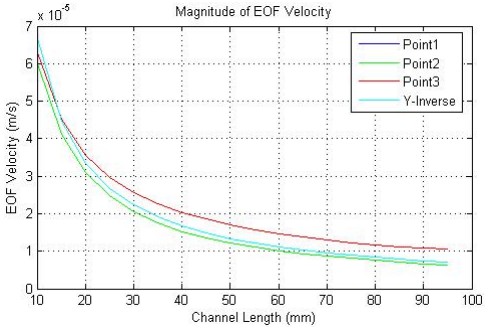

Fig. 7. Curves of magnitude of EOF velocity with variation of channel length

In Fig. 7, it can be shown that the relation of EOF velocity with the variation of channel length is not linear. From Eqs. (2) and (7), it is known that an inverse function defined by $u_{eo} = c / x_L$, should be able to fit the data. Here, u_{eo} is the EOF velocity, c is an arbitrary constant, and x_L is the channel length. Using the trial and error method, it can be known that the value of c is about 6.7×10^{-4}.

Another interesting phenomenon to be observed is that the curves move towards a saturation point, i.e. the point at which the EOF velocity does not change regardless of further extension of the channel length. It can be inferred

from Fig. 7 that the curves saturate when the channel length reaches approximately 100 mm.

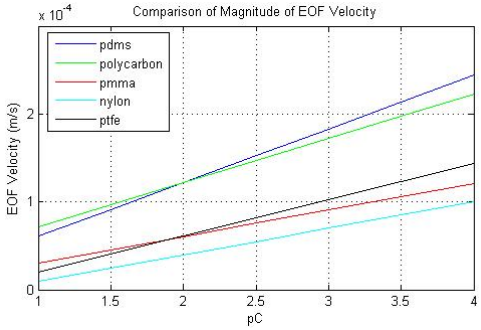

Fig. 8. Curves of magnitude of EOF velocity at Point 2 for various chip material with variation of variable concentration

8.3. Variation of Dielectric Constant and Salt Concentration

It can be shown from Fig. 8 that the relation of EOF velocity with the variation of concentration variable, pC, is linear. The relation can be derived analytically by combining Eq. (2) with the relation of ζ potential and pC in [6]. Therefore, the EOF velocity can be concluded to have linear relationship (indirectly) with pC, and due to Eq. (6), it is also proportional to the negative logarithm of the salt concentration, $-\log M$.

9. CONCLUSIONS

Based on the discussed analyses, it can be concluded that the EOF velocity is:

1. linearly proportional to the variation of voltage difference across the channel.
2. inversely proportional to the variation of channel length.
3. linearly proportional to variation of concentration variable, pC, or proportional to the variation of negative logarithm of salt concentration in the fluid, $-\log M$.

In this work, we also successfully use our own Matlab code, rather than commercial software (e.g. COMSOL) that may not always be cost efficient for research in Indonesia, to simulate the electric field leakage in the channel, which represents a practical and important phenomenon in LOC applications.

ABSTRACT

Part of Cuk converter Slobodan, was modified with toroid core, which was used as the controller of the ripple current and load, in watt-meter. So the watt-meter could measure the active, reactive power and power factor. And the result of measurement could be transmitted to the receiver. In order to solve this problem, the real toroid with some models of air gap, surface material must have chosen, to find a better one, and then use the approachment methods from magnetic circuit to electric circuit.

Modified Cuk converter with RLC loads and ripple current around less than 1% has a good geometry of core toroid in Cuk converter Slobodan. The twisted coil winding could be reduce the frequencies, so the ripple current become lower and increase the efficiency.

Toroid core as magnetic circuit could be calculated as approachment method applied to electric circuit where the matterial could be generate the source like air gap, and the real sources coil winding in primary and secondary. Modification conductor in coil winding in primary and scondary was fifty degrees twisted. The Twist could minimize the ripple from 3.2% become 0.21%.

Keywords

Toroid core, Cuk converter, air gap, surface of conductor, low ripple and high frequency.

1. INTRODUCTION

In nano technology era, all devices become smaller, more compact, higher efficiency, lower in ripples and automatically controlled. Cuk Slobodan converter was always used in any system such as in automotive technology, electrical measurement, sound system, home theatre, and etc., but the real of Cuk Slobodan converter has ripple around 30%. In better system, like in industrial applications, the chemical coloring only allowed the ripple current around 3%.

Special design of toroid transformer for winding, shape, material and size with higher permeability could increase the efficiency and minimize the ripple. The good material air gap with low losses could increase the potential as gyrator capacitor. The core magnetic as inductor, capacitor and resistor, as equivalent capacitor and the winding as generated magnetomotance or Gyrator which is control the variable load as variable voltage control current source VVCS or curent controlled voltage source CCVS if the load has variable R,L and C. All of them could be reduce the ripple until 0.3 % and can generate the frequencies become KHz, with paralleling the material like two port and twisted more than one conductor. The winding could increase the frecuencies about GHz. [1]

Before twisted with the radius of conductor about r = 4.10^{-4} m, 8.10^{-4} m, 16.10^{-4} m has efficiences about 3.2 %, 4.3 %, 5% and after twisted be come 81 %, 85 %, 92 %

The output rippel current of Cuk converter where the inductance are 3 μH, 2.27 μH, and 1.83 μH before modification coil winding about 2.5 %, 1.6 %, 1.2 % after modification with twisted about 2.1 %, 1.2 % and 0.98 %, with toroid core become 98 %.

Gyrator capacitor which are increase the energy, could be minimise the losses [2] could be controlled the variable load RL and C .

2. GYRATOR CAPACITOR

Gyrator [3] as generate the voltage as two port could be increase the current source as hybrid circuit like Figure 1.

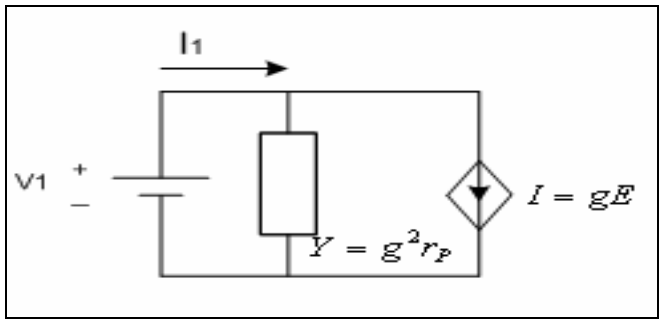

Figure 1: Gyrator as Voltage control current source.

From figure 1, the electric circuit is

$$i_a = V_s g^2 r_P + gE \quad (1)$$

And the gyrator load is

$$i_a = gV_s \quad (2)$$

Where:

r_p	:	The inner resistive.
i_a	:	Load current
i_s	:	Current source
g	:	Conductor of Gyrator.
i_{sc}	:	The short circuit current
RL	:	Resistance load

The sensitivity of current source with voltage system:

$$S_{V_S}^{i_S} \to 0$$

$$S_{E}^{i_S} \to 1$$

$$S_{g}^{i_S} \to 1 \quad (3)$$

3. CAPACITOR

The capacitor, as storage device has loading electricity, it takes from permanent magnetic air gap [4] which is depend on the material, circular mill, the long of magnet permanent, and permeability of magnetic permanent, if the force depend on reluctance it's hybrid of the electric as for hybrid parameter given by

$I_1 = g_{11}V_1 + g_{12}I_2$

$V_2 = g_{21}V_1 + g_{22}I_2 \quad (4)$

The equivalence magnetic circuit to electricity from equation 3 is showed in table 1. From the capacitance of magnetic circuit such as the twisted winding was taken from skin effect of current conductor.

4. DESIGN OF THE TOROIDAL CORE

The design for any type of air gap and the core of toroidal with the twisted conductor, in primary and scondary coil winding, with the angle of twisted, could reduce the qualities and efficiency. For the first step, the inductance of cunductor must be taken from the lentgh, radius, circular mill, resistivity the material of coil winding conductor where the data length of conductor are $l_1 = l_2 = 3$ m, for one conductor which is change with two conductor, $r_1 = r2 = 8.10^{-4}$, 4.10^{-4} , or 16.10^{-4} m, so it could calculated of the effective long l_{1e} wire gauge. The long efective coil winding in primary and scondary l_{1e} are : 1 - 2.7 m, so it could fixing some parameters [5] :

- the length of $l_e = l \cos(\beta/2)$,
- Where $\beta = 50^0$,
- $l_{1e} = 3\cos(50^0/2) = 3 \times 0.9 = 2.7$,
- resistivity of Cu, $\rho = 1.72.10^{-8}$ ohm/m,
- permeability of air $\mu_0 = 4\pi^7$ weber/amp,
- frequencies f = 25 KHz,
- conductivities $\sigma = 5.8.10^7$ Ω/m,

so the coupling could be calculated

$$k_1 = r\sqrt{\omega.\mu_0.\pi/2\rho}$$

$$k_1 = 1{,}7 \quad (5)$$

The efficiency will depend on the resistance DC of magnetic circuit toroidal from the modify coil winding

$R_{D\,1} = \rho\, l_1/(\pi\, r_) = 0.1$ Ohm,

Where the resistance DC is as resistance of Gyrator R_G.

Coupling factor in primary winding is alternating current AC resistance R_{A1}, which is depend on the coupling factor. Because of coupling factor in primary K_1 is bigger or equal than 1, the AC resistance AC RA1:

$R_{A1} = R_{D1}\,[(1/4) + k_1 + (1/64)(1/k_1^3)] = 0{,}19\ \Omega$ so

The self inductance in wire gauge primary coil winding L_{i1}:

$L_{i1} = (\mu_0.l_1/2).[(1/k_1) - (1/64)(1/k_1^3)] = 1{,}09\ \mu H$

The mutual inductance M because $l_{1e} \le l_2$,

$M = (\mu_0/2\pi).l_{1e}.\{\log[2.l_{2e}/(r_1+r_2)] - 1 = 1{,}53\ \mu H$

Inductance on in primary in AC L_1,

$L_1 = L_{i1} + (\mu_0/2\pi)l_1.\{\log[2l_1/r_1] - 1\} = 3\ \mu H$

So it cold be calculate the new efficiency

$$\eta = (R_L.M^2.w^2)/\sqrt{\left[L_1L_2w^2 - M^2w^2 - R_{A1}(R_L + R_{A2})\right]^2} + \sqrt{\left[L_1w(R_l + R_{A2} + R_{A1}L_2w\right]^2\left[(L_2w)^2 + (R_L + R_{A2})^2\right]}\cos\phi_1 \quad (6)$$

5. DISCUSSION

For the first condition where's the original Cuk konverter have big rippel like showed in Figure 2.

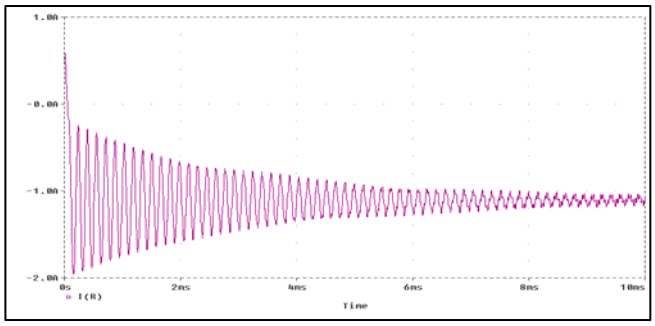

Figure 2: The Output ripple current of Cuk convertor Slobodan.

In figure 2 the output ripple current of Cuk converter Slobodan before the modification is more than 30 %.

After reduced with any component like one inductor coventional with two inductor but still the result was not

ISSN 114-1284

reduce the ripple current. After that, two Inductors changed with a special transformator torroidal design. The first is show the capacitance approachment like in Figure 3.

From the new parameter and the result of data input calculation in Pspice simulator software, it is found that the performance of toroidal capacitance is going better. So it will show any capacitance approachment in one shape toroidal.

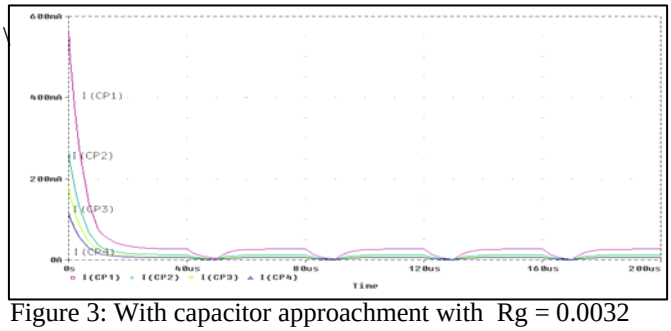

Figure 3: With capacitor approachment with Rg = 0.0032

With some variable, resistance of gyrator depend on the size of toroid shape and air gap. the smaller resistance of gyrator would make the smaller ripple current graphic as shown in figure 4.

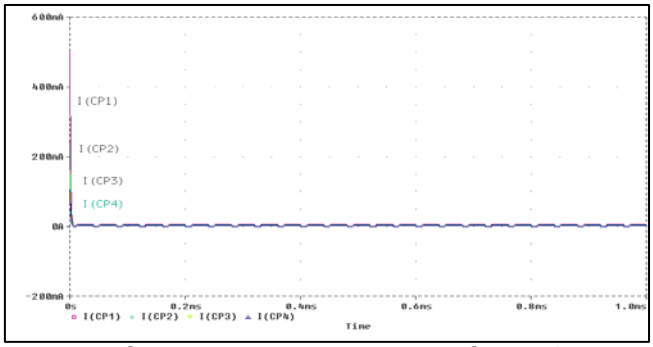

Figure 4: The current capacitance approachment (I_{CP1}, I_{CP2}, I_{CP3}, I_{CP4}) Vs Gyrator resistan R_G = 0.0064 Ohm

In figure 4 the current capacitor approachment, looks like more stable and the ripple is smaller. In condition of RL and C loading (I_{CP1}, I_{CP2}, I_{CP3}, I_{CP4}) vs. R_G =0.0012 ohm. The ripple current is shown in Figure 5.

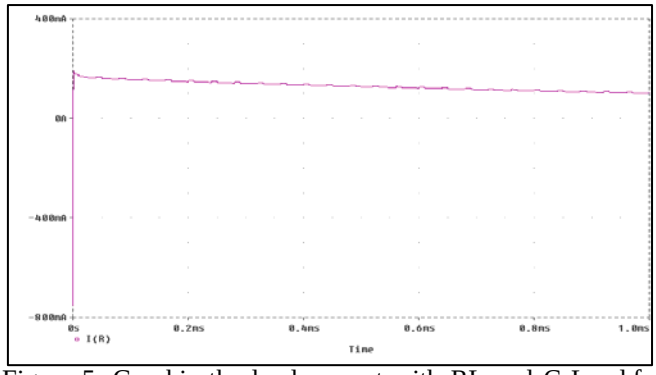

Figure 5: Graphic the load current with RL and C Load.for resistan Gyrator = 0.0012 Ohm.

The polygon curves introduce the output ripple current in twisted moment and the twisted chart is shown in figure 6.

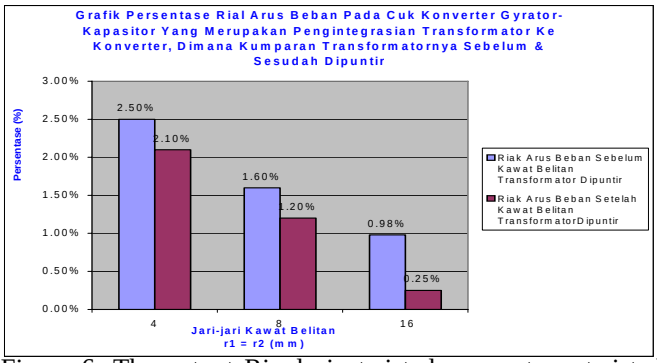

Figure 6: The output Ripple in twisted moment vs. twisted coil winding.

The polygon curve explains the current output of ripple current for the twisted is minimized the ripple current output.

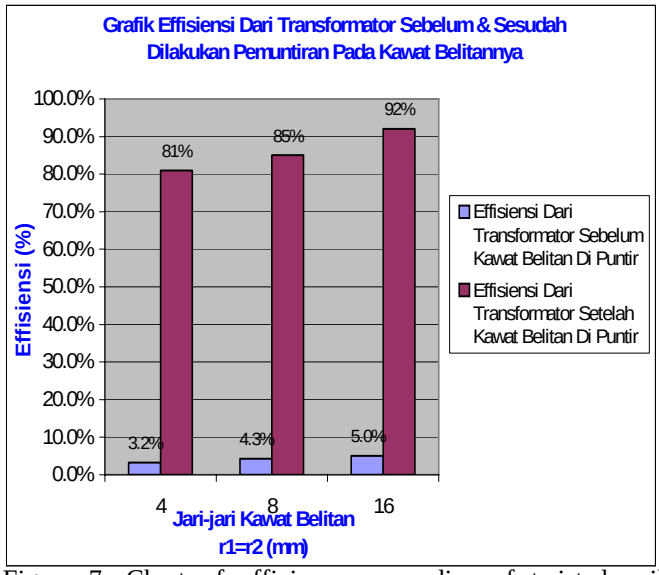

Figure 7: Chart of efficiency vs. radius of twisted coil winding.

In figure 7 the efficiency the cu coil winding after twisted and before twisted. The efficiency is higher when the twisted coil winding.

6. CONCLUSION

The size of toroid core as variable resistance of Gyrator, is causing the less of resistor Gyrator which have lower ripple current and higher efficiency.

ABSTRACT

Hybrid power plants based on diesel generator and renewable energy sources, like photovoltaic and wind energy, are an effective option to solve the power-supply problem for remote and isolated areas far from the grids

HOMER, a micropower optimization modeling software is used to analyze data for both wind speed and solar radiation in Sebesi Island. The software optimize the system configuration of the hybrid system by calculating energy balance on an hourly basis for each of the yearly 8760 hours, simulating system configurations at once and rank them according to its net present cost [1]. In this paper, configuration design optimization of the hybrid system is analyzed to fulfill the electricity demand in Sebesi Island taken into account the issue of CO_2 emission reduction due to utilization of fossil fuel during diesel generator operation.

Optimization is done with three conditions, a first condition with 2 diesel generating unit 40 kW and 50 kW each, second condition a hybrid system with 25% maximum renewable fraction and a third condition a hybrid system with more than 25% minimum renewable fraction. The result obtained for the PV - wind - diesel hybrid are with 30% renewable fraction : 25% reduced CO_2 emissions or 48 ton / year or 25% from the first condition with 2 diesel generating unit, and the cost of electricity is the highest at $ 0,786 per kWh, the net present cost of $ 1.503.710, the initial capital cost of $ 738.010 and excess power reaching 85.212 kWh or 31.4%.

Key words: *Simulation, Hybrid Power Plant, Renewable fraction, Cost of Electricity, CO_2 emission*

1. INTRODUCTION

The Sebesi island is located south of Lampung Bay with 5° 55 '37.43 "- 5° 58'44, 48" latitude and 105° 27' 30.50 "- 105° 30 '47.54" longitude , close to the Krakatau islands. Administratively, this island is located in the Tejang Village Sebesi Island, Rajabasa Subdistrict, South Lampung Regency. The region consists of 4 (four) villages : Regahan Lada, Inpres, Tejang, and Segenom. The island covers a total area of 2620 ha and is inhabited by more than 2500 people, living mostly on agricultural products and fisheries. The island with a coastlines of 19.5 km has enough resources such as mangrove, the yet, and coral reefs [2].

It is a beauty islands located close to the Krakatau islands making it a tourist destination after the Krakatau islands. Unfortunately, potential tourism island is not supported by sufficient facilities by the local government, such as electricity. Nowadays the island get electricity only at night for about eight hours from 16.00 afternoon until 00.00 at night with a peak load of 49 kW which is supplied by two diesel generators with an installed capacity of 40 kW and 50 kW each.

In this study the electrical demand of the island will be analyzed using 2 units of diesel generating sets of 40 kW and 50 kW as first condition, and comparing them with the optimized hybrid system using HOMER software. Also analyzing CO_2 emissions, cost of electricity, and excess electricity of the system.

2. THE HYBRID SYSTEM AND ITS COMPONENTS

The hybrid system consists of two diesel generators 40 kW, 50 kW each, a photovoltaic array of 60 WP, a 7,5 kW wind turbine, a battery and an inverter. Figure 1 shows the hybrid system .

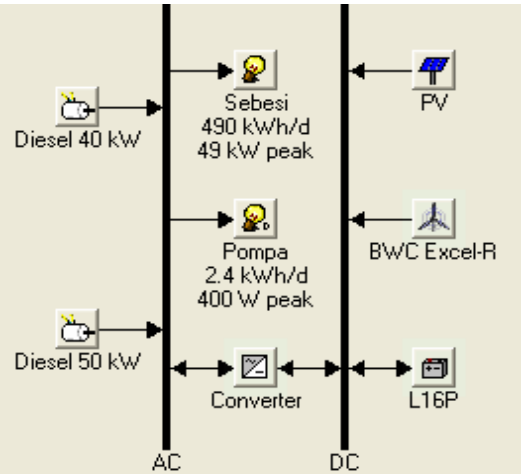

Figure 1. The Hybrid System

The hybrid system is simulated by three conditions, the first condition using 40 kW and 50 kW diesel, second condition a hybrid system with 25% maximum renewable fraction and a third condition a hybrid system with more than 25% minimum renewable fraction. All conditions are simulated with fixed load, wind speeds between 3 m/s - 7 m/s, fuel price between 0.4 – 1.0 $/l. Project lifetime of the system is 25 years, interest rate is 8%, the dispatch strategy is cycle charging and the generators are allowed to operate under the peak load.

3.1 The Load Demand

The load demand consists of 2 types, namely:

3.1.1 Primary Load

The electricity is consumpted majorly for household lighting, television and others. The daily average load on the island is about 490 kWh/day with 49 kW peak load from 19.00 till 20.00 o'clock.

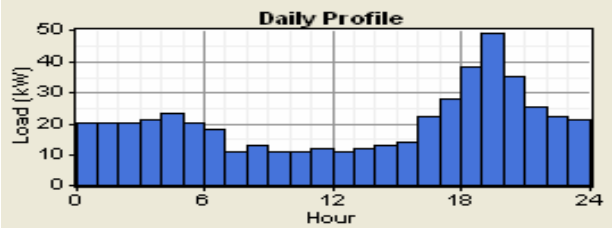

Figure 2. The Daily Load Profile of Sebesi Island [3]

3.1.2 Deferrable Load

A water pump of 400 Watts power has to be operated 6 hours per day to fill a fresh water tank designed to have a storage capacity of two days demand. So, there will be a 2.4 kWh/day average deferrable load or 4.8 kWh for two days storage. The minimum load ratio is 50%. Figure 3. shows the deferrable load of the water pump.

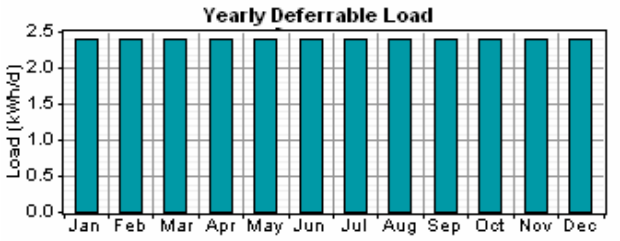

Figure 3. The yearly Deferrable Load of the Water Pump[4]

3.2 Wind turbines

The wind turbine used in this system is a 7.5 kW DC, 20 meter hub height, and a project lifetime of 15 years. Initial capital cost of the 7.5 kW wind turbine is $ 27.170, replacement cost $ 19.950, operation and maintenance cost is $ 1.000 a year

The HOMER software need the wind speed data to optimize the hybrid power plant. The following figure is the average wind speed data in Sebesi island, measured at 10 meters height.

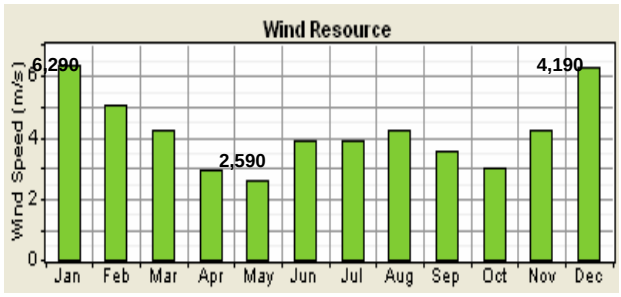

Figure 4. Wind Speeds on the Sebesi Island [5]

3.3 Photovoltaic Modules

The PV module used in this hybrid power plant has a maximum power of 60 Watt Peak (WP). The module derating factor is 90%, at a slope of 5.92 degrees, 180 degrees of azimuth, a ground reflectance of 20%, and a project lifetime of 25 years without tracking. The Initial capital cost for the 12 kW PV module is $ 66,000, replacement cost is $ 66,000 with no operating and maintenance costs.

To optimize the performance of the hybrid system, the software also needs yearly clearness index and daily radiation (kWh/m^2/day) data at the island. The yearly average clearness index is 0,477 and the daily average

radiation is 4,761 kWh/m^2/day. In figure 5 the clearness index and daily radiation data of the island is shown.

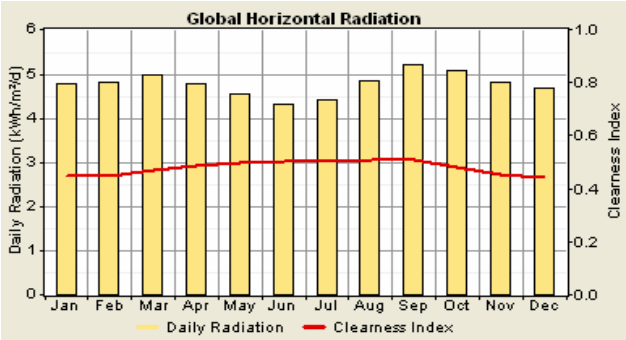

Figure 5. The yearly clearness index and daily radiation of Sebesi island [5]

3.4 The Diesel Generator

Two units of diesel generator is used in the hybrid system with an installed capacity of 40 kW and 50 kW each. The operating hour for each diesel generator is estimated to be 15,000 hours with a minimum load ratio of 30%. The 40 kW diesel generators has initial capital costs of $ 22,000, a replacement cost of $ 18,000, an daily operation and maintenance cost of $ 0.5. While the 50 kW diesel generators have an initial capital costs $ 27,000, a replacement cost $ 22,000, and an daily operation and maintenance cost of $ 0.5.

3.5 The Battery System

The hybrid system is designed to use lead acid batteries with nominal voltage of 6 V, a nominal capacity of 360 Ah, an initial capital cost of $ 620, a replacement cost of $ 620 and a 50 $ yearly operation and maintenance cost.

3.6 The Inverter

A bidirectional inverter (rectifier-inverter) is used in this hybrid system with a 90 % inverter efficiency, and a lifetime of 10 years. The rectifier has efficiency 85% relative to the inverter capacity of 100%. The 8 kW bidirectional inverter has an initial capital cost of $ 5960, replacement cost of $ 5,960 and an yearly operating and maintenance cost of $ 596.

4 CALCULATION OF THE HYBRID SYSTEM DESIGN

4.1 Calculation of the PV Array Power Output

The software uses the following equation to calculate the power output of the PV array:

$$P_{PV} = Y_{PV} f_{PV} \left[\frac{\overline{G}_T}{\overline{G}_{T,STC}} \right] \left[1 + \alpha_p \left(T_c - T_{c,STC} \right) \right]$$

where:

Y_{PV} is the rated capacity of the PV array, meaning its power output under standard test conditions [kW]

f_{PV} is the PV derating factor [%]

$\overline{G}_T$ is the solar radiation incident on the PV array in the current time step [kW/m2]

$\overline{G}_{T,STC}$ is the incident radiation at standard test conditions [1 kW/m^2]

α_p is the temperature coefficient of power [%/°C]

T_c is the PV cell temperature in the current time step [°C]

$T_{c,STC}$ is the PV cell temperature under standard test conditions [25 °C]

5. SIMULATION RESULTS

Different results of simulation and optimization are using the software in accordance to its minimum renewable fraction.

The result of simulation and optimization of the first condition using two diesel generating units of 40 kW and 50 kW are the cost of electricity (COE) of 0,510 $/kWh, an excess of electricity of 0.01% and CO_2 emission of 191 ton/year.

Figure 6 is shows the load demand supplied by two diesel generator of 40 kW and 50 kW.

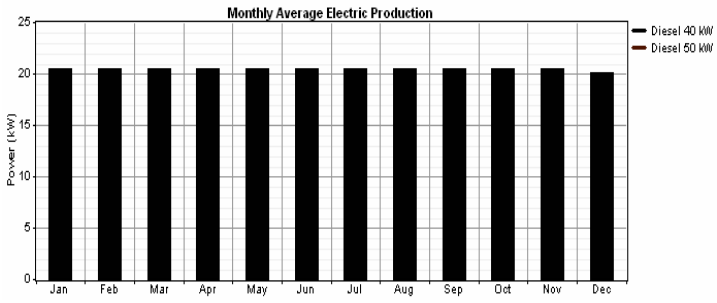

Figure 6. Supply of Load Demand by 40 kW and 50 kW diesel generators

In the second condition the minimum renewable fraction is 0%, the configuration of the hybrid system consist of 1 diesel generating unit – photovoltaic modules (PV) - wind turbines without battery. The results are as follows: for PV - diesel having 0,515 $/kWh of COE, excess electricity is 1.202 kWh/year or 0.66%, and the CO_2 emission is 188 ton/year. For wind - PV - diesel having COE 0,496 $/kWh, excess of electricity is 2.288 kWh/year or 1.24%, and the CO_2 emission is 173 ton/year.

The load demand is supplied by the hybrid system consisting of 82% by diesel generating unit, 3% by PV and 15% by wind turbine.

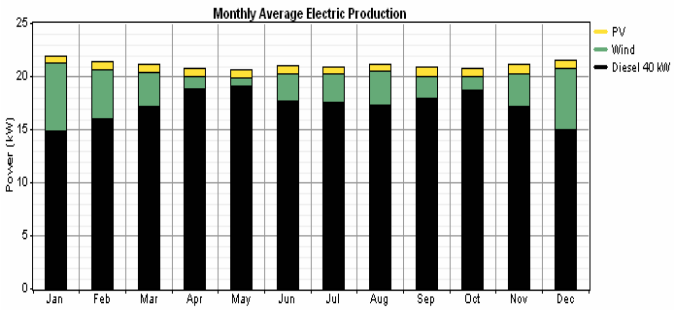

Figure 7. Supply of load demand by diesel, PV, and wind turbine with a maximum renewable fraction of 25%

When the hybrid system is simulated and optimized with 25% of maximum renewable fraction, the CO_2, SOx decrease caused by reduction of fuel consumption of the diesel generating unit. In figure 8, the blue line is the CO_2 emission and the pink line is the SOx. If the renewable fraction is 0% the CO_2 emission is 192 tons/year. CO_2 emission become 174 tons/year if the renewable fraction is 18%, a reduction of CO_2 emission as much as 18 tons/year decrease from 385 kg/year to 349 kg/year for a renewable fraction of 0% to 18%. This means a 36 kg reduction of SOx.

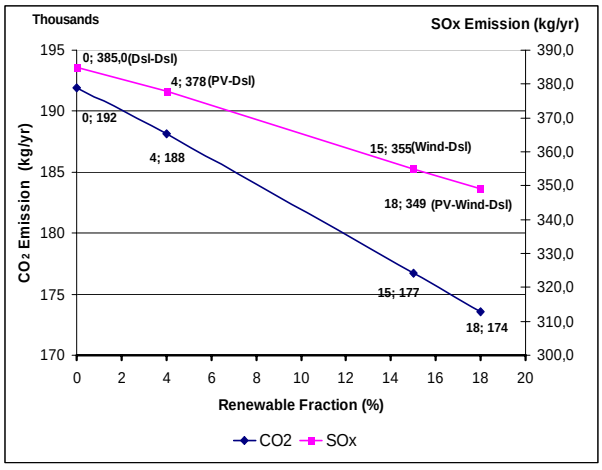

Figure 8. CO_2, SOx emissions – 25% maximum renewable fraction

In Figure 9, CO2 emissions decreased if renewable fraction increased as described above. The value of COE fluctuates with the changement of renewable fraction. When the renewable fraction is 0%, the load is supplied by 2 diesel generating units with a COE of 0,510 $/kWh, total NPC of $ 976.834. While the of renewable fraction is 4%, the hybrid system consisting of PV – diesel without battery, the COE increases to 0,515 $/kWh, NPC increases to $ 986.761. The lowest COE is 0,496 $/kWh if the renewable fraction is 15% and the hybrid system is consisting of wind-diesel with no battery, its NPC is $ 950.510. if the COE increase again to 0,510 $/kWh, the renewable fraction is 18%, the system consists of PV-wind-diesel without battery, its NPC is $ 976,801. Based on the conditions above, the author recommended a hybrid system consisting of wind-diesel.

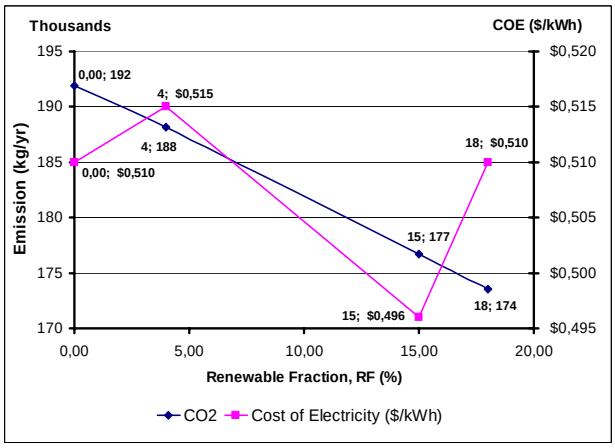

Figure 9. CO_2 emissions – cost of electricity (COE) – 25% maximum renewable fraction

In the third condition with a more than 25% renewable fraction the hybrid system consists of 1 diesel generating unit – PV – wind turbine without battery. The results for this condition are as follows: for PV – diesel, COE is 0,607 $/kWh, excess of electricity 22.464 kWh/year or 11%, and CO_2 emission is 174 ton/year. For wind - PV – diesel, COE is 0,785 $/kWh, excess of electricity 85.212 kWh/year or 31,4%, and CO_2 emission is 144 kg / year.

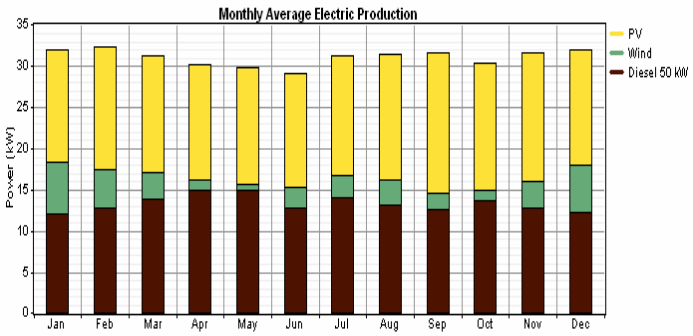

Figure 10. Supply of Load Demand by Diesel Generator, PV, Wind turbine with more than 25% renewable fraction

A Configuration of PV – wind – diesel with renewable fraction more than 25%, COE 0,510 $/kWh having the highest NPC of $ 738,010, excess electricity reaching 85,212 kWh/year or 31.4%, CO_2 emissions decreased as much as 48 ton/year or 25%. The load served by the hybrid system can be seen in figure 10 above.

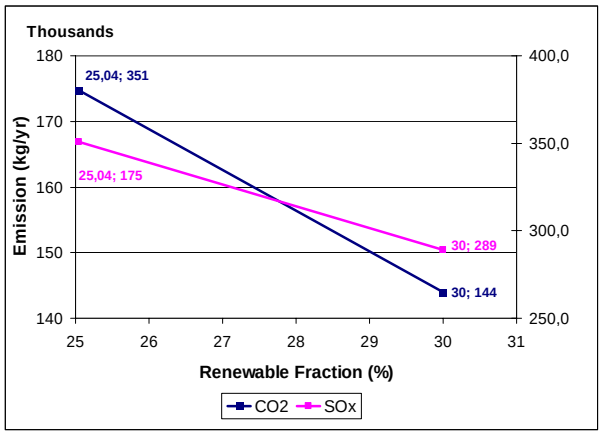

Figure 11. CO_2, SOx emission – more than 25% renewable fraction

In figure 11 above, the hybrid system is simulated and optimized with a more than 25% renewable fraction, the CO_2 and SOx emission levels decrease with decrease of the fuel consumption effect diesel generating unit. The CO_2 emission becomes 144 tons/year if renewable fraction 30% reduced as much as 48 tons/year. The SOx emissions, is reduced from 385 kg/year to 289 kg/year when renewable fraction increase from 0% to 30%. The SOx emission is reduced as much as 96 kg/year.

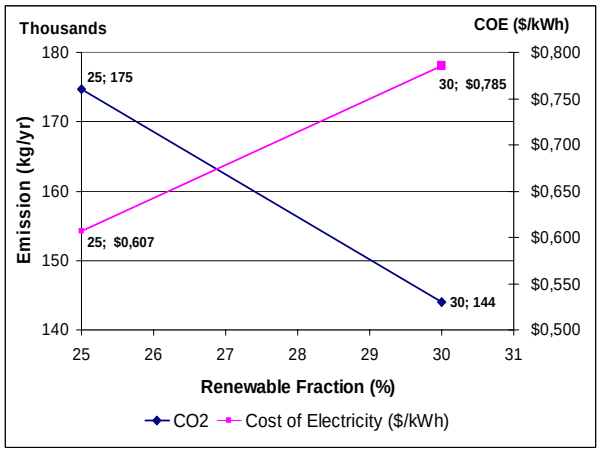

Figure 12. CO_2 emission – with a renewable fraction of 30%

In figure 12 the value of COE increased if the renewable fraction increases from 25% to 30%. If the renewable fraction is 25%, the COE is 0,607 $/kWh and the hybrid system consists of PV - diesel with no battery with 48 kW capacity of PV. Total NPC for this system is $ 1.163.327 with initial capital cost of PV is $ 264.000. If the renewable fraction is 30%, the COE is 0.785 $/kWh, the hybrid system consisting of PV - wind – diesel with no battery. Total NPC for this system is $ 1.503.710, the initial capital cost of 120 kW PV is $ 660.000. Based on results of simulation and optimization with a more than 25% renewable fraction, it is recommended to select a hybrid system consisting of PV-diesel with the lowest value of COE.

6 CONCLUSIONS

The value of COE, CO_2 and SOx emissions and excess of electricity fluctuated on different renewable fraction, it depending on total power generated and the total load served by the system. Which is the same following daily load curve of Sebesi Island? The largest excess power occurred at 30% of renewable fraction. A water pump as a deferrable load can be used to absorb this excess electricity.

The optimum hybrid system at 15% of renewable fraction, consist of wind – diesel with COE 0,496 $/kWh, NPC is $ 950.510 and the CO_2 emissions is 177 ton/year.

ABSTRACT

Photovoltaic (PV) converts solar energy directly into direct current electric energy. The amount of electrical energy which will be obtained from the photovoltaic (PV) system is directly proportional to the intensity of the sun light which falls on the module surface. Sun tracking system is designed in a way to track the sun on single axis. The movement of PV module is controlled to follow the sun's radiation by LDR sensor using smart relay SR2 B121JD. Maximum benefit is derived from solar energy by providing that the PV module system be oriented at a right angle to the sun which will be got maximum power. Each of two 50 W of PV modules is compared, one of PV modules placed on fix position (without solar tracking) and the other with solar tracking. PV module output terminal is loaded by a lamp 12 V/5 W. Open circuit voltage (V_{oc}), load voltage (V_L), load current (I_L) and power (P) of PV module output terminal are measured every 30 minutes from 9.00 am to 5.00 pm. The result the average improvement of V_{oc} = 4.5 %, V_L = 11.43 %, I_L = 4.70 %, and P = 16.45 %.

Keywords
Photovoltaic, solar tracking, smart relay

1. INTRODUCTION

Photovoltaic system is a very important alternative energy and its efficiency been increasing by researcher. There are three method for increasing the efficiency of PV, the first is the increasing the efficiency of solar cell, the second is the energy conversion system included MPPT control algorithm and the third is the using solar tracking system [1]. The method of maximum power point is based on closed loop current control, in which the reference current is determined from the fitted function of I_{mpp} versus $P_{\max}$, points of a particular photovoltaic generator (PVG) [2]. A simplified computer model of the PVG is given and computer simulation for demonstrating the effectiveness of the proposed algorithm are presented. From the result of the simulations and experiment studies, it is concluded that that the proposed approach can be used as a robust and fast acting maximum power point tracking.

In this paper is proposed to developed PV of 50 W tracking system using smart relay SR2 B121JD. The system was designed into two parts, that are mechanical movement and electrical controller. The mechanical movement consist of dc motor and gears for moving the PV module from east to west. The electrical controller consist of a voltage and current divider circuit [3] and smart relay.

2. PHOTOVOLTAIC AND SOLAR TRACKING

2.1 Photovoltaic

Physics of the photovoltaic (PV) cell is very similar to the classical p-n junction diode (Figure 1). When light is absorbed by the junction, the energy of the absorbed photon is transferred to the electron system of the material, resulting in the creation of charge carriers that are separated at the junction.

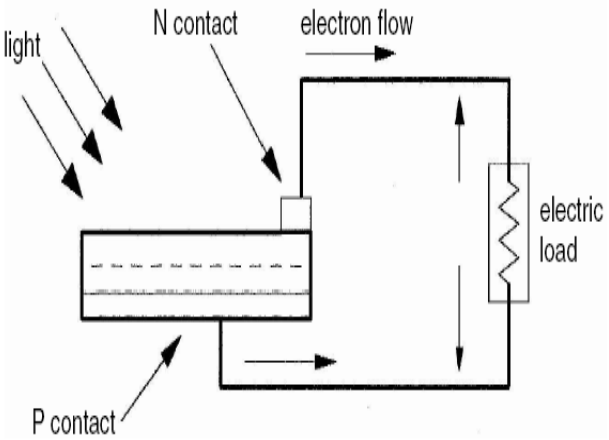

Figure 1: Photovoltaic effect converts the photon energy into voltage across the p-n junction

The charge carriers may be electron-ion pairs in an electron hole pairs in a solid semiconducting material. The charge carriers in the junction region create a potential gradient, get accelerated under the electric field and circulate as the current through an external circuit. The current squared times the resistance of the circuit is the power convert into electricity. The remaining power of the photon elevates the temperature of the cell [4].

For obtaining high power, numerous such cell are connected in series and parallel circuits on a module area of several square feet (Figure 2). The solar array or panel is defined as a group of several modules electrically connected in series and parallel combinations to generate the required current and voltage.

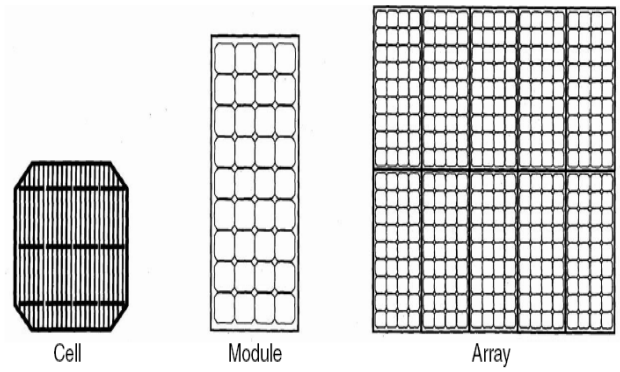

Figure 2: Several pv cells make a module and several modules make an array

Figure 3 shows the actual construction of a polycrystal silicon solar module in a frame.

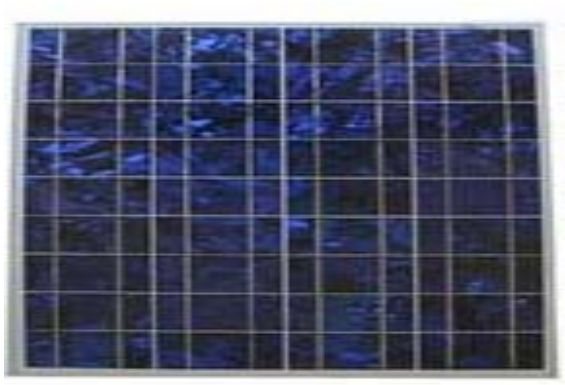

Figure 3 : A polycrystal silicon solar module in a frame

PV converts solar energy directly into direct current electric energy. The amount of electrical energy which will be obtained from the photovoltaic (PV) system is directly proportional to the intensity of the sun light which falls on the module surface. However, the change observed in sun light does not occur linearly, for this reason it is desired that the solar panel be fixed in a way that they face the sun or that they have a system which tracks the sun. Sun tracking system is designed in a way to track the sun on single axis. The movement of PV module is controlled to follow the sun's radiation by LDR sensor using smart relay SR2B121JD. Maximum benefit is derived from solar energy by providing that the PV module system be oriented at a right angle to the sun which will be got maximum power.

2.2 Solar Tracking Circuit

The solar tracking circuit is be shown in Figure 4.

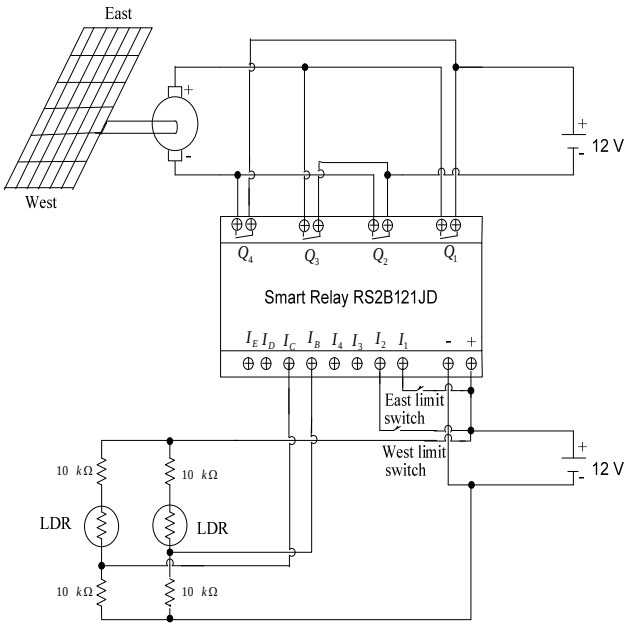

Figure 4 : Solar tracking circuit

Two LDRs are installed on east and west of PV module. If the east LDR gets intensity of the sun light is higher than west LDR, the PV module will move to east. Otherwise, if the west LDR gets higher intensity , the PV module will move to west. When the intensities of both LDRs are same, the DC motor will stop. The east and west limit switch will stop DC motor, when they are touched by PV module.

3. RESEARCH METHODOLOGY

3.1 The Used Devices in This Research

The used devices in this research consist of :

1. Hardware
   The hardware that were used in this research :
   a. Photovoltaic 50 W
   b. Direct current motor
   c. Smart relay SR2B121JD
   d. Voltage and current divider circuit

2. Software
   The used software is Zeliosoft2. This software is needed to create ladder diagram and loaded to smart relay.

3. 2 Research Procedure

The research procedure can be drawn by a flow chart in figure 5.

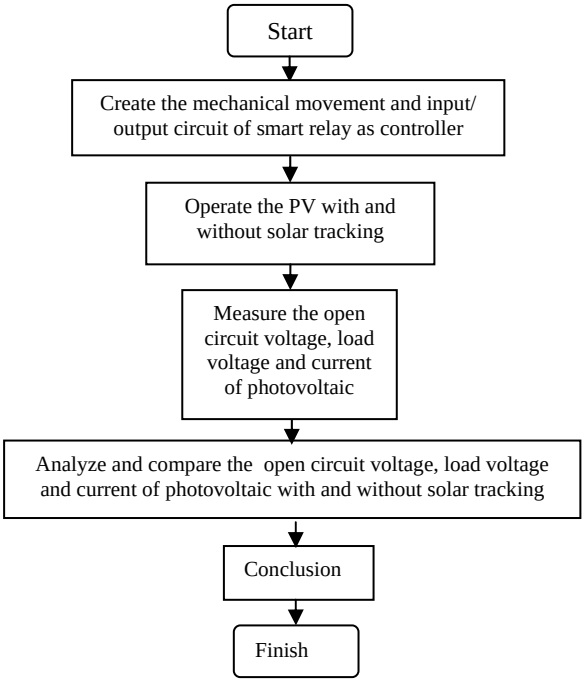

Figure 5: Flow chart of research procedure

4. RESULT AND DISCUSSION

Each two 50 W of PV modules is compared, one of PV modules placed on fix position (without solar tracking) and one other with solar tracking. PV module output terminal is loaded by a lamp 12 V/5 W. Open circuit voltage (V_{oc}), load voltage (V_L), load current (I_L) and power of PV module output terminal are measured every 30 minutes from 9.00 AM to 5.00 PM. V_{oc} - H, V_L - H, I_L -H, and P-H curve are shown in Figure 6,7, 8and 9, respectively.

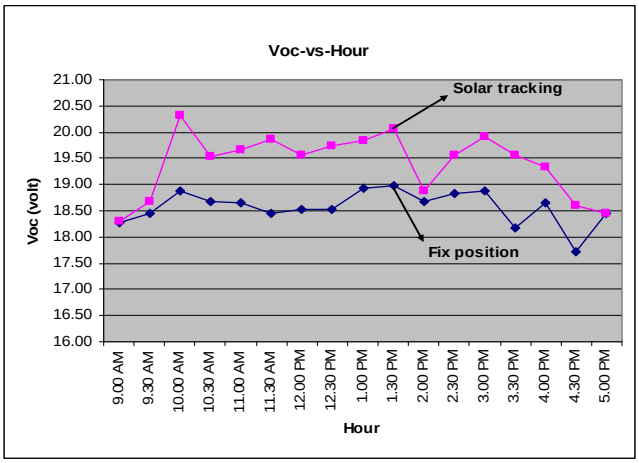

Figure 6. V_{oc} - H curve

Figure 6 shows that with solar tracking open circuit voltage V_{oc} of PV module increase compared to fix position.

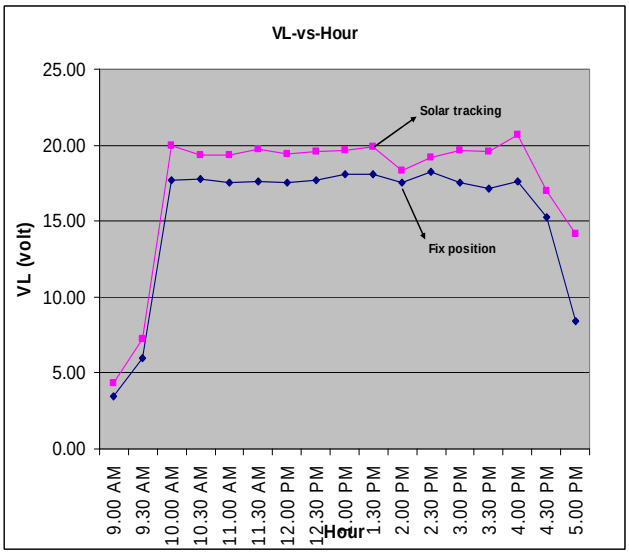

Figure 7: V_L - H curve

Figure 7 shows that with solar tracking load voltage V_L of PV module increase compared to fix position.

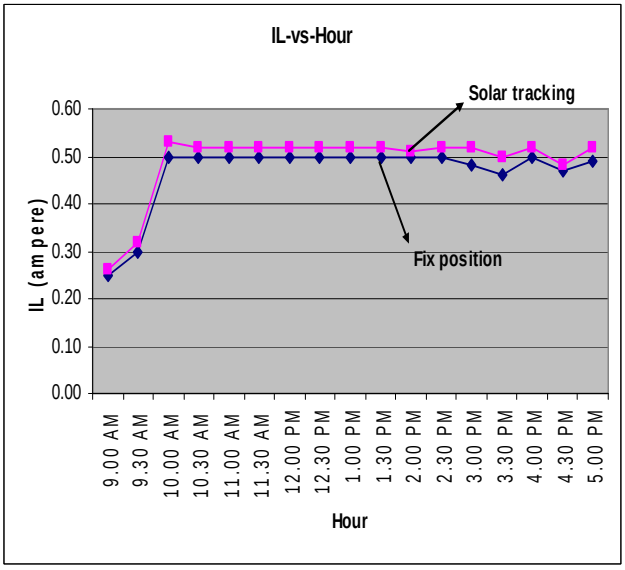

Figure 8: I_L -H curve

Figure 8 shows that with solar tracking load current I_L of PV module increase compared to fix position.

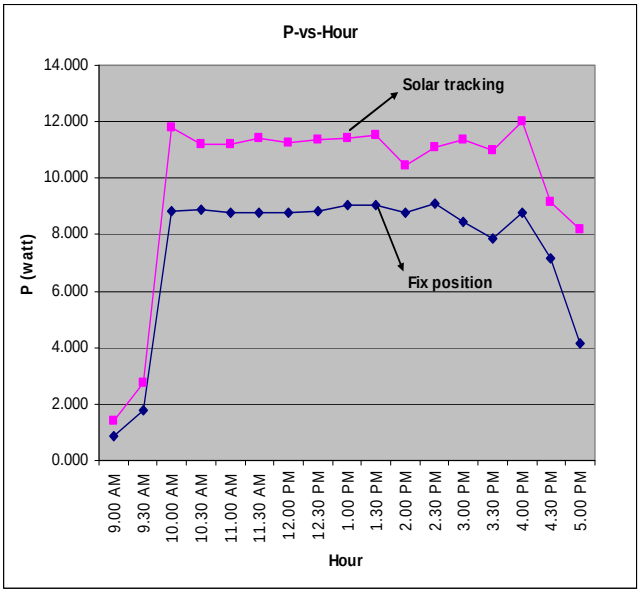

Figure 9. P-H curve

Figure 9 shows that with solar tracking power P of PV module increase compared to fix position.

From Figure 6 to 9 are seen that the PV module with solar tracking better than fix position (without solar tracking). The average improvement of open circuit voltage (V_{oc}), load voltage (V_L), load current (I_L) and power (P) are shown as below.

Table 1. Electric variable average improvement of PV module

Electric variable	V_{oc}	V_L	I_L	P
Average improvement (%)	4.50	11.43	4.70	16.45

5. CONCLUSION

According to the research result can be concluded

1. The smart relay and its input circuit (voltage and current divider circuit) can be used to track solar.
2. The performance of PV module with solar tracking is better than fix position (without solar tracking). The average improvement of Open circuit voltage (V_{oc}) is 4.5 %, load voltage (V_L) is 11.43 %, load current (I_L) is 4.70 %, and power (P) is 16.45 %.

ABSTRACT

This paper presents the effects of harmonic distortion load current and voltages on distribution transformers. A delta-wye transformers are usually used in distribution power system with load may be either the single-phase or the three-phase. Three-phase four-wire distribution power system has been widely used for supplying low-level voltage to office buildings, commercial complexes, manufacturing facilities etc. Most of these loads have nonlinear input characteristic and high input current harmonics that will effect to the transformer losses. The primary effect of the power system harmonics on the transformers are the additional losses, heating and reduce of a transformer life. The load losses components get affected by the harmonic current are the I^2R_{dc} loss, winding eddy current loss & the other stray losses.

Keywords: *Transformer, Harmonics and Power Loss.*

1. INTRODUCTION

Harmonics current and voltage distortion in power system have been present for decades ago. However the advanced technologies in power electronics development over the past decade, the application of power electronics in commercial and industrial buildings can cause of significant increase the level of harmonics distortion in the power system networks. Many distribution transformers were designed to operate at rated frequency but their loads gradually replaced with non-linear that inject the harmonic currents to the systems. The principal effect of non-sinusoidal voltages on the transformer's performance is the generation of extra losses in the core [1]. Non-sinusoidal currents generate extra losses & heating of the conductors, enclosures, clamps, bolts etc, thus reducing the efficiency of the transformer & accelerating the loss of life of the insulation due to the additional heating of the windings. The harmonic currents will have some effects to the distribution transformer such as [1]:

- Increase temperatures of windings, cleats, leads, insulation and can reach unacceptable levels.
- Increase leakage flux density outside the active parts and can cause the additional eddy current heating in metallic parts linked by the flux.
- The combination of the main flux & the increased leakage & zero sequence flux imposes restrictions on possible core over excitation.
- As the temperature changes, the moisture & gas content in the insulation & in oil will change.
- Bushings, tap changers, cable-end connections and current transformers will also be exposed to higher stresses, which encroach upon their design & application margins.

The most important effects of power system harmonics to the transformer are winding eddy losses, stray losses in other structural parts and potential regions of excessive heating. Due to the skin effect, the electromagnetic flux may not totally penetrate the strands in the winding at high frequencies. The increased of eddy current losses produced by a non-sinusoidal load current can cause excessive winding losses and hence abnormal temperature rise. Therefore the influence of the current harmonics is more important, not only because of the assumed square of the harmonic order but also because of the relatively large harmonic currents present in the power system.

2. REVIEW OF POWER TRANSFORMER LOSSES

Traditionally, transformer losses are divided into no load losses and load losses. The total loss can be expressed as:

$$P_T = P_{NL} + P_{LL}$$

Where: P_{NL} core or no load loss (watt), P_{LL} load loss (watt), P_T is total loss in watt.

P_{NL} is the loss due to the voltage excitation of the core and P_{LL} is loss due to P_{dc} and stray losses (P_{SL}). Stray loss is caused by electromagnetic fields in the winding, core clamps, magnetic shields, enclosure or tank wall, etc [2]. The stray losses can be further divided into winding eddy losses and structural part stray losses. Winding eddy losses consist of eddy current losses and circulating current losses. Other stray losses are due to losses in structures other than windings, such as clamps, tank or enclosure walls, etc.; this can be expressed in equation form [2]:

$$P_{LL} = P_{dc} + P_{EC} + P_{OSL}$$

The total stray losses P_{SL} is:

$$P_{SL} = P_{EC} + P_{OSL} = P_{LL} - P_{dc}$$

3. EFFECT OF POWER SYSTEM HARMONICS ON TRANSFORMERS LOSSES

3.1 Effect of voltage harmonics

According to Faraday's law the transformer voltage terminal can be determines by the flux level.

$$N_1.\frac{d\phi}{dt} \cong u_1(t) \qquad (1)$$

Transfer equation (1) into the frequency domain which shows the relation between the voltage harmonics and the flux components.

$$N_1.j(h\omega).\phi_h \cong U_h \qquad h = 1,3,... \qquad (2)$$

3.2 Effect of current harmonics

a. P_{dc} Losses

The increasing of rms value of the load current caused by harmonic component, the I^2R loss will be increase accordingly.

b. Winding eddy losses

Conventionally, the eddy current losses (P_{EC}) generated by the electromagnetic flux are assumed to be proportional with the square of the rms load current and the square of the frequency (harmonic order *h*), [3]-[4]

$$P_{EC} = P_{EC-R}\sum_{h=1}^{h=\max} h^2\left(\frac{I_h}{I_R}\right)^2$$

c. Other stray losses

The other stray losses are assumed to vary with the square of the rms load current and the harmonic frequency to the power of 0.8, [3]-[4].

$$P_{OSL} = P_{OSL-R}\sum_{h=1}^{h=\max} h^{0.8}\left(\frac{I_h}{I_R}\right)^2$$

The factor of 0.8 has been verified in studies by manufacturers and others, and accepted in the standards.

3.2.1 Winding eddy-current loss factor for transformers

The winding loss at a certain spot can be calculated as:

$$P_W = P_{dc} + P_{EC} \text{ W/m}$$

The normalized winding loss with the P_{dc} losses can be expressed as:

$$\frac{P_W}{P_{dc-R}} = \frac{P_{dc}}{P_{dc-R}} + \frac{P_{EC}}{P_{dc-R}} \qquad (3)$$

The first term,

$$\frac{P_{dc}}{P_{dc-R}} = \left(\frac{I}{I_R}\right)^2 = \frac{\sum_{h=1}^{h=\max} I_h^2}{I_R^2} \qquad (4)$$

The contribution of eddy current losses caused by magnetic field is obtained:

$$P_{EC} \approx \frac{\pi^2 f^2 T^2 B^2}{3\rho}$$

The leakage magnetic field *B* is directly proportional to the load current *I*, i.e

$$B = K_B I$$

When the load current is periodic but non-sinusoidal, its rms value,

$$I = \sqrt{\sum_{h=1}^{h=\max} I_h^2}$$

Where, I_h is the rms current harmonic of order *h*,
Hence,

$$P_{EC} \cong K\sum_{h=1}^{h=\max} h^2 I_h^2 \qquad (5)$$

where, $K = \frac{\pi^2 f^2 T^2 K_B^2}{3\rho}$

f is the rated frequency.

When the transformer is loaded at rated current I_R, the corresponding rated eddy current losses are

$$P_{EC-R} = KI_R^2 \qquad (6)$$

From (5) and (6)

$$P_{EC} = P_{EC-R}\sum_{h=1}^{h=\max} h^2\left(\frac{I_h}{I_R}\right)^2 \qquad (7)$$

Hence, the eddy current losses produced by a harmonic current load can be predicted based on the eddy current losses at rated current and fundamental frequency.
Substituting (4) and (7) into (3) gives:

$$\frac{P_W}{P_{dc-R}} = \left[\frac{\sum_{h=1}^{h=\max} I_h^2}{I_R^2} + \frac{P_{EC-R}}{P_{dc-R}}\sum_{h=1}^{h=\max} h^2\left(\frac{I_h}{I_R}\right)^2\right] \qquad (8)$$

Equation (8) was derived based on the assumption that the measured applied currents are taken at the rated currents of the transformer. Since this is seldom encountered in the field, a new term is defined based on the winding eddy losses at the measured current and power frequency, which may be read directly on a meter. A harmonic loss factor is defined in the IEEE standard [4].

$$\frac{P_W}{P_{dc-R}} = \frac{\sum_{h=1}^{h=h_{\max}} I_h^2 I_h^2}{I_R^2}\left[1 + \frac{P_{EC-R}}{P_{dc-R}}\frac{\sum_{h=1}^{h=h_{\max}} h^2 I_h^2}{\sum_{h=1}^{h=h_{\max}} I_h^2}\right]$$

The harmonic loss factor can be normalized to either the fundamental or the rms current:

$$F_{HL} = \frac{\sum_{h=1}^{h=h_{\max}} h^2 I_h^2}{\sum_{h=1}^{h=h_{\max}} I_h^2} = \frac{\sum_{h=1}^{h=h_{\max}} h^2\left(\frac{I_h}{I_1}\right)^2}{\sum_{h=1}^{h=h_{\max}}\left(\frac{I_h}{I_1}\right)^2}$$

$$P_W(pu) = I^2(pu)\left[1 + P_{EC-R}(pu)F_{HL}\right]$$

Where, $I^2(pu)$ is the normalized current squared, $P_{EC\text{-}R}(pu)$ is the normalized eddy current loss under rated conditions, F_{HL} is the harmonic loss factor. The harmonic loss factor is a key indicator of the current harmonic impact on the winding eddy losses. Under rated sinusoidal current $I(pu)=1$, $F_{HL}=1$ and the hot spot specific power loss is:

$$P_W(pu) = 1 + P_{EC-R}(pu)$$

4. CORRECTED WINDING EDDY CURRENT LOSS FACTOR

The assumption of eddy current losses in a winding are proportional to the square of harmonic order is only reasonable for transformers with small conductors. For larger conductors such an assumption leads to conservative results. A more accurate winding eddy current loss factor based on the following equation published in [5].

$$P_{EC} = \frac{\pi^2 f^2 T^2 B^2}{3\rho} F(\xi)$$

Where,

$$F(\xi) = \left[\frac{3\sinh\xi - \sin\xi}{\xi\cosh\xi - \cos\xi} \right]$$

When the current is non-sinusoidal as in (5),

$$P_{EC} = K' F(\xi) h^2 I^2$$

Where,

$$K' = \frac{\pi^2 f^2 T^2 K_B^2}{3\rho}$$

f is the rated frequency.

Hence,

$$P_{EC} = K' \sum_{h=1}^{h=\max} F(\xi) h^2 I_h^2$$

Normalizing the eddy current losses produced by a harmonic current load to the eddy current losses at rated condition a corrected eddy loss factor $h^2 F(\xi_h)/F(\xi_R)$ is achieved.

$$\frac{P_{EC}}{P_{EC-R}} = \frac{\sum_{h=1}^{h=\max} F(\xi_h) h^2 I_h^2}{F(\xi_R) I_R^2} \qquad (9)$$

Substituting (4) and (9) into (3) gives:

$$\frac{P_W}{P_{dc-R}} = \left[\frac{\sum_{h=1}^{h=\max} I_h^2}{I_R^2} + \frac{P_{EC-R}}{P_{dc-R}} \frac{\sum_{h=1}^{h=\max} h^2 F(\xi_h) \left(\frac{I_h}{I_R} \right)^2}{F(\xi_R)} \right] \qquad (10)$$

The corrected eddy losses factor as a function of the harmonic order h at 75°C immersed in an alternating field with 50 Hz fundamental frequency is shown in Figure 1. Figure 2 shows the corrected loss factor which is based on equation (9). The harmonic loss factors are presented as a function of the harmonic order, for different copper conductor thicknesses at 75°C immersed in alternating fields based on 50 Hz fundamental.

It can be seen that for small conductors skin effect is insignificant and only for large conductor dimensions at high harmonics does the difference become significant. It can be said that using the assumed eddy current loss factor h^2 predicts losses accurately for small conductors and low harmonics but produces a certain degree of error for a combination of large conductors and higher frequencies.

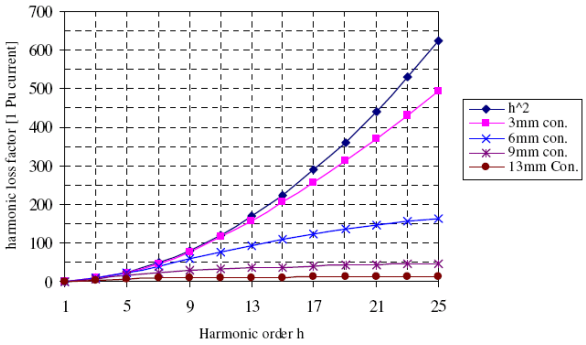

Figure1: Corrected winding eddy-current loss factor as a function of harmonic order h for different rectangular copper conductor dimensions [6]

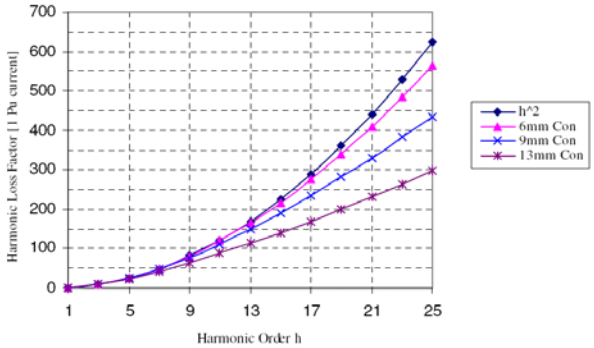

Figure 2: Corrected winding eddy-current loss factor as a function of harmonic order h for different rectangular copper conductor thickness [5]

5. COMPONENTS OF TRANSFORMER STRAY LOSS

The stray loss components can be estimated by thorough loss measurements at different frequencies or simply as recommended in [7].

$$P_h = P_{dc} + (P_{EC} x h^2) + (P_{SL} x h^{0.8})$$

$$P_1 = P_{dc} + P_{EC} + P_{SL}$$

Furthermore, Bendapudi [8] evaluated the frequency-dependent factors of winding eddy losses and other stray losses for specific transformer designs based on measurements at different frequencies. The harmonic loss factor K_h was defined as:

$$K_h = \frac{P_1 - P_o}{P_1} \left[w h^q + (1-w) h^r \right] + \frac{P_o}{P_1}$$

where, h is the harmonic order, K_h is the harmonic factor P_n/P_1, P_n is the load loss at the h^{th} harmonic, P_1 is the load loss at fundamental frequency, P_o is the loss due to the DC resistance, w are the winding eddy losses as a fraction of the total stray losses at fundamental frequency, (1-w) are the other stray losses as a fraction of the total stray losses at fundamental frequency.

The value of w is based on the calculation of the particular transformer design. Curve fitting was used to determine the best value for q and r. J. Drisen [9] suggested a

practical method to determine the winding frequency dependent factor with short circuit tests at harmonic frequencies. The loss factor was defined as:

$$K(f) = \frac{R_{AC}(f) - R_{DC}}{R_{AC}(f_1) - R_{DC}}$$

5. CONCLUSION

Harmonics effects on power system components and loads are important considerations in evaluating of harmonics impact on the distribution transformer. The main effects of harmonics on transformer are excessive winding loss and hence abnormal temperature. The excessive winding loss is due to the increasing of eddy current losses caused by harmonics.

Eddy current losses can be assumed to vary with the square of current and the square of the frequency for a small conductor. For large conductors and high frequencies, a corrected loss factor which considers the skin effect is needed. This leads to a more accurate prediction of transformer capability when subject to non-sinusoidal load currents.

ABSTRACT

Wimax is a wireless broadband technology which suitable for data communication. Modern communication system, such as satellite, radar and Wimax requires operation at two frequencies. When the system require at two frequencies too far apart, dual band patch antenna may avoid the use of two different antennas. This paper proposed a design of dual band triangular microstrip antenna using two slots feed by electromagnetic coupling. The two resonant frequencies can be generated by controlling the height and the distance between the two slots. Also adjusting the right length of the triangular and the second slot and the left length of the triangular and the first slot. Return loss of -31.90 dB with VSWR 1.05 for the first resonant frequency at 2.3 GHz and return loss of -13.49 dB with VSWR 1.49 for the second resonant frequency at 3.32 GHz. The results shown that the proposed antenna have the impedance bandwidth of 5.72% for the first frequency and 3.01% for the second frequency.
Keywords*: Dual band, triangular microstrip antenna, electromagnetic coupling*

1. INTRODUCTION

Patch antenna possesses many advantages such as low profile, light weight, small volume and compability with microwave integrated circuit (MIC) and monolithic microwave integrated circuit (MMIC). When modern communication system, such as for satellite, radar and wimax requires operation at two frequencies, dual frequency patch antennas may avoid the use of two different antennas [1]. Although rectangular and circular geometries are most commonly used, other geometries having greater size reduction find wide applications in modern communication systems, where the prime concern is compactness. The triangular patch antenna configuration is chosen because it has the advantage of occupying less metalized area on substrate than other existing configurations. Dual band operation of triangular patch microstrip antenna have been studied by many researchers using probe feed or direct coupling [2][3].

Basically, feeding system can be divided into two types such as direct coupling and electromagnetic coupling [4]. The use of electromagnetically coupled is to avoid the disadvantages of probe mechanism and can permit for improving bandwidth. In further development, the electromagnetic coupling will be identified as microstrip line and coplanar waveguide. To create dual frequency operation of triangular microstrip antenna using microstrip feed line from the top of the triangular patch antenna is already reported [5].

This paper therefore proposed a new design of dual band operation of triangular microstrip antenna using two different height slots and the feeding line is in the bottom of the triangular patch antenna. Details of the proposed antenna design and the results of the dual band performances are presented.

2. ANTENNA DESIGN

The geometry of the proposed antenna using two slot with different height for dual band operation feed by microstrip line can be shown in Figure 1a and 1b. The proposed antenna is constructed on two layers with the same dielectric substrate. On the first layer, the patch antenna is realized on FR 4 substrate having a relative permittivity (ε_r) = 4.98, substrate of thickness (***h***) = 1.53 mm and loss tangent ($\tan\delta$) = 0.09 and the microstrip feed line is realized on the second layer. Therefore the microstrip line feeding system is electromagnetically coupled to the patch.

From Figure 1a, ***a*** is the dimension of the side length of the triangular patch antenna, ***a1*** is the left length of the triangular and the first slot, ***a2*** is distance between the first slot and the second slot, ***a3*** is the right length of the triangular and the second slot. Beside that, ***x1*** and ***y1*** are the length and width of the first slot, ***x2*** and ***y2*** are the length and the width of the second slot. From Figure 1b, ***W1*** and ***L1*** are the length and width of the proposed feeding system and ***r*** is the distance from the left side of the triangular patch antenna to microstrip feed line. Table 1 shown the parameters of the proposed antenna and the microstrip feed line.

3. EXPERIMENTAL RESULTS

The dual band operation can be generated by inserting the two slots at the bottom side of the triangular patch antenna. The two resonant frequencies can be generated by controlling the two height slots while keeping the width of the slot fixed at 1 mm. By varying the distance of the two slots ***(a2),*** the input impedance matching of the feeding system can be characterized. This result is achieved by using an ordinary triangular patch antenna then is realized using this result.

Figure 2a and 2b shows the measured return loss can be achieved at ***a2*** = 5 mm. The first band frequencies from 2.238 GHz until 2.37 GHz, return loss of -31.90 dB can be obtained at the frequency 2.3 GHz with VSWR 1.05. While at the second band frequencies 3.27 GHz until 3.37 GHz, return loss of -17.27 dB can be reached at the frequency 3.3 GHz with VSWR 1.49.

Figure 3a and 3b, also Figure 4a and 4b shows the comparison between the simulation and the measurement results for the return loss and VSWR from the patch antenna. From Figure 3a and Figure 4a, the impedance bandwidth at frequency 2.3 GHz from the simulation is at 2169 MHz until 2442 MHz and the centre frequency is at 2.302 GHz with return loss -22.65 dB and VSWR 1.159. While the centre frequency from the measurement result is at 2.304 GHz with return loss -31.90 dB and VSWR 1.05 and has the impedance bandwidth from 2238 MHz until 2370 MHz or about 5.72%.

Figure 3b and Figure 4b shows that at frequency 3.3 GHz, the impedance bandwidth from the simulation is at 3155 MHz until 3449 MHz and the centre frequency is at 3.3 GHz with return loss -20.37 dB and VSWR 1.212. The impedance bandwidth from the measurement result is from 3270 MHz until 3370 MHz or about 3.01% at frequency 3.3 GHz. The centre frequency is at 3.32 GHz with return loss -13.49 dB and VSWR 1.49.

In general, the impedance bandwidth of the traditional microstrip antenna using probe feed is only a few percent. From the simulation results shown that the impedance bandwidth at frequency 2.3 GHz can be increased until 11.86% and at frequency 3.3 GHz is about 8.9%. One of the advantages using microstrip feed line is to enhance bandwidth. But from the measurement results, the impedance bandwidth is only 5.72% at the first frequency and 3.01% for the second frequency. It is shown that the impedance bandwidth for the simulation is wider than the measurement results, because the simulation is an ideal condition. Beside that, there is a movement when the patch and the feed line were combined each other. Table 2 shows the comparison parameters between the simulation and measurement results.

4. CONCLUSIONS

A novel configuration to excite dual band operation for Wimax application using slot feed by microstrip line has been experimentally studied. It is shown that the two frequencies can be easily controlled by varying the slot height and adjusting the distance between the two slots. It is observed that return loss of -31.90 dB with VSWR 1.05 can be achieved for the first frequency at 2.3 GHz and the impedance bandwidth is about 5.72%. For the second frequency at 3.32 GHz, return loss of -13.49 dB with VSWR 1.49 has the impedance bandwidth of 3.01%. Therefore the proposed antenna is applicable as a new candidate for dual band antenna microstrip for Wimax application.

ABSTRACT

This paper describes the result of measurement of in-plane flux distribution on 100kVA 3phase distribution transformer assembled with 23^o T-joint and mitred lap corner joint with stagger yoke of 10mm. The measurement involves the fundamental, third and fifth harmonic of the easy and hard direction of flux density at each location measurement. The flux distributions have been measured using no load test by arrays of search coil in M5 (CGO) grades material of transformer core laminations. The localised flux density at the outer 23^o T-joint is 0.147T and rises to be 0.206T at the inner edges of 23^o T-joint when the transformer core energized 1.5 T 50Hz. Harmonic occurs mostly in the T-joint where local regions are saturated and the flux deviates from the rolling direction.A small amount of flux deviation from the rolling direction occurs at the overlap, but no rotational flux is present in the joint.

Keywords
Grain oriented silicon iron, transformer core, in-plane flux distribution.

1. INTRODUCTION

Transformer iron loss can be reduced either by improving the quality of the steel or by using better building and design techniques. The efficiency of a transformer core is also largely dependent upon the design of the joints at the junctions of the yoke and limbs. In these regions the flux may deviate from the rolling direction of the steel or become distorted so that local areas of the high loss are produced. [1] The use of grain-oriented silicon iron has been the main beneficial factor in increasing transformer efficiency. [2]

The behaviour of this investigation is to understand the in-plane flux distribution of the transformer core built from electrical steel (M5) with 3% silicon iron assembled with 23^o T-joint and mitred lap corner joint with stagger yoke of 10mm by using arrays of search coil.

2. EXPERIMENT APPARATUS AND MEASURING TECHNIQUES

The main apparatus consist of a model cores three-phase 100kVA transformer assembled with three limbs core with T-joint cutting angle 23^o assembled from CRGO (M5 grades) 3% Si-Fe material. The core has 550 mm x 580 mm with the limbs and yokes 100 mm wide as shown in Figure 1. The experimental cores assembled with T-joint 23^o, mitred overlap corner joints with staggered yoke and overlap length is 10mm as shown in Figure 2 and assembled from 0.3 mm thick laminations of M5 grain-oriented silicon iron (CRGO). Associated instruments are used to measurement fundamental, third and fifth harmonic content of the localised flux density distribution.

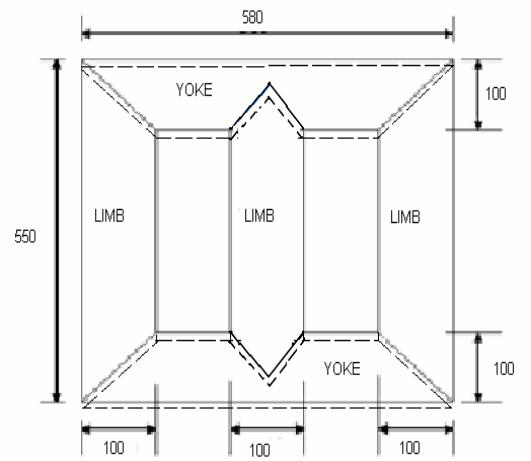

Figure 1: Dimension (mm) of 100kVA transformer model

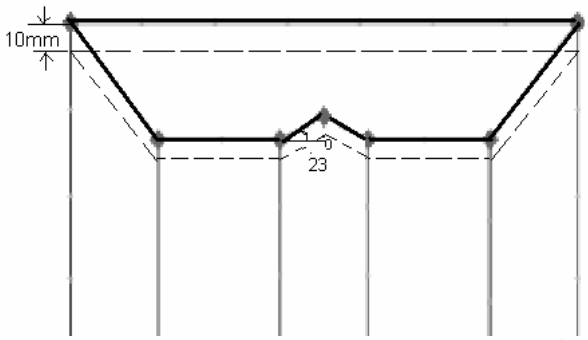

Figure 2: Transformer core type T-joint 23°

The localized flux density distribution in individual laminations is measured using search coils. The samples are drilled with an aid of drilling machine. It is constructed from 0.15 mm diameter wire treaded through 0.8 mm diameter holes 10 mm a part as shown in Figure 3. Each measuring position suitable coils are wound to measure the easy and hard direction flux density. The search coil induced voltages are analysed to find the magnitude and plane coil induced voltage of flux density by using power analyzer [PM6000] as shown in Figure 4.

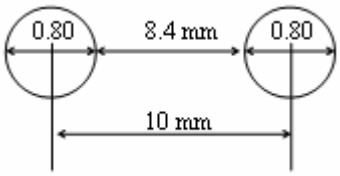

Figure 3: Dimensions [mm] of the holes drilled in the specimen

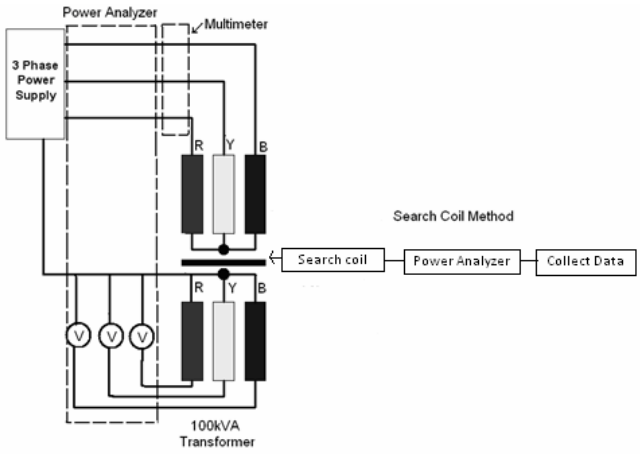

Figure 4: The diagram of the methods that used to measure the localised flux density.

The magnitude and direction with reference to the x axis of the in-plane instantaneous flux density can be written in the form [3]:

$$|b| = \frac{1}{4\,fNAn}[\bar{e}_x{}^2 + \bar{e}_y{}^2]^{1/2} \qquad (1)$$

And

$$\alpha = \tan^{-1}\left(\frac{e_y}{e_x}\right) \qquad (2)$$

Where
f = frequency supply
N = Number of transformer winding
A = Cross section area of transformer core lamination that measured
n = number of layer of transformer core lamination
e_x = maximum value of the component of induced emf in the easy direction
e_y = maximum value of the component of induced emf in the hard direction

Sample calculation as follow:
From transformer frame are obtain number of turn is 254 turns, area of lamination is 0.000003m^2 with number of layer is 15 layers and frequency supply is 50 Hz. When the supply adjusted to transformer at 1.5T so at the search coil will find the induced emf by oscilloscope measurements at easy direction is 190mV and hard direction is 180mV. By using the equation (1) will find the flux density at this point is 103mT.

The primary induced emfs in the windings of the three phase transformers core were monitored by three identical voltmeters and voltages displayed during the measurement were only allowed to vary well within ± 0.4% of the induced voltage corresponding to the required flux density.

Flux distribution in the Cold Rolled Grain Oriented (CRGO) is measured by using an array of search coils to get the

ISSN 114-1284

satisfactory result. In this investigation an array of single turn search coil is employed to measure in-plane (longitudinal and transverse) of flux density in the lamination within the transformer core as indicated in figure 5.Because the flux tends to deviate out of the longitudinal direction in some region, small 10mm search coils are used to measure localized longitudinal and transverse flux component. The locations are chosen to cover the areas where the flux is more likely to vary direction so as to find distribution of the flux behavior as shown in Figure 5.

The testing process is done by using the No-Load Test Frame. The No-Load Test Frame consisting of three windings for each three phase core are designed in order not only to avoid introducing stress to the laminations but also to keep the magnetism exactly constant in all limbs of the cores. Each winding only extends along 85% on each limb in order to enable the stagger length of the three phase core to be varied. An extra softwood base 200mm high is used to raise the overall height of the core, in order to minimize the effect of the stray flux on the localized measurements.

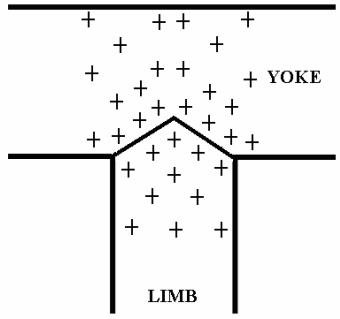

Figure 5: Location of orthogonal search coils in the three phase core.

Installation search coil takes quite a long time in completing this step which every hole needs to be inserted with search coil. Search coil is the enamel copper coated 0.1mm diameter wire. Each set of test point (4 holes) consist of easy and hard direction where the holes of easy and hard direction will be inserted search coil and the leads are twisted together. All the holes at testing point need to be repeated the same method of inserting and twisting the leads.

After the search coils are wound and the leads twisted together, the holes are filled with polyurethane varnish to give added insulation protection. The search coil leads, which are twisted to prevent any spurious pick up, are stuck to the lamination by a polyurethane varnish. The leads from all the search coils are taken to a junction box placed in the core to prevent any interference from the core or magnetising windings.

3. RESULTS AND DISCUSSION

The instantaneous magnitude and direction of flux at this instant is shown in Figure 6 on a larger scale. At this instant the total flux in the centre limb reaches its maximum and outer limb carry half their maximum flux. A small amount of flux deviation from the rolling direction occurs at the overlap.

The rotational flux produced in the T-joint region of the three-phase three limbs transformer core are due to a combined effect of alternating and rotating fields. This rotational flux illustrates the locus of the variation of the variation of the localized flux distribution throughout the magnetizing cycle. The rotational flux of the fundamental component (50Hz) of flux density in the 10mm staggered core at a core flux density of 1.5T is shown in Figure 7. A large rotational flux is present in the yoke area which near with centre limb. Rotational flux in this region is more circular. Some large rotational flux is also observed in or near the T-joint region.

Figure 8 shows the rotational flux of the third harmonic component of flux density in the T-joint of the core assembled with 23^0 at core flux density of 1.5T. The extent of rotating flux at this frequency is more widespread. As with the 50Hz component, a large amount of rotating flux is present in the T-joint region between the right yoke and centre limb in all four cores. A small rotating flux occurs also observed in the middle of centre limb region in all four cores. There is more rotational flux present in this region.

The major axes of the locus do not always follow those of the fundamental component (particularly the 23^0 T-joint of core) but tend to be parallel to butt joints over much of the core where the fundamental components also deviate from the longitudinal direction of the strip in the yoke.

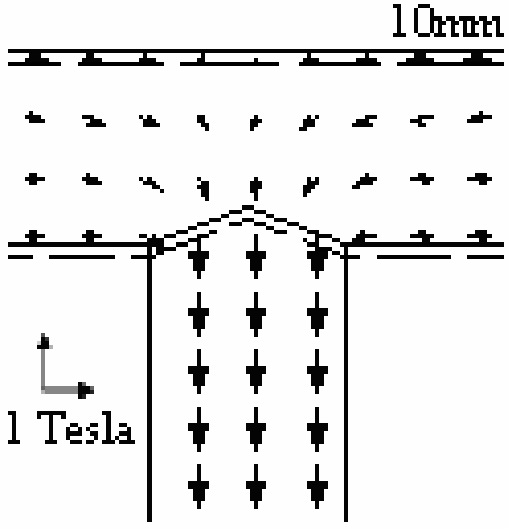

Figure 6: Distribution of localized flux density at 23^o T-joint

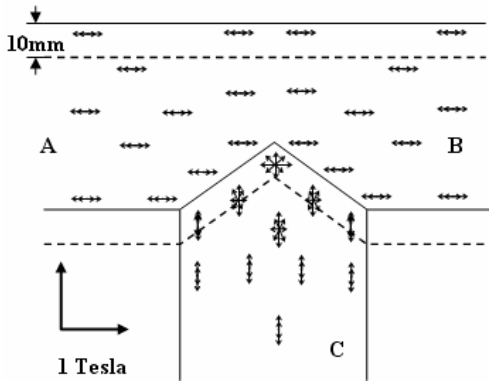

Figure 7: Locus of the fundamental component of localised flux density in 23^0 T-joint staggered core with overlap length 10 mm at 1.5T, 50Hz

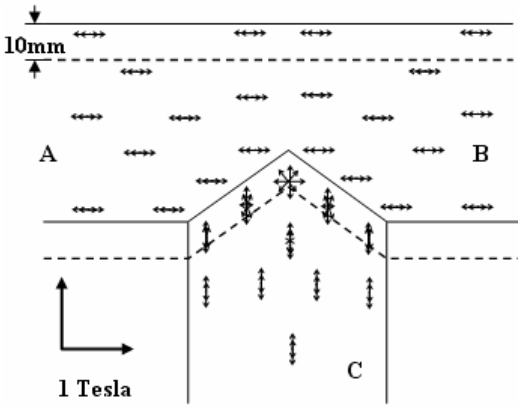

Figure 8: Locus of the third harmonic component of localised flux density in 23^0 T-joint staggered Core with overlap length 10 mm at 1.5T, 50Hz.

Figure 9 shows that the rotational flux of the fifth harmonic component of flux density in the T-joint of the core assembled with 23^0 at core flux density of 1.5T is more widespread. The magnitude of the rotational flux is small compared with that of the fundamental and third harmonic. The distribution of the fifth harmonic component is classified to a region near to and within the T-joint.

A large amount of rotating flux is present in the T-joint region between the right yoke and centre limb in the core. Rotating flux in this region is elliptical with the 23^0 T-joint of core showing the highest value. A small rotating flux occurs also observed in the middle of centre limb region in the core.

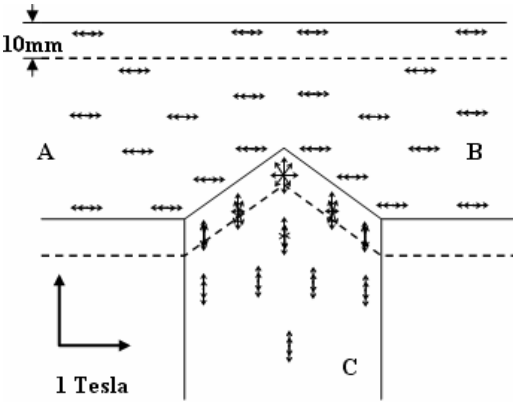

Figure 9: Locus of the fifth harmonic component of localised flux density in 23^0 T-joint staggered cores with overlap length 10 mm at 1.5T, 50Hz

Figure 10 shows the measuring point of location and localized flux densities at 23^o T-joint that are measured by using the search coil on transformer core. This result is produced by calculating localized flux density after the search coil measures the vector of the voltage in the easy and hard direction at the lamination.

The flux density in the yoke then drops rapidly as the flux distributes itself equally between the laminations. The flux density reaches a peak at the inner of 23^o T-joint; this is caused by the saturated material. The minimum flux density occurs at the outer of 23^o T-joint of transformer core lamination. The localised flux density will increase from the outer to the inner edge of the 23^o T-joint. The localised flux density at the outer 23^o T-joint is 0.190T and rises to be 0.217T at the inner edges of yoke at 23^o T-joint when the transformer core energized 1.5 T 50Hz.

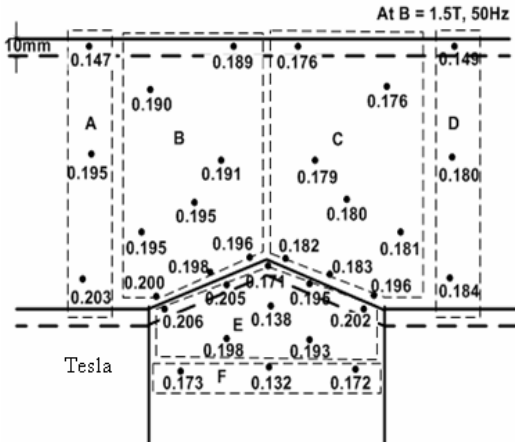

Figure 10: Local variations in the Tesla of the fundamental peak in-plane flux density of the lamination in 23^0 T-joint of three phase staggered core with overlap length 10 mm at 1.5T, 50Hz.

The local variation in magnitude of the third harmonic component of peak in-plane flux density in the 23° T-joint at a core flux density of 1.5T is shown in Figure 11. Most of the high third harmonic flux occurs in the T-joint region. The high third harmonic of peak in-plane flux occurs at the inner edge of right yoke passes over to the Butt-joint of centre limb is 23.4mT. Harmonic occurs mostly in the T-joint where local regions are saturated and the flux deviates from the rolling direction. However, it has been confirmed experimentally that harmonics circulated in individual laminations in the limbs and yokes.

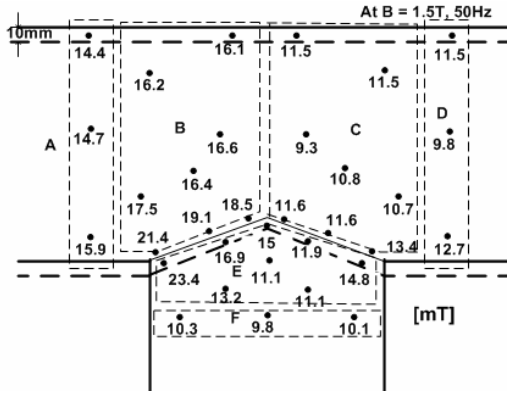

Figure 11 Local variations in the mT of the third harmonic peak flux density to the fundamental component in-plane of the lamination in 23^0 T-joint of three phase staggered core with overlap length 10 mm at 1.5T, 50Hz.

The local variation in magnitude of the fifth harmonic component of peak in-plane flux density in the 90° T-joint at a core flux density of 1.5T is shown in Figure 12 to be very small.

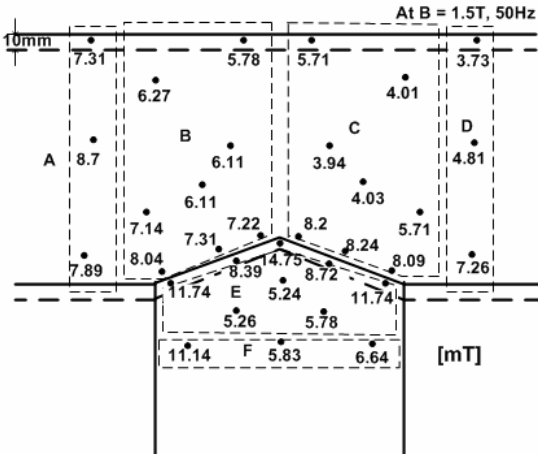

Figure 12: Local variations in mT of the fifth harmonic peak flux density to the fundamental component in-plane of the lamination in different T-joint of three phase staggered core with overlap length 10 mm at 1.5T, 50Hz.

4. CONCLUSION

The flux distribution in cores assembled with M5 material was found varies along overlap area of the stagger at the T-joint. The localised in-plane flux density will increase from the outer to the inner of the 23° T-joint. The localised flux density at the outer edges 23° T-joint is 0.147T and rises to be 0.206T at the inner edges of 23° T-joint when the transformer core energized 1.5 T 50Hz. A large rotational flux is present in the yoke area which near with centre limb. Rotational flux in this region is more circular.

The high third harmonic of peak in-plane flux occurs at the inner edge of right yoke passes over to the Butt-joint of centre limb is 22.2mT.Harmonic occurs mostly in the T-joint where local regions are saturated and the flux deviates from the rolling direction.
A small amount of flux deviation from the rolling direction occurs at the overlap, but no rotational flux is present in the joint.

The local variation in magnitude of the fifth harmonic component of peak in-plane flux density in the 23° T-joint at a core flux density of 1.5T is to be very small

ACKNOWLEDGMENT

The authors would like to express their gratitude to the Malaysian Transformer Manufacturing (MTM) for the supply of transformer core material.

ABSTRACT

This paper describes the result of measurement of localized loss distribution on 100kVA 3phase distribution transformer assembled with 23° T-joint and mitred lap corner joint with staggered yoke. The measurement involves the variation of temperature rise. The localized loss have been measured using no load test by arrays of thermistor on the surface of M5 (CGO) grades material of transformer core laminations. The localised loss at the outer 23° T-joint is 1.05 W/kg and rises to be 1.26 W/kg at the inner 23° T-joint when the transformer core energized 1.5 T 50Hz. The several harmful effects can occur because the flux flows out of the rolling direction.

Keywords
Grain oriented silicon iron, transformer core ,temperature rise, power loss..

1. INTRODUCTION

An important factor in the design of the T-joint in three limbs, three-phase power transformers is the localized loss variation within the joint. Not only is the overall loss of the core affected by the T-joint, but high localized losses can generate hot spots in the core. The power-loss distribution depends upon the localized flux density variation, which in turn depends on the design of the joint. A particular joint configuration might produce rotational flux, normal flux between layers of laminations, or alternating flux directed away from the rolling direction of the laminations, all of which tend to increase the core loss. [1]

The objective of this investigation is to obtain the localised loss distribution of the transformer core built from electrical steel (M5) with 3% silicon iron assembled with 23° T-joint and mitred lap corner joint with stagger yoke by using thermistor.

2. EXPERIMENT APPARATUS AND MEASURING TECHNIQUES

A 3-phase,3 limb stacked cores are assembled with 23° T-joint and mitred lap corner joints as indicated in Figure 1.The core is 550 mm x 580 mm with the limbs and yokes 100 mm wide. The core is assembled from 0.3 mm thick laminations of M5 grain-oriented silicon iron (CGO) as indicated in Figure 2 and the core comprises of 15 layers has staggered yoke of core with overlap length of 5 mm from other adjacent lamination. Staggering alternate layers of laminations in the

yoke direction as indicated in figure 2 is known to reduce the losses of core assembled from silicon iron [2]

Localised loss on the Cold Rolled Grain Oriented (CRGO) is measured by using an array of thermistor to get the satisfactory result. The locations chosen must cover the areas where the loss is more likely to vary direction so as to find distribution of the flux behavior as shown in Figure 3.

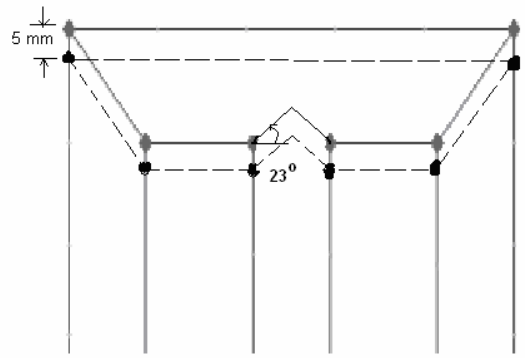

Figure 1: Transformer core type with T-joint 23°

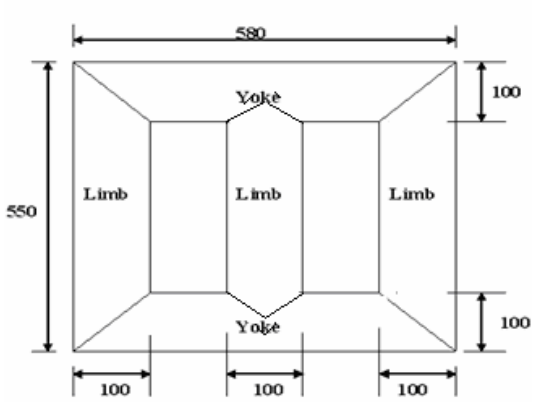

Figure 2: Dimension (mm) of 100kVA transformer model

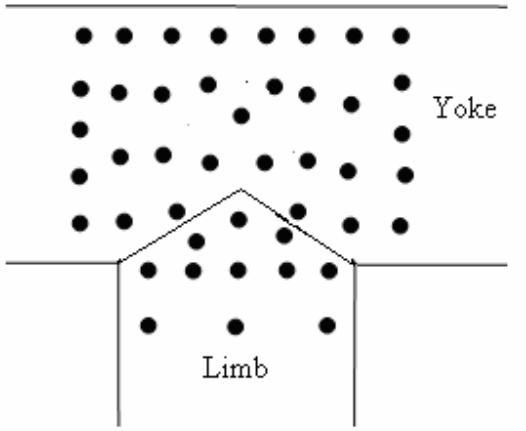

Figure 3: The thermistor position on the T-joint of transformer core

The testing process is done by using the No-Load Test Frame. The No-Load Test Frame consisting of three windings for each three phase core are designed in order not only to avoid introducing stress to the laminations but also to keep the magnetism exactly constant in all limbs of the cores as indicated in figure 4. The core could be energized to 1.5 T (50Hz)

Loss will be obtained by calculating the multiple of gradient temperature on the lamination to relationship constant of gradient temperature and power loss reference. The power loss reference is obtained by using Epstein Test measurement with comparison temperature rise in the the middle of the limb of core lamination and nominal loss at adjusted 1.5T, 50Hz.

The relationship between loss and temperature rise will be found from the equation as follows:

$$P_{loss} = C \, dT/dt \qquad (1)$$

where C is the relationship constant that is C = 14 [W-minutes/kg-°C]

dT/dt is temperature rise from measurement

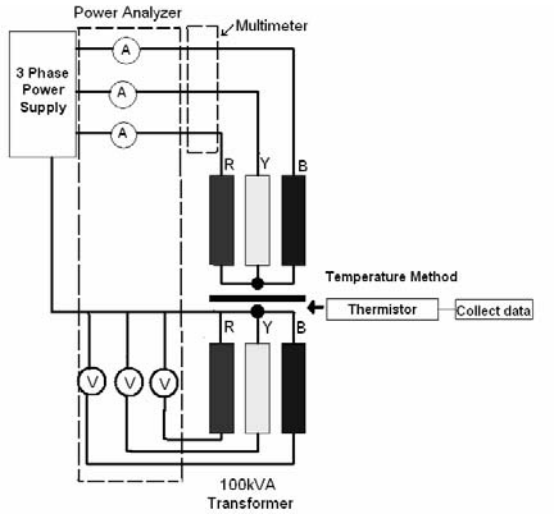

Figure 4: The diagram of the methods that is used to measure the localised temperature rise

3. RESULTS AND DISCUSSION

Figure 5 shows the mesh graph of the localised loss measured by using the thermistor at the 23° T-joint of transformer core lamination. This mesh graph is drawn by using the Matlab software based on the result of this investigation. The power loss at 23° T-joint shows that the power loss reaches a peak at the inner edge of 23° T-joint and the minimum power loss occurs at the outer edge of 23° T-joint of transformer core lamination. The localised power loss will increase from the outer edge to the inner edge of the 23° T-joint. The localised

power loss at the outer edge of 23° T-joint is 1.05 W/kg and rise to be 1.26 W/kg at the inner edge of 23° T-joint when the transformer core energized 1.5 T 50Hz. The major regions where the flux deviates from the rolling direction are at the 23° T-joint where the flux passes from the yoke to the limbs. Here several harmful effects can occur because the flux flows out of the rolling direction.

Figure 6 shows the measuring point of location and localised power loss that are measured by using thermistor at 23° T-joint. This result is produced by calculating the multiple of temperature rise on the lamination to relationship constant of temperature rise and power loss reference.

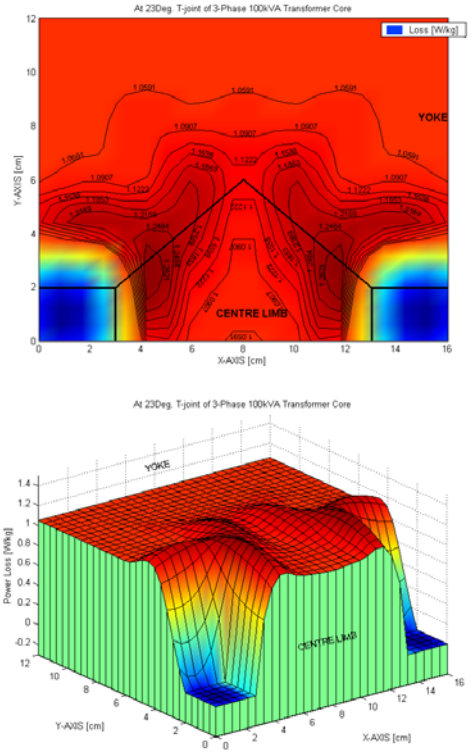

Figure 5: The mesh graph of the localised loss measured by the temperature method at the 23° T-joint.

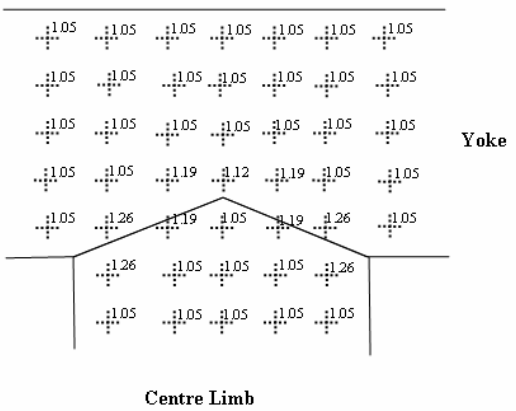

Figure 6: The average localized power loss at 23° T-joint (the values are expressed in W/kg) is measured by using temperature method.

4. CONCLUSION

The localised loss distribution on cores assembled with M5 materials varies along overlap length of 23° T-joint of core laminations. The localised power loss will increase from the outer edge to the inner edge of the 23° T-joint. The localised power loss at the outer edge of 23° T-joint is 1.05 W/kg and rise to be 1.26 W/kg at the inner edge of 23° T-joint when the transformer core energized 1.5 T 50Hz. The T-joint of core lamination occur several harmful effects caused by the flux flows out of the rolling direction.

ACKNOWLEDGMENT

ABSTRACT

This paper describes the result of simulation of flux distribution on 100kVA 3phase distribution transformer assembled with 23° T-joint and mitred lap corner joint with stagger yoke and limb for one lamination. The simulation involves the variation of flux. The flux distributions have been simulated using 2DFEM by Quickfield Software built from M5 (CGO) grades material of transformer core laminations. The flux density is 1.78 T maximum at the centre limb of transformer core and the loss calculation is 1.274 W/kg.

Keywords
Grain oriented silicon iron, transformer core, 2DFEM, power loss calculation.

1. INTRODUCTION

The electrical transformer was invented by an American electrical engineer, William Stanley, in 1885 and was used in the first ac lighting installation at Great Barrington, Massachusetts. The first transformer was used to step up the power from 500 to 3000 V and transmitted for a distance of 1219 m (4000 ft). At the receiving end the voltage was stepped down to 500 V to street power and office lighting. By comparison, present transformers are designed to transmit hundreds of megawatts of power at voltages of 700 kV and beyond for distances of several hundred miles. [1]
Loss evaluation has become important because of high energy cost. Therefore, it is necessary to know in detail the behaviours of flux in transformer in order to develop cores with higher efficiency.

The efficient operation of power transformer cores depends to a large extent on the design of the joints between their limbs and yokes. In the three-phase, three limb core the most complex joints are the T-joints at the intersection the centre limb and yokes.[5]

The quantitative analysis of localized flux and loss distributions has become easier through the remarkable progress of numerical field calculations such as the finite element method. The numerical simulation is more effective and economical than experimental method. Moreover, useful suggestions for improving transformer can be obtained from the calculated flux and loss distribution

The objective of this simulation is to know the flux distribution and calculate the losses occur on the transformer core with 23° T-joint built from M5 grade material using 2D FEM.

2. METHODOLOGY

Methodology that is used to complete this investigation had been divided into three major tasks:

1. Drawing transformer core assemble with 23° T-Joint and M5 grade material
2. Simulation of the transformer core drawing
3. Loss calculation for the transformer core material

Drawing the transformer core configuration is the first step before doing the simulation. In this simulation, this drawing had been done using Quickfield v5.2 software. QuickField is an interactive environment for electromagnetic, thermal and stress analysis. In QuickField, it works with several types of documents: problems, geometry models, material libraries and others. QuickField can perform linear and nonlinear magnetostatic analysis for 2-D and asymmetric models. The program is based on a vector potential formulation.
Dimension of the 100kVA transformer core model are as figure 1. The configuration of T-Joint is drawing in Figure 2.

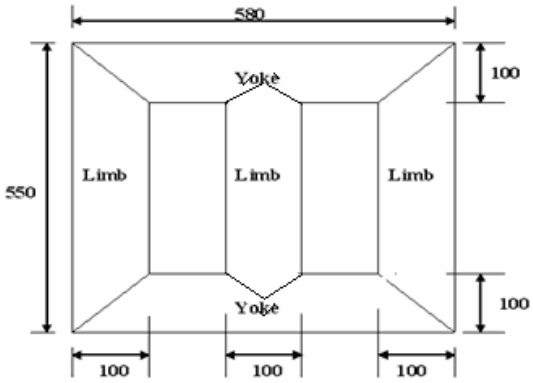

Figure 1: Dimension (mm) of 100kVA transformer core model

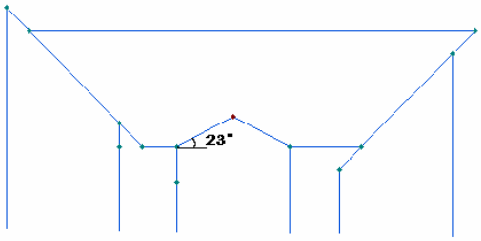

Figure 2 : Transformer core type 23° T-joint

To identify the material, B-H curve reading need to be tuck at the data column for each of the limb. The values for material can be obtained from the B-H curve. The data should be tucking as indicated in table 1.

Table 1: B-H curve data from the exciting force

Flux Density [T]	M5 grades H (Am/g)
0.5	-130
0.6	-129.4
0.7	-129.2
1	-120
1.1	-116.5
1.3	-110.5
1.4	-96
1.5	-80
1.6	0
1.7	310
1.8	1870
1.9	9370

B-H curve data can be took from the hysteresis loop magnetizing curve of the material. Magnetizing curve for M5 grade material is obtained from the technical details of the CRGO material. Each of the limb and yokes block label need to be entering with the data such as coercive force of magnet, field source and others.

Directions of the coercive force of magnet are set to same to both of right and left limb. Only the centre limb are set different direction pole from the both right and left limb. In this drawing, the pole were set to be 90˚ for the right and left limb and the centre limb will be set to -90˚. This will make sure flux from left and right limb will flow through the centre limb. Meanwhile for the upper yoke and lower yoke the direction were set to zero degree for both upper and lower yokes. [2]

After entering the related data for each of the block label properties, data label for edge also need to be set also. In this drawing, only air type and steel type need to be set for the edge label property. In the edge properties, for every edge of the steel need to be assign to tangential field and for the air edge, it need to be assign to magnetic potential

Before any simulation took place, the drawing should be check either mesh can produce all over the drawing or not. There is button build mesh on top of the drawing toolbar. When building mesh is finish, the drawing will be cover with green line all over the drawing.

Simulation only can be executed after mesh had been built off. To execute the simulation, there is executing button on the toolbar icon. If the simulation success without having any error on the drawing a result with flux line flow through the core will come out. Value of flux density can be obtained from the field picture by right clicking on the result drawing. To check the local value, click on local value button and just pointing mouse at any space of the simulation result to get the result value.

3. ANALYSIS

Flux Density formula:

$$B = \mu H \quad (1)$$

$$\mu = \mu_o \mu_r \quad (2)$$

where μ = material permeability
H = material intensity from the table

The flux density is assumed to lie in the plane of model (xy or zr), while the vector of electric current density **j** and the vector potential **A** are orthogonal to it. Only j_z and A_z in planar or j_θ and A_θ in axisymmetric case are not equal to zero. We will denote them simply j and A. Finally, the equation for planar case is

$$\frac{\partial}{\partial_y}\left(\frac{1}{\mu_y}\frac{\partial A}{\partial y}\right)+\frac{\partial}{\partial y}\left(\frac{1}{\mu_x}\frac{\partial A}{\partial y}\right)=-j+\left(\frac{\partial H_{cy}}{\partial x}-\frac{\partial H_{cx}}{\partial y}\right) \quad (3)$$

and for axisymmetric case is

$$\frac{\partial}{\partial_r}\left(\frac{1}{r\mu_z}\frac{\partial (rA)}{\partial y}\right)+\frac{\partial}{\partial z}\left(\frac{1}{\mu_y}\frac{\partial A}{\partial z}\right)=-j+\left(\frac{\partial H_{cy}}{\partial z}-\frac{\partial H_{cz}}{\partial r}\right) \quad (4)$$

where components of magnetic permeability tensor μ_x and μ_y (μ_z and μ_r), components of coercive force vector H_{cx} and H_{cy} (H_{cz} and H_{cr}), and current density j are constants within each block of the model.

In order to find the loss of energy per cycle or magnetization of transformer core lamination as follow;
Let l = mean of iron bar
A = its area of cross section
N = No of turns of wire of the solenoid.
with relate the B-H curve of core material shown in figure 3.

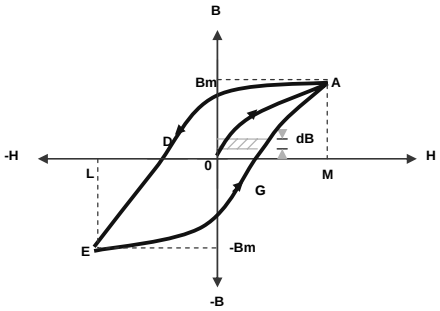

Figure 3: Hysteresis curve

If B is the flux density at any instant, then $\Phi = BA$ when current through solenoid changes, then flux also changes and so produces and induced e.m.f whose value is

$$e = N\frac{d\Phi}{dt} volt \quad (5)$$

$$e = N\frac{d(BA)}{dt} = NA\frac{dB}{dt} volt \quad (6)$$

Now, $H = NI/l$ or $I = Hl/N$ (7)

The power of rate of expenditure of energy is maintaining the current 'I' against induced e.m.f 'e' is

$$= eI.watt = \frac{H.l}{N}\times N.A\frac{dB}{dt} = A.l.H\frac{dB}{dt} \text{ Watt} \quad (8)$$

Energy spent in time 'dt

$$A.l.H\frac{dB}{dt}\times dt = A.l.H.dB \text{ Joule}$$

Total network done for one cycle of magnetization is

$$W = A.l.\oint H.dB \text{ Joule} \quad (9)$$

Hence $\oint H.dB$ = area of the loop, i.e the area between B-H curve and the B-axis.
So, *work done, cycle = A.l x (area of the loop)* Joule
Now *A.l = volume of material*
So *net work done/cycle/m^3 = (loop area)* Joule
Or W = (area of B-H loop) joule/m^3/cycle

4. RESULT AND DISCUSSION

As an overview flux will flow through the core limb in various patterns. From figure 4 it shows that flux flow through centre limb from each left and right limb. Simulation using Quickfield software showing the flux lines flow through the limb and yoke of transformer core.

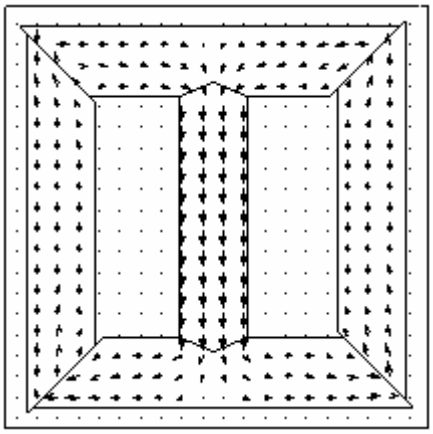

Figure 4: Flux lines flow through transformer core

The flux density value from simulation is 1.78 T as indicated in figure 5. Flux density that is flow through the transformer core is not uniform. The maximum flux density is found in the centre limb of transformer core. Because the flux density that is flow from the left and right limb of the transformer core is enter toward the centre limb of transformer core.

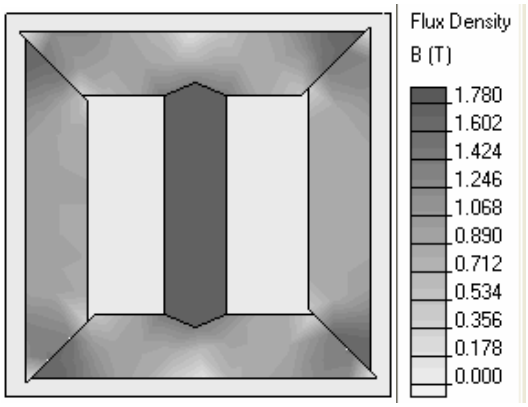

Figure 5: The flux density occur in the transformer core lamination

An energy density value is recorded in unit J/m³. For M5 grade material of the transformer core has the value of energy density is 195 J/m³. Energy density obtained from the simulation result is shown in figure 6. In this figure shows the energy density occurs at the left and right limb of transformer core.

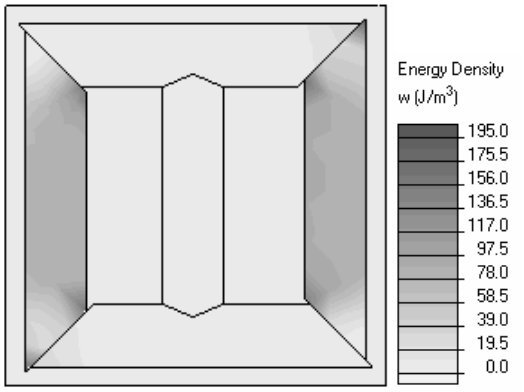

Figure 6: Energy density simulations on transformer core

From the simulation result, some data can be obtained such as;
Energy Density, ωH = 195 J/m^3
Density = 7.65kg/dm^3 (from the B-H curve)

In order to find frequency, the equation is;

$$f = \frac{1}{t} = \frac{1}{t\,\text{sec}} = 50Hz \;;\; t = \frac{1}{50}\text{sec} = 0.02\,\text{sec}$$

From simulation result data, power loss per kg can be calculated using;

$$Power.Loss/kg = \frac{195J/m^3}{7.65kg/dm} = \frac{195J/m^3}{7.65\times10^3 kg/m^3}$$

$$= \frac{195}{7.65\times10^3} J/kg = \frac{195\times50}{7.65\times10^3} J/\text{sec}/kg \quad \mathbf{= 1.274 Watt/kg}$$

5. CONCLUSION

Loss evaluation has become important because of high energy cost. Therefore, it is necessary to know in detail the behaviours of flux in transformer in order to develop cores with higher efficiency.The values for material can be obtained from the B-H curve

From the result of simulation found the flux density is 1.78 T and the loss calculation is 1.274 W/kg. Flux density that is flow through the transformer core is not uniform. The maximum flux density is found in the centre limb of the transformer core.

ABSTRACT

In this research, we focus to the customer side of the meter, which is the effect of harmonic on a laboratory in Electrical System Engineering School at K.Wai Perlis due to nonlinear loads. Harmonic currents in equipments can cause them to experience overheating and increased losses, while harmonic voltage produces magnetic fields rotating at a speed corresponding to the harmonic frequency. This also results in equipments heating, mechanical vibrations and noise, reduced efficiency, reduced life, and voltage stress on insulation of equipment windings.

With the operation of varying nonlinear loads, the injected harmonic current magnitudes and phase angles vary in a random way. In order to attack the problem of power quality, this study will also focus on the development of a computer program to detect and compensate any effects of harmonic distortions. Models are developed to represent the main electrical devices

This research offers the advantage of providing the utility a wealth of information on the effects of harmonics in their equipments. This will subsequently makes them aware of the causes of increased cost and reduced efficiency that may be experienced by using the equipments. In this paper described the investigation cost of harmonic effect as THD, and harmonic energy losses cost

Keyword: *nonlinear loads, Energy losses cost, harmonic, THD.*

1. INTRODUCTION

Because electrical devices that act as nonlinear loads draw current non linearity, they are responsible for injecting harmonic currents into the electricity network. Harmonic is a more important issue for the industry, commerce and the home consumer now than it was a few decades ago. The equipments in laboratory are motor, transformer instrumentations, generator, lamps, Adjustable Speed Drives (ASD), and a variety of load, cable etc, where all of them can be similarly as medium scale industry. There are many causes of harmonics on a power system. In distribution system, transformers are capable of producing harmonics due to magnetic core saturation [1-4]. The effects of harmonics on equipment are: cause additional heating and higher dielectric stress on the capacitors, interruption capability of circuit breakers, the skin effect of the conductors, reduce lamp life, measurement errors in instrument like wattmeter, voltmeter etc, overheating, pulsating torque and noise on rotating machines, etc [5]. The cost to end users comes when the harmonic currents add to the normal load and increase losses and loading on their distribution systems. The increased losses reduce the capacity of the system, including conductors, transformers and motors. The increased loading generates heat and accelerates the aging of power equipment, like transformers and motors [5-6].

2. LITERATURE REVIEW

Harmonic distortion is not new and it constitutes at present one of the main concerns for engineers in the several stages of energy utilization within the power industry. In the past, harmonics represented less of a problem due to the conservative design of power equipment and to the common use of delta-grounded wye connections in distribution transformer. But, the increasing use of nonlinear loads in industry, is keeping harmonic distortion in distribution networks on the rise. Before analyze the harmonic effect, we define the characteristic and model of equipment as below.

2.1 Characteristics and Modeling of Equipment

One important step in harmonic analysis is to characterize and to model harmonic source and all components in system. As we know, the equipments in laboratory are motors, transformers instrumentations, generators, lamps, Adjustable Speed Drives (ASD), and a variety of load, cable etc, where all of them can be similarly as medium scale industry. So, the each equipment can be model as follow:

2.1.1 Personal Computer

Personal computer has significant contribute of harmonics problem to low voltage distribution system

2.1.2. Fluorescent Lamp

The fluorescent lamp was the first major advance to be a commercial success in small-scale lighting since the tungsten incandescent bulb. Fluorescent lamps are about 2 to 4 times as efficient as incandescent lamps at producing light at the wavelengths that are useful to useful to humans [3]. Due to heavy use of non-linearity gas discharge lamp, the fluorescent lamps that employ magnetic or electronics ballast are considered as a significant contributor to

2.1.3. Current source

Each current source data consist of the bus number at which the current source is provided. This followed by injected current at the bus for harmonic orders.

2.1.4. Loads

The three-phase group is used mainly in industry applications and in the power system. For example: Adjustable speed drive, Large UPS's, Arc furnaces, HVDC-links, SVC's [3]. The load is modeled as: a) loads are not considered in the power flow at harmonic frequency, b) parallel combination of resistance and inductive reactance, c) reactance is assumed to be frequency dependent while parallel resistance is kept constant, d) derived by measurements on medium voltage load using audio frequency ripple control generators, e) the load impedance calculated at 50 Hz remains constant for all frequencies and f) series combination of resistance and inductive reactance. In this paper the load model as parallel combination of resistance and reactance.

2.1.5. Series Capacitors

Series capacitors can be modeled as series element consisting of resistance (usually zero or negligible value) in series with reactance

2.1.6. Transmission Line

The series impedance of a line section *l* is represented by z=r+jx as a 3x 3 matrix r, x, and the susceptance too [1]

2.2 Harmonic Indices

The most common harmonic index, which related to the voltage waveform, is the THD, as the root mean square (rms) of the harmonics expressed as a percentage of the fundamental component. It can for voltage and current as follow:

$$THD = \frac{\sqrt{\sum_{h=2}^{\infty} V_h^2}}{V_1} \quad (1)$$

And the power losses due to harmonic:

Active Power:

$$P = \frac{1}{T}\int_0^T p(t)dt = \sum_{h=1}^{\infty} V_h I_h \cos(\theta_h - \delta_h) = \sum_{h=1}^{\infty} P_h \quad (2)$$

Reactive Power:

$$Q = \frac{1}{T}\int_0^T q(t)dt = \sum_{h=1}^{\infty} V_h I_h \sin(\theta_h - \delta_h) = \sum_{h=1}^{\infty} Q_h \quad (3)$$

Apparent Power:

$$S^2 = P^2 + \sum_{i=1}^{n} V_i I_i \sin(\varphi_i) + D^2 \quad (4)$$

And for three phase systems, the per phase (*k*) vector apparent power S_v:[3]

$$S_v = \sqrt{\left(\left(\sum_k P_k\right)^2 + \left(\sum_k Q_{bk}\right)^2 + \left(\sum_k D_k\right)^2\right)} \quad (7)$$

2.3. Standardization of harmonic levels

The rms value of a voltage waveform, considering the distortion produced by harmonic current, IEEE-519 defines the limits as a function of the ratio between the short circuit current at the PCC (I_{sc}) and the average current corresponding to the maximum demand during a period of 12 months (I_L).

3. METHODOLOGY

The methodology in this research as Figure 1 below:

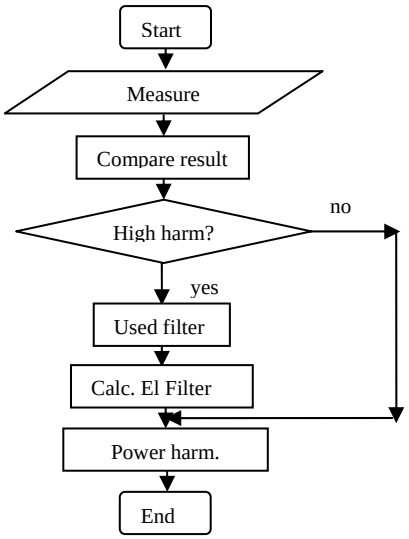

Figure 1 Flow Chart research

4. DATA AND RESULT

The research was measured with PM300 as Figure 2.

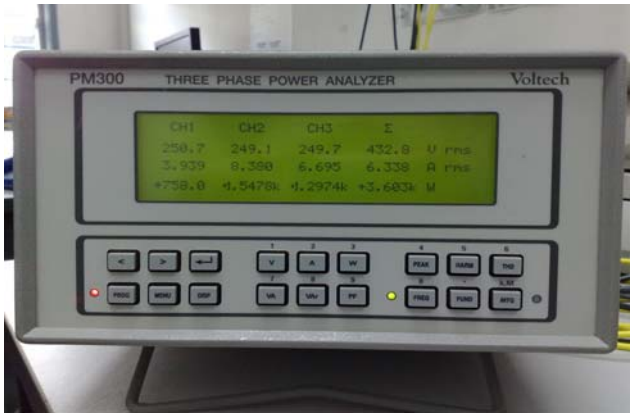

Figure 2.Three phase power analyzer (PM300)

The data at the laboratory is as follow:

5. ANALYSIS

From the data and results, we find that the system has unbalanced nonlinear loads, where in fundamental condition Ch1, CH2 and CH3 have 2.597 A, 5.458 A, and 5.914 A. And voltage at CH1, CH2, and CH3 are: 243.8V, 241.0V and 242.8V. Also, it can be shown from Figure 3 to 5.

Powers for each channel in fundamental condition are: 630.3W, 1.3142KW, and 1.4152KW, while for RMS result are: 629.5W, 1.310KW, and 1.4339KW. This due to the each harmonic powers maybe plus or minus sign. So, the power at fundamental is bigger then RMS result. The total power losses due to harmonic for channel CH1, CH2 and CH3 are: -0.368W, -3.209W and -1.46W. For Apparent power (VA) at channel CH1, CH2 and CH3 in fundamental condition are: 633.2VA, 1.3152KVA and 1.4361KVA, while in RMS are: 790.6VA, 1.6393KVA, and 1.6791KVA. This is due to harmonic orders. For reactive power (VAR) at channel CH1, CH2 and CH3 in fundamental condition are: 60.5VAR, 52.15VAR and 45.18VAR, while in RMS are: 478.2VAR, 984.6VAR and 873.8VAR. This is due to harmonic too.

The voltage THD for CH1, CH2 and CH3 are: 1.92%, 1.81% and 1.96%. And from calculation are: 2.12%, 2.12% and 2.2%. The current THD for channel CH1, CH2 and CH3 are: 71.38%, 72.72% and 59.46%, while from calculation are: 72.5%, 74.8% and 60.2%.

In fundamental condition, the cosφ at channel CH1, CH2 and CH3 are: -0.995, -0.999 and 0.999, while in RMS, p.f. at channel CH1, CH2 and CH3 are: 0.796, 0.799 and 0.854. This is due to cosφ is ratio between load power and apparent power of fundamental component, while p.f. is ratio between load power and total apparent power (including harmonics).

6. CONCLUSION

From result and analysis we conclude as follow:

1 Loads are unbalanced and nonlinear.
2 THD for voltage in each channel are smaller than standardization level IEEE519, where 2.12%, 2.12% and 2.2%. are smaller than 5% in system <6.9KV.
3 THD for current in each channel are smaller than standardization level IEEE519, where 71.38%, 72.72% and 59.46% are smaller than 115%,
4 So, the system do not required filter.

7 AKNOWLEDGEMENTS

The authors would like to express their gratitude to the Fundamental Research Grant Scheme (FRGS), School of Electrical System Engineering of Universiti Malaysia Perlis (UniMAP) and Power Electronics and Electrical Machine Design Research Cluster for the supply of research facility respectively.

ABSTRACT

Power transformers are an integral part of almost all electrical transmission and distribution networks. Their reliable service is of the utmost importance in modern society which is dependent on a constant electricity supply. There are a range of factors that can hinder the operation of power transformer. The harmonic components of the no-load current of the transformer are influenced by many factors, such as the frequency of voltage supply, the flux density, the degree of saturation and the core stacking technique. The affect of high frequency supply (i.e. lower than 50 Hz) to the no-load current harmonic in term of volt ampere reactive (VAR) power consumption is discussed in this paper. The total harmonic distortion percentage (THD) and crest factor (CF) as the harmonic contents are evaluated also. The transformer is connected to variable voltage variable frequency (VVVF) source and the investigation is done on the same flux density. The result has been compared with normal frequency supply (50 Hz). It was found that the harmonic content of no-load current with high frequency were slightly higher than normal one

Key words: *VAR power, single phase transformer, no- load current harmonic, low frequency, VVVF*

1. INTRODUCTION

The no-load loss of a power transformer is the active power loss in the power transformer when it is energized but not supplying a load. Primarily, it consists of a core loss, which is a function of the magnitude, frequency and wave shape of the excitation voltage. It is also varies with temperature, and it is particularly sensitive to distortion of the supply voltage waveform. The no-load loss is very small part of power rating of a power transformer, usually less than 1%. For a constant operating voltage and frequency, it is essentially constant and does not vary with load. However, it can represent a significant operating expense for a utility, especially if its energy costs are high. Accurate measurement of these losses are essential for the correct evaluation of power transformer since the no-load losses are often a determining factor when electrical utilities select a supplier for their power transformer purchases [1][2].

No-load losses are usually reported based on a sinusoidal voltage excitation and normal (50 or 60 Hz) frequency. However, even with a sinusoidal source voltage, the nonlinear relation between the flux density and the magnetic field strength in the transformer core will introduce significant harmonics into the excitation current. The harmonic components of the no-load current of the transformer are influenced by many factors, such as the frequency of voltage supply, the flux density, the degree of saturation and the core stacking technique [3].

The measurements of the transformer no-load current is addressed in IEC Standard 76-1 under clause 10.6 “Measurement of the harmonics of no-load current”[4]

An effect which can also stem from core saturation is increased volt ampere reactive (VAR) power consumption, leading to voltage-control problems, generating significant harmonic currents, and cause heating of the internal components of transformer itself, leading to gas relay alarm/operation as well as possible damage [2]. The VAR absorption can be explained by realizing that core saturation result in magnetizing current which is basically an inductive current. If saturation is severe the VAR absorption will increase and become noticeable, along with an associated in displacement power factor.

Real power

$$P = V I \cos\varphi \quad (1)$$

Reactive power

$$Q = V I \sin\varphi = P \tan\varphi \quad (2)$$

Where: P = real power (watt)
Q = reactive power (VAR)
V = input voltage (volt)
I = input current (Ampere)
$\cos\varphi$ = input power factor

ISSN 114-1284

2. TRANSFORMER OPERATION WITH LOW FREQUENCY SUPPLY

The general form of emf induced in primary and secondary windings of a single-phase transformer is

$$E = 4.44\ N\ f\ B_{max}.A \qquad (3)$$

where N is number of windings, f is supply frequency (Hertz), B_{max} is magnetic flux density in core (Tesla) and A is effective core area (m^2). Because of A is constant (can be calculated from core configuration), and by assuming, that the input voltage equal to primary emf induced, the magnetic flux density can be varied by varying the input voltage, meanwhile the frequency is maintained constant.

There are three methods of estimating harmonic load content: the Crest-factor (CF), Harmonic Factor or Percent Total Harmonic Distortion (%THD) and "K-Factor". In this paper we focuses on the very simple harmonic estimation technique is the Crest Factor. Crest Factor is a measure of the peak value of the waveform compared to the true rms value. The mathematical definition, of the crest factor is the ratio of the peak value of the waveform divided by the rms value of the waveform:

$$CF = \frac{Peak\ of\ waveform}{rms\ of\ waveform} \qquad (4)$$

By definition, a perfect sine wave current or voltage will have a crest factor of the square root of 2 or 1.414 and any deviation of this value represents a distorted waveform. Note that the crest factor can also be lower than 1.414. A square wave, for example, would have a CF of 1 [6].

The percent total harmonic distortion (%THD) can be defined in two different ways, as a percentage of the fundamental component (the IEEE definition of THD) or as a percentage of the rms (used by the Canadian Standards Association and the IEC) [6]. In this paper we uses the later one.

$$THD = \frac{\sqrt{\sum_{h=2}^{\infty} V_{h,rms}^2}}{V_{rms}} x100\% \qquad (5)$$

where $V_{h,rms}$ is the amplitude of the harmonic component of order h (i.e., the *h*th harmonic) and V_{rms} is the rms values of all the harmonics) that can be represented as

$$V_{rms} = \sqrt{\sum_{h=1}^{\infty} V_{h,rms}^2} \qquad (6)$$

The total power factor is called distortion power and results from the harmonic component of the current:

$$PF = \frac{1}{\sqrt{1+\left(\frac{THD}{100\%}\right)^2}} \qquad (7)$$

3. MODEL

The transformer test (handheld based) has the specification as: single-phase transformer, core type with primary winding of 220 turns and secondary of 220 turns respectively. The lamination of core material is M5, 3 millimeter thickness and 10 cm width. It consists of 12 layers with 10 cm corner overlap length configuration.

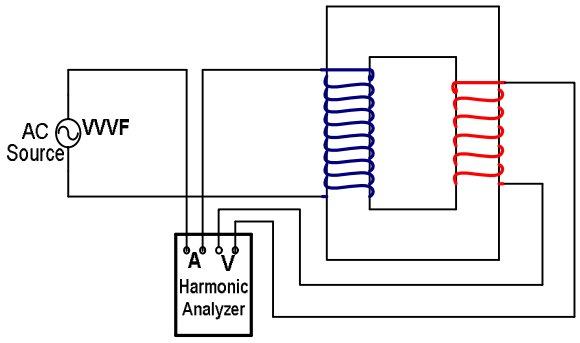

Figure 1 Arrangement of experimental set-up

The arrangement of equipment set-up which used in this research work is as shown in Figure 1. The input current to harmonic analyzer (PM 300) is connected to ac variable voltage variable frequency supply and its voltage is come from the secondary side of transformer test. The experiment was conducted with different flux density by varying the input voltage and frequency.

Example of voltage supply calculation:
Core Area, A = 17 x 0.1 x 0.0003 = 0.00051 m^2
for N = 220
f = 40 Hz
B = 1.5 T
Voltage, V = 4.44 x 220 x 40 x 1.5 x 0.00051
V = 19.93 V
The same procedures is used to calculate the voltage supply for the others frequency and magnetic flux density values.

4. RESULT

The examples of current and voltage waveforms and the individual harmonic distribution for the different input (primary) voltages or different magnetic flux density (1.5 T and 1.8T) with frequency 40 Hz are shown in Figure 2 to Figure 5.

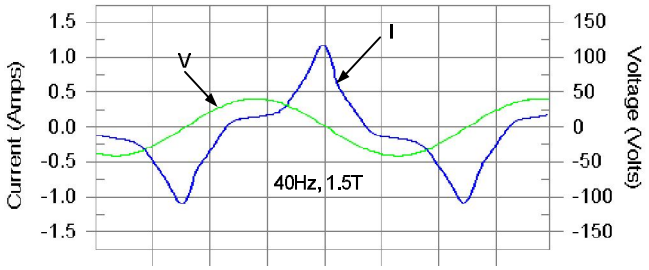

Figure 2 Current and Voltage waveforms for B = 1.5T

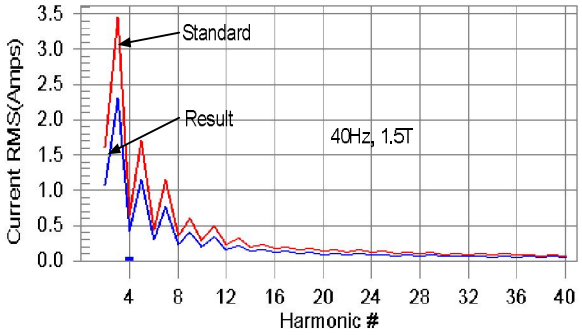

Figure 3 Individual harmonic distribution of input current for f = 40Hz, B=1.5T

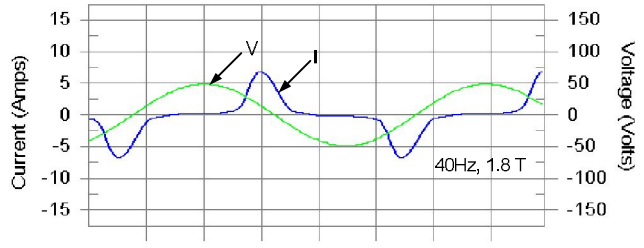

Figure 4 Current and Voltage waveforms for B = 1.8 T

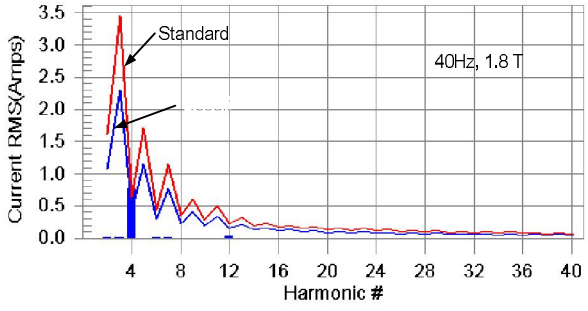

Figure 5 Individual harmonic distribution of input current for f = 40Hz, B=1.8T

5. DISCUSSION

Figure 2 shows that the input current waveform for lower magnetic flux density (B = 1.5 T) is better (more sinusoidal) than for B = 1.8 T as its shown in Figure 4. These conditions are more clearly displayed in term of individual harmonic distribution in Figure 3 and Figure 5. The distortion pattern displayed in Figure 5 is a result of waveform for f = 40Hz, B=1.8T. As the magnetic core tends to saturate, some of individual harmonic has reach out of limit (Standard). This situation can be used as the reason why the transformer is always suggested to operate at magnetic flux density below the saturation condition.

The characteristics of volt ampere reactive (VAR) power consumption to variable magnetic flux density is shown in Figure 6. The graphs of the percentage of input current total harmonic distortion and crest factor to magnetic flux density are displayed in Figure 7 and Figure 8. With respect to Figure 7, the VAR absorption for higher frequency (in this investigation is 50 Hz) supply is slightly higher. The changes of harmonic contents are not so significant. These conditions are shown in Figure 7 and 8. One of the important thing is changes (increment) of VAR, %THD and CF are very significant when the magnetic flux density is increased from 1.5 T to 1.8 T. This phenomena can be used as saturated measured interm of VAR power consumption and harmonic contents.

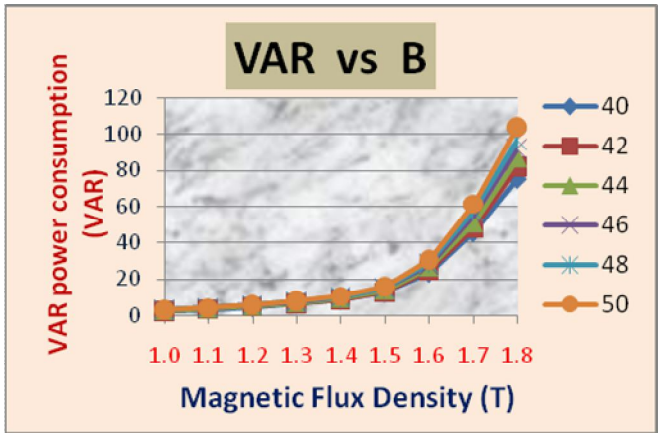

Figure 6 VAR vs Magnetic flux density(B)

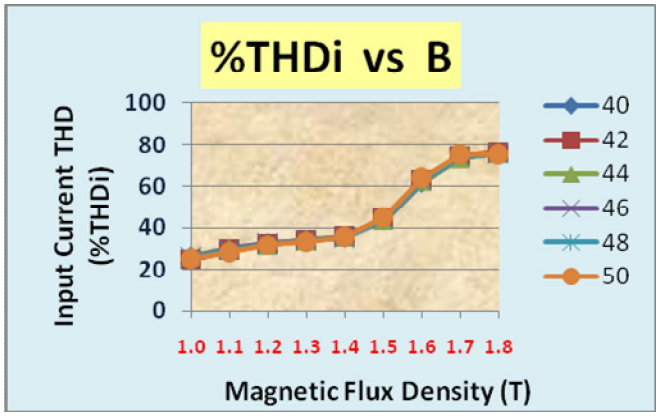

Figure 7 %THD vs Magnetic flux density(B)

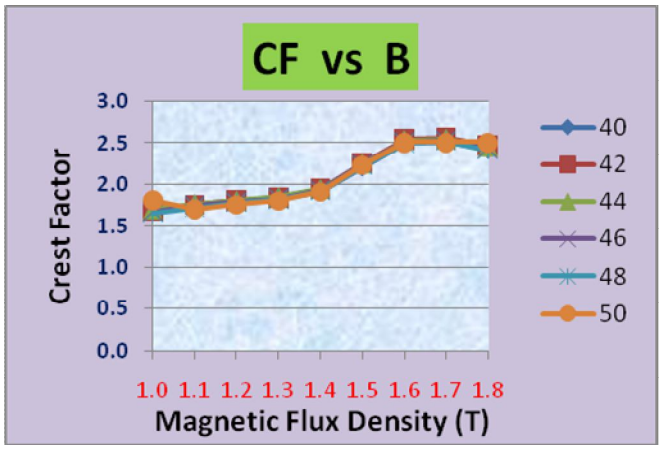

Figure 8 Crest Factor vs Magnetic flux density(B)

6. CONCLUSION

A number of investigations were conducted to determine the volt ampere reactive power consumption and harmonic performance of a single phase transformer operating under various low frequencies supply (i.e., 40 to 50 Hz) and at different magnetic flux density. The result shows that the VAR power consumption is lower when primary winding subjected to low frequency supply.

The harmonic content of the input currents are not so differ, however, the increasing of VAR and harmonic content are quite significant when the magnetik flux density increas from 1.5 to 1.8 T.

ACKNOWLEDGMENT

ABSTRACT

This paper describes the result of an investigation in 3-phase 100kVA transformer core assembled with staggered yoke of 10mmoverlap length. The investigation involves the variation of normal flux distribution in the core lamination. The normal flux distribution has been measured at T-joint core model of 15 layers of lamination by arrays of search coil. The highest normal flux distribution occurs at the upper edge of the middle limb that is 0.170T and lowest at upper edge of yoke that is 0.1T. The average value of normal flux distribution is high at flux transfer region of the lamination. The flux transfer mechanism shows that two separate path flowing horizontally in the yoke before leaving the lamination to vertically adjacent layer and combine with the flux in that layer. The Fluxs will drops in the T-joint are approached as flux diverts to adjacent laminations above and below to avoid the high reluctance air gap.

Keywords: Grain oriented silicon iron, transformer core, normal flux distribution, fundamental flux.

1. INTRODUCTION

Power transformers are usually employed in electric power stations, high voltage transmission lines and large utilities. On the other hand, distribution transformers can be found in small and midsize industries, hotels, hospitals, schools, entertainment centers, residential areas and etc [1]. Transformers are ubiquitous in all part of the power system, between all voltage levels, and exist in many different sizes, types and connections [2]. Grain-oriented 3% silicon-iron is used for transformer cores where high efficiency and low weight are often paramount [3]. The efficient operations of power transformer cores depend on a large extend on the design of the joints between their limbs and yokes. The most complex joint in three limb cores are the T-joints at the intersection of the centre limb and yokes. Under ideal conditions the total flux in the limbs of a transformer core has a sinusoidal waveform, but in the corners of the core the flux is far from sinusoidal. The additional loss caused by the flux distortion can lead to localized heating within the joints [4]. The objective of this research is to measure normal flux distribution on the lamination of transformer core that built from the electrical steel (M5 grade material) 3% silicon-iron assembled with 23o T-joint mitred lap corner joint with staggered yoke by using array of search coils.

2. EXPERIMENT APPARATUS AND MEASURING TECHNIQUES

Three phase 100kVA distribution transformers are assembled with 23° T-joint, mitred overlap corner joints length of 10mm as indicated in figure 1. Each core is 550 mm x 580 mm with the limbs and yokes 100 mm wide as indicated in figure 2. The main apparatus consisted of three phase cores, two yoke cores and three limbed cores and the cores are assembled from 0.3 mm thick laminations of M5 grain oriented silicon iron (CRGO) [7]. Each core comprises of 15 layers. The system for measuring normal flux density is shown in Figure 3.

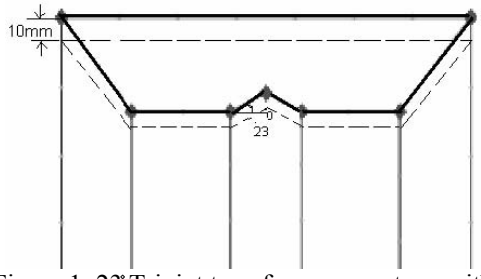

Figure 1: 23° T-joint transformer core type with staggered yoke 10mm

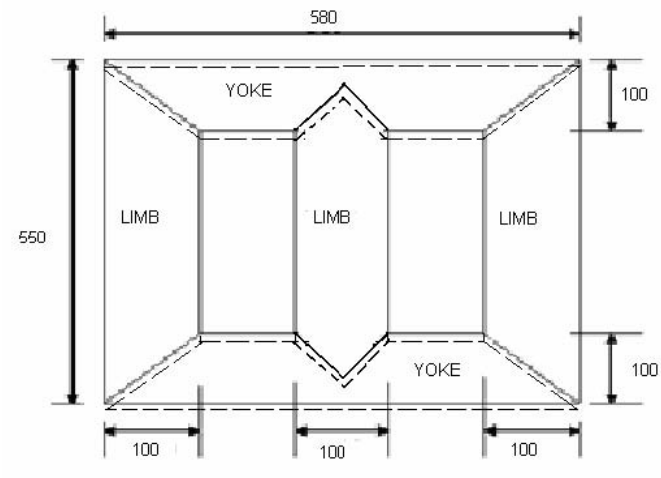

Figure 2: Dimension (mm) of 23° T-joint 100kVA transformer model

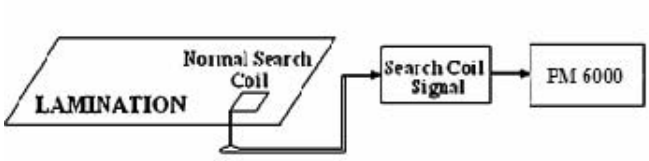

Figure 3: Associated system for measuring normal flux density.

In order to study the normal flux density variation, normal search coil arrays are used to measure normal flux density variation along and across the lamination. The squares of 10mm x 10mm normal search coils are placed on a layer of lamination at the T-joint of the transformer core. The locations chosen must cover the areas where the flux is more likely to vary direction so as to find the mechanism distribution of the flux behavior. The location of the investigation for the transformer core is shown in figure 4.

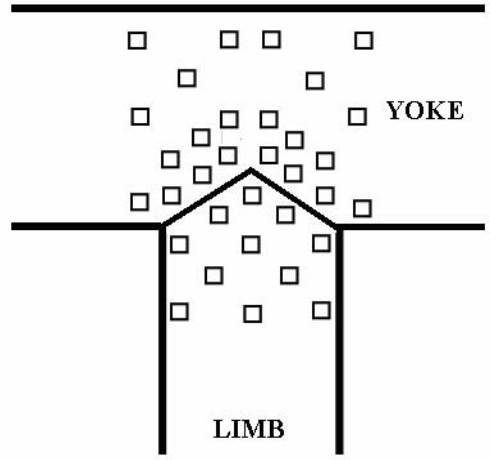

Figure 4: The normal search coils position in the T-joint of transformer core

3. RESULTS AND DISCUSSION

Fundamental normal flux density at T-joint flowing in a direction normal to the plane of the lamination in the staggered yoke 10mm 1.5T, 50Hz is shown in figure 5.

The magnitude of the normal flux density is high at and close to an intersection between two adjacent laminations. The highest normal flux occurs at the corner edges of centre limb that is 0.170T at flux density 1.5T, 50Hz. The average magnitude of normal flux density is largest at the overlap region and smallest at the upper edge of the right yoke. The fundamental normal flux density increases as it approaches the T-joint and gradually decrease as it travels further away from the joint. The magnitude of fundamental normal flux density traveling between joints reaches minimum at the mid point of centre limb. This alteration in the fundamental normal flux density is due to increase and decrease of flux density that has been energized.

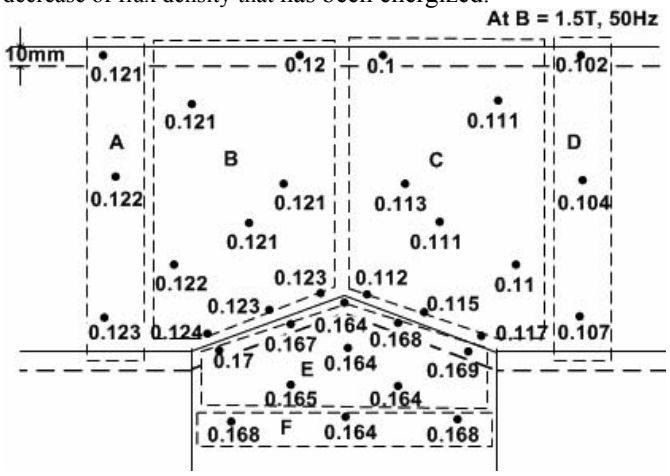

Figure 5: Distribution of the normal direction of fundamental flux density at T-joint with overlap length of 10mm during 1.5 at 50Hz.

The instantaneous magnitude and direction of flux at this instant is shown in figure 6 at this instant the total flux in the centre limb reaches its maximum and both right and left yoke carry half their maximum flux.
Since the yokes carry only half the maximum value of the total flux, the majority of the flux from the outer of right and left yoke is carried through the inner half of junction of middle limb and the largest flux concentration is found in the upper edges of middle limb.

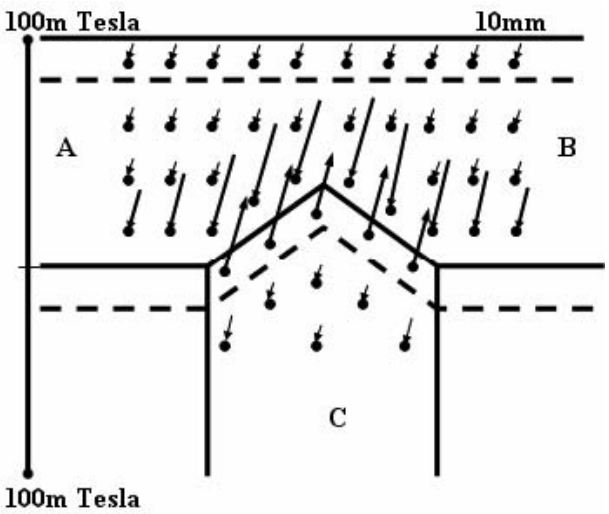

Figure 6: Distribution of the fundamental component of localised normal flux density in the 23° T-joint of three phase core built at different instant in time when ωt=60°.

Flux path and flux transfer mechanism between laminations at the T-joint has been illustrated as figure 7 for staggered yoke arrangement. The diagram shows that the flux transfer mechanism between yoke and limb in the T-joint may occur simultaneously at the same instant in time. This can be seen for example at the A and B region where two separate path flowing horizontally before leaving the lamination to vertically adjacent layer of D and F respectively and combines with the flux in that layer. Consequently, the core material in this region approaches saturation. At the same time, this existing flux will transfer back to the C region and extend to the whole length of the middle limb. It has been noticed that the magnitude of normal flux density high at the inner edges of yoke at junction between yoke and middle limb and decrease as the distance away from the joint.

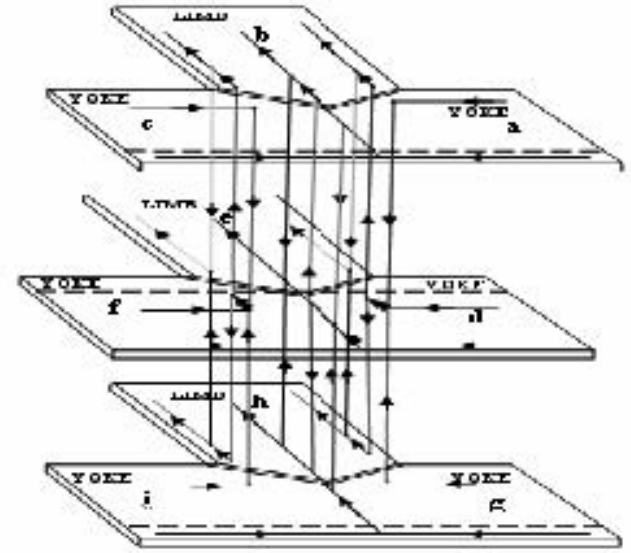

Fig. 7: Flux transfer between laminations of staggered yoke limb arrangement at the T-joint.

4. CONCLUSION

From the result of this investigation, the normal flux distribution in the cores assembled with 23° T-joint was found varies along overlap area of the staggered at the T-joint. High normal flux distributions occur in the corner edge of the centre limb that is 0.170T and gradually decrease as it travels far away from the joint area.
The flux transfer mechanism between yoke and limb in the T-joint may occur simultaneously at the same instant in time. The flux transfer mechanism most occur at T-joint of the transformer core compared to the other places. The magnitude of normal flux density is high at nearest of the junction of T-joint and decrease as the distance away from the joint.

ACKNOWLEDGEMENTS

The authors would like to express their gratitude to the Malaysian Transformer Manufacturing (MTM) for the supply of transformer core material.

ABSTRACT

A new method for operating a stand-alone wind/diesel/battery system is presented in this paper. The diesel generator is controlled so that the state of charge (SOC) of the battery may be maintained at a certain specified charge level in daily time. The battery is discharged when the SOC is higher than the specified charge level and charged when lower. A simulation is carried out over one year using the hourly data of electric load, wind speed, and atmospheric temperature on Kamishima Island, Japan in 2006. This method is compared with other operating methods: a conventional operating method maintaining the battery charge level at the full level (FCL), and dynamic programming (DP) operating method. The results show that for diesel generator fuel consumption, this method is better than FCL, although not to the DP.

Keywords

Hybrid system, fuel consumption, simulation, battery charge level.

1. INTRODUCTION

Many stand-alone wind/diesel/battery systems have been installed on remote islands. These systems are operated so that the fuel consumption of the diesel generator (DG) is minimized without causing any blackouts. In such operation, the battery has the role of storing surplus energy or of assisting a wind turbine generator. The operation method of the battery differs with the purpose for which it is controlled. For example, if the battery is used as an energy sink, it is desirable to hold the state of charge at a limited low level. On the other hand, if it is used as an energy source, it is desirable to hold the state of charge at a limited high level. In this study, the purpose is to reduce the yearly fuel consumption of DG as low as possible. For that purpose, the wind energy is stored temporarily in the battery when wind turbine generator (WTG) output is higher than electric load, and used effectively when WTG output is lower than electric load. To do this, the state of charge must be held at an intermediate level between the limited high and low levels. For this reason, the Specified Charge Level operating method (SCL) is proposed. A simulation was performed for over one year using the hourly data of electric load and wind speed on Kamishima Island, Japan in 2006. The most suitable battery charge level was sought, i.e., the level at which fuel consumption is lowest. The SCL method is compared with other methods from the viewpoints of annual fuel consumption and excess energy.

2. ENERGY FLOWS

Energy flows in the wind/diesel/battery power system are shown in figure 1, in which $P_W(t_i)$ is the output of the wind generator, $P_d(t_i)$ is the output of diesel generator, $P_l(t_i)$ is the electric load, $P_{dl}(t_i)$ is the excess energy dumped to dummy load, and $P_b(t_i)$ is the charge or discharge energy of the battery. $P_b(t_i)$ is positive when the battery is discharged, otherwise is negative. t_i is the hourly time. These flows must satisfy the equation (1).

$$P_w(t_i) + P_d(t_i) + P_b(t_i) = P_l(t_i) + P_{dl}(t_i) \qquad (1)$$

The operation of the system is divided into three scenarios depending on the electric load, $P_l(t_i)$, the output of WTG, $P_w(t_i)$, and the battery charge level, $X(t_i)$, as follow:

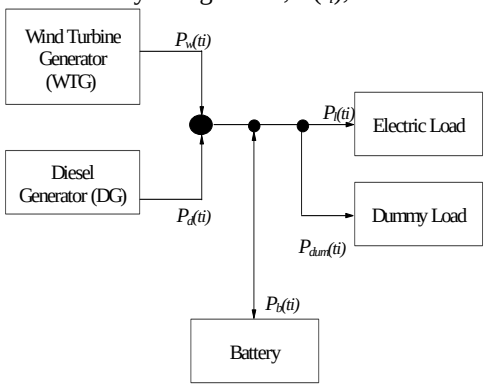

Figure 1: Energy flows in wind/diesel/battery system

ISSN 114-1284

Scenario 1: $P_l(t_i) > P_w(t_i) + P_{dr}$
Scenario 2: $P_l(t_i) \le P_w(t_i) + P_{dr}$ and $X(t_i) \le X_s$
Scenario 3: $P_l(t_i) \le P_w(t_i) + P_{dr}$ and $X(t_i) > X_s$
Where, P_{dr} : the rated output of DG
X_s : a specified charge level of battery

3. ELECTRIC LOAD AND WIND ENERGY

The monthly variations of electric load and wind turbine generator output at Kamishima Island are shown in figure 2. The electric load is high in July and August. Since the yearly electric load energy is 1,538 MWh and the peak load is 393 kW, so the load factor is 46%. The average daily electric load is 4,336 kWh.

Matching the power-wind speed characteristics of a commercial wind turbine generator with hourly wind speed data from over one year makes the wind energy calculations. The characteristics of the wind turbine generator are described by an equation (2). The calculation result is for a case in which the rated output of WTG is 250 kW. The wind energy is high in January, February, March, November and December.

4. OUTPUT CHARACTERISTIC OF SYSTEM COMPONENTS

4.1 Characteristic of Wind Turbine Generator

Output - wind speed characteristics (P_w - v characteristics) of WTG is shown in Figure 3. It is formulated as equation (2):

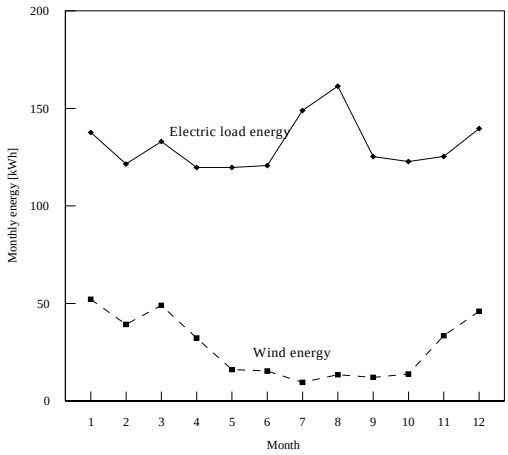

Figure 2: Monthly variations in electric load and wind energy.

$$P_w(t_i) = \begin{cases} 0 & (v(t_i) < v_c,\ v_o \leqq v(t_i)) \\ P_{wr} \times (v(t_i) - v_c)/(v_r - v_c) & (v_c \leqq v(t_i) < v_r) \\ P_{wr} & (v_r \leqq v(t_i) < v_o) \end{cases} \quad (2)$$

Where P_{wr} is the rated output of WTG, v_c is the cut-in wind speed, v_r is the rated wind speed and v_o is the cut-out wind speed. Here, P_{wr} = 250 kW, v_c = 3 m/s, v_r = 12 m/s, v_o = 25 m/s.

4.2 Characteristic of Diesel Generator

The fuel consumption of the diesel generator is calculated using the following equation:

$$F_d = a \cdot P_d^{\,2} + b \cdot P_d + c \quad (3)$$

Where F_d is the fuel consumption and P_d is the output. The coefficients a, b, and c are determined by fitting the equation (3) to the characteristic of a commercial DG. The DG output is controlled between 20% and 100% of the rated power. In this study, the rated outputs are taken as parameters: 250, 300, 350, and 400 kW.

4.3 Characteristic of Battery

At present, a lead battery is exclusively used as the energy storage. In the near future, however, a sodium sulfur (NaS) battery will be commercially available. NaS battery's performance is higher than the lead battery. The characteristic of NaS battery is utilized in this study.

The battery capacity is taken as a parameter and expressed in percentages. The capacity of 100% is equivalent to an average daily electric load (4,336 kWh). Charging and discharging efficiencies are 85% and 100% respectively. Battery hourly charge rates are limited to 10% and 20% of the battery capacity when charging and discharging, respectively.

5. THE OPERATING METHOD

The integrated wind/diesel/battery system must meet the daily and annual energy demand as well as the peak load at any time. In that condition, it is technically desirable to reduce fuel consumption and excess energy to as low a level as possible. The fuel is consumed in DG. In the event that the output from WTG exceeds the electric load and the battery charge level is maximum, then the excess energy is drained away to the dummy load that is installed parallel to the electric load. Therefore, the battery and the DG have to be so operated that the system may meet these requirements. Here the WTG is assumed to be uncontrollable. In this study, a new operating method that we call the Specified Charge Level method (SCL) is proposed. In this method, the system is so operated that the battery charge is kept at a specified level as long as possible. That level is between 20 and 100 % of battery capacity. When the charge is lower than the specified level, the output of DG has to be increased to charge the battery, but when the charge is higher than the specified level, the output of DG has to be decreased to discharge the battery. Should the charge drop to less than a 20 % level, a shortage supply would occur. On the other hand, when the charge rises to around the 100 % level, excess energy generated by the WTG must be dissipated. Therefore the specified charge level has to be selected appropriately.

The operation of the system is divided into three scenarios depending on the electric load, $P_l(t_i)$, the output of WTG, $P_w(t_i)$, and the battery charge level, $X(t_i)$.

A Flow chart of the SCL method is shown in figure 3. First, data of the electric load, wind speed, and system parameters are read. After reading the specified charge level of the battery, X_s, the initial charge level $X(0)$ is set as same as X_s. Then the output of WTG is calculated, and the diesel generator and the battery are operated comparing $X(ti)$ with X_s such as in scenarios 1, 2, and 3. The calculation is repeated hourly, and finally the annual fuel consumption is obtained.

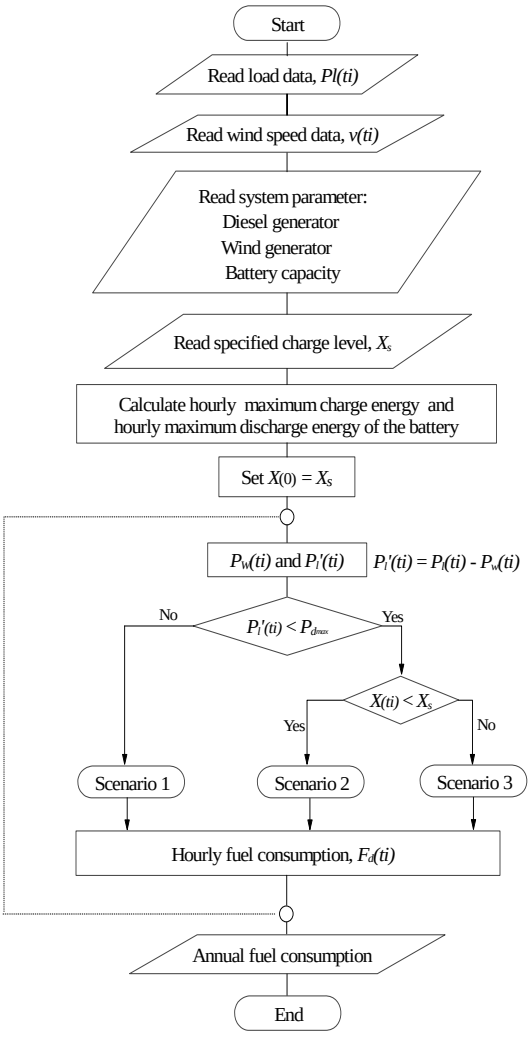

Figure 3: Flowchart of SCL operating method.

6. RESULTS AND DISCUSSION

6.1 Fuel Consumption and Minimum Specified Charge Level

Figure 4 shows annual fuel consumption as functions of the battery specified charge level for different rated outputs of DG, the battery capacity is 100 %. Fuel consumption is almost constant at specified levels from 20 % to 90 % and increases as the specified level rises from 90 % to 100 %. It also increases as the rated power of DG increases.

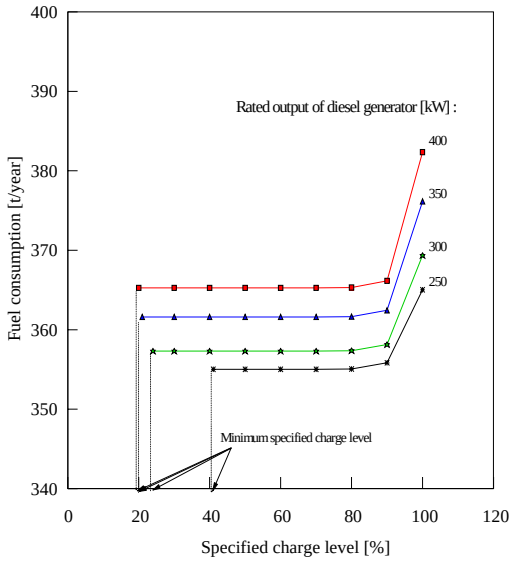

Figure 4: Annual fuel consumption vs. specified charge level.

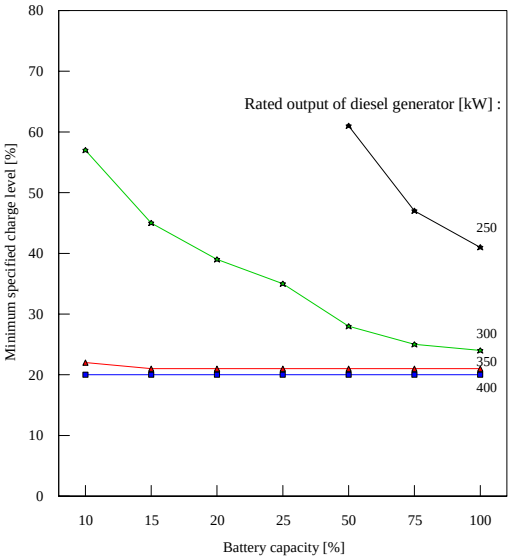

Figure 5: Minimum specified charge level vs. battery capacity for various diesel generator sizes.

Figure 5 shows the minimum specified charge level as a function of battery capacity for different rated outputs of DG. When the rated output of DG is 400 kW, the minimum specified charge level remains at 20 %, and rises to 21 % if the rated output of DG is 350 kW. However, when the rated output of DG is 300 or 250 kW, the minimum specified level would increase at the same battery capacity.

6.2 Comparison to Other Operating Methods

In order to estimate the SCL operating method, it has to be compared to other operating methods. Here, two methods are adopted: The full charge level (FCL) operating method and the dynamic programming (DP) operating method.

6.2.1 FCL Operating Method

As mentioned above, the stand-alone wind/ diesel/battery power system has to avoid the shortage of power supply to the electric load. Hence, it is favorable to maintain the battery charge at a full level, i.e., 100%. The FCL operating method is the common operating method and corresponds to the SCL operating method in which the specified charge level is set to 100%.

6.2.2 DP Operating Method

If the hourly data on electric load, and wind speed are known for one full year, the dynamic programming (DP) method could be available as the system operating method. In the DP method, the estimated value is the annual fuel consumption, the control variable is the DG output, and the state variable is the battery charge level. The DP operating method theoretically gives the lowest fuel consumption.

6.2.3 Comparison Results

Figure 6 shows the annual fuel consumption as functions of battery capacity for different operation methods, FCL, MSCL (SCL at minimum charge level), and DP. It is evident that the fuel consumption of the MSCL method is lower than that of the FCL method by 12 t (3 %), although higher than that of the DP method by 14 t (4 %). It is concluded that the MSCL method is superior to the FCL method although inferior to the DP method.

7. CONCLUSION

An operating method, SCL operating method, applicable to a stand-alone wind/diesel/battery power system is introduced in this paper. The output of diesel generator is controlled not only to meet the electric load but also to maintain the battery charge at certain specified charge level. A simulation is performed over one year using the hourly data of electric load and wind speed of Kamishima Island, Japan in 2006.

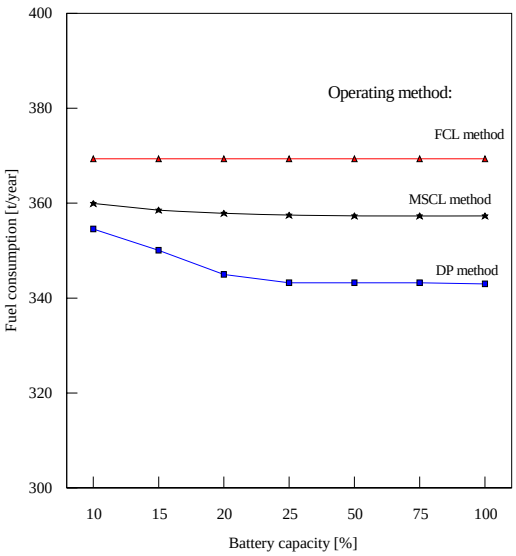

Figure 5: Fuel Consumption of Various Methods.

The SCL operating method is compared with others, i.e., the FCL operating method and the DP operating method. By the simulation results, the fuel consumption of the SCL operating method is lower than that of the FCL operating method but not than the DP.

ABSTRACT

This paper proposes an algorithm for RFID-based red light violation detection. Previous works of red light violation detection were developed using by the camera or the video and the combination digital camera-sensor of magnetic flux systems. We propose a red light violation detection algorithm using by combine of the RFID technology and the sensor of magnetic flux. Two algorithms is used, the first algorithm uses the ID track from one RFID Reader to another to detect vehicle movement. The second algorithm measures timing between the RFID Reader and the RFID Flux sensor and tags detection.

We hope our proposed system is better than previous system using the camera or the video and the combination of camera-RFID systems. Our design opens the possibility of detecting the violating vehicle in more accurate manner in terms of: able to detect dynamic vehicle speed, independent of lighting condition and more numbers of vehicles detection on a capture time.

1. INTRODUCTION

RFID (radio frequency identification) is a flexible technology that is convenient, easy to use, and well-suited for automatic operation. It combines advantages not available with other identification technologies. RFID can be supplied as read-only or read/write, does not require contact or line-of-sight to operate, can function under a variety of environmental conditions, and provides a high level of data integrity. In addition, because the technology is difficult to counterfeit, RFID provides a high level of security.

The term RFID describes the use of radio frequency signals to provide automatic identification of items. RFID is used in applications such as:

- Electronic toll collection (ETC)
- Railway car identification and tracking
- Intermodal container identification
- Asset identification and tracking
- Item management for retail, health care, and logistics applications
- Access control
- Animal identification
- Fuel dispensing loyalty programs
- Automobile immobilizing (security)

Radio frequency (RF) refers to electromagnetic waves that have a wavelength suited for use in radio communication. Radio waves are classified by their frequencies, which are expressed in kilohertz, megahertz, or gigahertz. Radio frequencies range from very low frequency (VLF), which has a range of 10 to 30 kHz, to extremely high frequency (EHF), which has a range of 30 to 300 GHz [1],[2]. RFID components are RFID tag, RFID reader and RFID database.

In this paper, we propose on the rfid application issues with red light violation detection. The previous papers [3],[4] have explained the red light violation detection by using a video or a camera and combine a digital camera and a sensor of magnetic flux . By video or camera is resulted video detect up to 50% of the capturing rate on day time and up to 45% of the capturing rate on night time. By combine a digital camera and a magnetic flux is resulted coil detect fewer than 95% of the capturing rate on day time and fewer than 90% of the capturing rate on night day [4]. We propose the red light detection violation using by combine the RFID technology and the sensor of magnetic flux.

Automatic license plate recognition plays an importance role in numerous applications and a number of techniques have been proposed. The former characterized by fuzzy disciplines attempts to extract license plates from an input image, while the latter conceptualized in terms of neural subjects aims to identify the number present in a license plate [5]. A high-resolution image of the number plate is obtained by fusing the information derived from multiple, subpixel shifted, and noisy low-resolution observations. The image to be superresolved is modeled as a Markov random field and is estimated from the observations by a graduated nonconvexity optimization procedure. A discontinuity adaptive regularizer is used to preserve the edges in the reconstructed number plate for improved readability [6].

In the proposal method, a tracking algorithm is presented to monitor a vehicle movement. A vehicle with RFID tag moves inside RFID network that is placed at a road cross-section. The RFID tag fills a license number information of the vehicle. For simplicity we assume a quarter of road cross-

section. The RFID reader is placed on a left side of road corner of each section. A radiation area of antenna of RFID reader is adjacent each others, there are not overlapping.

This paper is organized as follows. In section 2, the tracking method is discussed. In section 3, we propose a tracking algorithm for red light violation detection. Section 4 presents the performance evaluation by computer simulations. Finally we conclude this paper in section 5.

2. TRACKING METHOD FOR OBJECT MOVEMENT

2.1 Principle of VRT Algorithm [7]

The theoretical basis of virtual route tracking (VRT) algorithm is that the interrogation range of RFID system is very short compared to the distance between readers. Instead of powering the RFID tag directly by battery, it gets power through magnetic, electric and electromagnetic coupling with RFID readers. RFID tags are grouped into two categories: Passive and Active. All power supply of Passive tag is induced from RFID readers in contactless method. For Active tag, one or more batteries are embedded. However, the embedded battery only provides power to run chips, and data are transferred from transponder to reader by modulating on reflected electromagnetic waves emitted by RFID reader, like the ways of Radars. Consequently, the achievable range of RFID system is very small, varied from a few millimeters to several meters.

On the contrast, the range of wireless technology used to connect RFID readers is large. It can connect two readers within 10 meters, and Bluetooth or Wi-Fi is effective at the distance of 100 meters. Therefore, when a tag is sensed by a reader, i.e., the tag is located in the interrogation zone of this reader; the real distance between reader and tag is less than the range of the RFID system. So we use the position of the corresponding reader to stand for the current position of tag. When the scale of the RFID Reader Network is large enough and the distance of deployed readers is relatively long, VRT algorithm is very accurate.

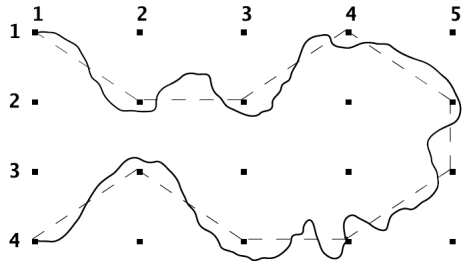

Figure 1: Principle of VRT algorithm

In Figure 1, the black point stands for a RFID reader and the matrix is a RFID Reader Network. As Figure 1 depicted, when a transponder moves from reader (1, 1) to reader (2, 2), the straight line between them is regarded as the track of the transponder by us. Therefore, when moving along the thick curve in the figure, which denotes the real path of a person or object in the RFID Network, the transponder is interrogated by readers along the path. And the virtual line (coined Virtual Route) is defined as the track of the transponder. So the track in Figure 1 is:

Track = *Virtual Route* = (1,1)→(2,2)→(2,3)→(1,4)→(2,5)
→(3,5)→(4,4)→(4,3)→(3,2)→(4,1)

It is noted that, when a reader interrogates one transponder, the next reader interrogating it along the track MUST be adjacent to the previous reader. In Figure 1, it is obvious that the transponder at (2, 3) cannot jump to (2, 5) directly without activating reader (1, 4), (2, 4) or (3, 4). Hence, the next reader of (2, 3) along the track MUST be one of following readers:

$\{(1,2), (1,3), (1,4), (2,2), (2,4), (3,2), (3,3), (3,4)\}$

Therefore, VRT algorithm MUST choose adjacent readers along the track. If two successive readers along the track are not adjacent to each other, special mechanism will be executed to guarantee that each reader along the track is contiguous to its last and next reader in real-word position. The virtual line connecting readers in Fig. 1 looks like a Route transferring data packets along the nodes. Due to this route is not real we name it "Virtual Route". In VRT algorithm, we use "Virtual Route" to stand for track of transponder in the RFID Reader Network. And that is why this algorithm is coined Virtual Route Tracking (VRT).

Of course, real-world RFID Reader Network is impossible to place readers so regular (exactly like a Matrix), and Figure 1 here only depicts fundamental of this algorithm theoretically.

2.2 Definition of Tracking Vector

More important, the concept of Tracking Vector (TV) is proposed here. Tracking vector plays a key role in collecting tracking information and calculating the track. We define the combination of the transponder identity, the interrogation time and the identifier of reader as Tracking Vector. The structure of TV is:

$$<T_i, t_j, R_k> = < Tag\ i, timestamp\ j, Reader\ k >$$

Here, the tag identity is a global unique number stored in the electronic chip of each tag and interrogated by reader. VRT algorithm can simultaneously track tens, even hundreds of tags tagged on objects or persons within a single network by classifying different tags according to the unique identity in each Tracking Vector.

Timestamp is the interrogation time of RFID reader when the tag entering its interrogation zone. We assume that all RFID readers in RFID Reader Network are synchronous. And only one tracking vector is generated no matter how long a tag stays within the interrogation zone of one reader.

The third parameter in tracking vector is the identifier of the reader. VRT algorithm uses the position of readers to track tags. It is noted that successive selected readers are all adjacent to each other and therefore can form a Virtual Route, therefore, reader identifiers of two successive Tracking vectors MUST stand for two contiguous readers in real network.

2.3 Two Special Conditions

As Figure 2 shows, when one tag moves along path *a*, three tracking vectors containing the same reader identifier are generated by reader R_1. At this time, VRT algorithm only chooses the first vector and deletes others.

$$\left.\begin{matrix} <T_x,t_1,R_1> & <T_x,t_2,R_1> \\ <T_x,t_3,R_1> & \end{matrix}\right\} \Rightarrow \{<T_x,t_1,R_1>\}, (t_1 < t_2 < t_3)$$

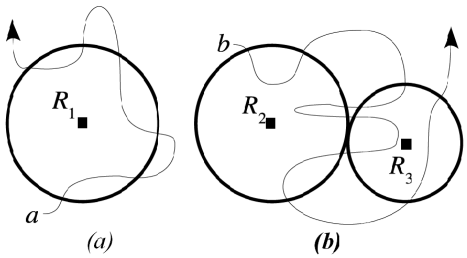

Figure 2: Two special paths

Suppose the tag alternates between two readers, e.g., R_2 and R_3 in Figure 2, only the first two or three tracking vectors should be remained. The method is specified as follows.

$$\begin{cases} R_2 & \Rightarrow R_2 \\ R_2 \to R_3 & \Rightarrow R_2 \to R_3 \\ R_2 \to R_3 \to R_2 & \Rightarrow R_2 \to R_3 \to R_2 \\ R_2 \to R_3 \to R_2 \to R_3 & \Rightarrow R_2 \to R_3 \\ R_2 \to R_3 \to R_2 \to R_3 \to R_2 & \Rightarrow R_2 \to R_3 \to R_2 \\ R_2 \to R_3 \to R_2 \to R_3 \to R_2 \to R_3 & \Rightarrow R_2 \to R_3 \\ R_2 \to R_3 \to R_2 \to \cdots\cdots\cdots \to R_2 & \Rightarrow R_2 \to R_3 \to R_2 \\ R_2 \to R_3 \to R_2 \to \cdots\cdots\cdots \to R_3 & \Rightarrow R_2 \to R_3 \end{cases}$$

For example, according to the above method, the tracking vectors of path *b* in Figure 2 are processed as:

$$\begin{Bmatrix} <T_x,t_1,R_2> & <T_x,t_2,R_3> & <T_x,t_3,R_2> \\ <T_x,t_4,R_3> & <T_x,t_5,R_2> & <T_x,t_6,R_3> \end{Bmatrix} \Rightarrow \begin{Bmatrix} <T_x,t_1,R_2> \\ <T_x,t_2,R_3> \end{Bmatrix}$$

$$(t_1 < t_2 < t_3 < t_4 < t_5 < t_6)$$

3. RESEARCH METHOD

3.1 Research Design

Figure 3 is shown diagram block of the research design. The system constrains traffic light controller (TLC), microcontroller for control management system, RFID readers, RFID tags, personal computer (PC) for database system and sensors of magnetic flux.

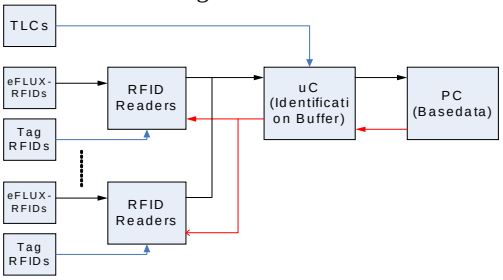

Figure 3: Block diagram of the research design.

The architecture of the research method of the RFID-based red light violation detection is shown at Figure 4. The crossroad is quarter section. The RFID readers make an adjacent network at the each left corner of the crossroad to monitor rfid tags movement. We assume that the range of antenna radiation of the RFID Reader. Three sensors of magnetic flux place at three lines of road branch, respectively. First sensor detect turn left of vehicle, second sensor detect straight destination and third sensor is turn right detection. We assume that Indonesia traffic is turn left go ahead.

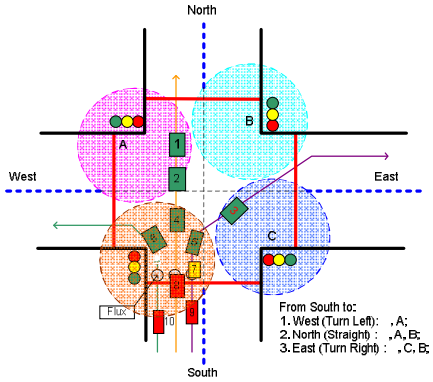

Figure 4: The architecture of the RFID-based red light violation detection

3.2 Algorithm Detail

The previous papers have been proposed in development of algorithm, for examples are Design of Traffic Light Control Systems Using Statecharts [8], Road Data Input System using Digital Map in Roadtraffic Simulation [9] and The Vehicle Junction Model and its Verification in Traffic Simulation [10] The speed of vehicle pass on crossroad is low until medium speed. In this algorithm, we take the vehicle speed up to 60 km/h or 0.0167 m/ms. If a range of antenna radiation of RFID readers are 10 meters and the time of sampling per RFID reader is 120 ms, so we result 5 samplings.

$$v = 0.0167 m/ms$$

$$x = 10m$$

$$t = \frac{x}{v} = \frac{10}{0.0167} = 600ms$$

$$T_s = 120ms$$

$$S = \frac{t}{T_s} = \frac{600}{120} = 5times$$

Where, v = vehicle speed (*meter/millisecond, m/ms*)
x = range of antenna radiation (*meter, m*)
t = time to pass antenna radiation (*millisecond, ms*)
T_s = Time of sampling (*ms*)
S = number of sampling (*time*)

The time of sampling is important to determine accuracy of violation detection.

The procedure algorithm is below:

1. Set Structure of Vector Tag ID
2. Choose direction road to check its status lamp
3. Note time-checking
4. If status lamp is green or yellow read ID tags from RFID Reader. Flux status is neglected.
5. Save time-checking, code of RFID Reader and ID tags into temporary memory address.
6. Monitor and track the ID tags, if there are IDs moves to another RFID Reader, delete the IDs from temporary memory address.
7. If status lamp is red, then check flux status. If flux status is not active, do step 5th.

8. If flux status is active/enable, read ID tags from RFID Reader and save time-checking, RFID Reader code and ID tags into temporary address of violator candidate.
9. Monitor and track the ID tags in temporary address of violator candidate to known its movements. If there are IDs moves to another RFID Reader, so the IDs are violator. Save the violator into violator memory address.

Figure 5 is shown the flow-chart of this algorithm.
From this algorithm, we hope to result some informations of the ID such as: (1) red light violator; (2) speed prediction of vehicle; and (3) number of vehicle on a capturing.

The vehicle is indicated as violator if on a capturing it is read by Reader as time as sensor of magnetic flux detection. The microcontroller system tracks its ID to monitor movement. If the vehicle ID have not read this Reader and/or read other Reader, so the vehicle is violator.

By assuming that the time of sampling is 120*ms* and the range of the antenna radiation of Readers is 10 meters, we can prediction speed of vehicle in Table 1. As comparing we take only if the time of sampling is 100*ms* in Table 2. As Table 1, we see that the time sampling will determine number of sampling. However, smaller number of sampling is very influence in determine speed of vehicle. So we assume that the maximum speed of vehicle passed crossroad is 60*km/h*.

Table 1: Speed prediction. (a) T_s = 120ms; (b) T_s = 100ms

Continuation of Figure 5

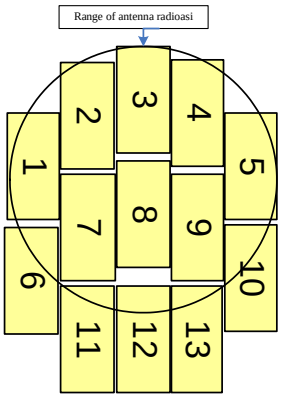

Figure 6: Prediction of vehicle number on a capturing

4. DISCUSSION

In this paper, we propose a tracking algorithm for RFID-based red light violation detection. We will do to simulate this use MadLab/Simulink. The database generator is built with the Visual Query Builder (VQB) or Microsoft Office Access.

5. CONCLUSION

By scenario in this proposal, we can take some in formations: (1) vehicle violator; (2) scalability on prediction system; (3) detection system of object on dynamic speed; (4) visibility of system is independent by solar.

ABSTRACT

This paper presents the way to investigate 0.5 hp three phase induction motor parameters by performing the DC resistance and the block rotor test. The data is produced based on lab tests and the relevant formula is used to investigate the parameters. The parameters obtained in this paper from stator and rotor of the induction motor. Several parameters such as R_1, R_2, I_2, X_1, X_2 and Z_2 are presented here.

Keywords
DC resistance, Block rotor, Induction motor test etc

1. INTRODUCTION

For many years the blocked-rotor test has been the accepted procedure for determining the AC winding resistances and the leakage reactance of three phase induction motors. Therefore, it has been necessary to lock the rotor of the machine in a fixed position (a carefully-selected position in the case of wound-rotor motors) with the stator windings energized with full-load current. Further, a reduced-frequency, reduced-voltage power source has been needed to provide that rated current for all but the smallest machines. The very-detailed procedure for the testing of induction machines is contained in IEEE Standard 112-1984 [l]. Squirrel cage induction rotors can be one of the toughest things to analyze. Rotor Defects were estimated to be responsible for approximately 10% of motor failures based on a 1980's research effort on squirrel cage induction motors sponsored by EPRI and performed by General Electric. Things have certainly changed since the 1980's. Not only in rotor design, but more importantly, in the analysis equipment available to detect rotor defects. Equipment like the MCE has increased the ability for the technician to identify rotor defects long before they become catastrophic. [9]

The squirrel cage induction rotor comes in many different varieties. These various types of rotor designs may affect the severity of a rotor defect. The first thing that usually comes to mind when discussing a squirrel cage induction rotor design is whether the rotor bars are comprised of copper or aluminum. These bars are either cast or pressed into the rotor slots then shorted together at either end of the rotor using copper or aluminum "shorting" rings. Shorting rings are commonly referred to as end rings. The rotor bars are welded, brazed, or bolted to the end rings. If it is a cast aluminum rotor the shorting ring and the rotor bars are cast at the same time and no connecting joints exist. Both aluminum and copper have advantages and disadvantages. Aluminum is more likely to have porosity, while copper is more likely to develop high resistance connections at the end rings. There is a test for stator coil R_1 independent of R_2, X_1, and X_2 .This test is called the DC resistance test. There is another test that can be performed on an induction motor to determine its rotor circuit parameters is called the block rotor test or sometimes called the locked rotor test [9].

2. DC RESISTANCE TEST

Basically, a DC voltage is applied to the stator windings of an induction motor, because the current is DC; there is no induced voltage in the rotor circuit and no resulting rotor current flow. Also, the reactance of the motor is zero at direct current. Therefore, the only quantity limiting current flow in the motor is the stator resistance and that resistance can be determined .The basic circuit is shown in Figure 3 .This figure shows the DC power supply connected to two of three terminals of a star connected induction motor. To perform the test, based on Figure 1, the current in the stator windings is adjusted to the rated value, and the voltage between the terminals of a star connected induction motor is measured. The current in the stator windings is adjusted to the rated value in an attempt to heat the windings to the same temperature they would have during normal operation (remember, winding resistance is a function of temperature) the current in Figure 3 flows through two of the windings, so the total resistance in the current path is $2R_1$.
Therefore,

$$R_1 = \frac{V_{DC}}{2I_{DC}} \qquad (1)$$

With the value of R_1 the stator copper loss at no load may be determined, and the rotational losses maybe found as the difference between the input power at no load and the stator

copper losses. This test is verifying the winding balanced resistance at ambient temperature. The standards accept a deviation (dispersion) of 5% from the average value. However, it has been demonstrated that such a deviation could lead to a wrong assessment of the winding connection brazing points. At the brazing point small discharges (sparks) may occur between the unconnected wire and the brazed point generating a "hot connection". The heat will be transferred in the neighborhood causing long term degeneration of inter turns or a short circuit of interconnections [1] [7].

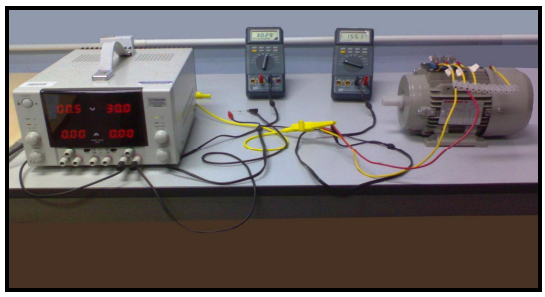

Figure 1: DC Resistance Lab Setup.

3. BLOCK ROTOR TEST

This test is used to determine the series parameters of circuit model of an induction motor. The circuit is similar to that of a transformer short circuit test. Short circuiting the load resistance in the circuit model corresponding to making the slip= 1 so that $R_2^{'}\frac{1}{s-1}=0$. This means that the rotor must be stationary during this test, which requires that it be blocked mechanically from rotating while the stator is excited with appropriate reduce voltage [2]. The resulting voltage, current, and power are measured. Figure 2 shows the test setup for the block rotor test. Figure 5 shows the connections for the blocked rotor test.

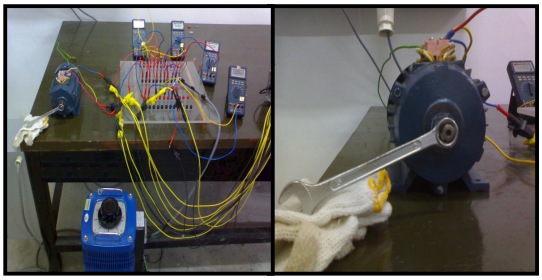

Figure 2: Block rotor lab test setup.

To perform the blocked rotor test, an AC voltage is applied to the stator, and the current flow is adjusted to be approximately full-load value. When the current is full load value, the voltage, current, and power flowing into the motor are measured. The equivalent circuit for this test is shown in Figure 5. Notice that since the rotor is not moving, the slip=1, and so the rotor resistance R_2 / s is just equal to R_2 (quite a small value),Since R_2 and X_2 are so small, almost all the input current will flow through them, instead of through the much larger magnetizing reactance X_m. Therefore, the circuits under these condition looks like a series combination of X_1, R_1, X_2 and R_2 as in Figure 6.

After a test voltage and frequency have been setup, the current flow in the motor is quickly adjusted to about the rated value, and the input power, voltage, and current are measured before the rotor can heat up too much. Unfortunately, there is no simple way to separate the contributions of the stator and rotor reactance from each other. Over the years, experience has shown that motors of certain design types have certain proportion between rotor and stator reactance [5] [6].

4. DC RESISTANCE TEST ANALYSIS

Based on Figure 3 the circuit shows the test circuit for a DC resistance test that is assembled.Table 1 shows the test data after the experiment is conducted.

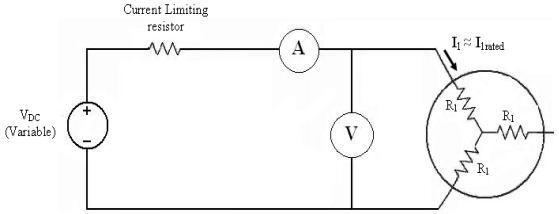

Figure 3: Test Circuit for DC Resistance Test.

Since the 0.5 Hp induction motor has a rated current of 1.07 A, the motor is tested at rated current and Table 1 shows the data.

Table 1: DC Resistance Test Data

Supply Voltage (V)	V_{dc}	I_{dc}	Coil resistance (R1)
10	54.7	1.07	25.6

Based on equation (1), it gives the stator coil resistances as:

$$R_1 = \frac{54.7V}{2\times 1.07A} = 25.6\Omega$$

So with this we know the value of stator resistor is 25.6Ω and this will be easy in obtaining the value of rotor resistance.

ISSN 114-1284

5. BLOCK ROTOR TEST ANALYSIS

The block rotor is assembled as shown in Figure 4

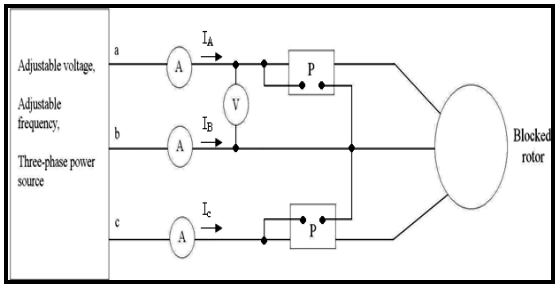

Figure 4: Blocked rotor test circuit for AC induction motor.

Based on the test analysis, Table 2 is obtained for further analysis.

Table 2: Blocked Rotor Test Measurement Data

Voltage line-line (V_{L-L}/V_{BR})	Phase Voltage (V_{Phase})	Input power (P_{in})	Input Current (I_{in})	Power Factor
210.1	121.32	149.59	1.0598	0.386

Since in the blocked rotor condition the value of n_r is 0 (the shaft of the induction motor is clamped to avoid rotation) so the slip will be,

$$s = \frac{n_{slip}}{n_s} = \frac{1500-0}{1500} \times 100\%$$
$$= 1$$

The slip is equals to 1 and so the rotor resistance R_2/s is just equal to R_2 (quite a small value).

$$\text{At} V_{BR} = 210.1V \quad I_{BR} = 1.0598A \ (I_{rated} = 1.07A)$$
$$P_{BR} = \sqrt{3} V_{BR} I_{BR} Cos\theta$$

$$\text{Angle}, \theta = \cos^{-1} 0.386 = 62.29°$$

Block rotor impedance:

$$|Z_{BR}| = \frac{V_{BR}}{\sqrt{3} I_{BR}} = \frac{210.1V}{\sqrt{3}1.0598} = 114.46\Omega$$

$$R_{BR} = Z_{BR} Cos\theta = 114.46 \times 0.386 = 44.182\Omega$$
$$R_{BR} = R_1 + R_2$$

From DC Resistance Test: R_1 =25.6 Ω

Then rotor resistance

$$R_2 = R_{BR} - R_1 = 44.18 - 25.6 = 18.58\Omega$$

Block rotor reactance

$$X'_{BR} = |Z_{Br}| Sin\theta_{BR} = |114.46| \times 0.9225 = 105.6\Omega$$

For normal motors of less than 20 hp rating, the effects of frequency are negligible and the blocked rotor test can be performed directly at the rated frequency [6]. But if it is above 20hp rating of any motor, must be reduced the frequency to 50% of the rated frequency.

(At 50 Hz, the block-rotor power factor angle is typically around 50^0)

$$X_{BR} = \frac{f_B}{f_t} \times X'_{BR} = \frac{50}{50} \times 105.6 = 105.6\Omega$$

$$x_1 = x_2 = \frac{1}{2} X_{BR} = \frac{105.6}{2} = 52.8\Omega$$

f_t = Frequency of the blocked-rotor test voltage

f_B = Rated frequency

The rotor current is given by;

$$I_2 = \frac{V_p}{(R_2/s) + jX_2} = = 0.3232A\angle -8°$$

The rotor loss is given by

$$P_{RCL} = 3I_r^2 R_r = 3I_2^2 R_2$$
$$= 3 \times (0.3232)^2 \times (18.58) = 5.82W$$

Through both the DC resistance and block rotor analysis, Table 3 can be summarized for 0.5Hp induction motor.

Table 3: Induction Motor Parameters

0.5 HP Induction Motor Parameters	Value
Line-Line Voltage(V_{L-L})	210.1V
Power Factor (pf)	0.386
Slip At Block Rotor	1
Rotor Current (I_2)	0.3232A
Stator Resistance (R_1)	25.6Ω
Rotor Resistance (R_2)	18.58Ω
Block Rotor Input Power (P_{br})	149.59W
Block Rotor Impedance (Z_{br})	114.46Ω
Block Rotor Reactance(X_{br})	105.6Ω
Leakage Reactance (X_1 & X_2)	52.8Ω
Rotor Copper Loss (P_{RCL})	62.61W

6. DRAWBACKS OF BLOCK ROTOR TEST

There is one problem with this test, however. In normal operation, the stator frequency is line frequency of power system i.e. 50 or 60Hz. At starting conditions, the rotor is also line frequency .However, at normal operating conditions, the slip of most motors is only 2 to 4 percent, and the resulting rotor frequency is in the range of 1-3 Hz. This creates a problem in that the line frequency does not represent the normal operating conditions of the rotor. Since effective rotor resistance is a strong function of frequency for design class B and C motors, the incorrect rotor frequency can lead to misleading results in this test. A typical compromise is to use a frequency 25-50 percent less of the rated frequency. While this approach is acceptable for essential constant resistance rotors (design class A and D), it leaves a lot to be desired when one is trying to find the normal rotor resistance of a variable-resistance rotor. Because of these and similar problems, a great deal of care must be exercised in taking measurements for these tests [6].

7. DISCUSSION

In the conventional squirrel-cage motor at full load, the slip and the current are low but the power factor and the efficiency are high. However, at start, the torque and power factor are low but the current is high. If the load requires a high starting torque, the motor will accelerate slowly. This will make a large current flow for a longer time, thereby creating a heating problem. The resistances in the rotor circuit greatly influence the performance of an induction motor. A low rotor resistance is required for normal operation, when running, so that the slip is low and the efficiency is high. However a higher rotor resistance is required for starting so that the starting torque and power factor are high and the starting current is low. An induction motor with fixed rotor circuit resistance therefore requires a compromise design of the rotor for starting and running conditions.

The block rotor test on an induction motor, like the short circuit test on the transformer, gives information about block rotor impedances (Z_{BR}) [4]. In this test the rotor is blocked so that the motor cannot rotate, and balanced poly phase voltages are applied to the stator terminals. The blocked rotor test should be performed under the same condition of the rotor current and frequency that will prevail in the normal operating conditions. For example, if the performance characteristics in the normal running condition (i.e. low-slip region) are required, the blocked rotor test should be reduced frequency (corresponding to lower values of slip).When an induction motor is operating normally, the slip is so small that the frequency of the magnetic reversal in the rotor core is only of the order of one or two per sec, therefore iron losses occurring in the rotor are very small and can be neglected, hence output of stator becomes the input of rotor and the input of rotor is the output of rotor plus with copper loss in rotor.

The slip for the blocked rotor test is unity since the rotor is stationary. The resulting speed-dependent equivalent resistance $\frac{R_2}{s}(1-s)$ goes to zero and the resistance of the rotor branch of the equivalent circuit becomes very small. Thus, the rotor current is much larger than current in the excitation branch of the circuit.

7. CONCLUSION

The purpose of this paper is to evaluate the performance characteristics 0.5 hp three phase induction motor parameters by performing the DC resistance and the block rotor test.

During starting moment of block rotor condition, the induction motor speed is zero (S = 1), but the electromagnetic torque is positive so when three-phase fed, the induction motor tends to start (rotate); to prevent this, the rotor has to be stalled. Thorough testing of induction motor at zero speed generally completed up to rated current. Consequently, lower voltages are required, thus avoiding machine overheating. A quick test at rated voltage is done on prototypes or random induction motors from, production line to measure the peak starting current and the starting torque. This is a must for heavy starting applications (nuclear power plant cooling pump-motors, for example) as both skin effect and leakage saturation notably modifies the motor starting parameters.

Abstract-Reduced Instruction Set Computer (RISC) is a computer architecture that reduces chip complexity by executing only simple instructions, which allows high speed operation. NICCOLO32 is a RISC processor with SPARC V8 architecture.

RISC processor NICCOLO32 is verified to ensure system functionality. Verification is done using modelsim. NICCOLO32 is then implemented as chip layout using Astro from Synopsys with CMOS 0.18 µm standard cell. Implementation gives maximum clock speed of 31.46 MHz and core area of 0.512 mm^2.

Keywords : *RISC, SPARC, processor*

I. INTRODUCTION

Microprocessors are divided into two groups, complex instruction set computer (CISC) and reduced instruction set computer (RISC). CISC is designed using as few instructions as possible to execute a task. While in RISC, to execute the same task CISC perform, more instruction required to achieve one instruction per cycle.

RISC is designed to reduce instruction complexity to allow high speed operation. Several technique used in RISC design are one instruction per cycle, fixed instruction length, only load / store access memory, simplified addressing mode, fewer and simpler operations, and let the compiler do it. Using these technique, smaller memory is required and access time can be reduced.

The objective of this research is to design RISC processor NICCOLO32 and implement it as chip layout with CMOS standard cell 0.18 µm.

II. DESIGN METHOD

NICCOLO32 design is divided into several steps

Step 1 : chose instructions NICCOLO32 can perform.

Step 2 : design register transfer notation (RTN) for each instruction chosen. RTN is a notation which describe inter register data transfer in the system designed.

Step 3 : design datapath that supports all instructions chosen. Datapath is a diagram describing data transfer in the system.

Step 4 : design control unit. Control unit is a unit controlling data transfer in a system.

Step 5 : integrate datapath and control unit.

Step 6 : verification to ensure system functionality. System is verified by feeding test vector into the system. Instruction is chosen to be the test vector to show system functionality.

Step 7 : implement RISC processor NICCOLO32 into chip layout with CMOS 0.18 µm standard cell technology using Astro CAD tool from Synopsys.

III. NICCOLO32 INSTRUCTION

NICCOLO32 is a RISC processor with SPARC V8 architecture. To design RISC processor NICCOLO32, instruction and register must compatible with SPARC V8 architecture.

Instructions are divided into three categories, load / store, arithmetic / logic / shift / sethi, and control transfer.

- Load / store : the only instructions access memory. **Load** instruction gets data from memory and store it in registers, while **store** instruction **store** data from registers to memory.
- Arithmetic / shift / logic / sethi : this type of instructions computate two operands and store the result in register.
- Control transfer : this type of instructions change program counter (PC).

Table 1. Instruction to be Implemented

No.	Mnemonic	Operation
1.	**ADD**	Rd = Rs1 + Rs2/simm13
2.	**ADDCC**	Rd = Rs1 + Rs2/simm13
3.	**SUB**	Rd = Rs1 - Rs2/simm13
4.	**SUBCC**	Rd = Rs1 - Rs2/simm13
5.	**UMUL**	Rd = Rs1 **x** Rs2/simm13
6.	**UMULCC**	Rd = Rs1 **x** Rs2/simm13
7.	**AND**	Rd = Rs1 **AND** Rs2/simm13
8.	**ANDCC**	Rd = Rs1 **AND** Rs2/simm13
9.	**ANDN**	Rd = Rs1 **ANDN** Rs2/simm13
10.	**ANDNCC**	Rd = Rs1 **ANDN** Rs2/simm13
11.	**OR**	Rd = Rs1 **OR** Rs2/simm13
12.	**ORCC**	Rd = Rs1 **OR** Rs2/simm13
13.	**ORN**	Rd = Rs1 **ORN** Rs2/simm13
14.	**ORNCC**	Rd = Rs1 **ORN** Rs2/simm13
15.	**XOR**	Rd = Rs1 **XOR** Rs2/simm13
16.	**XORCC**	Rd = Rs1 **XOR** Rs2/simm13
17.	**XNOR**	Rd = Rs1 **XNOR** Rs2/simm13
18.	**XNORCC**	Rd = Rs1 **XNOR** Rs2/simm13
19.	**SLL**	temp:=(IR<13>=0→R[IR<4..0>]<4..0>:IR<13>≠0→IR<4..0>); Rd = Rs1<(31-temp)..0>#0@temp
20.	**SRL**	temp := (IR<13>=0→R[IR<4..0>]<4..0>:IR<13>≠0→IR<4..0>); Rd = 0@temp#Rs1<31..temp>
21.	**SRA**	temp := (IR<13>=0→R[IR<4..0>]<4..0>:IR<13>≠0→IR<4..0>); Rd←Rs1<31>@temp#Rs1<31..temp>

Fig 1 shows SPARC V8 instruction format.

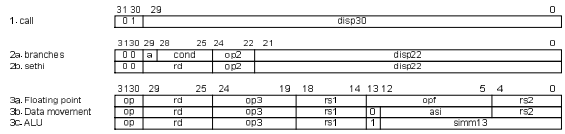

Fig.1. SPARC V8 instruction format.

Load / Store instructions need 5 clock cycle, arithmetic / shift / logic instructions need 3 clock cycle, while control transfer instructions need 4 clock cycle.

Table 1 shows instructions to be implemented by RISC processor NICCOLO32.

IV. SYSTEM SPECIFICATION AND DESIGN

System specifications are:

- Use load-store architecture, only load and store access memory. Data transfer can be done from register to register, from register to memory, and from memory to register, but not from memory to memory in one instruction.
- 32-bit data format.
- Fixed length 32-bit instruction
- External and separated data and instruction memory.
- Multicycle with no pipeline, each instruction has its own cycle, instruction must be completely performed before another instruction is fetched.
- 32 registers, with no register window mechanism.
- Three buses used, bus a is for operand 1, bus b is for operand 2, and bus c for the result.
- 32 bit linear memory address.
- Two addressing modes, register-register and register-immediate.
- Triadic register addresses, most instructions compute two operands and store the result in the third operand.

V. REGISTER TRANSFER NOTATION DESIGN

Register Transfer Notation (RTN) is a notation describing data transfer in a system. Data is transferred between registers. It is uniquely designed for each instruction each clock cycle.

RISC processor NICCOLO32 registers are divided into two groups, special purpose registers and general purpose registers. Special purpose registers are registers with certain function, it can not be used for other purposes. General purpose registers are used to store instruction result.

Special purpose registers are processor status register (PSR), program counter (PC), next program counter (nPC), memory data register (MDR), memory address register (MAR), instruction register (IR) and Y register.

General purpose registers are 32 registers in register bank and named r0, r1, r2, …, r30, and r31. These registers store the operation results and can be used in any order.

Table 2 shows RTN for **Add** instruction. Table 3 shows RTN for **Addcc** instruction. At cycle T0, the content of memory pointed by Program Counter (PC) is copied into instruction register (IR). At cycle T1, operands are available. The first operand is directly taken from RS1, while the second operand is multiplexed by the selector i. If i = 0, RS2 is selected as the second operand. If i = 1, signed extended 13 (simm13) is selected as the second operand. **Add** operation performed by arithmetic logic unit (ALU). At cycle T2, the result is then stored in RD. For **Addcc,** suitable condition codes are changed.

VI. DATAPATH AND CONTROL UNIT DESIGN

Based on RTN, datapath is designed. Datapath must support RTN of all instructions. Fig 2 shows RISC processor NICCOLO32 datapath.

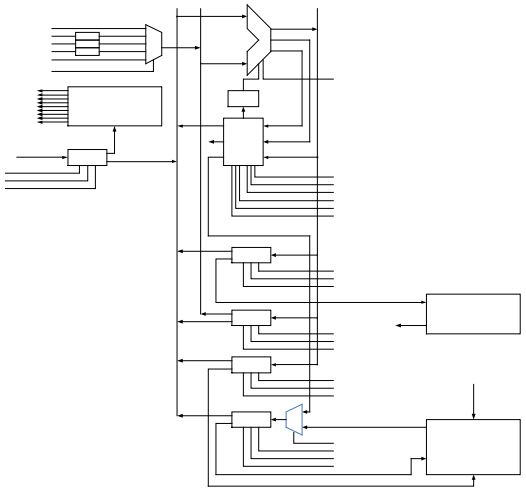

Fig.2. RISC processor NICCOLO32 datapath.

Add instruction is for an example. At cycle T0, instruction is fetched from instruction memory and stored in IR. The value of PC is increased by 4. This is where the next instruction is located. At cycle T1, operands are ready. ALU performs **Add** operation. The result is then stored in RD.

ALU performs arithmetic, logic, and shift operation. Each kind of operation consists of several specific operations. Specific arithmetic operations are **Add, Sub,** and **Umul**. Specific logic operations are **And, Andn, Or, Orn, Xor, Xnor,** and **Not**. Shift operations are **SRL, SRA,** and **SLL.** Fig 3 shows ALU block diagram.

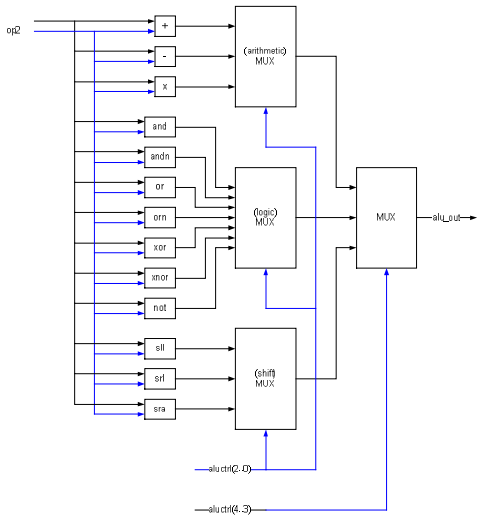

Fig 3. Arithmetic Logic Unit

ALU is controlled by 5-bit-signal "aluctrl". The first 2 bit determine the type of the operation, while the last 3 bit determine the specific operand, as seen on Table 26.

Table 26. Signal aluctrl Description

aluctrl<4..3> aluctrl<2..0>	00 arithmetic	01 logic	10 shift	11 Inc4/dec4
000	**Bypass**	**And**	**SRL**	**Inc4**
001	**Add**	**Or**	**SRA**	**Dec4**
010	**Sub**	**Xor**	**SLL**	
011	**Umul**	**Not**		
100		**Andn**		
101		**Orn**		
110		**Xnor**		

To ensure data transfer works properly, control unit is designed. Control unit is designed by finite state machine (FSM) for each type of instructions. Fig.4. shows FSM of each type of instructions. At first, the processor is in the "idle" state. When the "enable" signal is '1', it is then in the T0 state. At T0, instruction is fetched from instruction memory and stored in IR. The next state is T1. At T1, operands are ready. The next state is T2. At T2, operands are processed by ALU and the result is stored in register. If the instruction is arithmetic/shift/logic, the processor will go back to T0, which mean the next instruction will be fetched. If the instruction is not arithmetic/shift/logic, the processor will proceed to T3. If the instruction is control transfer, the processor will go back to T0 to fetch the next instruction, otherwise it will proceed to T4. At T4, for load instruction, loaded data will be stored in register, while for store instruction, data will be stored in memory.

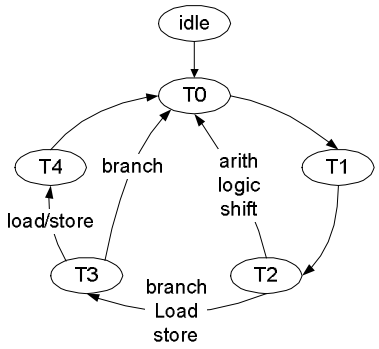

Fig.4. Instruction FSM.

VII. SYSTEM VERIFICATION

System is verified to ensure system functionality. RISC processor NICCOLO32 is verified using modelsim. To obtain the result that show system functionality, instruction is set to be the test vector. Instructions are generated by compiling C language program into SPARC assembly. NICCOLO32 core is connected to instruction memory (ROM) and data memory (RAM) as Fig.5. shows.

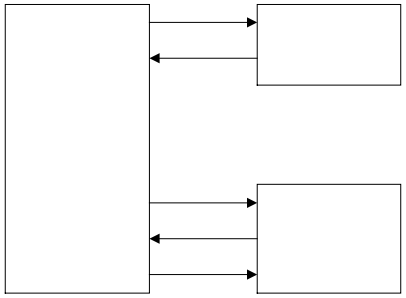

Fig..5. System verification block Diagram.

For example, Fig 6 shows **Add** and **Addcc** instruction.

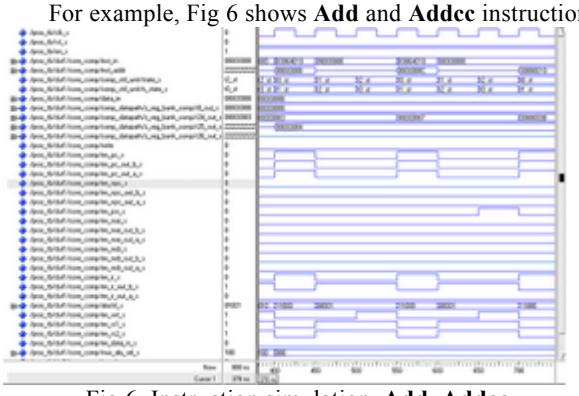

Fig 6. Instruction simulation, **Add**, **Addcc.**

VIII. NICCOLO32 IMPLEMENTATION

RISC processor NICCOLO32 is then implemented as chip layout with CMOS 0.18 µm standard cell technology. Layout processes are data preparation, floorplanning, placement and routing. Report shows 31 MHz timing constraint fulfilled. No design rule error and layout versus schematic error. Chip layout is shown in Fig 8.

IX. SUMMARY

RISC processor NICCOLO32 functionally works, instructions are correctly executed.

RISC processor NICCOLO32 can execute instruction generated by compiling C language program.

Multicycle instruction implemented. Each type of instructions requires various cycle.

ABSTRACT

The take-off pattern used by LAPAN's UAV RKX-530 Sengkelat is a throwing system using rocket booster. Separator would be the element key for the UAV to detach the rocket as booster from the body fuselage which use turbojet machine as sustainer. The main aim of this designing process is to find the right configuration to separate the rocket that is efficient but also safe. The methodology of designing this separator is design totality.

Keywords :
UAV, rocket, jet, configuration, trade-off, design

1. INTRODUCTION

UAV-jet type is still not a major player in aeronautical world of Indonesia. There's still no jet-powered UAV that is used intensively by state's defense department to protect this nation's sovereignty. To answer this need, LAPAN develops a jet-powered UAV that would be used as main tool in a big surveillance system deployed in the outer border of Indonesia's territory.

RKX-530 Program is a LAPAN's most important project that is beginned from year 2008 as a framework to guard this country's sovereignty especially at the outmost borders. RKX-530 is a combination of a jet-powered UAV with rocket booster as launching device. This kind of launching mode is very useful for mobility pattern required in the military system in the air, sea and land.

Figure 1. RKX-530 Sengkelat

Main tasks in this project is to design and to build the flying vehicle prototype, to find and test its flight dynamics characteristic, to design and test the autopilot control for cruise phase and homing phase, and finally to find a launching system which would be the most suitable with the LAPAN's rocketry. The RKX-530 design which has a diameter of 530 mm, must be examined first through the making of few scaled-down model prototype with diameter of 300 mm that would be used as testbed for the launching system, rocket booster separation system, flight control stability system, and for ground testing system. These model prototypes are born from Rumpin, the fabrication is done in Bandung, while the flight tests and launch tests are done in Batujajar and Pameungpeuk. Those model prototypes are named HSFTB (high speed flying testbed), Dummy of the HSFTB, Dummy of the dummy of the HSFTB (dum-dum). The numerical simulation are done for each vehicle using Matlab dan Xplane, the parameter sought are aerodynamic characteristic, flight dynamic, flight performance, and flight control.

Figure 2. High Speed Flying Testbed (HSFTB)

Figure 3. Dummy of the HSFTB

Figure 4. Dummy of the dummy of the HSFTB (dum-dum)

Rocket used to catapult HSFTB is an RX-100 which has 100 mm of diameter, with average thrust of 1500 N or 150 kg. If we put it side by side with the vehicles's MTOW (maximum takeoff weight) at 55 kg, we will get thrust-to-weight ratio 3, quite big even for a vertical launch. After including the drag factor, this rocket could give an acceleration of 2.5 to 3G. This RX-100 have a burntime no more than 2.5second, and at burnout the vehicle will have velocity of 60 m/s or 216 km/h or 0.18 Mach. This speed is more than enough to propel the aircraft to take-off (Vto = 100km/h), therefore this method of launching using this rocket is expected to work effectively with zero-length runway.

Figure 5. Booster Roket RX-100

2. STATEMENT OF THE PROBLEM

Using rocket with such capability means that the selection of a robust separation system is going to be a delicate task. The choice of booster placement location should be taken care with extra precaution, because it will determine the failure or success of the launching phase.

The main consideration of finding the location of rocket placement are :

- Flight Performance
- Separation effectivity
- Practicability of Production
- Flight Safety

These four basic consideration are called the design requirements, which would be concluded from three rocket placement configuration.

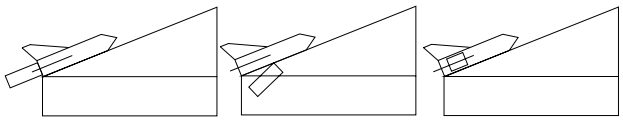

Figure 6. Three configuration of rocket placement (left: aft of fuselage, center : under belly, right : both side of fuselage)

Each rocket placement configuration has its own characteristic. Those design characteristics include:

- Position of Xcg, Zcg and Ycg
- Ballast Placing Mode
- Difficulty of measuring of Xcg, Zcg andYcg
- Elevation Angle of the rail launcher
- Complexity to install the rocket and the separator
- Reliability of Rocket Separation Mechanism

3. CONCEPTUAL SOLUTION TO SOLVE THE PROBLEM

HSFTB as a small aircraft is constructed from composite material with various degree of strength. The wing is the most heavy-duty component which would absorb all major forces including lift & weight, so its material is the strongest. The fuselage has weaker strength, due to its thinner skin, but gives weight reduction in return. The wing and fuselage are detachable, so it can be carried easily inside a pickup box. The strength of the wing structure comes from the thick spar, so that it could act as a hanger and as shock absorber when tthe belly crash occur, or any rollover tumbling. Over this consideration of strength, it is expected that the vehicle will achieve belly landing rather than nose diving. This is the main reason for placing the rocket under belly.
Main obstacle to place the rocket underbelly is the necessity to point the rocket thrustline right into the c.g. position of the vehicle. The center of gravity in the X-line (longitudinal axis) is easy to find, but not for the Z-line (directional axis) because of asymmetry of an aircraft. For the sake of easiness of finding the Z-c.g and to aim thrustline into it, that's the main reason for placing the rocket aft (behind) of the fuselage exhaust.
Main obstacle to place the rocket aft of the fuselage is the existence of the jet exhaust that has average temperature at 600 deg Celsius (http://www.jetaces8rc.com/Jetcat/jetcat_usa.htm) which can augment the heat of the rocket body and accidentally explode it. The second obstacle is the landing pattern that tends to be nose-diving and will cause fuselage breakup. But this could be avoided by commanding the airplane to pitchup.
At the same time, the third configuration is to put 2 rockets in both side of the fuselage. Its main obstacles are the rocket flame exhaust will burn the elevator, the alignment of the rocket must be symmetrically accurate, the separation mode would be twice the complexity of the underbelly configuration, and the timing of burn between right and left rocket must be uniform.

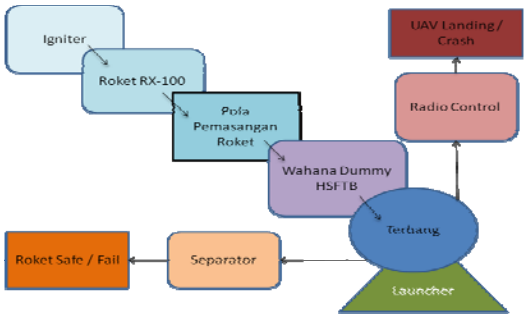

Figure 7. Diagram of interaction between subsystem and the effect results.

4. METHODOLOGY

To minimize failure and in addition to optimize the cost, this research looking for the best configuration is done in 4 steps. First, computation. Two, dummy launch to prove concept. Three, dummy launch to train piloting. Fourth, flight test using jet-powered HSFTB.

4.1. Computation

This computation phase aims for :
-To adjust the dynamic stability of the vehicle
-To predict the flight trajectory and aircraft's attitude for each configuration of rocket placement
-To find the best maneuver command to control the aircraft to achieve the best trajectory

Software used are Matlab-Simulink dan X-Plane

4.2. Dummy launch to prove concept the configuration

To reduce risk of destruction of the High Speed Flying Testbed, we make dummy HSFTB which has the same appearance with the actual vehicle just without jet and electronic control unit. But apparently, the cost is still high, so that we make another type of vehicle that is far cheaper and so simple that it just focus on the configuration of the placement of the rocket. This vehicle functions as the dummy of the dummy of the HSFTB, we call it dum-dum. The rocket used for this vehicle is also a scaled down from the real one, it has diameter of 70 mm with the thrust of 90 N and two rocket with thrust of 35 N.

4.3. Dummy launch to train pilot

Before launching the real HSFTB, the pilot must train to control the vehicle right after the burnout. Starting from the boost phase, continue to gliding phase and maintain until landing phase.
This replica of the HSFTB is so authentic that it can be used to test the structural damage pattern on the fuselage if the crash landing occur.
The rocket used is the real RX-100.

4.4. Flight Test of the Jet-powered HSFTB

In this phase, the HSFTB used turbojet engine and the launching system used the best configuration of rocket placement. The autopilot system ideally is also applicated in this phase.

5. Experimental Results

5.1. Computation

From the numerical simulation, we produce data that shows that all configuration could achieve succesful flight trajectory. The rail launch elevation is set to 20 deg. The launches are simulated in 2 mode, without control and with pitchup control.

Table 1. Uncontrolled flight results.

	Underbelly		Aft of Fuselage	
	HSFTB/ dummy	Dum-dum	HSFTB/ dummy	Dum-dum
Distance	90 m	140 m	180 m	80 m
Height	90 m	10 m	14 m	6 m

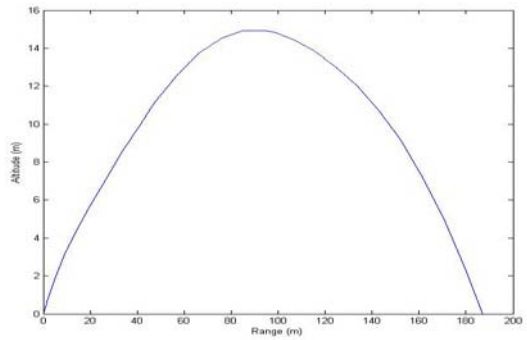

Figure 8. HSFTB Dummy's Aft of Fuselage Uncontrolled Flight Trajectory

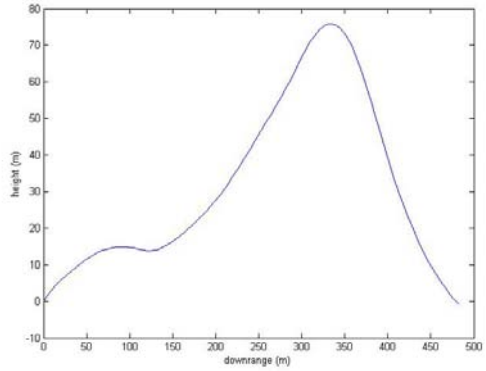

Figure 9. HSFTB Dummy with Underbelly Rocket Controlled Flight Trajectory

From table 1, it seems that dum-dum launched using underbelly configuration would have a better flight performance than from the aft of the fuselage. The reason is, the thrustline from underbelly rocket would be projected into horizontal axis and vertical axis. That is why we put the underbelly rocket configuration as our top priority to be tested.
The configuration of aft of the fuselage is considered as second priority because of its simplicity in the matter of pointing the thrustline to c.g. position.
While the third configuration (both-side of the fuselage) has the latest priority, due to its complexity of installation, c.g. pointing, and separation process.

5.2. Dummy launch to prove concept the configuration

The experiment results show that :

- The separator doesn't work unless the aircraft crash severely
- The dumdum vehicle doesn't even slide in the rail launcher, and it just directly lift-off

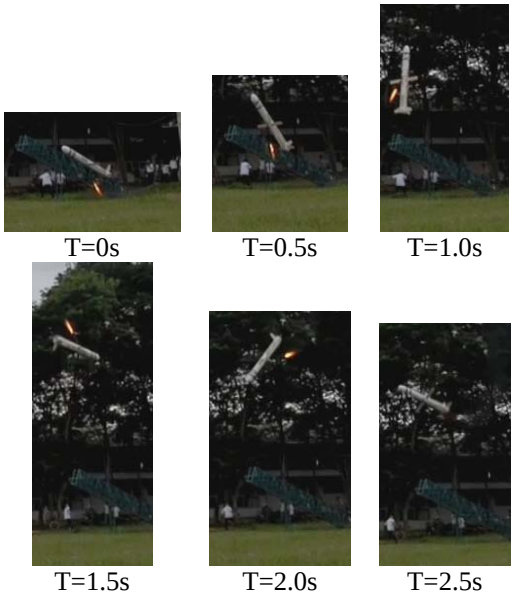

Figure 10. Chronology of Launch Test of the Dum-dum using Underbelly Rocket

- The flight vehicle pitches up easily and make a loop or two (630 deg for 2 seconds), this was caused by the existence of a GIGANTIC moment arm (25 cm) between thrustline and c.g. position

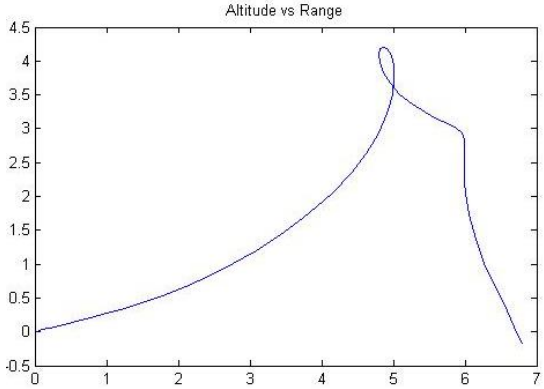

Figure 11. Flight Trajectory of Launch Test of the Dum-dum using Underbelly Rocket with moment arm 25cm

- The vehicle tends to roll or bank to its right side

5.3. Dummy launch to train pilot

On the launch test of the HSFTB dummy at Pameungpeuk, December 2008, with moment arm 2 cm, there was a torque force whose magnitude is equal to 150kg x 0.03m that produced a pitchup loop of 90 degrees in 2 seconds. This moment arm was not yet able to be minimized because the installation of the ballast was not practical then, the door access at the nose was too far behind to reach and complicate to put the ballast properly. The experiment results showed that the launch test trajectory was similar with the computational trajectory.

t= 2.5s

t= 2.0s

t=1.0s

t=0.5s

Figure 12. Chronology Pitchup Loop of the Dummy HSFTB using Underbelly Rocket

GPS Data

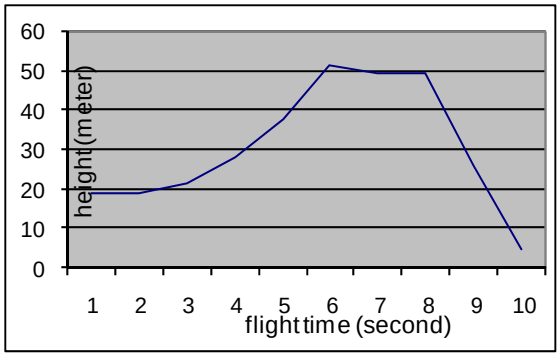

Figure 13. Flight Trajectory History from GPS data

From the first second until 2nd second the aircraft pitches up 90 deg, pilot act quickly by compensating it using pitch down maneuver using elevator, but the vehicle is still climbing with same angle until the 6th second. From 6th to 8th seconds, the altitude of the aircraft is hold on 50 meter height, where the aircraft is making an aerobatic pitchup loop with the intention is to avoid crash landing accidentally upon the spectator. From 8th to 10th the aircraft glides in 2 seconds with the Falling Speed about 45 m/s or 162 km/hour.

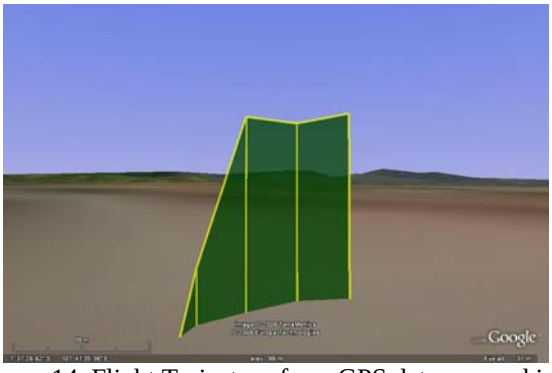

Figure 14. Flight Trajectory from GPS data mapped into Google Earth

The graphic above shows that the dummy of HSFTB's launch test make flight trajectory to the right-side, and plunge vertically from the height of 50 meter til the ground impact.

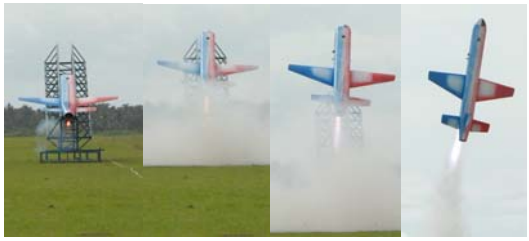

Figure 15. The dummy HSFTB tends to produce roll-yaw coupling to the right side of the fuselage

When the vehicle takes off, the maneuver happened was not just pitching up but also roll-yaw coupling. This roll movement was caused by two possibility, the elevators are not in the same deflection angle, or there must be yawing moment from the beginning of the boost. This yawing moment could be caused by rail shoes that are not really parallel, so that the longitudinal axis of the fuselage is not aligned with the longitudinal axis of the rail launcher.

Accelerometer Data

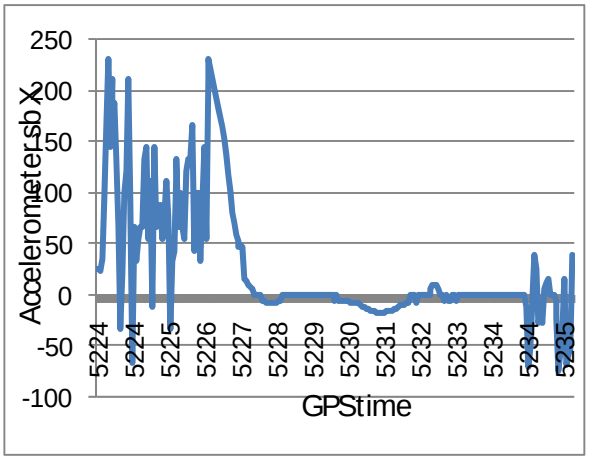

Figure 16.a. Accelerometer X-axis

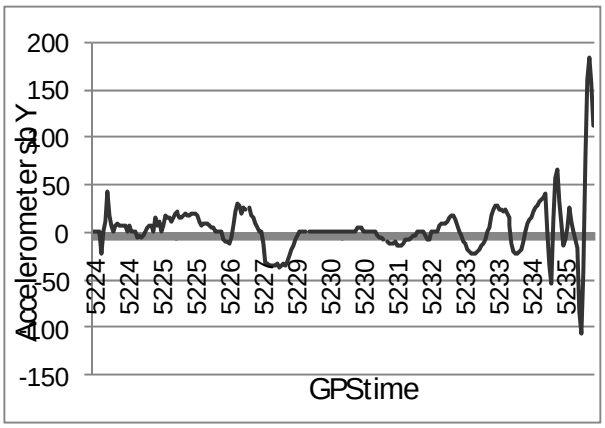

Figure 16.b. Accelerometer Y-axis

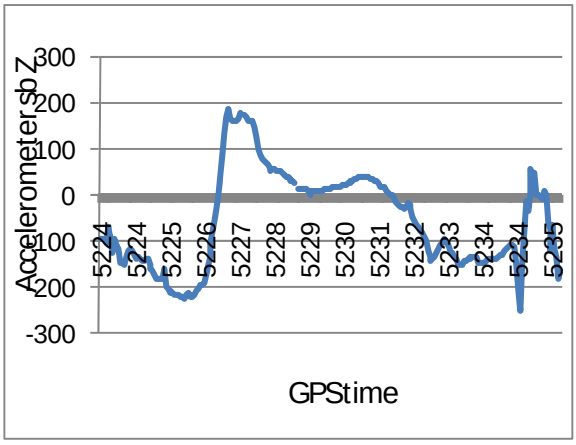

Figure 16.c. Accelerometer Z-axis

From the accelerometer data above, the booster rocket start burning at the GPS-time of 5224 and burning out at GPS-time of 5226. That means the burning time is 2 seconds.
From the perspective of flight dynamics the graphics informations are :

- The aircraft experiences a big acceleration in the longitudinal axis of the body at the boost start time, this is noticeable from the vibration at GPS-time 5224-5226. In theory, the axial acceleration happened was 2.7G (thrust*cos20 / Wbody).
- At the burnout, the X-acceleration drop to zero in one second (gliding). More interesting is to examine the acceleration in the Z-axis. From 5224-5226 the aircraft experience a negative G (average -200 units) that means pitchup with high degree (Figure 16c). While from 5226 to 5227 the aircraft experience an inversion of G (from -200 to 200) that means the aircraft is commanded to compensate the pitchup by pitching down abruptly. After that, from 5227 to 5229 the aircraft pitchup is diminishing, this was caused by looping without power (in the gliding phase).

Rate Gyroscope Data

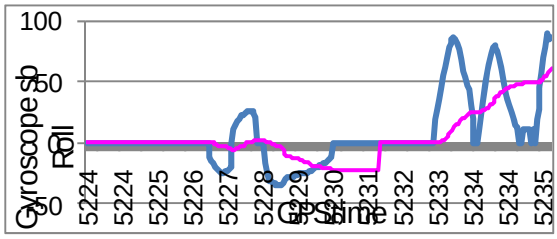

Figure 17.a. Gyroscope at Roll-axis

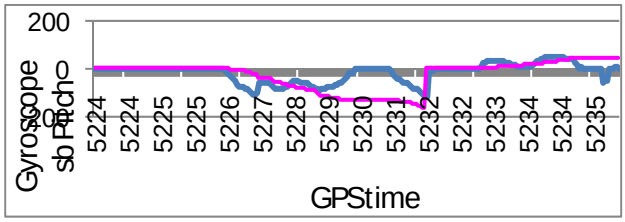

Figure 17.b. Gyroscope at Pitch-axis

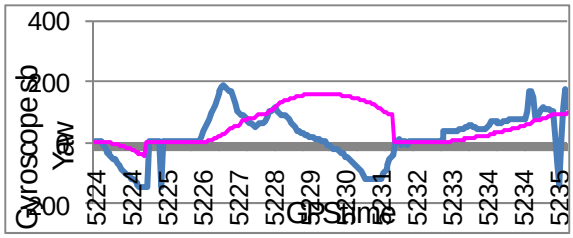

Figure 17.c. Gyroscope at Yaw-axis

From all graphics above, it could be seen (darkline-angle rate, lightline-angle) that since GPS time 5226 until 5232, the vehicle tends to make a looping constant maneuver that develops into a helix to the right side of the body.

6. Discussion

Some remarks that constructed from discussion about these experiments are :

- The underbelly rocket configuration has great potential to generate arm moment. Using delicate photometry we could reduce the magnitude of this arm moment, but the arm is still there.

Figure 18. Manual method photometry to discover the c.g location

- The vertical force generated from the underbelly rocket configuration is beneficial for extending range of the gliding phase, but very reactive to generate trouble in the boosting phase due to its big influence to form moment arm.
- There is a constant tendency for the aircraft to generate roll-yaw coupling to the right direction. More experiments needed to comprehend the moment of inertia nature of each vehicles and to control it

7. Conclusion

Conclusion that could be drawn from these experiments are :

- It is understood from the simulation that the underbelly rocket configuration has better flight performance than any other configuration. But the experiments show that it has narrow margin of success to launch the HSFTB vehicle, due to the magnitude of the vertical projection of the thrust. So the top-priority configuration now is not underbelly rocket anymore, but rocket at the aft of fuselage would be used for the fourth phase of this research.
- The existence of a pilot as human in the loop is proved to be beneficial to comprehend and apprehend the flight dynamics characteristic of the aircrafts, although the pilot will give extra precaution to the safety of the launch flight, the research could take benefit from the unpredicted maneuver done by the pilot

ACKNOWLEDGMENT

This work is supported by LAPAN, Pustekwagan, under the direction of Mr. Yus Markis, Dipl-Ing. The Rocket Control Division is headed by Mrs. Rika Andiarti, Dr. The first author would like to thank also Mrs. Wijaya Dewi Wuri Handayani from Physic Department, ITB for her generous technical support.

ABSTRACT

This paper presents dynamic modelling of a two-link flexible manipulator system. The kinematic model is based on standard frame transformation matrices describing both rigid rotation and modal displacement, under small deflection assumption. A two-link flexible manipulator incorporating structural damping, hub inertia and payload is considered. An explicit, complete, and accurate nonlinear dynamic model of the system is developed using assumed mode method. Moreover, the effects of payload on the response of a two-link flexible manipulator are studied.

Keywords *:*
Assumed mode, modelling, two-link flexible manipulator

1. INTRODUCTION

Flexible robot manipulators exhibit many advantages over rigid robots. They require smaller actuator, consume less power, require less material, are lighter in weight, have less overall cost, are more manoeuvarable and transportable and higher payload to robot weight ratio. In order to control the two-link flexible manipulators to achieve and maintain accurate positioning is challenging. Due to the flexible nature of the system, the dynamics are significantly more complex. Moreover, flexible link causes significant technical problems. The problem increases dramatically for a two-link flexible manipulator with varying payload. In order to achieve high-speed and accurate positioning, it is necessary to control the manipulator's response in a cost effective manner. Control algorithms are required to compensate for both the vibration and the static deflection of the system.

The main goal on the modelling of a two-link flexible manipulator is to achieve an accurate model representing the actual system behaviour. Each flexible link can be modelled as distributed parameter system where the motion is described by a coupled system of ordinary and partial differential equations (PDE). Various approaches have been developed which can mainly be divided into two categories: the numerical analysis approach and the assumed mode method (AMM). The numerical analysis methods that are utilised include finite difference and finite element methods. Both approaches have been used in obtaining the dynamic characterisation of a single-link flexible manipulator system incorporating damping, hub inertia and payload [1,2]. Subudhi and Morris [3] have used a combined Euler-Lagrange formulation and AMM approach to model the planar motion of a manipulator consisting of two flexible links and joints. The conventional Lagrangian modeling of flexible link robots does not fully incorporate the bending mechanism of flexible link as it allows free link elongation in addition to link deflection. De Luca and Siciliano [4] have utilised the AMM to derive a dynamic model of multilink flexible robot arms limiting to the case of planar manipulators with no torsional effects. The equations of motion that can be arranged in a computationally efficient closed form with respect to a suitable set of constant mechanical parameters have been obtained [5].

This paper presents modelling of a two-link flexible manipulator using Lagrangian technique in conjunction with the AMM. The links are modelled as Euler-Bernoulli beams satisfying proper mass boundary conditions. A payload is added to the tip of the outer link, while hub inertias are included at the actuator joints. Simulation of the dynamic model is performed using Matlab and Simulink. Angular position and modal displacement responses of the system responses are investigated. The effects of payload on the dynamic characteristics of the system are also studied.

ISSN 114-1284

2. A TWO-LINK FLEXIBLE ROBOT MANIPULATOR

Figure 1 shows the schematic diagram of a two-link flexible manipulator system considered in this study. The links are cascaded in serial fashion and are actuated by rotors and hubs with individual motors. An inertial payload of mass M_P and inertia I_P is connected to the distal link. The proximal link is clamped and connected to the rotor with a hub. The *i*th link has length l_i and uniform mass density per unit length ρ_i. E and I represent Young modulus and area moment of inertia of both links respectively. A payload is attached at the end-point of link-2.

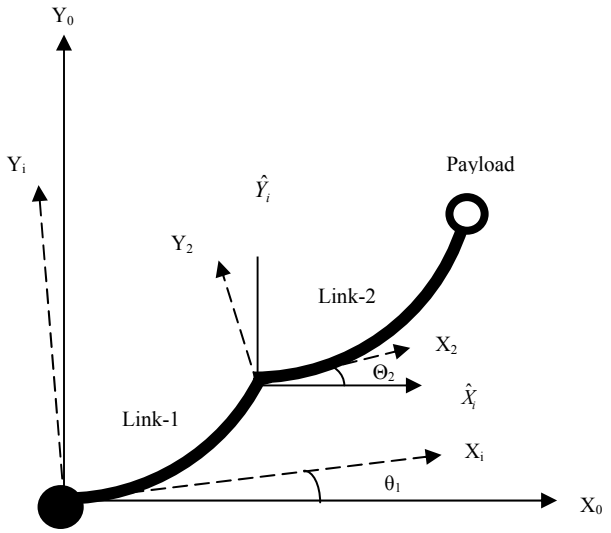

Figure 1: Schematic diagram of a two-link flexible manipulator

The first link is clamped on the rotor of the first motor. The second motor is attached to the tip of the first link. X_0 and Y_0 are the inertial coordinate frame. θ_1 and θ_2 are the angular position and $v_i(x_i,t)$ are the transverse component of the displacement vector. M_p is an inertial payload mass with inertia J_p at the end-point of second link. The description of kinematics is developed for a chain of n serially connected flexible links, revolute joints and motion of the manipulator on a two-dimensional plane, the rigid transformation matrix, A_i, from $X_{i-1}Y_{i-1}$ to $X_i Y_i$ is written as

$$A_i = \begin{bmatrix} \cos\theta_i & -\sin\theta_i \\ \sin\theta_i & \cos\theta_i \end{bmatrix} \quad (1)$$

The global transformation matrix T_i transforming co-ordinates from X_0Y_0 to X_iY_i follows a recursion as below

$$T_i = T_{i-1}E_{i-1}A_i \quad (2)$$

The dynamic equations of motion is derived for a two-link flexible manipulator, the total energy associated with the manipulator system needs to be computed using the kinematics formulations explained previously. The total kinetic energy of the manipulator (T) is given by

$$T = T_R + T_L + T_{PL} \quad (3)$$

where T_R, T_L and T_{PL} are the kinetic energies associated with the rotors, links and the hubs, respectively.

As Figure 1 show and the kinematics formulation described previously, the kinetic energy associated with the payload can be written as

$$T_{PL} = \frac{1}{2}M_p \dot{p}_{n+1}^T \dot{p}_{n+1} + \frac{1}{2}I_P(\dot{\Omega}_n + \dot{\upsilon}_n'(l_n))^2 \quad (4)$$

where $\dot{\Omega}_n = \sum_{j=1}^{n}\theta_j + \sum_{k=1}^{n-1}\dot{\upsilon}_k'(l_k)$; n being the link number, prime and dot represent the first derivatives with respect to spatial variable x and time, respectively. The potential energy of the system due to the deformation of the link i by neglecting the effects of the gravity can be written as

$$U = \sum_i^n \frac{1}{2}\int_0^{l_i}(EI)_i\left(\frac{d^2\upsilon_i(x_i)}{dx_i^2}\right)^2 dx_i \quad (5)$$

A two-link flexible manipulator motion equation is derived using the generalized modelling scheme. Consider two units of the n-link with the first one clamped and a payload attached at the tip of the second link.

Using the generalized modeling scheme described, equations with a two-link flexible manipulator links are described in this section. In this case, the effectiveness masses at the end of the individual links are set as

$$M_{L1} = m_2 + m_{h2} + M_p$$

$$J_{L1} = J_{o2} + J_{h2} + J_p + M_p l_2^2 \quad (6)$$

where

$$MD_1 = 0 \qquad M_{L2} = M_p$$

$$J_{L2} = J_p \; MD_2 = 0$$

The co-ordinate vector consists of link positions, (θ_1, θ_2) and modal displacements (q_{11}, q_{12}, q_{21}, q_{22}). The force vector is F = $\{\tau_1, \tau_2, 0, 0, 0, 0\}^T$, where τ_1 and τ_2 are the torques applied by rotor-1 and rotor-2, respectively. Therefore, the following Euler–Lagrange's equations result, with i = 1 and 2 and j = 1 and 2:

$$\frac{\partial}{\partial t}\left(\frac{\partial L}{\partial \dot{\theta}_i}\right) - \frac{\partial L}{\partial \theta_i} = \tau_i \qquad (7)$$

$$\frac{\partial}{\partial t}\left(\frac{\partial L}{\partial \dot{q}_{ij}}\right) - \frac{\partial L}{\partial q_{ij}} = 0 \qquad (8)$$

A set of dynamic equations can be written in compact form as

$$M(\theta,q)\begin{Bmatrix}\ddot{\theta}\\ \ddot{q}\end{Bmatrix} + \begin{Bmatrix}f_1(\theta,\dot{\theta})\\ f_2(\theta,\dot{\theta})\end{Bmatrix} + \begin{Bmatrix}g_1(\theta,\dot{\theta},q,\dot{q})\\ g_2(\theta,\dot{\theta},q,\dot{q})\end{Bmatrix} + \begin{Bmatrix}0\\ D\dot{q}\end{Bmatrix} + \begin{Bmatrix}0\\ Kq\end{Bmatrix} = \begin{Bmatrix}\tau\\ 0\end{Bmatrix} \qquad (9)$$

where f_1 and f_2 are the vectors containing terms due to coriolis and centrifugal forces, M is the mass matrix, and g_1 and g_2 are the vectors containing terms due to the interactions of the link angles and their rates with the modal displacements. K is the diagonal stiffness matrix which takes on the values $\omega_{ij}^2 m_i$ and D is the passive structural damping.

3. SIMULATION RESULT

Table 1 shows the physical parameter of the two-link flexible manipulator used in this simulation. M_{Li}, EI and G represent the mass of link, flexural rigidity and gear ratio respectively. J_{hi} is the inertia of the motor and hub and M_{h2} is the mass of centre rotor at the second motor.

Table 1: Parameters of The System

Symbol	Parameter	Value	Unit
M_{L1}=M_{L2}	Mass of link	0.1	kg
ρ	Mass density	0.2	kgm^{-1}
G	Gear ratio	1	-
EI	Flexural rigidity	1.0	Nm^2
J_h	Motor and hub inertia	0.02	kgm^2
M_p	Payload mass	0.4	kg
l	Length	0.5	m
I_p	Payload inertia	0.002	kgm^2
M_{h2}	Mass of the centre rotor	1	kg

A two-link flexible manipulator was excited with symmetric bang-bang torque inputs with amplitude of 0.2 Nm and 1 s width as shown in Figure. 2. For validation of the dynamic models, simulations were conducted on the manipulators with the same input trajectories. A bang-bang torque has a positive (acceleration) and negative (deceleration) period allowing the manipulator to, initially, accelerate and then decelerate and eventually stop at target location.

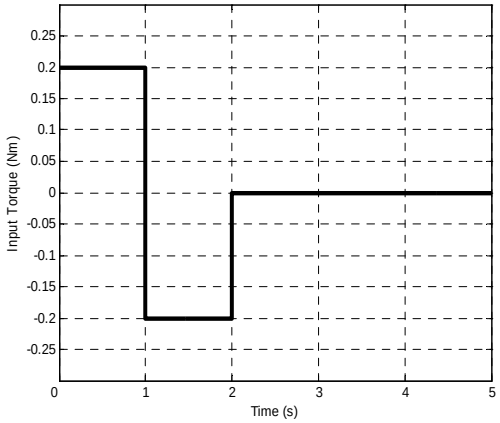

Figure 2. The Bang – bang Input Torque

Figures 3 and 4 show the angular positions, modal displacement and end-point acceleration responses of the two-link flexible manipulator without payload for both links. It is noted that a steady-state angular position levels of 54.56 degrees and -122.33 degrees were achieved within 1.8 s for link-1 and link-2 respectively. The time responses specifications of angular position for link-1 were achieved within the settling time and overshoot of 2.00 s and 1.35 % respectively. On the other hand, the settling time and overshoot for link-2 were obtained as 1.99 s and 0.35 % respectively.

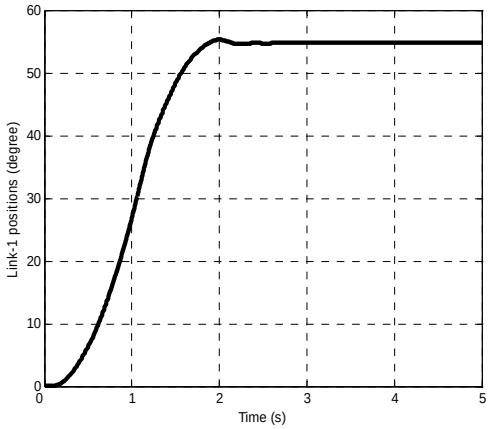

Figure 3: Angular position of link-1 the system without load.

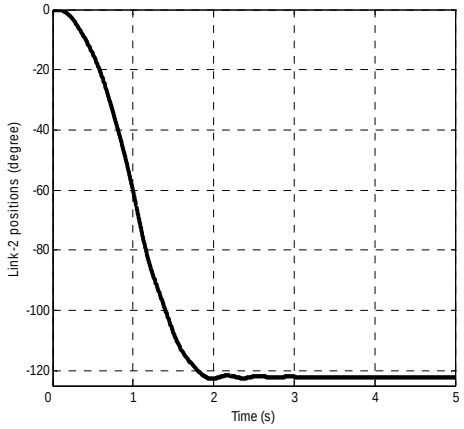

Figure 4: Angular position of link-2 the system without load.

Figures 5 and 6 show The modal displacement responses of link-1 and link-2 were found to oscillate between -6.1x10^{-3} m to 9.3x10^{-3} m and -11.2x10^{-3} m to 17.3x10^{-3} m respectively.

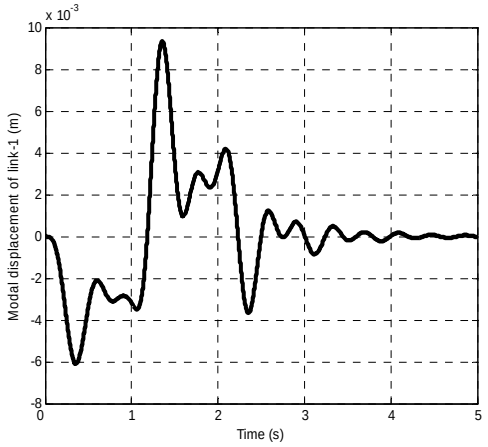

Figure 5: Modal displacement of link-1 of the system without load.

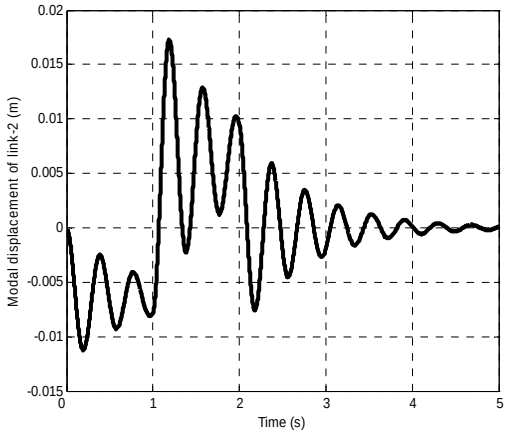

Figure 6: Modal displacement of link-2 of the system without load.

To demonstrate the effects of payload on the dynamic characteristics of the system, the payload of up to 0.4 kg was examined. Figures 7 and 8 show the system responses of the flexible manipulator with payloads of 0.4 kg for link-1 and link-2 respectively. It is noted that the angular positions for link-1 decrease towards the positive direction whereas the angular positions of link-2 decrease in the negative direction with increasing payloads. For payloads 0.4 kg, the steady-state angular position levels for link-1 were obtained as 20.36 degrees respectively whereas for link-2, these were obtained as -40.19 degrees.

The time response specifications of angular positions have shown significant changes with the variations of payloads. With increasing payload, the system exhibits higher settling times and overshoots for both links. For link-1, the response exhibits an overshoot of 7.26 % with the settling time of 4.32 s 0.4 kg respectively. For link-2, the response exhibits a percentage overshoot of 2.68 % with the settling time of 2.98 s for 0.4 kg payload.

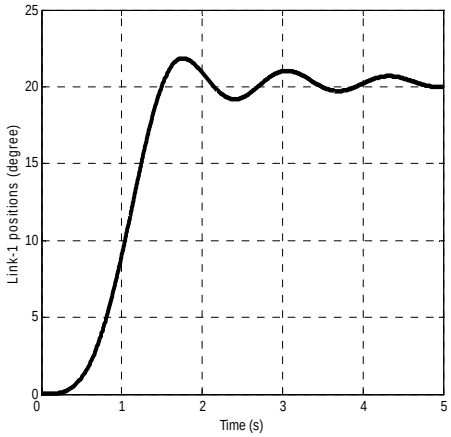

Figure 7: Angular position of link-1 the system with load 0.4 kg.

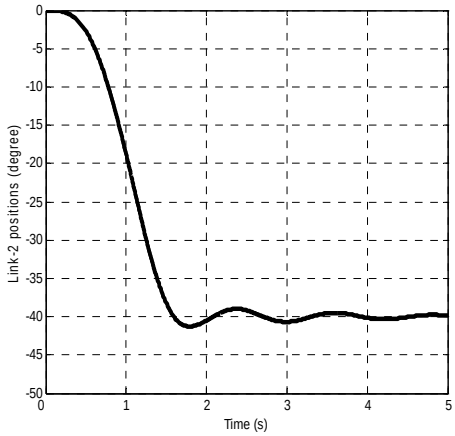

Figure 8. Angular position of link-2 the system with load 0.4 kg.

Figures 9 and 10 show modal displacements and end-point acceleration responses of the system with payloads respectively. It is noted with increasing payloads, the magnitudes of vibration of modal displacement increase for both links. In this case, the modal displacement responses of link-2 were found to oscillate between -8.73×10^{-3} m to 13.7×10^{-3} m and -53.9×10^{-3} to 74.0×10^{-3} m for payloads of 0.1 kg and 0.5 kg respectively.

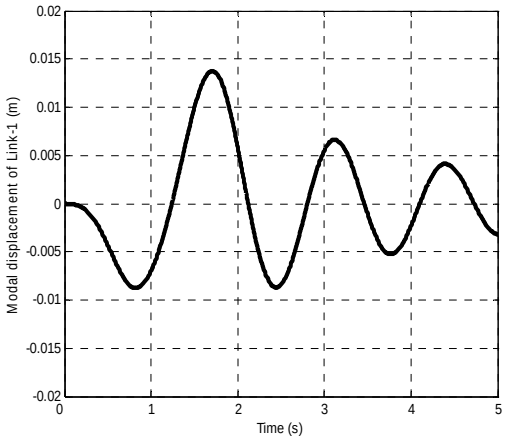

Figure 9: Modal displacement of link-1 of the system with load 0.4 kg.

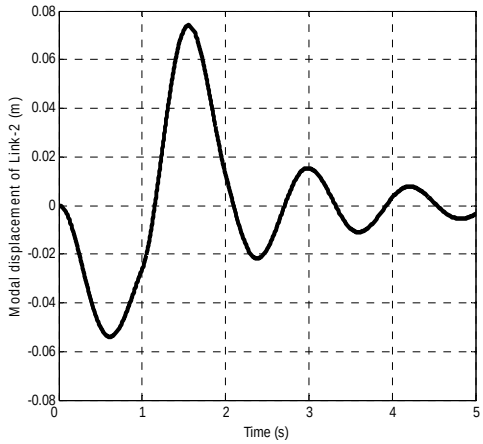

Figure 10: Modal displacement of link-2 of the system with load 0.4 kg.

Table 2 summarises the relationship between time response specifications (rise time, settling time and overshoot) and payload.

Table 2: Relation between payload and specifications of angular position

Payloads (kg)	Time responses specifications of angular positions			
	Link-1		Link-2	
	Settling time (s)	Overshoot (%)	Settling time (s)	Overshoot (%)
0	1.76	1.35	1.80	0.35
0.4	4.32	7.26	2.98	2.68

5. CONCLUSSION

The development of a dynamic model of a two-link flexible manipulator has been presented. The model has been derived using Eular-Lagrange and AMM. Simulation exercises have been conducted without and with payload to study and verify the performance of the system. The angular positions and displacements of link-1 and link-2 of the systems have been obtained and analysed.

ABSTRACT

This paper presents a dynamic modelling of a two-link flexible manipulator model. An explicit, complete, and accurate nonlinear dynamic model of the system is developed using assumed mode method. The Lagrangian approach is used to derive the dynamic model of the structure. To study the effectiveness of the controller, a PID control is developed. PID controller will implement to the system of a two-link Flexible Manipulator.

Keywords *:*
Assumed mode, modelling, PID, two-link flexible manipulator

1. INTRODUCTION

Robot manipulators are constructed very massively to make them precise and stiff. The arms of these can be considered rigid, which allows a simple control joints. The drawback of their heavy construction is, that the robots need very powerful actuators and their operating speed is strongly limited by their own inertia. Lightweight robots are developed to overcome these drawbacks and allow high speed movements with the same or even better precision. These are commonly used in space applications, because the take-off weight of space shuttles is strongly limited. In order to improve higher productivity, it is required to reduce the weight of the arms and/or to increase their speed of operation. For these purposes it is very desirable to build flexible robotic manipulators. Morever, flexible manipulators are lighter, faster and less expensive than rigid ones.

Each flexible link can be modeled as distributed parameter system where the motion is described by a coupled system of ordinary and partial differential equations (PDE). Various approaches have been developed which can mainly be divided into two categories: the numerical analysis approach and the assumed mode method (AMM). The numerical analysis methods that are utilised include finite difference (FD) and finite element (FE) methods.

The FD and FE approaches have been used in obtaining the dynamic characterisation of a single-link flexible manipulator system incorporating damping, hub inertia and payload [1,2].

Subudhi and Morries [3] have used a combined Euler-Lagrange formulation and AMM approach to model the planar motion of a manipulator consisting of two flexible links and joints. The conventional Lagrangian modeling of flexible link robots does not fully incorporate the bending mechanism of flexible link as it allows free link elongation in addition to link deflection. De Luca and Siciliano [4] have utilized the AMM to derive a dynamic model of multilink flexible robot arms limiting to the case of planar manipulators with no torsional effects. The equations of motion which can be arranged in a computationally efficient closed form that is also linear with respect to a suitable set of constant mechanical parameters have been obtained [5].

The controller strategies for flexible manipulator systems can be classified as feedforward and feedback control schemes. A number of techniques have been proposed as feedforward control schemes for control of vibration [6].

This paper presents modeling of a two-link flexible manipulator using Lagrangian technique in conjunction with the AMM. The links are modeled as Euler-Bernoulli beams satisfying proper mass boundary conditions. A payload is added to the tip of the outer link, while hub inertias are included at the actuator joints. To demonstrate the effectiveness of the controllers in reducing vibration of a two-link flexible manipulator, PID controller utilizing the hub angle and hub velocity is developed.

ISSN 114-1284

2. A TWO-LINK FLEXIBLE ROBOT MANIPULATOR

The structure of a two-link flexible manipulator system is shown in Figure 1. The links are cascaded in serial fashion and are actuated by rotors and hubs with individual motors. An inertial payload of mass M_P and inertia I_P is connected to the distal link. The proximal link is clamped and connected to the rotor with a hub.

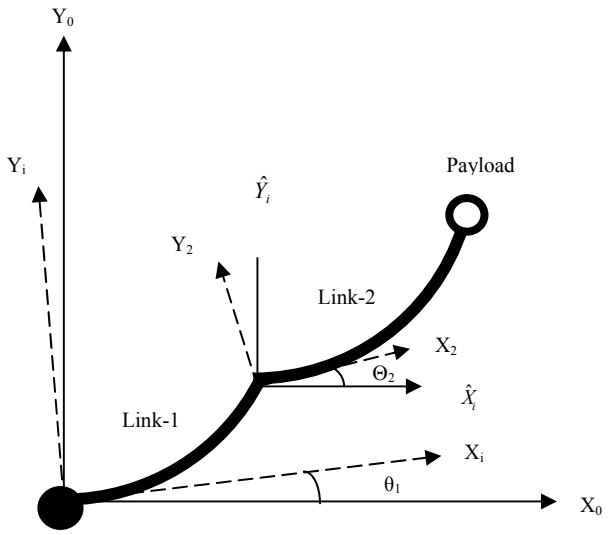

Figure 1: Schematic diagram of a two-link flexible manipulator

The *i*th link has length l_i and uniform mass density per unit length ρ_i. The first link is clamped on the rotor of the first motor. The second motor, is attached to the tip of the first link. *E* and *I* represent Young modulus and area moment of inertia of both link. A payload is attached at the end-point of link-2. X_0Y_0 is the inertial coordinate frame. θ_1 and θ_2 are the angular position and $v_i(x_i,t)$ are the transverse component of the displacement vector. M_p is an inertial payload mass with inertia J_p at the end-point of link 2.

The description of kinematics is developed for a chain of *n* serially connected flexible links, revolute joints and motion of the manipulator on a two-dimensional plane, the rigid transformation matrix, A_i, from $X_{i-1}Y_{i-1}$ to X_iY_i is written as

$$A_i = \begin{bmatrix} \cos\theta_i & -\sin\theta_i \\ \sin\theta_i & \cos\theta_i \end{bmatrix} \qquad (1)$$

The global transformation matrix T_i transforming co-ordinates from X_0Y_0 to X_iY_i follows a recursion as below

$$T_i = T_{i-1}E_{i-1}A_i \qquad (2)$$

The dynamic equations of motion is derived for a two-link flexible manipulator, the total energy associated with the manipulator system needs to be computed using the kinematics formulations explained previously. The total kinetic energy of the manipulator (*T*) is given by

$$T = T_R + T_L + T_{PL} \qquad (3)$$

where T_R, T_L and T_{PL} are the kinetic energies associated with the rotors, links and the hubs, respectively.

As Figure 1 show and the kinematics formulation described previously, the kinetic energy associated with the payload can be written as

$$T_{PL} = \frac{1}{2}M_p\dot{p}_{n+1}^T\dot{p}_{n+1} + \frac{1}{2}I_P(\dot{\Omega}_n + \dot{\upsilon}_n'(l_n))^2 \qquad (4)$$

where $\dot{\Omega}_n = \sum_{j=1}^{n}\theta_j + \sum_{k=1}^{n-1}\dot{\upsilon}_k'(l_k)$; *n* being the link number, prime and dot represent the first derivatives with respect to spatial variable *x* and time, respectively. The potential energy of the system due to the deformation of the link *i* by neglecting the effects of the gravity can be written as

$$U = \sum_i^n \frac{1}{2}\int_0^{l_i}(EI)_i\left(\frac{d^2\upsilon_i(x_i)}{dx_i^{\,2}}\right)^2 dx_i \qquad (5)$$

A two-link flexible manipulator motion equation is derived using the generalized modelling scheme. Consider two units of the *n*-link with the first one clamped and a payload attached at the tip of the second link.

Using the generalized modeling scheme described, equations with a two-link flexible manipulator links are described in this section. In this case, the effectiveness masses at the end of the individual links are set as

$$M_{L1} = m_2 + m_{h2} + M_p$$

$$J_{L1} = J_{o2} + J_{h2} + J_p + M_p l_2^2 \qquad (6)$$

where

$$MD_1 = 0 \qquad M_{L2} = M_p$$

$$J_{L2} = J_p \; MD_2 = 0$$

The co-ordinate vector consists of link positions, (θ_1, θ_2) and modal displacements (q_{11}, q_{12}, q_{21}, q_{22}). The force vector is F = $\{\tau_1, \tau_2, 0, 0, 0, 0\}^T$, where τ_1 and τ_2 are the torques applied by rotor-1 and rotor-2, respectively. Therefore, the

following Euler–Lagrange's equations result, with i = 1 and 2 and j = 1 and 2:

$$\frac{\partial}{\partial t}\left(\frac{\partial L}{\partial \dot{\theta}_i}\right)-\frac{\partial L}{\partial \theta_i}=\tau_i \qquad (7)$$

$$\frac{\partial}{\partial t}\left(\frac{\partial L}{\partial \dot{q}_{ij}}\right)-\frac{\partial L}{\partial q_{ij}}=0 \qquad (8)$$

A set of dynamic equations can be written in compact form as

$$M(\theta,q)\begin{Bmatrix}\ddot{\theta}\\ \ddot{q}\end{Bmatrix}+\begin{Bmatrix}f_1(\theta,\dot{\theta})\\ f_2(\theta,\dot{\theta})\end{Bmatrix}+\begin{Bmatrix}g_1(\theta,\dot{\theta},q,\dot{q})\\ g_2(\theta,\dot{\theta},q,\dot{q})\end{Bmatrix}+\begin{Bmatrix}0\\ D\dot{q}\end{Bmatrix}+\begin{Bmatrix}0\\ Kq\end{Bmatrix}=\begin{Bmatrix}\tau\\ 0\end{Bmatrix} \qquad (9)$$

where f_1 and f_2 are the vectors containing terms due to coriolis and centrifugal forces, M is the mass matrix, and g_1 and g_2 are the vectors containing terms due to the interactions of the link angles and their rates with the modal displacements. K is the diagonal stiffness matrix which takes on the values $\omega_{ij}{}^2 m_i$ and D is the passive structural damping.

3. SIMULATION RESULT

Table 1 shows the physical parameter of the two-link flexible manipulator used in this simulation. M_{Li}, EI and G represent the mass of link, flexural rigidity and gear ratio respectively. J_{hi} is the inertia of the motor and hub and M_{h2} is the mass of centre rotor at the second motor.

Table 1: Parameters of The System

Symbol	Parameter	Value	Unit
M_{L1}=M_{L2}	Mass of link	0.1	kg
ρ	Mass density	0.2	kgm^{-1}
G	Gear ratio	1	-
EI	Flexural rigidity	1.0	Nm^2
J_h	Motor and hub inertia	0.02	kgm^2
M_p	Payload mass	0.5	kg
l	Length	0.5	m
I_p	Payload inertia	0.0025	kgm^2
M_{h2}	Mass of the centre rotor	1	kg

A two-link flexible manipulator was excited with symmetric bang-bang torque inputs with amplitude of 0.2 Nm and 1 s width as shown in Figure. 2. For validation of the dynamic models, simulations were conducted on the manipulators with the same input trajectories. A bang-bang torque has a positive (acceleration) and negative (deceleration) period allowing the manipulator to, initially, accelerate and then decelerate and eventually stop at target location.

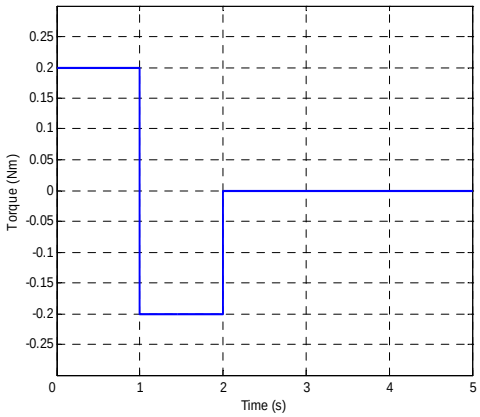

Figure 2. The Bang – bang Input Torque

Figure 3 shows the response of the angular positions of link-1 and link-2 of the system with torque amplitudes of 0.2 Nm. As expected, by increasing the payload mass, the angular position decreases. Moreover overshoot increases by increasing torque amplitude. It is also noted that the angular positions for Link-1 of 16.5 degree and Link-2 is -34 degree, respectively, were achieved within 2 s.

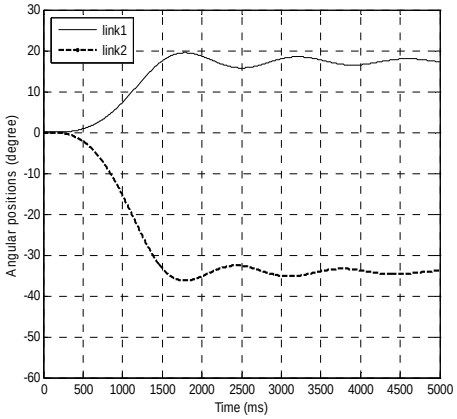

Figure 3. Angular Position of Link-1 and Link-2

Figure 4 and 5 show modal displacement of link-1 and link-2. The pattern of modal displacement of link-1 between $\pm 8.8\times10^{-3}$ m and $\pm 5.5\times10^{-3}$ m and link-2 between ± 0.08 m and $\pm 2.5\times10^{-3}$ m for the first and second modes respectively.

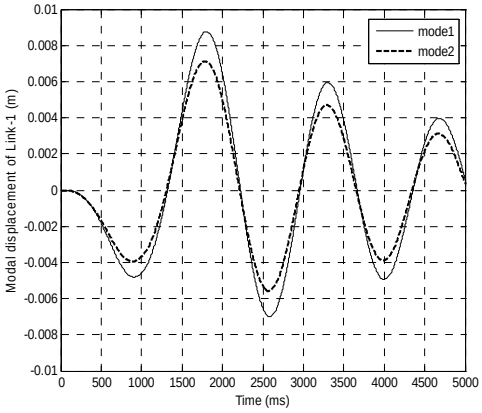

Figure 4. Modal Displacement of Link-1.

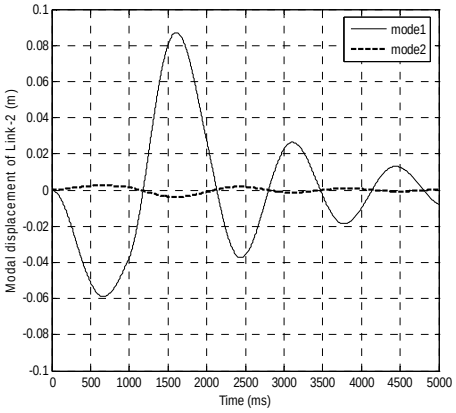

Figure 5. Modal Displacement of Link-2.

Figure 6 shows response of the end-point acceleration of link-1 and link-2. The end-point acceleration results which were found to oscillate between $\pm$ 0.23 m/sec^2 for link-1 and $\pm$ 1.30 m/sec^2.

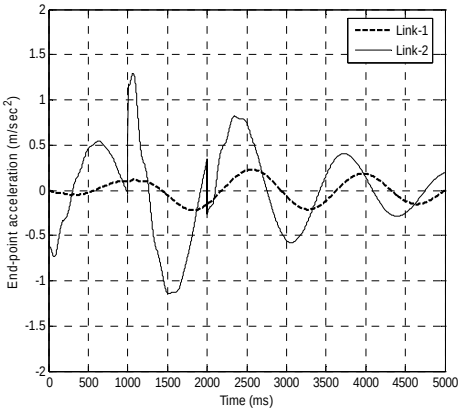

Figure 6. Response of end-point acceleration.

Figure 7 shows response of PSD of end-point acceleration of link-1 and link-2. For payload 0.5 kg, the resonance frequencies for the first two modes of vibration respectively were obtained as 1 Hz and 7 Hz for link-1 and 1 Hz and 7 Hz for link-2.

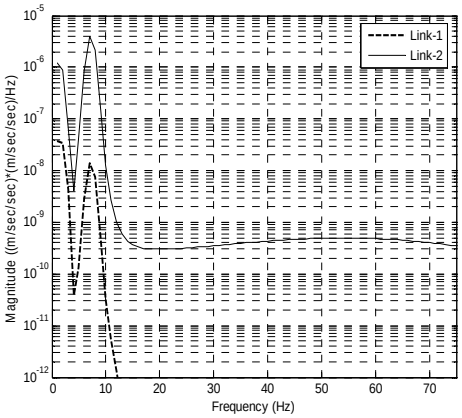

Figure 7. PSD of end-point acceleration.

4. PID CONTROL

In this study, Ziegler-Nichols closed loop method is used in designing the PID controller. The Ziegler-Nichols closed loop method is one of the more common method used to tune control loops. The closed loop method determines the gain at which a loop with proportional only control will oscillate, and then derives the controller gain, integrator, and derivative values from the gain at which the oscillation are sustained and the period of oscillation at that gain.

The closed loop method also known as ultimate cycle method tuning Kp, Ki and Kd components based on Ku and Pu. Practically, the ultimate gain (Ku) and the ultimate period (Pu) is found by setting the integral (Ki) and derivative (Kd) components of the PID controller to zero and incrementally increasing the proportional (Kp) component until oscillations begin. In other words, the trial process is repeated which increased or decreased controller gain Kp (Ki=Kd=0) until a stable oscillation is achieved.

Then, from the format of PID controller as

$$G_c = K(1 + \frac{R}{s} + T \bullet s) \qquad (10)$$

The value of Kp=0.6, Ki=0.24 and Kd=0.375 components is found and installed into the systems as figure 8.

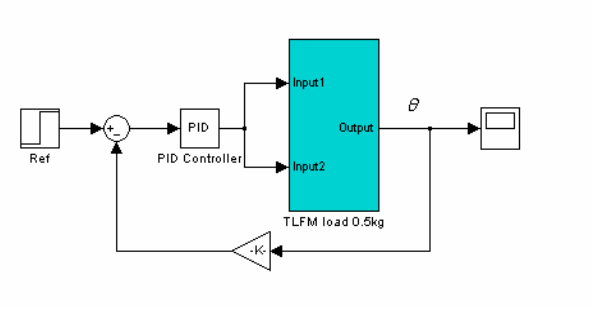

Figure 8. The PID control structure

Figure 9 shows the response of angular positions of link-1 of the system with PID controller and without controller using the step input of 1.5 degrees. As expected, by inserting the controller, the angular position enhances. Moreover overshoot decreases by inserting the PD controller. The vibration of link-1 can be reduced by inserting PID controller. The vibration of angular positions can be reduced by PID controller, for link-1 of 1.53 degrees.

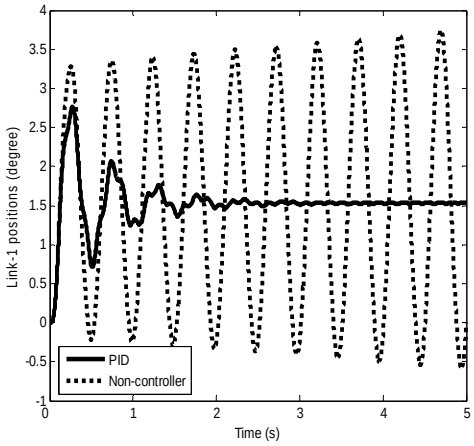

Figure 9. Angular Position of Link-1

Figure 10 shows the response of angular positions of link-2 of the system with PID controller and without controller using the step input of -3 degrees. It is noted the vibrations of link-2 reduce by inserting the PID controller. The angular positions for link-2 is -3.07 degrees.

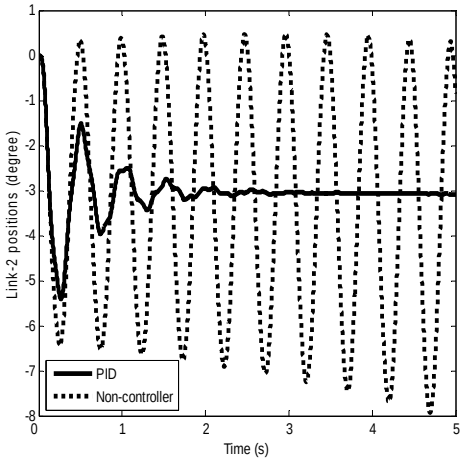

Figure 10. Angular Position of Link-2

5. CONCLUSSION

The development of dynamic model of a two-link flexible manipulator has been presented. The model has been derived using Eular-Lagrange and AMM. Simulation exercises have been conducted with various torque amplitudes to study and verify the performance of the system. A PID controller has been developed for control of a two-link flexible manipulator. It has been demonstrated that reduction in the system vibration with the PID controller.

ABSTARCT

In a row with fast development of Fuel Cell device, hydrogen as energy carrier could replace the petrochemical fuel. The challange is to produce hydrogen at a cost competitive with current fuels and morever the hydrogen production methods must use renewable sources and environmental friendly. The last two characteristics can be fulfiled by elelectrolysis method. Furthemore,low cost production could be achieved by increasing the conversion energy efficiency of electrolysis system. At present , ultrasonics energy was used to increase the efficiency. The cell was constructed using 2 cm^2 surface area of nickel cathode/anode with diaphragm between theme, so hydrogen and oxygen gas can be separated in diffrent gasket. The rod of ultrasonics horn was put in the midle of electrodes with max power 80 watt. As electrolyte 36 cm^3 of 5M KOH was used and its temperature can be varied to 60^0 C. The electrical current was adjusted between 100 mA to 1000 mA. The data shows that the energy efficiency increases to about 3 % in comparison with cell without ultrasonics. In this paper the evaluation of ultrasonics effects on the cell performance also be discussed.

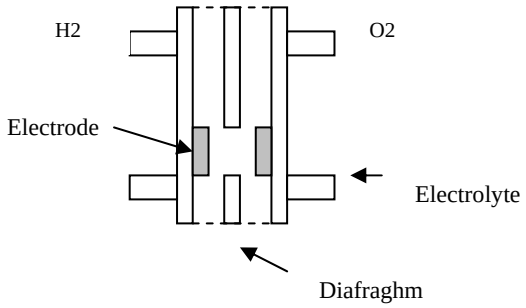
hydrogen,electrolysis,ultrasonics,efficiency,energy

1.INTRODUCTION

Due to usage of fossil fuel, the increament of carbon polution is difficult to avoid. In the year 2001, CO2 concentration increase from 280 ppm to be 370 ppm at the area around industries locations [1]. The experts agree the increament of CO2 as principle cause of global warming. To reduce the rate of increase of CO2 concentration, the shift to free emission fuels is necessary. Hydrogen is the excellent choice.
Hydrogen can be produced by water electrolysis method. As electrical source used to separate water molecule come from wind turbine or solar cell energy, so the H2 production system is CO2 free or environmental clean. The process also renewable because of only water is used as input materials. Therefore, this production method is to agree with hydrogen economy concept.
But the efficiency of this method is still low. Efforts have been carried out to increase the efficiency. At present, we try to use ultrasonic energy to increase the efficiency. This idea is based on cavitation fenomena in which from some research results can accelerate the chemical processes.
The preliminary study data show the over potential of cell electrolysis decrease as ultrasonic wave irradiated in electrolyte solution [2-5]. In this paper, we construct cell sono-electrolyzer i.e: the device represents of integration ultrasonic source with cell electrolysis. That cell was equipped with separated hydrogen and oxygen gas channels, so the hydrogen/oxygen production rate can be observed. From the change of hydrogen production rate data, it can be calculated the cell efficiency.

2.EXPERIMENTAL

The cell designed use two nickel electrodes dimension 2 x 1 cm and put paralel with distance 6 mm (fig 1a,b,c)



(a)

(b)

Figure :1 Sono -Electrolysis system a: cell schematic, b:photo of the system

5M KOH as electrolyte put into the cell and circulated so the KOH concentration not change during process. The electrolyte volume in the cell is about 6 x 6 x 1 cm and the themperature was kept at 60 C. Here, it could be observed the different of cell performance with or without ultrasonic wave iirradiation on electrolyte. The electrical current source was adjusted from 100 mA to 1 A.

Figure 2: The equipments to test sono electrolyzer cell.

The sono electrolyzer test system set up is pointed out at fig. 3 with ultrasonic frequency is 20 kHz and the maximum power 80 watt. The ultrasonic probe is silinder in the shape 1 cm in diameter.

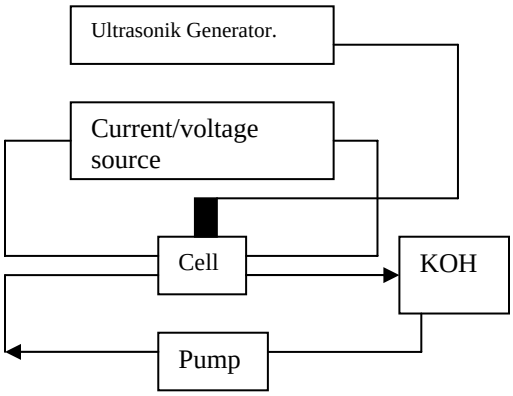


Figure3: Cell performance test model

3.DATA AND ANALYSIS

Fig.4 shows hydrogen production rate increase during ultrasonic irradiation to 0.6 Liter/h.
This fenomena clearly seem at the electrical current reach 1 Amp.

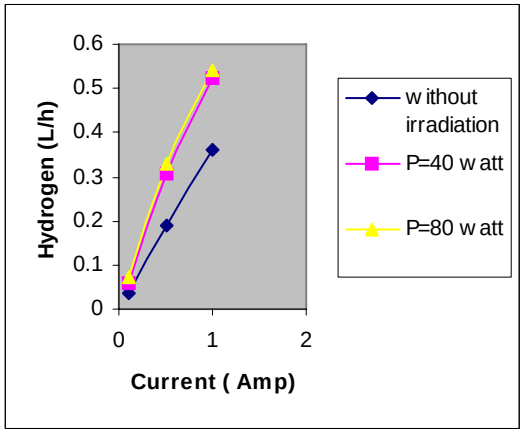

Figure 4: Hydrogen rate production with and without ultrasonic irradiation

From Faraday formula that rate equal the increase in electrical current 0.35 A (fig. 5).

Faraday formula:[6]

$Vol.H_2=R.I.T.t/(F.p.z)$ (1)

Here: R gas constant, I current,T themperature, t time, F faraday constant,p pressure and z =2 (for hydrogen)
This data confirm the preliminary study that this fenomena related existance of the surface electrode characteristic changes .

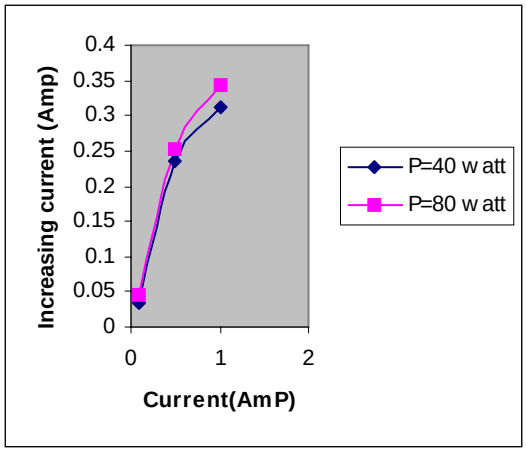

Figure5: Increasing in electrical current during irradiation

However if the ultrasonic power increased two times, but then the production rate do not increase two times too. It was supposed not all ultrasonic power can be converted to increase the current, the other part was wasted in heat form of energy. The ultrasonic energy accept capability probably depend on the electrode dimension. It needs more investigation.
The cell efficiency can be calculated from relation:[6]

$E_{ff}=1.42/celloverpotential$ (2)

More low of overpotensial more efficient of the cell. From fig. 6 it can be seen the overpotensial decrease during irradiation especially at low current.As consequencely, the cell efficiency increase bigger allmost 3% at low current . word, ultrasonic irradiation cause the increase in electrical current. The increasing value do not follow linier propotion of ultrasonik energy. At the cell sono - electrolyzer has been constructed the increase of efficiency is about 3% at low current.
As hypotetical suggestion: for energy balance investigation adding number of the cell is necessary so the ultrasonic energy can be irradiated to all the cell.

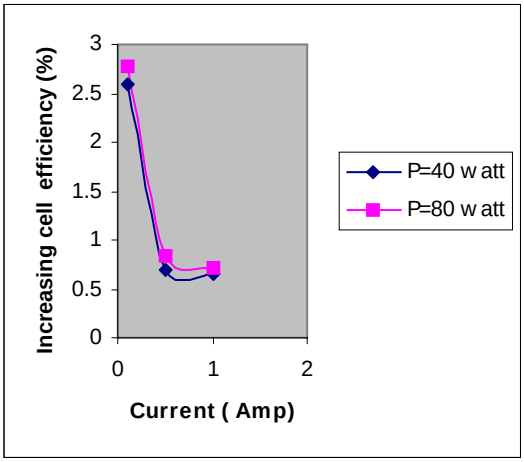

Figure 6: The change in efficiency caused by irradiation

4.Conclusions

Generally, it can be say that the use of ultrasonic energy can increase the hydrogen rate production.

ABSTRACT

Universitas Pelita Harapan (UPH) uses RFID (Radio Frequency Identification) system, also known as smart card, for many applications such as building access, paying fine in the library, paying for food in the Food Junction, identifying books borrowers in the library, and using the copy-machine in the library. Because of the many applications, it is necessary to know whether the smart card is secure enough for those applications. The research was done by trying to figure out the weaknesses and testing the smartcard through its weaknesses. The testing was done in two ways, technical probing and social probing. It was found that there are several flaws in the system implementation using smart card. A security level of RFID system is then proposed based on the mechanism of the access bit. Every application is grouped according to its security level. The probing revealed some data stored in the smart card and the key that is being used in some applications. According to the probing results, the flaws that have been found so far are not critical to the security of the whole system.

1. INTRODUCTION

Radio-frequency identification (RFID) is an automatic identification method which can transmit and receive data using devices called RFID tags or transponders. RFID tags consist of two parts. The first is an integrated circuit for storing and processing information, modulating and demodulating RF (radio frequency) signal, and other special functions. The second part is an antenna to receive and transmit signals.

One of international standards, ISO 14443 RFID, controls the use of proximity card (smart card proximity) for identification. ISO 14443 is divided into four sections, which are [1]:

1. Physical characteristics.
2. Characteristics of radio frequency (RF).
3. Protocol for initialization and collision control.
4. Transmission protocol.

The use of RFID systems have become common and varied, ranging from building access-control until payment transaction. It is also being used as a form of identification. Universitas Pelita Harapan (UPH) is one of the institutions that take advantage of RFID systems, which are known as smart cards. Smart card applications in UPH are organized for many activities. UPH smart cards are used for identification cards, instruments for paying fine in the library and for transactions in the Food Junction, for building access, photocopying, printing, and controlling students' meal quota. It can be seen that many applications are using smart card. Therefore, an analysis is conducted to determine the security level of smart card applications in UPH.

UPH smart card is an RFID-based system of MIFARE Standard 1k card. In this work, the security of the system was tested by technical probing, using software and a Universal Reader. Another testing method was the social probing, which took a closer look at the whole operation of the smartcard system to identify its weaknesses. The aim of the work is to reveal the weaknesses in the UPH smart card system. An analysis was also performed to clarify available security levels based on the access conditions of the smart cards. Appropriate security levels for specific applications will be proposed.

2. MIFARE SMART CARD AND UPH APPLICATIONS

2.1 MIFARE Classic Logic Structure

MIFARE Classic Card is in essence a memory card with some additional functionality. The memory on the card is divided into several blocks of data each consisting of 16 bytes. Blocks of data are grouped into sectors. MIFARE Classic 1k has 16 sectors, each sector consists of 4 blocks of data. The last block of data on each sector is called the sector trailer. The schematic of the MIFARE Classic 1k memory is shown in Figure 1.

Block 0 and sector 0 contain special data. The first four bytes of data contain the unique identifier of the card (UID) followed by 1 byte bit count check (BCC). BCC is obtained as a result of applying XOR on all UID bytes. The bytes after the BCC are used to insert the manufacture data. This data block can only be read.

Sector trailer contains key A and B for the authentication process. Access condition determines the operations that can be done in the sector. Sector trailer has special access conditions. Key A can never be read, and key B can be set

to be readable. Beside the access condition (AC) and the key, there is one byte of data (U) that does not have any important meaning. The schematic of the sector trailer is shown in Figure 2.

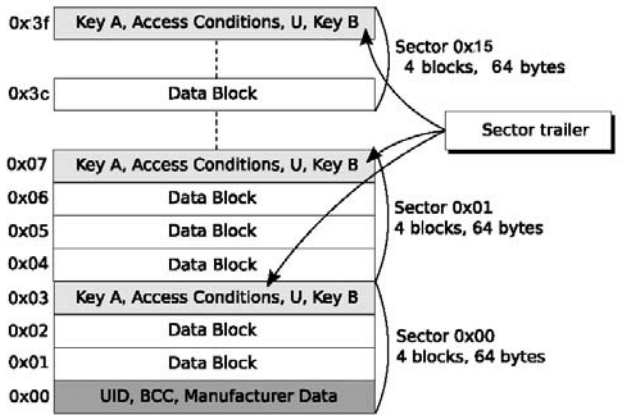

Figure 1: Schematic of MIFARE *Classic* 1k memory [2]

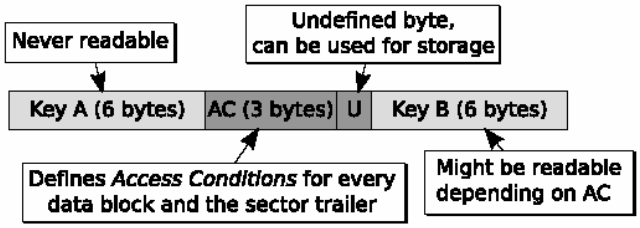

Figure 2: Sector Trailer [2]

There are several commands on the MIFARE Classic to access blocks and sectors. The access condition is always checked each time a command occurs, to determine whether the command can be executed in the requested sector. Read and write commands are for reading or writing one block of data or value blocks. The write command can format a block into a value block or just for storing data only.

The next commands are decrement, increment, restore, and transfer. All commands can only be done in the value block. Increment and decrement commands will increase or decrease the value in the value block with a particular value and save the result in the register memory. Restore command takes the value from the register memory without changing it and then move it to the same or a different block with the command transfer.

2.2. Smart Card Applications in Universitas Pelita Harapan

The first application in UPH is the building access. Here, the smart card is used for opening the door of the library or laboratory facilities such as the English Laboratory. For example, to enter the library, visitors must tap the smart card, which is an RFID tag, to the reader. The reader will check if the card holder can enter the library.

The second application is the identification for borrowing books in the library. The borrowing procedure is started by tapping the smart card to the RFID reader. The content of the smart card is displayed on the screen, and the ID number (NIM) and the name that appear on the display are checked whether they match the data listed on the smart card. Other data that can be seen are the borrowed books, the status of the student and the amount of unpaid fines. Students who are working on their final project may borrow one extra book.

The third application is using the smart card to pay for photocopies. Smart cards are placed on the balance reader of a photocopy machine. The reader checks the balance available to do photocopies. If there were sufficient balance, the photocopy process can be carried out and the balance in the smart card will be reduced according to the number of photocopies. The photocopies balance is different from the micropayment balance.

The fourth application is the fine payment in the library. The smart card is brought to the reader to see the amount of the remaining balance. If the balance is insufficient or the smart card has not been activated for micropayment, it can not be used for paying fine. If there were sufficient balance, it would be debited as much as the fine that must be paid.

The fifth application is the micropayment. Smart cards are charged with some amount of money, and then used for transactions in the Food Junction. The micropayment system is also applicable for the payment of fines in the library.

3. SECURITY ANALYSIS

3.1 Smart Card Types, Personalization and Activation Procedures

The UPH smart card is owned by every staffs and students of UPH. There are some differences between the smart card of students and staffs. The cards for students are printed with red stripes, green stripes are for lecturers and blue stripes for the non-academic staffs. The words “undergraduate”, “faculty” are also printed accordingly.

According to the status or condition of a smart card, it can be divided into:

1. impersonalized smart cards (similar condition to the newly released cards from the factory),
2. smart cards that have been personalized but not activated for micropayment,
3. smart cards that have been activated for micropayment.

The micropayment activation is required so that the smart card can be used for transactions in the Food Junction and paying fine in the library. In addition, the cash balance in the smart card can be exchanged with a number of photocopies in the library.

The physical difference, which distinguishes smart cards that has been activated for micropayment and the one that

has not, is the appearance of a virtual bank account number on the back of the card. The account number of each card is different, which is used to receive and transfer money. Through top-ups the amount of money is added onto the smart card.

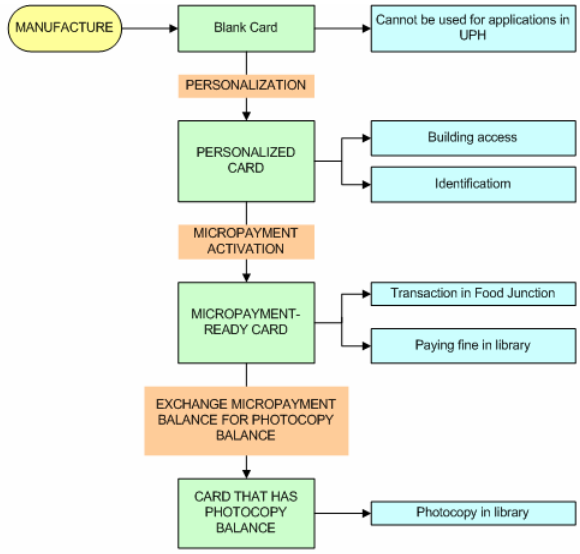

Figure 3: Smart card activation procedure

Smart cards which have not been personalized are in similar conditions to the newly released ones from the factory and contain only the UID. This type of smart cards can not be used for any application in UPH. The content of this smart card can be accessed with the key A: FFFFFFFFFFFF. In this kind of smart card the content from sector 1 until sector 15 is the same as sector 0 except for block 0. The sector 0 block 0 contains the UID, whereas block 0 in sector 1 until sector 15 are still empty, as well as the data on sector 0 block 1 and block 2. Block 3 in each sector contains the access bits that set the access configuration of that sector. Access bits for sector 0 until 15 are FF0780. The key A can not be displayed, therefore the reader indicates 0000000000000 as a result. The key B is not used and the content of the data is FFFFFFFFFFFF.

After the personalization, the smart card can be used for identification and to access the library or a specific room. The change in the card after the personalization is resulted from some new data stored through the personalization process. Additionally, all access bits are changed. The only sector that can be read using the universal key A: A0A1A2A3A4A5 is only sector 4.

Results from reading sector 4 showed that the data are in ASCII (HEX). Examples of the reading of sector 4 are shown as follows:

Block 0:
ASCII (HEX) : 303332323030343030323307E7E7E7E7E
Character : 03220040020~~~~~
Block 1:
ASCII (HEX) : 7E7E7E7E7E7E4D617267617269746966
Character : ~~~~~~Margaritif
Block 2:
ASCII (HEX) : 6572612054696C6161727E7E30303100
Character : era Tilaar~~001

From the results of the reading, block 0 contains the student number, block 1 and 2 contain the name of the student. Sector 4 in the lecturer's smart card was also read. The results show differences in the pattern of data between smart card for lecturers and students, and basically the content of sector 4 remains the same, namely the number and the name of the owner. After the personalization, the smart card can be activated for micropayment. The sector 0 on the micropayment-ready smart card can be read with the key A: A0A1A2A3A4A5.

Contents of block 0 until block 2 in the sector 0 do not change through personalization. However, the difference can be seen in block 3, which is a sector trailer. The access bits, which were initially FF0780 are changed to F78780. In addition, the byte where key B is stored, is no longer readable (the data show 0000000000000). This indicates that the key B is used to process the data exchange between tag and reader. For security reasons the key B is showed to be unreadable. Thus it can be concluded that the smart card system of UPH is using the two keys for security purposes.

.

Table 1: Comparison of smart card types in UPH

Comparison Factor	Impersonalized	Personalized	Activated for Micropayment
Key A	FFFFFFFFFFFF.	Key A is different for each sector.	Key A is different for each sector.
	Can read all sectors.	The use of key A in each sector is different, depends on the access bits.	The use of key A in each sector is different, depends on the access bits.
	Can modify all blocks in sector 0 except for block 0.		
Key B	Unused.	Key B is used, but remains unknown.	Key B is used, but remains unknown.
Access bits	Access bits for all sectors are same, FF0780.	Access bits for each sector can be different.	Access bits for each sector can be different.
Sector 0	Can be accessed using key A, FFFFFFFFFFFF.	Cannot be accessed because keys are unknown.	Can be accessed using key A, A01A2A3A4A5.
	Access bits are FF0780.	Access bits are unknown.	Access bits are F78780.
	Data block contains nothing except for block 0.	Data block contains nothing except for block 0.	Data block contains nothing except for block 0.
Sector 4	Can be accessed using key A, FFFFFFFFFFFF.	Can be accessed using key A, A01A2A3A4 A5.	Can be accessed using key A, A01A2A3A4A5.
	Block data contains nothing.	Block data contains name and ID number.	Block data contains name and ID number.
	Access bits are FF0780.	Access bits are 878787.	Access bits are 878787.
Other sectors	The condition is the same as sector 0 and 4.	Cannot be accessed because keys are unknown.	Cannot be accessed because keys are unknown.

3.2 Security Test for UPH Smart Card

The security test was done by changing the contents of the data block and the key on the card whose contents can still be modified. This includes testing the security of the smart card implementation such as:

1. building access (the library and the English language laboratory),
2. personalization test using card that has been altered,
3. identification for borrowing books in the library,
4. micropayment.

Smart card that can be used for building access is the one that has been personalized. Therefore, this application's security was tested using empty card, which could not be used for any application in UPH.

The attempts were done by:

1. changing the key of sectors 0 to 15 in the blank card,
2. changing the contents of data block in sector 4 in accordance with the contents of one of the smart card that has been personalized.

Test results indicate that the card that has not been personalized can not give access to the library even though the key was changed to another default key. Changing the contents of sector 4 gave the same result. Thus, it can be concluded that the sector 4 does not set the ability of the smart card for building access.

The next test is to find out whether we can impair (or possibly) destroy the function of the smartcard by simply changing the key or the data. The content and key of pre-personalized smart card were modified; the smart card was then handed over for personalization. As the key A was changed, the reader could not read the contents of the smart card. However, there is an option in the personalization program that can restore the initial condition of the smart card. The key A can be reset to FFFFFFFFFFFF. Thus, the threat is not very meaningful for the UPH smart card system.

The security test for identification is to determine whether the blank card can be used for identification by changing the content of sector 4, which contains the name and the ID number of the card owner. The security test was done using a smart card that has not been personalized. This proved successful because the smart card owner can display his ID in the library, although the card is not personalized. This shows the existence of a threat, in which someone can use a blank card to borrow books using the name of another person, provided he/she gets passed the library door without using a smart card.

The next test is the probing of the micropayment security using an impersonalized card. Before handed over for personalization, the blank smart card data were filled with specific patterns. Each data block is filled with specific data following a certain pattern according to the location of the data block. It was hoped that the personalization process will not reset the data to zero, thus some sectors may still contain the data. The data with the pattern were intended to reveal the micropayment sector through the pattern. However, after personalization and activation for micropayment, the balance in the smart card remains zero. With the results and the limited knowledge about the sector that stores micropayment data, it can be concluded that there is no significant threat to the security of the micropayment system.

3.3 Configurations of Sectors and Blocks

One sector has 12 access bits. These access bits are divided into four groups, each group consists of three bits. Each group set up the configuration of one block. The first three groups (C10C20C30, C11C21C31, and C12C22C32) contain data access bits, and the last group (C13C23C33) contains trailer access bits.

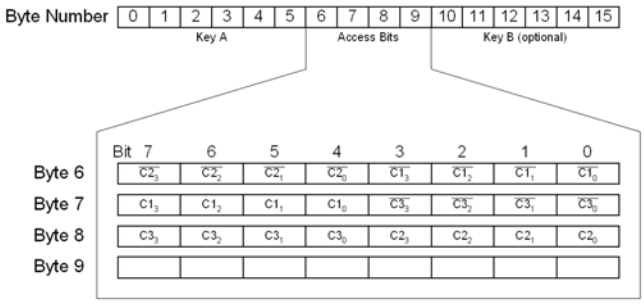

Figure 4: Access Bits [3]

The sector trailer can be set into three conditions based on the access bits. Sector trailers with the access bits 001, 011, 101 are in fluid condition, where the access bits can be replaced by knowing the correct key. Sector trailers with the access bits 000 and 100 are on restricted condition, where the access bits and the free byte can not be changed, but the key can still be changed. The last condition is frozen condition, with the access bits 010, 110, 111, where the sector trailer can not be modified anymore.

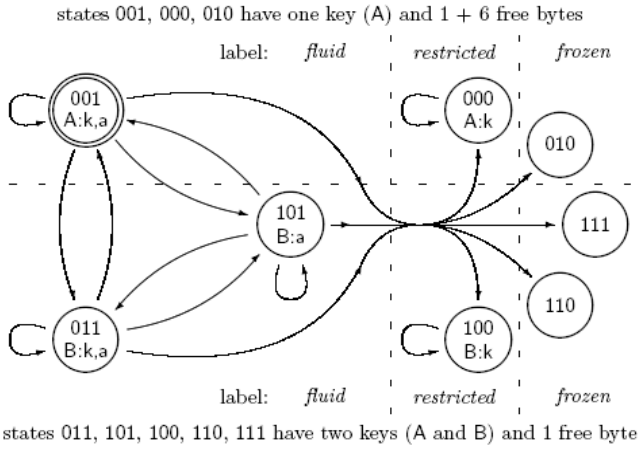

Figure 5: Diagram of state transition of trailer access bits [4]

ISSN 114-1284

The available setting for the data block is rather different from the sector trailer. The dead condition for the data block means that it can not be accessed at all. While the frozen condition means that it can only be read. Restricted condition means that the block content can be changed, but cannot be changed to all conditions. The fluid condition offers the highest freedom, which means that the block content can be changed to any conditions. All these settings for the data block are shown in Table 2.

Table 2: Data access bits [4]

$C1_3C2_3C3_3$	one-key, i.e. 000, 001*, 010		Two-key, i.e. 011, 100, 101, 110, 111		
$C1_jC2_jC3_j$	A	label	A	B	label
000*	r w d i	Fluid	r w d i	r w d i	fluid
110	r d	restricted	r d	r w d i	Fluid
100	R	frozen	r	r w	fluid
011		Dead		r w	fluid
001	r d	restricted	r d	r d	restricted
010	R	frozen	r	r	frozen
101		Dead		r	frozen
111		Dead			dead

3.4 Security Level of Smart Card

By setting the access bits configuration of data blocks and sectors, various security levels for smart card implementations can be setup. Because smart cards are used for a variety of applications where each application requires a different level of security, a general security scheme can be helpful. Such general security scheme is shown in Table 3.

Table 3: Smart card security level

Security Level	Description
A	• Access bits cannot be changed. • Keys can be changed. • Data block cannot be modified, can be read only.
B	• Access bits cannot be changed. • Key can be changed. • Block can be changed but only to certain values (read and decrement).
C	• Access bits cannot be changed. • Keys can be changed. • Data block can be changed (read dan write).
D	• Access bits cannot be changed. • Keys can be changed. • Data block can be changed (read, write, decrement, increment).
E	• Access bits can be changed, where trailer access bits and data access bits are in fluid condition. • Keys can be arranged so that can be changed or not by changing access bits.

Considering the access bits, the keys and the configuration capabilities of the blocks and sectors, there are many possible setups for a sector. However, there are several considerations that can be used as guidelines for RFID applications. First, it is not recommended to use only one key (key A). With one key configuration, there are only three available options for the trailer access bits, namely 001, 000, 010. In addition, if only key A is used, the bytes for key B becomes a data block and it is readable. This is quite dangerous especially if the access bits can be replaced. The key B can therefore be replaced, and the access bits can be modified to a state requiring the key B. Thus the reader that has been programmed to only use the key A, cannot recognize the tags that have been modified.

Another important consideration is that the trailer access bits should not be in the frozen conditions. If key leakage occurs, the key of all operating tags can still be replaced. Frozen conditions make the modification of access bits and keys impossible. Similar to that, the data access bits should not be in the dead conditions. In this case the data block is not accessible. Non-operating smart card should better be destroyed physically.

With these three considerations, the options for smart card configurations are simplified. This configuration determines the security level that can be seen in Table 3. According to this scheme, the building access application is quite safe because using the UID of the smart card makes duplication rather difficult. It requires more than tempering with the data block with a universal reader,

For the identification application, the data block should better be in the frozen condition, as the name and ID number may not change, and the trailer access bits should be set in the restricted conditions so that the access bits can not be modified. This is the security level A.

For the micropayment, access bits should be in a fluid state so it is easy to change the data block. The trailer access bits should be at 101 state so that the key can not be replaced, unless the state changes. The data block or value block state should be changeable according to the smart card condition. While smart cards are in the hands of users and are not used, the value block should be in the restricted or frozen state. When the card is used for transaction, the value block becomes restricted when previously frozen, or remains unchanged when previously restricted. When the checking of the remaining balance or the top-up transfer takes place, the value block should be changed to the fluid state, which is 000 or 110. Then the procedure continues to check the content of value block or increases the data in the value block if top-up transfer was done. Once completed, the access bits of the value block are returned to 001.

4. CONCLUSIONS

The testing of Universitas Pelita Harapan (UPH) smart card system reveals no critical security threads which can be exploited by a simple tempering of the smart cards. Each smart card application in UPH occupies a different sector in the smart card. The smart card data are stored in the form of ASCII hex. The application for identification, whose data located in sector 4, shows a weakness. One can falsify his identity in the process of borrowing books in the library. However, this weakness can be simply patched by making

sure that all distributed smart cards are personalized with the security level A.

No serious weakness was found in the building access application. The sector for the micropayment application cannot be identified through simple observation and tempering using a universal reader. It has also been discovered that the micropayment application is using both the key A and key B, thus ensuring more security of the system. Various security levels have also been proposed by analyzing the access configurations for the data and the keys.

ABSTRACT

This research work implements a robot for monitoring of production machines status in an industrial environment. The robot acts as the supervisor and switches a machine on when a task has to be done by the machine. In any case the machine is in idle status, it will be switched off by the robot. Video information of the cell path through which the robot is moving and the sounds from the turning machines have been used. The sounds acquired have been analyzed using cepstral analysis and the video information is processed with contextual clustering. An initial approach has been attempted and improvements leading to accuracy of recognition have to be done.

Keywords

Mobile robot, Prospective memory, Contextual clustering, Cepstrum analysis

1. INTRODUCTION

Mobile robots play an important role in executing herculus task that cannot be handled by human without extra protection for himself. Some of the situations like rumbled buildings, chemical handling, ore mining, underwater navigation where human cannot execute tasks by frequently sacrificing his life due to one form of natural accidents, that prevails. As such the concept of robot developed in one form or other have not really catered to human requirements without his assistance in the form of tele-control, wireless control. The robots can self navigate only in a safe environment without human assistance.

Existing robot that have been developed are mostly fixated to a place and they do repeated job in industry by rotating through an axis. Robots that have been developed for exploring purposes are not full-fledged in performing extreme tasks. They have predefined tasks. In this research work, Prospective Memory (PM) based tasks that warrant exposure to various information which must have been coded into the memory is implemented. Prospective Memory is the ability to remember and recollect to do things in the future (e.g., remembering a machining operation or loading / unloading operation at a given time on particular day, when robot is on move).

Given a sequence of manufacturing oriented tasks to the robot, it has to execute as and when required and it is not time based and it is occasion based, meaning task-1 will be executed when a situation comes across to definitely execute task-1 while performing task-2 to task-n.

An attempt is made to explore and find the possibilities of how to make a real time robot which can sense manufacturing information from machines by capturing the sound waves emanated at different frequencies. The waves emanated can be from heat, grease or oil odor from the work piece, type of machine, size of the object (surface area of the object) and many more.

In order to really implement a robot that can self navigate by understanding the environment, a combination of sensors that can do collaborative signal processing (CSP) using the different types of information received from the environment have to be implemented.

Herman et.al [1] tried to cast the phenomenon of cue-dependent prospective memory into a conceptual form, which can furthermore be cast into a mathematical description that eventually can be implemented on the computer. More specifically, the above formalism was developed in a way that allows a realization of the parallel synergetic neural network specified by Haken (1991) in synergetic computers and cognition, as well as on a serial computer whose output mimics the process of self organization. In this way, it might serve as a model of a real brain that operates by means of self-organization rather than by computer programs.

Recent recordings of place field activity in rodent hippocampus have revealed correlates of current, recent past, and imminent future events in spatial memory tasks. To analyze these properties, a brain-based device has been used. Darwin XI that incorporated a detailed model of medial temporal structures shaped by experience-dependent synaptic activity. Darwin XI was tested on a plus maze in which it approached a goal arm from different start arms. In the task, a journey corresponded to the route from a particular starting point to a particular goal. During maze navigation, the device developed place-dependent responses in its simulated hippocampus. Journey-dependent place fields, whose activity differed in different journeys through the same maze arm, were found in the recordings of simulated cortical sensory area (*CA1)* neuronal units. An approximately equal number of journey-independent place fields were found. The

journey-dependent responses were either retrospective, where activity was present in the goal arm, or prospective, where activity was present in the start arm. Detailed analysis of network dynamics of the neural simulation during behavior revealed that many different neural pathways could stimulate any single *CA1* unit. That analysis also revealed that place activity was driven more by hippocampal and entorhinal cortical influences than by sensory cortical input. Moreover, journey-dependent activity was driven more strongly by hippocampal influence than journey-independent activity. [2]

The Cellular Nonlinear Networks (CNN) wave based computation is an approach for real time robot navigation in a complex environment based on the idea of considering the environment in which the robot moves as an excitable medium. Obstacles represent the sources of auto wave generation. The waveform propagating in the CNN medium provides to the robot all the information to achieve an adaptive motion avoiding the obstacles. Arena et.al [3] implements entirely this strategy on the ACE16K CNN-chip.

Teruko et.al [4] aims at development of sensors for small size indoor mobile robots. A new sonar-ring which can measure accurate direction and distance to reflecting points rapidly for this purpose has been proposed. This new sonar ring needs to receive echo signal by multiple receivers and to detect multiple Time-of-Flights (TOFs) in received signal at each receiver simultaneously for achieving fast and accurate measurement. It is **i**mpossible to satisfy them by conventional circuit.

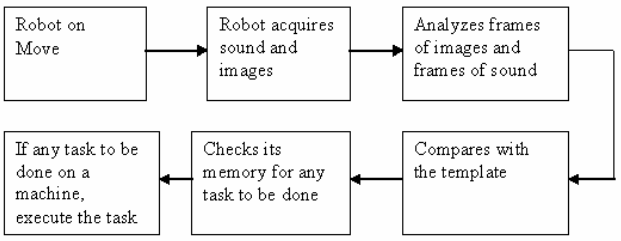
For the perception of spatial arrangements, Heiko Hoffman [5] demonstrates that this concept can be realized in a mobile robot. The robot first learned to predict how its visual input changes under movement commands. With this ability, two perceptual tasks could be solved: judging the distance to an obstacle in front by 'mentally' simulating a movement toward the obstacle and recognizing a dead end by simulating either an obstacle-avoidance algorithm or a recursive search for an exit. A simulated movement contained a series of prediction steps. In each step, a multilayer perceptron anticipated the next image, which, however, became increasingly noisy. To denoise an image, it was split into patches, and each patch was projected onto a manifold obtained by modeling the density of the distribution of training patches with a mixture of Gaussian functions.

Memory-based methods estimate self-location by directly comparing the input image with stored images in memory. This approach has received much attention, because the localization accuracy will increase by simply increasing the number of images to memorize. A novel self-localization method based on eigenspace analysis as one of memory-based methods has been proposed. An omni directional image sensor that can take an image of surrounding environment of the sensor at video-rate has been used. The proposed method identifies the sensor's location by evaluating the similarity between autocorrelation images which are converted from omni directional images and are invariant against the rotation of the sensor. To reduce the computational cost and memory space, autocorrelation images are projected into eigenspaces. The similarity is evaluated in eigenspaces to reduce the computational cost. The experimental results show that our method is capable of estimating the location of sensor even with low dimensional images. [6].

A new technique for vision-based robot navigation has been proposed. The basic framework is to localize the robot by comparing images taken at its current location with reference images stored in its memory. The only sensor mounted on the robot is an omni directional camera. The Fourier components of the omni directional image provide a signature for the views acquired by the robot and can be used to simplify the solution to the robot navigation problem. The proposed system can calculate the robot position with variable accuracy ("hierarchical localization") saving computational time when the robot does not need a precise localization (e.g. when it is traveling through a clear space). In addition, the system is able to self-organize its visual memory of the environment. The self-organization of visual memory is essential to realize a fully autonomous robot that is able to navigate in an unexplored environment. Experimental evidence of the robustness of this system is given in unmodified office environments. [7]

Yoshio et.al [8] applied the omni directional vision sensor to their view-based navigation method and proposes an extended model of a route called the "omni view sequence." Secondly we propose a map named the "view-sequenced map" which represents an entire corridor environment in a building. A method for the automatic acquisition of a view-sequenced map based on the exploration in a corridor using both stereo and omni directional vision is also described. Finally experimental results of the autonomous navigation and the map acquisition are presented to show the feasibility of the proposed methods.

2. SCHEMATIC DIAGRAM



3. CEPSTRUM ANALYSIS

Cepstral analysis is an important tool for processing nonlinear sound signal. This separates high frequency

noise from low frequency information signals. In this work, cepstrum analysis is used.

Steps involved in converting sound data are given below:

1. Acquire sound data at 44 KHz.
2. Remove zeros which does not give any information.
3. Apply linear predictive analysis.
4. Apply fast Fourier transform.
5. Apply log for the output in step 4.
6. Apply inverse fast Fourier transform.
7. Apply levinson Durban equation.
8. Repeat step 3 to step 7 for every 10 samples of the data acquired from microphone and average all values to finally get only 10 values.
9. Label the 10 features of each sound wave.
10. Repeat step 9 for 4 different working conditions of the machine. The labeling of each condition will be (1 – 4).

4. CONTEXTUAL CLUSTERING

Segmentation refers to the process of partitioning a digital image into multiple regions (sets of pixels). The goal of segmentation is to simplify and/or change the representation of an image into something that is more meaningful and easier to analyze. Image segmentation is typically used to locate objects and boundaries (lines, curves, etc.) in images. The result of image segmentation is a set of regions that collectively cover the entire image, or a set of contours extracted from the image. Each of the pixels in a region are similar with respect to some characteristic or computed property, such as color, intensity, or texture. Adjacent regions are significantly different with respect to the same characteristics. Several general-purpose algorithms and techniques have been developed for image segmentation.

Contextual clustering algorithms which segments an image into background (ω_0) and object region (ω_1). The pixel intensities of the background are assumed to be drawn from standard normal distribution.

1. Define decision parameter T_{cc} (positive) and weight of neighbourhood information β (positive). Let N_n be the total number of pixels in the neighbourhood. Let Z_i be the intensity value of pixel i.
2. Initialization: classify pixel with $z_i > T_\alpha$ to ω_1 and pixels to ω_0. Store the classification to C_0 and C_1.
3. For each pixel I, count the number of pixels u_i, belonging to class ω_1 in the neighbourhood of pixel i. Assume that the pixels outside the image area belong to ω_0.
4. Classify pixels with $z_i + \frac{\beta}{T_{cc}}(u_i - \frac{N_n}{2}) > T_\alpha$ to ω_1 and other pixels to ω_0. Store the classification to variable C_2.
5. If $C_2 \neq C_1$ and $C_2 \neq C_0$, copy C_1 to C_0, C_2 to C_1 and return to step 3, otherwise stop and return to C_2.

5. EXPERIMENTAL DATA

The experimental setup includes collection of sound from the turning machine under four different conditions: Tool approaching job (Figure 1), Spindle rotates (Figure 2), Machining taking place (Figure 3), Machine starting (Figure 4). The sound were collected using PCB 130 series of Array Microphones coupled with ICP sensor powered preamps and are thus referred to as ICP microphones. The 130 series provide an extremely cost effective method for large channel count sound pressure measurements.

Similarly video taken during the movement of robot along the cell is shown in Figure 5. Only 15 frames are shown due to space availability. The video has been taken using the special digital camera meant to be used on the real time robot.

6.2 Output of Contextual clustering

The video frames segmented by contextual clustering are shown in Figure 6. The black patched outputs indicate the path through which the robot is moving.

The microphone and the video camera fitted with the robot acquires sound and images and process them for easy navigation of the robot and for the robot to recognize different sounds coming from the machine. Any task that has been preloaded into the memory of robot will be used as Prospective Memory to implement tasks during its movement.

7. CONCLUSION:

In this work, sounds and video have been acquired during the movement of robot in an industrial environment. The robot can identify its path based on information in the video and can recognize different sounds from the machines. There is lot of improvements that have to be done as part of improvements in the robot performances.

ABSTRACT

Purpose: *To develop high order discontinuous galerkin method for solving steady and unsteady incompressible flow based on artificial compressibility method.*
Design/methodology/approach: *This paper uses discontinuous galerkin finite element procedure which is based on the artificial compressibility technique in connection with a dual time stepping approach. A second order implicit discretization is applied to achieve the required accuracy in real time while an explicit low storage fourth order Runge Kutta scheme is used to march in the pseudo-time domain. A nodal high order discontinuous galerkin finite element is used for the spatial discretization.*
Findings: *Provides stable and accurate methods for solving incompressible viscous flows compared with previous numerical results and experimental results.*
Research limitations: *It is limited to two-dimensional steady and unsteady laminar viscous flow.*
Practical implications *– A very useful source of information and favorable advice for people is applied to piping system and low speed aerodynamics.*
Originality*: This works presents an extension of the previous work of [1] and [2] to time and space accurate method for solving unsteady incompressible flows.*

Keywords: *steady and unsteady flows, discontinuous galerkin, artificial compressibility.*

1. INTRODUCTION

Numerical Solutions of the incompressible Navier-Stokes equations are of interest in many engineering applications. Problems which can be addressed by incompressible Navier-Stokes equations include internal flows, hydrodynamics flows, low speed aerodynamics and external flows. There is a continuing interest in finding solution methodologies which will produce accurate results in time and space. The problem of coupling changes in the velocity field with changes in pressure field while satisfying the continuity equation is the main difficulty in obtaining solutions to the incompressible Navier-Stokes.

There are two types of method using primitive variables which have been developed to solve the equations. The first type of methods can be classified as pressure-based methods. In these methods, the pressure field is solved by combining the momentum and mass continuity equations for form a pressure or pressure-correction equation. The second type of methods employs the artificial compressibility (AC) formulation. This idea was first introduced by Chorin [3] and extensively used by other researchers since. In this method, a pseudo-temporal pressure terms is added to continuity equation to impose the incompressibility constraint. Several authors have employed this method successfully in computing unsteady problems.

The original version of the AC method is only accurate for steady-state solutions to the incompressible flows [4, 5], however there are some efforts which conducted to solve unsteady flows using dual time stepping AC method. Reference [6] used third order flux difference technique for convective terms and second-order central difference for viscous terms. The semi discrete equations are solved implicitly by using block line-relaxation scheme. Reference [1] used finite element method for spatial discretization. A second-order discretization is employed in real time while an explicit multistage Runge Kutta is used to march in pseudo time domain.

This work presents an extension of the previous work of [1, 2] to time and space accurate method for solving unsteady incompressible flows. A nodal high order discontinuous galerkin finite element is used for the spatial discretization a second order implicit discretization is applied to achieve the required accuracy in real time while an explicit low storage fourth order Runge Kutta scheme is used to march in the pseudo-time domain. The computed results show accuracy of the code by presenting the steady and unsteady flow past a 2-dimensional circular cylinder.

2. PROBLEM DESCRIPTION

Artificial compressibility method is introduced by adding a time derivative of pressure to the continuity equation. In the steady-state formulation, the equations are marched in a time-like fashion until the divergence of velocity vanishes. The time variable for this process no longer represents physical time. Therefore, in the momentum equations t is replaced with τ , which can be thought of as an artificial time or iteration parameter [7]. As a result, the governing equations can be written in the following form:

$$\frac{\partial \mathbf{U}}{\partial \tau}+\frac{\partial \mathbf{F}^j}{\partial x_j}+\frac{\partial \mathbf{G}^j}{\partial x_j}=0\ , \quad j=1,2 \tag{1}$$

Where

$$\mathbf{U}=\begin{bmatrix} p \\ u_1 \\ u_2 \end{bmatrix} \quad \mathbf{F}^j=\begin{bmatrix} \varepsilon^2 u_j \\ u_1u_j+p\delta_{1j} \\ u_2u_j+p\delta_{2j} \end{bmatrix} \quad \mathbf{G}^j=\begin{bmatrix} 0 \\ \tau_{1j} \\ \tau_{2j} \end{bmatrix} \quad \tau_{ij}=\frac{1}{\mathrm{Re}}\left(\frac{\partial u_i}{\partial x_j}+\frac{\partial u_j}{\partial x_i}\right) \tag{2}$$

In these equations, τ is the artificial time variable, u_i is the velocity in direction x_i, p is the pressure, τ_{ij} is stress tensor, ε is an artificial compressibility parameter, δ_{ij} is Kronecker delta and Re is the Reynolds number.

The extension of artificial compressibility method to unsteady flow is introduced by adding physical time derivative of velocity components to 2 momentum equations in Equations (2) [6, 1]. The obtained equations can be written as:

$$\frac{\partial \mathbf{U}}{\partial \tau}+\mathbf{I}^M\frac{\partial \mathbf{U}}{\partial t}+\frac{\partial \mathbf{F}^j}{\partial x_j}+\frac{\partial \mathbf{G}^j}{\partial x_j}=0\ , \quad j=1,2 \tag{3}$$

Where

$$\mathbf{I}^M=\begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

3. DISCRETIZATION

The spatial derivatives are discretized by using a discontinuous galerkin method. The simplified of Eq. (3) according to Galerkin's procedure using the same basis function ϕ within each element is defined below:

$$\begin{aligned} &\left(\phi,\frac{\partial \mathbf{U}}{\partial \tau}+\mathbf{I}^M\frac{\partial \mathbf{U}}{\partial t}+\frac{\partial \mathbf{F}^j}{\partial x_j}+\frac{\partial \mathbf{G}^j}{\partial x_j}\right)=0 \\ &\Leftrightarrow\left(\phi,\frac{\partial \mathbf{U}}{\partial \tau}+\mathbf{I}^M\frac{\partial \mathbf{U}}{\partial t}\right)_\Omega+\left(\phi,n_j\mathbf{F}^j+n_j\mathbf{G}^j\right)_{\partial\Omega} \\ &-\left(\frac{\partial}{\partial x}\phi,\mathbf{F}^j\right)_\Omega-\left(\frac{\partial}{\partial x}\phi,\mathbf{G}^j\right)_\Omega=0 \end{aligned} \tag{4}$$

Integrate by parts again equation (4):

$$\begin{aligned} &\left(\phi,\frac{\partial \mathbf{U}}{\partial \tau}+\mathbf{I}^M\frac{\partial \mathbf{U}}{\partial t}+\frac{\partial \mathbf{F}^j}{\partial x_j}+\frac{\partial \mathbf{G}^j}{\partial x_j}\right)=0 \\ &\Leftrightarrow\left(\phi,\frac{\partial \mathbf{U}}{\partial \tau}+\mathbf{I}^M\frac{\partial \mathbf{U}}{\partial t}\right)_\Omega+\left(\phi,\frac{\partial}{\partial x}\mathbf{F}^j\right)_\Omega+\left(\phi,\frac{\partial}{\partial x}\mathbf{G}^j\right)_\Omega \\ &+\left(\phi,n_j\left(\hat{\mathbf{F}}^j-\mathbf{F}^{j-}\right)+n_j\left(\hat{\mathbf{G}}^j-\mathbf{G}^{j-}\right)\right)_{\partial\Omega}+=0 \end{aligned} \tag{5}$$

Where

$\hat{\mathbf{F}}^j{}_{\partial\Omega}=\hat{\mathbf{F}}^j\left(\hat{\mathbf{F}}^{j-},\hat{\mathbf{F}}^{j+}\right)\Big|_{\partial\Omega}$ and $\hat{\mathbf{G}}^j{}_{\partial\Omega}=\hat{\mathbf{G}}^j\left(\hat{\mathbf{G}}^{j-},\hat{\mathbf{G}}^{j+}\right)\Big|_{\partial\Omega}$

are the numerical fluxes.

Here $(.,.)$ represents the normal L_2 inner product and third term is flux vector. In this problem the numerical flux for convective terms is calculated by using the Lax-Friedrich flux and local discontinuous galerkin for viscous terms.

Here, we took the Kornwinder Dubiner function on straight sided triangle as the basis written in equation (5) (see figure 1 and 2):

$$\phi_{ij}(r,s)=\sqrt{\frac{2i+1}{2}}\sqrt{\frac{2i+2j+2}{2}}P_i^{0,0}\left(\frac{2(1+r)}{(1-s)}-1\right)P_j^{2i+1,0}(s) \tag{6}$$

where, $P^{\alpha,\beta}$ is orthogonal Jacobi polynomial. All straight sided triangles are the image of this triangle under the map:

$$\begin{pmatrix} x \\ y \end{pmatrix}=-\left(\frac{r+s}{2}\right)\begin{pmatrix} v_x^1 \\ v_y^1 \end{pmatrix}+\left(\frac{1+r}{2}\right)\begin{pmatrix} v_x^2 \\ v_y^2 \end{pmatrix}+\left(\frac{1+s}{2}\right)\begin{pmatrix} v_x^3 \\ v_y^3 \end{pmatrix} \tag{7}$$

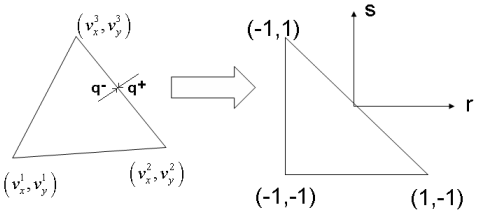

Figure 1: Coordinate transformation

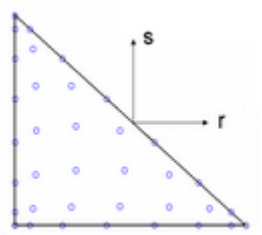

Figure 2: Seventh order Gauss Lobatto quadrature nodes ; equation (6),

$$p(r,s) = \sum_{i=0}^{N}\sum_{j=0}^{N-i}\phi_{ij}(r,s)\hat{p}_{ij} \qquad (8)$$

$$p(r_n,s_n) = \sum_{m=1}^{m=M}\mathbf{V}_{nm}\hat{p}_m \qquad (9)$$

$$\hat{p}_m = \sum_{m=1}^{m=M}\left(\mathbf{V}^{-1}\right)_{mj}p(r_j,s_j)$$

$$\frac{\partial p}{\partial r}(r,s) = \sum_{i=0}^{N}\sum_{j=0}^{N-i}\frac{\partial \phi_{ij}}{\partial r}(r,s)\hat{p}_{ij} = \hat{\mathrm{D}}^r\mathbf{V}^{-1}p(r,s)$$
$$\frac{\partial p}{\partial s}(r,s) = \sum_{i=0}^{N}\sum_{j=0}^{N-i}\frac{\partial \phi_{ij}}{\partial s}(r,s)\hat{p}_{ij} = \hat{\mathrm{D}}^s\mathbf{V}^{-1}p(r,s) \qquad (10)$$
$$\hat{\mathbf{D}}^r = \frac{\partial \phi}{\partial r}\ ;\ \hat{\mathbf{D}}^s = \frac{\partial \phi}{\partial s}$$

where $\mathbf{V}_{ij}$ and N are Vandermonde matrix and the order of Jacobi polynomial respectively.

The semi discrete of equation (5) can be written in the following form:

$$\frac{\mathrm{d}\mathbf{U}}{\mathrm{d}\tau} + \mathbf{I}^M\frac{\mathrm{d}\mathbf{U}}{\mathrm{d}t} = \mathbf{R} \qquad (11)$$

A dual time stepping approach is employed for marching equation (12) in time. The real time t is discretized using second order implicit backward difference formula. The resulting equation becomes:

$$\frac{\mathrm{d}\mathbf{U}^{n+1}}{\mathrm{d}\tau} + \mathbf{I}^M\frac{\left(3\mathbf{U}^{n+1} - 4\mathbf{U}^n + \mathbf{U}^{n-1}\right)}{2\Delta t} = \mathbf{R}^{n+1} \qquad (12)$$

where superscript n denotes the current time level t, and n-1 refers to the previous time step t-Δt, while the unknowns are calculated at time t+Δt by n+1. Equation (12) can be written in a simpler form as:

$$\frac{\mathrm{d}\mathbf{U}^{n+1}}{\mathrm{d}\tau} = \overline{\mathbf{R}}^{n+1} \qquad (13)$$

where $\overline{\mathbf{R}}$ contains the right hand side of equation (12) and the second term on left hand side of this equation. Equation (13) represents a pseudo-time evolution of flow field and has no physical meaning until the steady state in pseudo-time is reached.

The Equation (8) is integrated in pseudo-time marching by using five stage of fourth order 2N-storage Runge-Kutta scheme as developed by [8]. The final equations are found as written in Eqs. (14) and (15) :

$$\frac{\mathrm{d}\mathbf{U}}{\mathrm{d}\tau} = \overline{\mathbf{R}}(\tau,\mathbf{U}(\tau)) \qquad (14)$$

$$d\mathbf{U}_j = A_j d\mathbf{U}_{j-1} + d\tau\overline{\mathbf{R}}(\mathbf{U}_j) \quad ; \quad j = 1,5 \qquad (15)$$
$$\mathbf{U}_j = \mathbf{U}_{j-1} + B_j d\mathbf{U}_j$$

where $d\tau$ is the pseudo-time step. The vectors **A** and **B** are the coefficients that will be used to determine the properties of the scheme.

4. INITIAL AND BOUNDARY CONDITIONS

Initial and boundary conditions The governing equations (1) or (3) require initial condition to start the calculation as well as boundary conditions at every time step. In the calculations presented in this paper, the uniform free-stream values are use as initial conditions: $p = p_\infty$; $u_1 = u_{1\infty}$; $u_2 = u_{2\infty}$. For external flow applications, the far-field bound is placed far away from the solid surface. Therefore, the free-stream values are imposed at the far-field boundary except along the outflow boundary where extrapolation for velocity components in combination with $p = p_\infty$ is used. On the solid surface, the no-slip condition is imposed for velocity components: $u_1 = 0$; $u_2 = 0$. The surface pressure distribution is determined by setting the normal gradient of pressure to be zero: $\frac{\partial p}{\partial n} = 0$

5. RESULTS AND DISCUSSION

The accuracy of the proposed method is demonstrated by solving incompressible flow past 2-dimensional circular cylinder. The Reynolds number is varied from 20 to 40 for steady flow and from 100 to 200 for unsteady flow. The computational domain for steady flow is rectangle (-15, 25) × (-15, 15) and for unsteady flow is (-20, 20) × (-20, 80) wherein a circular cylinder of diameter d =1 placed at (0, 0). The mesh consists of 1228 triangles for steady flow and 5092 triangles for unsteady flow. For all the calculation, we took a

ISSN 114-1284

fixed order of polynomial N =4, Prandtl number is 0.717 and fixed artificial compressibility parameter is equal to unity.

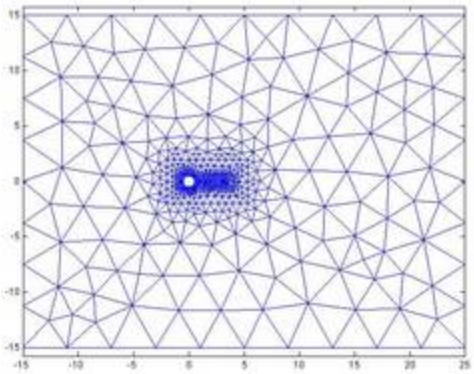

Figure 3a: Mesh for steady flow

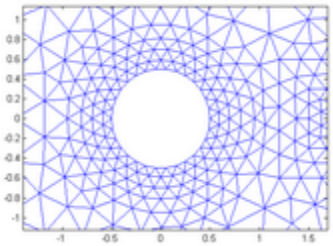

Figure 3b: Close-up mesh around cylinder for steady flow

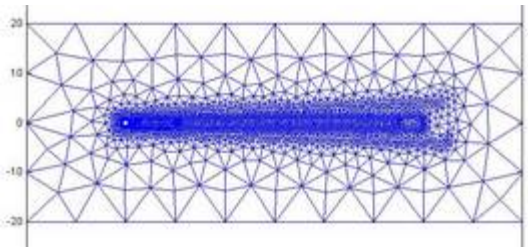

Figure 4a: Mesh for unsteady flow

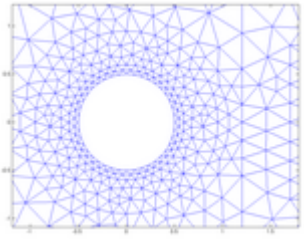

Figure 4b: Close-up mesh around cylinder for unsteady flow

Pseudo time step is $\Delta\tau = 0.0012$ for steady flow. The results can be seen in figure 5 and 6. In front of object, pressure strongly varies and a region of high pressure is formed near separation point and two regions of low pressure are developed next. From figure 5, it can be seen the development of a recirculation zone behind the object with reverse velocity. Figure 5 and 6 give the computed pressure for different values of Reynolds number (Re=20 and 40). As shown, the DG scheme gives excellent pressure stabilization, with the computed pressure contours being highly smooth and non-oscillatory.

The calculated results for steady flows are compared with the other numerical data. Table 1 compares the Drag coefficient (Cd). The agreement is quite good.

*: adapted from [9]

The ability of the discontinuous galerkin scheme with dual time-stepping to simulate transient flow is illustrated here by computing the vortex shedding in the wake of flow past a circular cylinder at Re = 100 and 200. This has been a popular test case for validating the transient part of numerical schemes. The problem is solved using is Δt = 0.1 and $\Delta\tau$ = 0.001 and total of 250 pseudo-time iterations. Figure 7 provides a full simulation analysis of the Cl and Cd histories for each real time step on the mesh. As can be seen, once the initial transient stage has passed, the simulation settles down to an almost periodic convergence pattern. After the initial transient, each variable develops a periodic variation. This is due to the periodic shedding of vortices from behind the cylinder. This can be seen more clearly in figure 7, 8 and 9. A quantitative analysis of the results was also conducted and is shown Table 2. Generally, all the results shown for DG scheme are in good agreement with the other results.

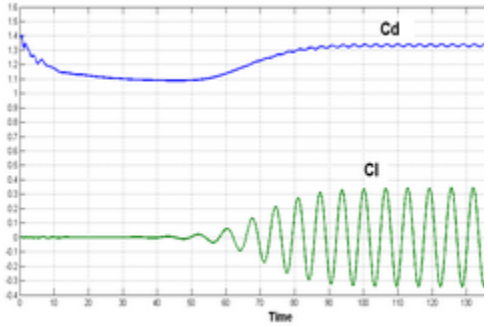

Figure 7a: Cd & Cl History for Re=100

The qualitative results are shown in figures 8 and 9. Here, the contours of pressure and vorticity are shown, for the real non-dimensional times of 100 and 120 respectively. All results are of high quality with no non-physical oscillations. The narrowing of the wake and the increase in shedding frequency, as the Reynolds number increases, is clear from these plots. We observe that at higher Reynolds numbers the vortices in the far-downstream wake coalesce and the region of coalescence moves upstream as the Reynolds number increases.

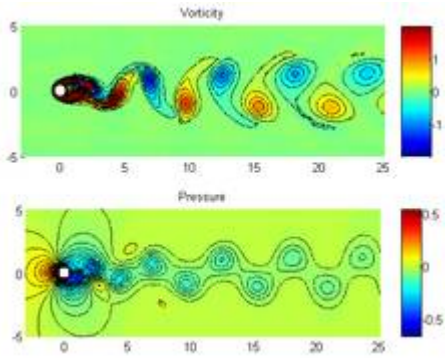

Figure 8a: Iso-vorticity and Isobar for Re=100 at t=100

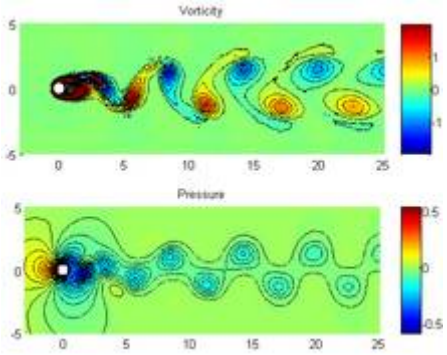

Figure 8b: Iso-vorticity and Isobar for Re=100 at t=120

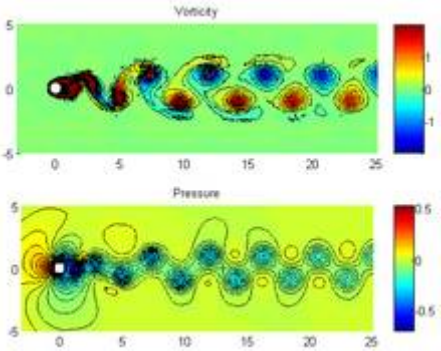

Figure 9a: Iso-vorticity and Isobar for Re=200 at t=100

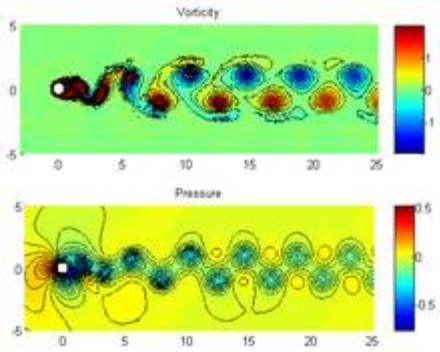

Figure 9a: Iso-vorticity and Isobar for Re=200 at t=120

It can be seen from the plots that the proposed method is stable for long time simulations. In addition, the plots show evidence that the outflow boundary condition allows for a smooth exit of the flow field and does not distort the flow upstream.

7. CONCLUSION

In this paper, we have presented a discontinuous galerkin method for steady and unsteady in artificial compressibility formulation connection with a dual time stepping approach. The method exhibits good numerical stability. The numerical results have a good agreement with the proposed experimental and numerical results reported in the previous studies.

ACKNOWLEDGMENT

We are very grateful to Prof. Hesthaven from Brown University USA for the valuable discussion and sharing his "Nudg" code.

ABSTRACT

Based on the gained experiences and some limitations founded in PASSENGER, a new synchronous groupware system is under development at the institute of Computer Engineering, University of Duisburg-Essen (UDE). The new system is envisioned to overcome the boundaries of limitations, thus providing a groupware that allows a tailor-made configuration of the system prior to a session and flexible adaptations to special scenarios and situations during a session. The approach to provide flexible and tailor-made groupware is done by using component based software for the development of the groupware and hybrid collaborative architecture for the replication and communication between server and clients. Further, several mechanism—floor control, concurrency control, replication, distribution—will be investigated. To bring flexibility and tailorability, the system will attempt to offer best choice, but decision will depend on the user.

I. INTRODUCTION

At University Duisburg-Essen, a synchronous groupware named PASSENGER has been developed at the institute of Computer Engineering throughout the last years. This client-server based groupware application enables student teams to communicate and cooperate via Internet, even if the members are located at distributed sites. The client application is implemented in a way that it consists of a fixed set of tools to support exactly one scenario (Software Engineering education).

Apart from its good feature, there are some limitations from the system that this thesis project wants to solve. First of all, the system does not allow integrating any other tools. Fixed tools of the system—CASE-tool, text messages, video streaming, voice conference—are always available. They neither can be turned off, nor can be added with other tools. Secondly, the usage of the system is limited to a fixed arrangement of groups. There is only 4 person allowed to joined a session at maximum, and there is no way for late joiners to enter an ongoing session. Furthermore, the system is only intended to be used in Software Engineering education. Therefore, the system is not suitable to be used in other scenarios. From these illustrations, it can be seen that PASSENGER has no flexibility. User must accept all conditions available. Or refuse it all.

Based on the gained experiences and some limitations founded, a new system is under development at the institute of Computer Engineering, University of Duisburg-Essen (UDE). The new system is envisioned to overcome the boundaries of limitations, thus providing a groupware that allows a tailor-made configuration of the system prior to a session and flexible adaptations to special scenarios and situations during a session.

The main problem of this thesis work is to provide flexible adaptation and tailor-made configuration of a synchronous groupware, which in this thesis defined as:

Tailor-made configuration: includes the selection of components and tools and their configuration according to special group parameters (e.g. number of members and their possible roles, openness of group) and scenarios (e.g. brainstorming, design session, text reviewing).

Flexible adaptation: regarding the change of situations during a session (for e.g. allowing the creation of sub-groups) and behaviors of members (e.g. change of floor control policy is due to multicultural background of members). The system should be flexible enough to provide alternatives or to suggest alternatives according to group parameters or profiles of participants.

The approach to provide flexible and tailor-made groupware by using component based software for the development of the groupware and hybrid collaborative architecture for the replication and communication between server and clients. Further, several mechanism—

floor control, concurrency control, replication, distribution—will be investigated. To bring flexibility and tailorability, the system will always offer best choice, but decision will be back to the user.

II. REQUIREMENT ANALYSIS

The future enterprise groupware applications need to be able to cover the whole range of all groupware aspects in a way that is flexible and that can dynamically change [1]. Or it can be broadly summarized in two categories: (a) increased flexibility of groupware applications and (b) increased support of dynamism by groupware technology [1]. To meet this requirement of enterprise groupware, we will develop a highly flexible and tailorable framework for groupware.

The system is intended to provide synchronous communication strategy. Because the main aim of this system is to provide a synchronous collaboration work, same time different place. This is translated into the use of available different tools and application at the same time for the users who joined the same session. The variety of tools and application will be described later. But it dos not mean that the system will not use asynchronous communication, because asynchronous communication will undeniably be needed to do the management issues. Below are the requirements for a highly flexible and tailorable framework for a synchronous groupware:

The system should bring a synchronous system strategy

The system will be based on client server architecture. The idea of client server architecture is by utilizing proxies in both sides, server and client, so that the invocations of program can be done as if the program is local.

Communications between clients are based on client server architecture

To support flexibility and tailor-ability, the system is build per object component based.

The program must be separated between master and client (GUI)

The system must be separated between program, data objects and user interface objects components

System will provide a list of applications for each phases of group work

A group can choose from the list of applications, which one they want to use in the working session at runtime

Main server will hold a database of every session

The database will save automatically every 15 minutes

Before a session start, a group may continue working on the previous work stored in the database

At the end of the session, user is asked whether he/she wants to save the work locally.

Authoring is implemented by using different colors for each member in the session.

The system can flexibly operate in centralized or hybrid/semi- replicated architecture

In a hybrid/semi-replicated, partitioning in the network is needed

In 1 partition, there will be 1 replication.

The system should be able to know the condition of the network connection to and between its client

The system should be able to know the condition of resource power of each user

The system is provided with the ability to give suggestion on distribution architecture as well as optimal partitioning based on user network condition and profile

To give tailor-ability feature, the system will only give suggestion, while the decision is depend on users.

The system must be provided with all basic distribution transparency; access transparency, location transparency, replication transparency and fragmentation transparency

The system must be provided with data consistency control mechanism; vector clock will be used to synchronize a shared object

The system must be provided with concurrency control, which will be translated into locking mechanism

Update and synchronization protocol is needed

Every user must register to the system by giving the required profile

Every group must register to the system by giving the required profile

User and Group registration must be done before requesting a session

A user can be associated to one or more group

The number of users may range from 2 to 8 people

System will allow session owner to define the session openness at session registration

A group will provide the characteristics of the session; openness (allowing latecomers or not), role of each user in a group (moderator, observer, custom), floor control model, which phase is the session

The website should provide 5W&1H information of sessions and users

The system has capacity of 10 session at a time

The system has an open table showing a free slot of time that can be chosen by a group. Each slot of time is defined as 1 hour

A group may register (request) a session before the requested date and time of the session or directly before the session start as long as there are free slots

A group can ask a session for one or more slot of time

III. DISTRIBUTION ARCHITECTURE

This system will provide 2 alternative of architecture of its components, namely centralized and hybrid/semi replicated architecture. This distributed system will also allow partitioning of the network. Network partition in this case will be based on client physical locations. The network partition can also be based on the version of this groupware (light version for low resource mobile device, and full version for PC) but that will be a future work.

3.1 Network Partitioning

Based on requirements, in one partition of network, there will be one or more clients which the number of client is corresponds to the number of UI and one program replica should be provided. The example of scenario of network partitioning can be seen in Figure 1.

In this sample scenario, Main Server is located in Germany. There are 6 Clients want to join a session. The sequence of request is based on the number on the client names. Another scenario possible is the group leader registers all clients at the same time when requesting a session. Server recognizes location of the client. Then, it suggests partition of the user network by observing the location. It can be seen in Figure 1 server makes 3 partitions; Region 1, 2 and 3. Server tests the network connection to each client and chooses the best connection in each region as the replicated master. Server asks the chosen clients if they are wiling to be a replicated master. If the chosen client is not willing to be replicated master, server asks another client in the same region to be the replicated master, only if the computer specification supported. If there is none of client in one region is able to be the replicated master, all clients in that region will be clients to a replicated master in the other region (start from the nearest neighbor). It can be the main server itself.

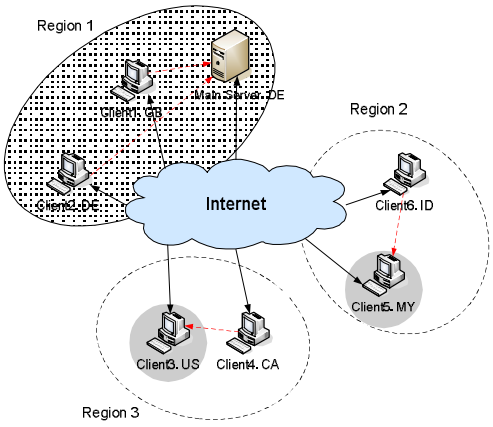

Figure 1. Network Partitioning Scenario

In this sample scenario, Main Server in Germany (DE) becomes a master for Client1 in United Kingdom (GB), and Client2 in Germany (DE). Client5 in Malaysia (MY) becomes a master for Client6 in Indonesia (ID), and Client2 in USA (US) becomes a master for Client4 in Canada (CA).

Late Joiners

When Late Joiners Mode is enabled, there are 3 possibilities of adaptability. The adaptability is based on the network connection to each user and condition of users. How server know this information will be described later. As usual, the system only suggests while the decision always at the user side. Continuing the above example, there is a late joiner, Client7 in Australia (AU) who wants to join a session. There will be 3 scenarios possible for adaptability of the system regarding this late joiner.

Late Joiner uses nearest replicated master. Because the nearest partition is Region 2, Client7 join Region 2 and become a client of Client5, as can be seen in Figure 2.

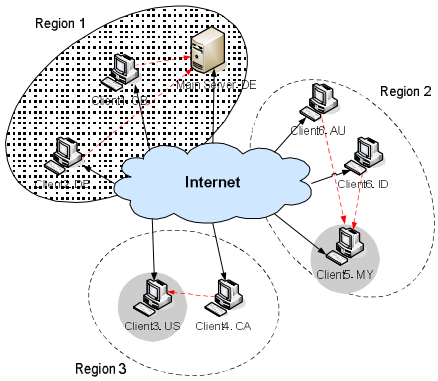

Figure 2. Late Joiner uses nearest replicated master

Late Joiner becomes a new replicated master in a new partition. The system suggests Client7 to make a new partition, because the network condition form AU to every existing replicated master is not good. The illustration can be seen in Figure 3.

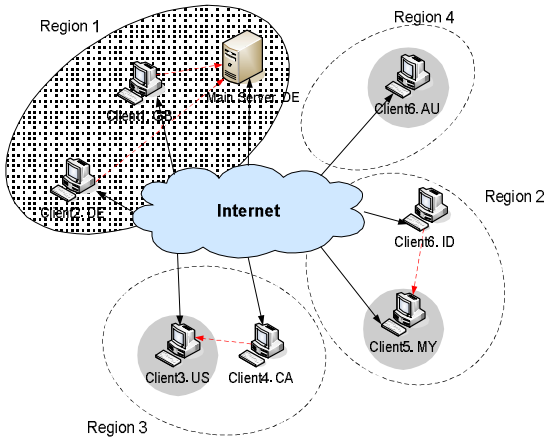

Figure 3. Late Joiner becomes new replicated master in a new partition

Late Joiner becomes a new replicated master in existing partition. The system suggest Late Joiner to become a new replicated master in existing region, because the connection of Late Joiner is better than the old replicated master in that region. Thus the network partitioning becomes like Figure 4.

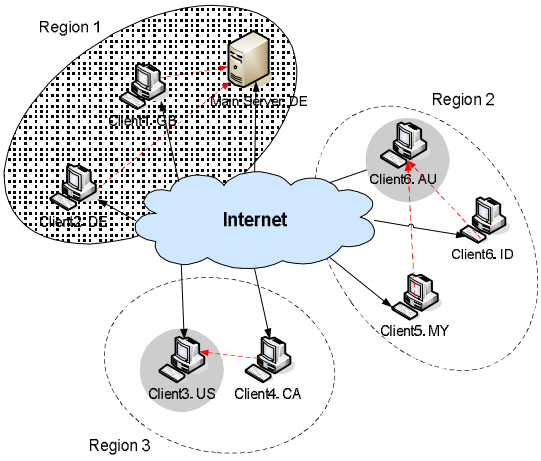

Figure 4. Late Joiner become a new replicated master in existing region

3.2 Role of User

There are 4 roles that are available in a session; moderator, member, floor handler, observer. Take into notice that moderator will have double role at the same time, which is a role as moderator and another role from 3 roles available. Class diagram of Role can be seen in 0Figure 5.

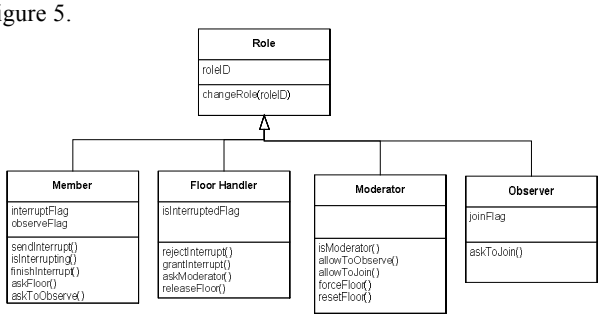

Figure 5. Role Class Diagram

The following are the roles and their corresponding privileges in a session:

Moderator

- Choose type of floor control model to be used in the session
- Force Member to leave a session (kick out)
- Reset floor list in Sequential Control Model
- Force to free the token from Floor Holder in Free Control Model
- Become the first Floor Holder in a session
- Grant or reject request to become an Observer
- Grant or reject latecomer

Member

- Ask to interrupt Floor Holder
- Ask a token before it is released by the Floor Holder
- Ask to become an Observer
- Leave a session early
- Join a session late

Floor Holder

- Can grant or reject interruption
- Can grant or reject request of token
- Release token

Observer

- Can ask to become a **Member** (rejoin a session)

In Figure 6, the state transition diagram of role transformation is illustrated.

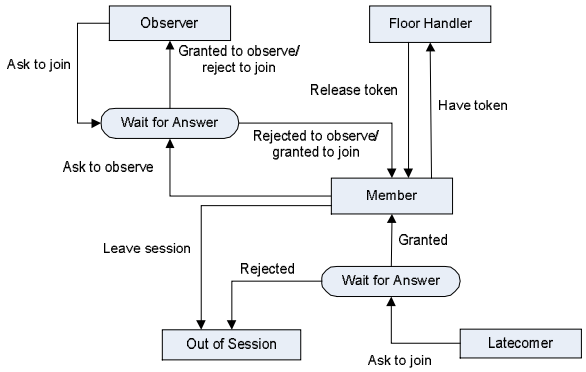

Figure 6. Role State Transition Diagram

3.3 Floor Control Model

At start up, moderator are given the right to choose between three types of floor control available from the system. To bring flexibility in more advanced way, moderator can also change the type of floor between these types anytime when the session is running as shown in Figure 7. The three type of floor control model available are Free Flow, Sequential Flow and Shared Floor Control Model.

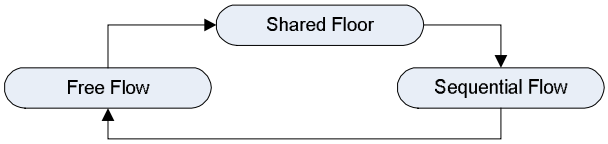

Figure 7. Control Model State Transition Diagram

Sequential Floor Control Model

In sequential flow control, user can access the system only if it is his turn according to the floor list. This floor list can also be analogically thought as token ring network. By default, a Member who is also a Moderator will be the first person in the list. The next sequence in the list is according to the sequence of Member asking for the floor, until all Members in the session is on the list. Notice that Observer will not be in the list, because he can not ask to have the floor unless he is a common Member.

To prevent the floor being possessed too long by the Floor Holder, the Moderator has the privilege to force the

Floor Holder to release the floor and allow the next Member in the list to become Floor Holder.

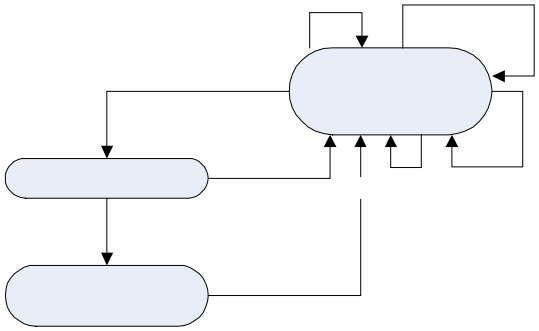

Figure 8. Sequential Flow Control Model State Transition Diagram

Member has privilege to make interruption, and possess the floor even though he is not the actual Floor Holder. But the actual Floor Holder has the right to grant or reject the request of this interruption. After this Member finish his interruption, the floor is passed to the actual Floor Holder and continue the floor possession based on floor list. 08 illustrates this model.

Whenever there is a change in the number of Member, the floor list will be updated, but not being reset. The change of number of Member in the session can be caused by early leaver, latecomer, a Member becomes Observer, or an Observer becomes a Member. The new Member should ask the floor to be updated in the floor list. If a Member leave, either he become an Observer or leave the session, his place on the list is deleted.

Whenever Moderator thinks that it is necessary, he has the privilege to reset the floor list. In this case, the list will be empty. The mechanism to fill the floor list is based on the sequence of request of the floor.

This model is best suited for all active users session, for example in brainstorming phase.

Free Flow Control Model

In this flow control, the system provides 1 token for all user on the session to possess a floor, or in other words to change his role from Member to Floor Holder.

To prevent the token being possessed too long by one Member, the Moderator has the privilege to force the Floor Holder to release the token. Member has privilege to ask the actual Floor Holder to pass the token, but Floor Holder can grant or reject his request. Figure 9 illustrates this model. Regarding the latecomer or early leaver, this flow control will not face a problem like in the previous model, since the token is independent. Update is not needed like in Sequential Flow Control Model.

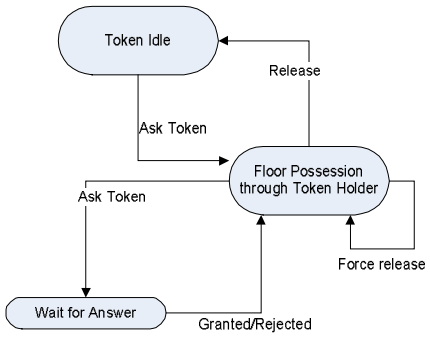

Figure 9. Free Flow Control Model State Transition Diagram

This flow control model is appropriate for presentation-like session, where only one person holds a session for a long time.

Shared Floor Control Model

In this model, there is no different role. All users are members and have the same privileges. In this flow control model, rigorous 2-phase locking [2] is applied. Shared floor control model leads to a pure distributed system. It may be suitable for some applications, but not all. One example is as example Electronic Brainstorming System (EBS).

The main idea of this floor control model is to provide comfortability to users to express their ideas in a session, without having to wait someone else to finish his work. It will also save the session time. But trade off should be taken into account, that a more complex locking and updating mechanism should be provided.

IV. COMPONENT

In component based software, applications are developed from components. These components themselves might be built up from several small components. Components might be added or removed during runtime. This solved the tailor-ability issue that we have. Since we use hybrid-replication architecture, a replication mechanism of the components, should also be determined.

4.1 Separation of Components

To support flexibility, in this system we will separate objects or components of the software based on its functionality into program, data, and user interface objects. Remember that components can be built up from other components.

Therefore, in a session there will be some clients, some program replica, and some data objects as illustrated in Figure 10.

ISSN 114-1284

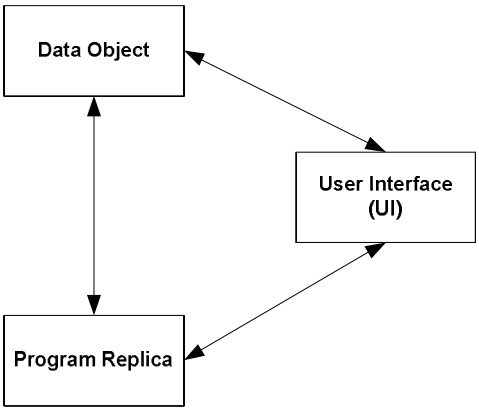

Figure 10. Separation of Components

The definitions of each object are described below:

User Interface (UI) is part of the program which provides interface to the main program. It is translated as the GUI of the program. UI is the medium for the user to interact with the program and the data object

Program replica is the copy of program, the brain, the processor with the computing and executing ability. Program replica has the ability to interact with the data object.

Data Object is part of the program where the information stored. It can be translated as a functional part of the program or as a part of the artifact.

4.2 Extensibility of Components

Components can be changed, extended or curtailed, during runtime. The changes however should not disrupt the application and it should be transparent to the user. The extensibility patterns of components proposed by Hummes and Merialdo [3] enable the extensibility to be encapsulated in one component. The extensibility pattern is intended to be used to provide a default behavior which can be changed at run time [3]. The application will only see the specific behavior of a Proxy class. The class diagram to illustrate it can be seen in Figure 11. The illustration of this pattern is slightly modified from the real one proposed by Hummes and Merialdo [3], to adopt the later design in this work.

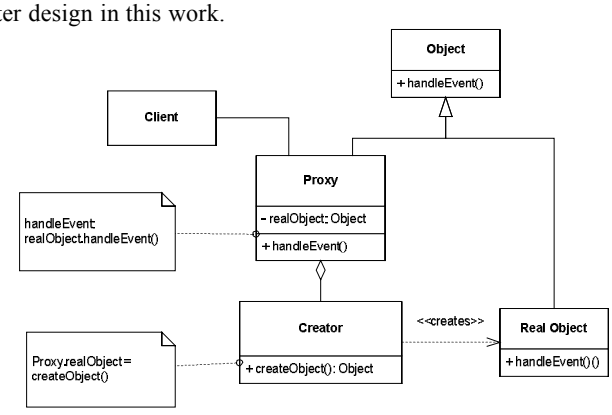

Figure 11. Class Diagram of Extensibility Patterns

According to this pattern, Proxy extends the interface of an Object, which may be inserted at run time. Inside this Proxy, exists a Creator which is responsible to create a new object of an arbitrary class Real Object corresponds with the interface Object. This pattern is combination of the Proxy and the Factory Method patterns.

The design is adapted from this pattern. Client will always communicate to the object through the Proxy. At start up, Creator will automatically instantiate an Object, a Default Object, and pass the reference of the Default Real Object to the Proxy. Any event that Proxy receives will be delegated to the Default Object. When the creator receive an event to create a new real subject, it instantiates the respective class and sets the reference in the Proxy to the newly created New Real Object. The Proxy from now, forward all subsequent events to this object, unless the Creator changes the reference to the Default Real Object again. The interaction between objects is illustrated in the sequence diagram in Figure 12.

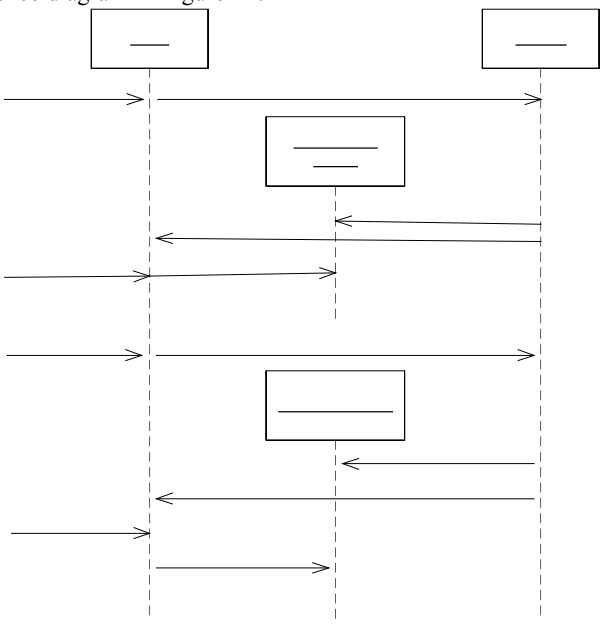

Figure 12. Sequence Diagram of Extensibility Pattern

Following the creation of a new Object, Proxy can delete the existing Real Object or simply create the new Real Object while storing the old ones. The incoming events are then forwarded to corresponding Real Objects. This variation will be best used if the newly added Real Object has a different functionality than the old ones.

V. CONCURENCY CONTROL

Concurrency control deals with the issues involved with allowing multiple people simultaneously access to shared entities, be they objects, data records, or some other representation [www1]. The goal of concurrency control is to allow several transactions to be executed simultaneously, but in such a way that the collection of data items (e.g. files or database records) being manipulated, is left to consistent state. This consistency is

achieved by giving transactions access to data items in a specific order whereby the final result is as the same as if all transactions had run sequentially.

Parallel operations on a shared data are possible to bring interference to each other. Possible problems that might occur are [www2]:

- Lost update. This problem occurs when overwrites uncommitted data.
- Inconsistency retrieval. This problem occurs when reading uncommitted data.
- Unrepeatable read. This problem occurs when reading one object twice with two different results.
- Incorrect summary problem. This problem occurs if one transaction is calculating an aggregate summary function on a number of records that are being updated at the same time by a second transaction.

To prevent those problems, in this system we will use locking and updating mechanism. Locking will be implemented for the role **Floor Holder**. While updating mechanism is implemented to all users.

5.1. Logging Mechanism

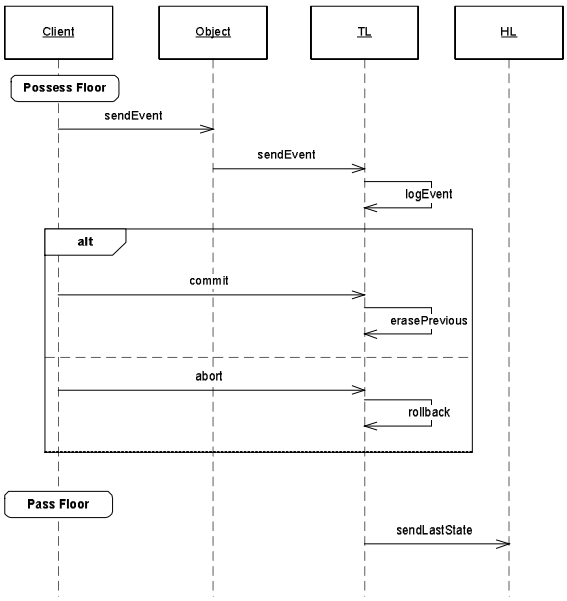

Figure 13. Sequence Diagram for Logging Mechanism

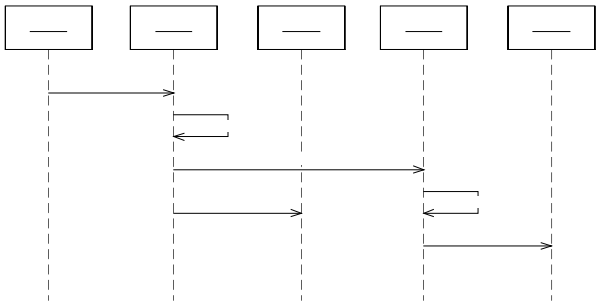
In this system we will need a dynamic replication mechanism, since this system use a hybrid-replicated architecture. The approach proposed in this thesis is by using logging mechanism. Logger and logable mechanism is based on mechanism proposed by [4]. But in our scenario, to implement logging mechanism, there will be two dedicated component which functioning as logger; History Logger (HL), and Temporary Logger (TL). The histories of all committed events are stored in the HL. While the events before a user who has the lock decided to commit or abort are stored in TL. Logger is a component that belongs to the program. Therefore it stays with the client who acts as replicated master. Synchronization and updating protocol should be implemented in the logger. Therefore, there is no need to synchronize all shared data objects, but only the logger. If all consequent states in the logger are synchronized, then the data objects will also be synchronized.

Every event will be stored temporarily in the TL until the user who holds the lock commit or abort those events. If the user decides to abort all subsequent events, then a rollback mechanism should be performed. The rollback mechanism is simply done by erasing all events in TL, and use the last state in HL. When the user decides to commit the subsequent events, the logger simply copy the last state in TL to HL and erases all events in TL.

5.2 Updating Mechanism

In this proposal, a logger is not only store the data, but also implements synchronization and updating protocol. Therefore, loggers will actively communicate with each other.



Figur 14. Sequence diagram for Updating Mechanism

This mechanism is also applied when generating components. Through a proxy, client command the proxy to generate objects, as explained in Figure 12. Local proxy will communicate to the other proxy with the same mechanism as Figure 14.

5.3 Locking Mechanism

There are 4 terms of locking mechanism used in distributed systems; lock, commit, abort, and unlock as defined in [5].

In a pure distributed system locking mechanism should be decided carefully. In a pure distributed system scenario, every task can have the same privilege to work on some shared objects at the same time. In groupware, it can be translated to the condition where every member in a session can work on the same artifact at the exactly same time. For example, in a design session by using CAD tools, every member may have his own cursor and modify the drawing at the same time as illustrated in Figure 14. Another example, in electronic Brainstorming System (EBS), every member might have possibility to write his ideas simultaneously, without having to wait the floor or token.

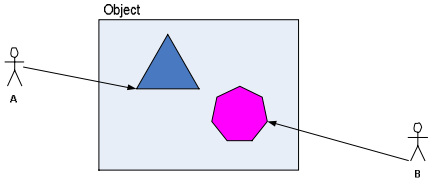


Figure 14. Pure distributed system

Thus, it leads to a situation where more than one task change an object and therefore possible problems mentioned above might be happened. To provide a pure distributed system, an expensive resource should be given.

In our scenario, when a user changes his role from Member to Floor Holder**,** automatically he will get a lock. Locking mechanism begins by the time the floor hands to him. There will be no further problem of locking in sequential and free floor control model, since there is one floor holder at a time. There is a single locking which the floor holder automatically receives. The groupware provide a commit and abort button that can be chosen by the floor holder either during his possession to the floor or at the end of his possession. System will prompt floor holder if he choose neither commit or abort at the end.

But when shared floor control model is used, locking should be applied carefully. Inside an application, there are some objects. Each user will only lock one object at a time. By the time he click an object, locking is applied, thus no one else can modified his possessed object. After he finished working on an object, he should choose either to commit or to abort. If for some period of time, he does not make any decision, the system will prompt him to make a decision.

This mechanism is only applied when there is many separated objects inside the application. Thus it can be applied to EBS, CAD tool, but not an application like Text Editor, or Presentation Display.

VII. IMPLEMENTATION TOOLS

The development of this groupware is designed to be implemented by using JavaBeans [www3], which based on Java [www4] language. As well as Java, JavaBeans implement the basic rules "Write Once, Run Anywhere™".

In our groupware, JavaBean components will be used as building blocks in composing applications. Such builder tool will be used to connect together and customize a set of JavaBean components to act as an application. But it does not necessarily that all programming are written in the shape of Beans (component). Classes, which are best written in modules, will be written in Java classes.

The communication of distributed components will be using the advantages of CORBA. Java is now supporting CORBA IDL. Thus, it is solving the problem that a basic JavaBeans could not support remote interaction in distributed applications. The other reason of choosing JavaBeans is because it supports communications to JDBC, Java RMI, as well as CORBA server.

CONCLUSION

It should be clearly enough how this paper contributes to the new highly tailorable and flexible groupware system by defining 32 main requirements for the system. The distribution architecture used in this proposal is hybrid architecture with network partitioning. Roles of user and the respective sequence in each flow controls are also explained. Concurrency control is applied by using logging, locking and updating mechanism. The system design in presented in this paper will be implemented using component based software, e.g. JavaBeans.

ACKNOWLEDGMENT

This research is conducted in University of Duisburg Essen, during final thesis in Double Degree Master Program Universitas Indonesia-Universität Duisburg-Essen. The study in Universität Duisburg-Essen is funded by the Ministry of National Education Republic of Indonesia.

ABSTRACT

Communication channels are one of the mandatory requirements to support RFID micro-cell network deployment in urban area. The communication channel infrastructures can be in the form of fiber-optic cable network, point-to-point microwave, RF wireless and coaxial ethernet cable network. However, in the case of dense and complex network, for instance a network which consists of many RFID mirocell, the use of fiber-optic and microwave is not flexible enough to support the communication channel requirements. The reason is because of the rigidity of the infrastructure and network topology. For those reasons, it is required to develope another new technology which is more flexible, less expensive and own large bandwidth.

To improve the flexibility of RFID Microcell Network Deployment, this paper introduces an initiative to develop optical free-space communication system. This system owns characteristics such as: wireless, point-to-point and having a capability to handle large bandwidth channel which is larger than the one microwave system does. The three main advantages of optical free-space communication system are: (1) more flexible and easy for installation; (2) own large bandwidth and (3) lower investment. However, this system has also some disadvantages, such as: non-immune to the atmospheric propagation noise and distorsion which cause high attenuation, hence it limits the distance of the channel not more than 2 kms.

The optical free-space communication system is technological engineering of the existing fiber-optic technology to obtain the new technology which is wireless, flexible, less expensive and large bandwidth. The entire components used in this optical free-space communication system are taken from the existing fiber-optics system. In this paper, the author elaborates optical free-space propagation characteristics, i.e., attenuation, polarizaton effect, Rayleigh scattering and possible fading. Further, the statistical model for spatial diversity reception is introduced to evaluate possible implementation of multi receivers. The model will be used to design the optimal optical free-space communication system.

Keywords: *free-space optical communication, RFID, microcell, atmospheric-propagation, atmospheric turbulence, spatial diversity reception*

1. INTRODUCTION

Free-space optical communications (FSOC) is a line-of-sight (LOS) technology where a modulated beam of visible or infrared light is transmitted through the atmosphere for broadband communications [1]. Similar to fiber optical communications, free-space optical communication uses a light emitting diode (LED) or laser source for data transmission [2]. The beam is collimated and transmitted through space or atmosphere rather than being guided through a fiber-optics cable. Free-space optical communications offer data rates comparable to fiber optical communications at a fraction of the deployment cost of microwave or fiber-optics links. The other advantages of this technology are flexible installation and extremely narrow laser beam widths provide no limit to the number of free-space optical links that may be installed in a given location. Thus advantages are justified and suitable to be implemented on microcell networks in urban area.

At this time, this technology can be installed license-free worldwide, can be installed in less than a day. This line-of-sight technology approach uses invisible beams of light to provide optical bandwidth connections [3]. It's capable of sending up to 1.25 Gbps of data, voice, and video communications simultaneously through the air — enabling fiber-optic connectivity without requiring physical fiber-optic cable. This optical connectivity doesn't require expensive fiber-optic cable or securing spectrum licenses for radio frequency (RF) solutions. While fiber-optic communications gained worldwide acceptance in the telecommunications industry, FSOC is still considered relatively new. This FSOC technology approach has a number of advantages:

1. Requires no RF spectrum license.
2. Easy to upgrade, and its open interfaces support equipment from a variety of vendors.
3. It is immune to radio frequency interference or saturation.
4. It can be deployed behind windows, eliminating the need for costly antenna building such as for RF technology.
5. No fiber-optic cables deployment required.

Applications:

FSOC technology can be applied for two different implementations. The first are applications for space communications between satellites, spacecrafts and deep-space between planets. The second are applications for terrestrial communications, similar to point-to-point or line-of-sight in microwave communication technology. For space communications, there are some facts that free-space optical communications will enable space missions to return 10 to 100 times more data with 1% of the antenna area of current state-of-the-art communications systems, while utilizing less mass and power. Data can also be exchanged between a more remote spacecraft and a station on /or near Earth. For example, planetary probes can generate a lot of image data, and a major challenge is to send large amount of data back to Earth. Until recently, radio links operating e.g. in the X band or Ka band were the only available technology. The basic advantage of the optical technology over radio links is that the much shorter wavelength allows for a much more directional sending and receiving of information. In technical terms, the antenna gain can be much higher. This is particularly important for bridging interplanetary distances. In the future FSOC will become the fundamental communication technology for deep-space communi-cations.

The second are applications for terrestrial communi-cations and omni-wireless, such as point-to-point communications between base-stations in cellular networks and omni Wi-Fi Local Area Networks (LANs). When the traffics increase, the cellular networks need to migrate become microcellular networks where the cell areas is about less than 1-km^2. The number of cellular base-stations (BTSs) increases in large number, the consequence is to deploy the communication channels between BTSs. Fiber-optics deployments are not flexible and very expensive for short distance between BTSs, while point-to-point microwaves do not give a good large bandwidth. The answer is FSOC, which gives us flexibility such as point-to-point microwaves, large bandwidth, easy deployment, not heavy and inexpensive investment. Applications for terrestrial are more challenging than applications for space communications, because terrestrial applications facing the effects of atmospheric turbulence.

The fundamental limitation of free-space optical communications for terrestrial links arises from the atmospheric medium through which it propagates. Free-space optical communication systems can be severely affected by fog and atmospheric turbulence [4]. Fog is vapor composed of water droplets, which are only a few hundred microns in diameter but can modify light characteristics or completely hinder the passage of light through a combination of absorption, scattering, and reflection. This can lead to a decrease in the power density of the transmitted beam, decreasing the effective distance of a free-space optical link. The atmospheric turbulence is mostly due to wind and temperature gradient, causes the index of refraction gradient by time and space. This refractive index gradient deflects and diverge the light beam, while the turbulence-wind will cause the light beam wandering.

The items that limit the FSOC performance, then listed in the following systematical parameters:

1) **Absorpsion** occurs when suspended water molecules in the terrestrial atmosphere absorb photons. This causes a decrease in the power density (attenuation) of the FSO beam and directly affects the availability of a system. Absorption occurs more readily at some wavelengths than others. However, the use of appropriate power, based on atmospheric conditions, and use of spatial diversity (multiple beams within an FSO-based unit) helps maintain the required level of network availability.
2) **Scattering** is caused when the wavelength collides with the scattering-particles. The physical size of the scattering-particles determines the type of scattering. When the particles are smaller than the wavelength, this is known as Rayleigh scattering. When the particles are of comparable size to the wavelength, this is known as Mie scattering. When the particles are much larger than the wavelength, this is known as non-selective scattering. In scattering — unlike absorption — there is no loss of energy, only a directional redistribution of energy that may have significant reduction in beam intensity for longer distances.
3) **Polarization-rotation** is caused by water molecules in the terrestrial atmosphere act like dipole-molecules with arbitrary orientation. Statistically it change the polarization of the light beam.
4) **Scintillation** is the temporaland spatial variation in light intensity caused by atmospheric turbulence. Such turbulence is caused by wind and temperature gradients that create pockets of air with rapidly varying densities and, therefore, fast-changing indices of optical reflection. These air pockets act like lenses with time-varying properties and can lead to sharp increases in the bit-error-rates of free-space optical communication systems, particularly in the presence of direct sunlight.

5) **Beam-Wandering** arises when turbulent wind current (eddies) larger than the diameter of the transmitted optical beam cause a slow, but significant, displacement of the transmitted beam. Beam wander may also be the result of seismic activity that causes a relative displacement between the position of the transmitting laser and the receiving photodetector.

Another concern in the implementation of FSOC is safety, because the technology uses lasers for transmission. The proper use and safety of lasers have been discussed since FSO devices first appeared in laboratories more than three decades ago. The two major concerns involve eye exposure to light beams and high voltages within the light systems and their power supplies. Strict international standards have been set for safety and performance, comply with the standards.

The main design challenges in FSOC are solving to overcome the effects of thus absorption, scattering, polarization rotation, scintillation and beam-wandering, which are due to the existence of fog and atmospheric turbulence. The first step prior to overcome the combination of atmospheric disadvantage parameters is by creating propagation model as explained in the next section.

Transmission Issues in Terrestrial Free Space Optical Communications

Particularly for large transmission distances, it is essential to direct the energy of the sender accurately in the form of a well-collimated coherence light beam. For long distance (5-km) applications with large bandwidth, it is suggested to use lasers that have narrower bandwidth and long coherence-length. However, for applications those require inexpensive investment with shorter distance and smaller bandwidth, it is sufficient to use collimated LED. The collimated light beam is required in order to limit the loss of power between the sender and the receiver due to beam expansion. However, the one needs large beam radius with high-quality optical front-wave to keep the receiver in line with the transmitter when beam-wandering happens. The one should use a diffraction-limited light source and a large high-quality optical telescope for collimating a large beam radius. Due to the short wavelength of light, the beam divergence of an optical transmitter can be much smaller than that of a radio or microwave source of similar size. Using a frequently used term in the area of radio transmission, the antenna gain can be much higher for optical transmitters over 100 dB even for moderate telescope diameters of e.g. 25 cm.

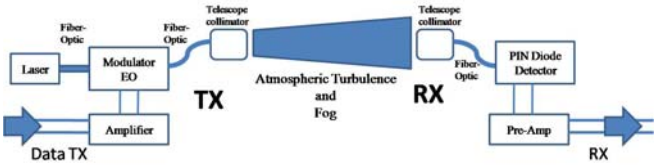

Fig. 1: Setup for a Simplex FSOC system. Although the transmitter signal is approximately collimated, part of the transmitted power may miss the detector.

It is also advantageous to have a large high-quality optical telescope on the side of the receiver. It is essential not only to collect as much of the sender's power as possible, but also to minimize disturbing influences, e.g. from background light, which introduces noise and thus reduces the data transmission capacity. Both high sensitivity and high directionality can be achieved by using a large high-quality telescope at the receiver end. High directionality also requires high precision in the alignment of the sender and receiver.

An important issue is the power budget of a free-space link, including the transmitter's power and all power losses. The remaining power at the receiver largely determines the possible data transmission rate, even though this is also influenced by the modulation format, the acceptable bit error rate, and various noise sources, in particular laser noise, pre-amplifier noise, excess noise in the receiver (e.g. an avalanche photodiode), and background light. The latter can often be efficiently suppressed with additional narrow-band optical filter and high-quality telescope, since the optical bandwidth of the signal is fairly limited, whereas background light is usually very broadb*a*nd.

Severe challenges can arise from the effects of atmospheric disturbances such as clouds, dust and fog, which can cause not only strong signal attenuation but also inter-symbol interference. To solve this problem, it is suggested to use sophisticated techniques of forward error correction embedded in the datalink layer, which allow for reliable high-capacity optical links even through thick clouds.

2. SPATIAL DIVERSITY RECEPTION MODEL TO IMPROVE PERFORMANCE

In this section, the authors will elaborate a statistical model of spatial diversity reception to overcome the effects of atmospheric turbulence. Spatial diversity reception, which has been introduced for RF applications, is a potential method to overcome the degradation due to atmospheric turbulence [5-9]. Application of spatial diversity reception in FSOC has been introduced in some researches [7-9]. The performance of spatial diversity reception on FSOC has been studied and proposed [8], Assuming that atmospheric-turbulence fading is

ISSN 114-1284

uncorrelated at each of the optical receivers. In order for this assumption reasonable, the spacing between receivers should exceed the fading correlation length in the plane of the receivers. It may be hard to satisfy this assumption in practical situation, for any reasons. Available space may not permit enough receivers spacing. In power-limited links, which employ collimated beam with large diameter, the receiver spacing required obtaining uncorrelated fading, may exceed the beam diameter.

2.1. Maximum-Likelihood (ML) Diversity Detection on Turbulence Channels

In the case of spatial diversity reception with n-receivers, the received signal is presented by *n*-component vector. Taking account of correlation between the receivers, bit-error probability equation for maximum-likelihood in [4] is modified as follows:

$$P\left(\vec{r}\,|\,Off\right)=\exp\left[-\sum_{i=1}^{n}\frac{r_i^2}{N_i}\right]\prod_{1}^{n}\frac{1}{\sqrt{\pi N_i}} \tag{1}$$

$$P\left(\vec{r}\,|\,Off\right)=\int_{\vec{X}} f_{\vec{X}}\left(\vec{X}\right)\bullet\exp\left[-\sum_{i=1}^{n}\frac{\left(r_i-\eta I_0 e^{2X_i-2E[X_i]}\right)^2}{N_i}\right]\bullet\prod_{1}^{n}\frac{dX_i}{\sqrt{\pi N_i}} \tag{2}$$

Where $N_i / 2$ is noise covariance of the *i-th* receiver and

$$f_{\vec{X}}\left(\vec{X}\right)=\frac{\exp\{-\frac{1}{2}\left[\left(X_1-E[X_1]\right)\cdots\left(X_n-E[X_n]\right)\right]C_X^{-1}\begin{bmatrix}\left(X_1-E[X_1]\right)\\ \vdots\\ \left(X_n-E[X_n]\right)\end{bmatrix}}{(2\pi)^{n/2}\,|C_X|^{1/2}} \tag{3}$$

C_X is the covariance matrix of the log-amplitude in the *n*-receivers. The likelihood function is

$$\Lambda\left(\vec{r}\right)=\frac{P\left(\vec{r}\,|\,On\right)}{P\left(\vec{r}\,|\,Off\right)}=\int_{\vec{X}} f_{\vec{X}}\left(\vec{X}\right)\bullet\exp\left[-\sum_{i=1}^{n}\frac{\left(r_i-\eta I_0 e^{2X_i-2E[X_i]}\right)^2-r_i^2}{N_i}\right]d\vec{X} \tag{4}$$

The ML detector uses the decision rule $\Lambda\left(\vec{r}\right)\underset{<Off}{>On}1$. Since the log-amplitude follows a joint log-normal distribution, calculation of the likelihood function in (4) involve multi-dimensional integration. It is emphasized that this decision rule has been derived under the assumption that the receiving side knows the fading correlation but not the instantaneous fading state.

The bit-error probability of the ML receiver is given by

$$P_b = P(Off)\ .\ P(Bit\ Error|\ Off) + P(On)\ .\ P(Bit\ Error|On) \tag{5}$$

where *P(Bit Error| Off)* and *P(Bit Error| On)* denote the bit-error probabilities when the transmitted bit is off and on, respectively. Without considering inter-symbol interference, which can be ignored when the bit rate is not high and multipath effects are not pronounced, we have:

$$P\left(Bit\ error\,|\,Off\right)=\int_{\Lambda\left(\vec{r}\right)>1} p\left(\vec{r}\,|\,Off\right)d\vec{r} \tag{6}$$

and

$$P\left(Bit\ error\,|\,On\right)=\int_{\Lambda\left(\vec{r}\right)<1} p\left(\vec{r}\,|\,On\right)d\vec{r} \tag{7}$$

To evaluate the optimal ML diversity detection scheme, we compare it with the conventional equal-gain combining (EGC) scheme [ ]. In the EGC scheme, it is assumed that the receiving side has knowledge of the marginal distribution of the channel fading, in every receiver, but has no knowledge of the fading correlation or the instantaneous fading state. For each single individual receiver output, it is able to find an optimum threshold τ_i. Then the EGC detector adds together the *n*-receivers output with equal gains and compares the sum to the threshold

$$T_{th}=\sum_{i=1}^{n}\tau_i \tag{8}$$

The error probability of EGC is

$$P_b=\int_{\vec{X}} f_{\vec{X}}\left(\vec{X}\right)P\left(Bit\ Error\,|\,\vec{X}\right)d\vec{X} \tag{9}$$

where

$$P\left(Bit\ Error|\vec{X}\right)=P(Off)\,Q\left(\frac{T_{th}}{\sqrt{2N}}\right)+P(On)\,Q\left(\frac{\eta I_0\left(e^{2X_1-2E[X_1]}+e^{2X_2-2E[X_2]}\right)-T_{th}}{\sqrt{2N}}\right) \tag{10}$$

2.2. Numerical Simulations for Multi Receivers

In this section, we intend to present numerical simulations of the performance of spatial-diversity reception/detection with multi-receivers and dual-receivers as well. However, up to this Conference submission deadline our research group has not finished the numerical simulation yet. The structure of multi-receiver link that is represented by dual-receiver is illustrated by Fig.2. As described above, the ML receiver (Fig.2a) has full knowledge of the turbulence-correlated fading matrix C_X, while the EGC receiver (Fig.2b) has knowledge only the marginal distribution of fading at the

receivers. It is assumed that $E[I_1] = E[I_2] = E[I]$ and $N_1 = N_2 = N$ and define the electrical signal-to-noise ratio $SNR = (\eta E[I]^2)/N$.

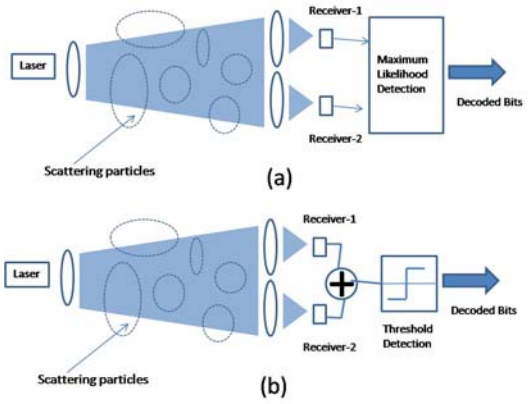

Fig. 2: Dual-receiver model on atmospheric turbulence channels with correlated turbulence fading. (a) Maximum-likelihood detection. (b) Equal-Gain combining with threshold detection.

To obtain simulation results, it is assumed that $E[X] = 0$ and $\sigma_X = 0.1$, varying the normalized correlation ρ_d from 0 to 0.9. It is also compared to set up value $\delta_X = 0.25$. We expect that turbulence correlated fading will cause a larger degradation of bit error probability when the standard deviation noise δ_X is larger. Hipothetically, with two-receivers, ML detection achieves a better performance than EGC for a given SNR. The advantage of ML over EGC method is more pronounced when the correlation ρ_d between the two receivers is high. It is more reasonable when the SNR is high, then the errors are caused mainly by turbulence-correlated fading, as opposite to the noise.

3. CONCLUSION

Free space optical communications through atmosphere is under intensive researches, where various methods have been proposed to overcome turbulence-effects communication signal fading. In this paper we introduce spatial diversity reception model for free space optical communications. This model can be use to analyze and later on to overcome the effects due to turbulence-correlated log-amplitude fluctuations.

ABSTRACT

This paper presents design and preliminary results of research on Content-Based Image Retrieval (CBIR) web-based system for osteoporosis X-Ray images database. In client-server architecture, server provides five query image result based on user's (client) image content. System's basic concept consists of two components: features extraction and similarity measurement. Feature extraction in offline process is conduct to find appropriate feature to role as image descriptor in CBIR. In online process, feature extraction is conduct to extract user's image content (feature) and similarity measurement is conduct in retrieval process. We used statistical approach Grey level co-occurance matrix (GLCM) and wavelet transform for extracting image feature. We also used log-polar transform prior to wavelet transform to reduce rotation and scaling effect. Selection on image feature is conduct by choosing feature vector gives optimum accuracy on image classification test. Experiment on small databases shows promising result in applying CBIR web-based systems for osteoporosis database. Feature vector selected as descriptor is two-dimension vector consist of Contrast measured from GLCM and norm-1 of approximation wavelet decomposed image. Test on log-polar transforms shows that this transforms is improving accuracy on classification.

Keywords
CBIR, osteoporosis, descriptor

1. INTRODUCTION

Application computer in telemedicine has improved medical service in healthcare area. One of the applications is in applying databases on medical information such as medical record or medical image. Several researchers devoted their works in designing such database and in finding the most efficient method in image retrieve from the databases. This attempt related to the specific purposes of medical image that is one of diagnostic tools.

Recently, compare to common method textual-base image retrieval, CBIR is considered as the more appropriate choice method for image retrieval in medical image databases. This method retrieves images from database using information directly derived from the contents of image themselves, rather than from accompanying text or annotation [1]. Time-consuming process in giving annotations on each image, on the textual-bases images retrieval method, is one of the reasons for choosing this method. The specific properties of medical image, such as recognition image from its pathological value give another difficulty on applying textual-base medical image retrieval. Difficulty found in describing medical image pathological area in word, because of irregular shape of pathological area in the image. Moreover, different radiologist would give different opinion on each medical image. All those difficulties expected to overcome by applying CBIR on medical image database.

In this paper, we present preliminary results in research on CBIR web-based systems for osteoporosis X-Ray image database. In this system, user could retrieve image based on user's example image. As the result, system presented five images which has similarity feature as example image. Data in this research are Digitized X-Ray image already known the osteoporosis level based on Index Singh due to simple verification on validity.

2. CBIR ON OSTEOPORISIS X-RAY IMAGE DATABASE

This section presents design on CBIR Web-based Systems for Osteoporosis X-Ray image database. We describe here the basic concept, method for feature extraction and selection, and software implementation.

2.1 Basic Concept

System built in this research is planed to be web-based system in client-server architecture (Fig. 1). In this system, server will provide image from database for user in client side. Retrieval image method in this system is based on client's image content. Principle process in this system consists of two components (Fig.1): Feature extraction and Similarity measurement. Feature extraction conduct for images on database (offline process) and user's image (online process). In offline process (only in server side), feature extracted from each images in database (descriptor) stored in database along with the image. In online process, system extract feature vector from user's image and uses it on image retrieval purposes. Image retrieval is conducted by computing distance (i.e., similarities) between feature vector of user's image and those of images in database. As result, the system will than provide five most similar images (five closest distance images). I this research we also provide textual information for each image in database if available.

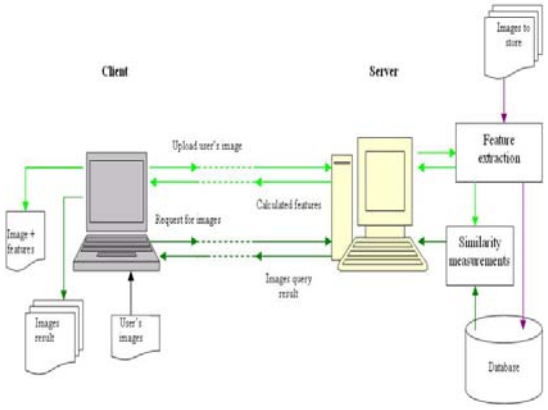

Figure 1. Web-based CBIR basic concept

2.2 Features Extraction and Selection

Osteoporosis is characterized by an absolute decrease in the amount of bone to a level below that required for mechanical support of normal activity and by the occurrence of non-traumatic skeletal fracture [2]. The observation of *trabecular* pattern change for diagnosis of osteoporosis was first proposed in the 1960s using radiographs of proximal femur. The diagnosis was known as Singh Index grading system.

In this research, we used this structure pattern as image feature. We used 4 grades of Singh indexed image (grade 3 to grade 6) from women patients between 45 – 65 years of age. Image feature extraction is done by image textural analyzing which will produce feature vector of each image. This feature vector is used as descriptor on the image retrieval systems. We used statistical approach and wavelet transform for extracting textural feature from image.

On statistical approach we use grey-level co-occurance matrix (GLCM) methods to extract feature (Fig.2). As X-Ray image represent as grey-level image, this method is considered as suitable method. From GLCM, quantities measured as feature are *Contrast* and *Uniformity*.

$$Contrast = \sum_{i=i}^{K}\sum_{j=1}^{K}(i-j)^2\, p_{ij} \qquad (1)$$

$$Uniformity = \sum_{i=1}^{K}\sum_{j=1}^{K} p_{ij}^2 \qquad (2)$$

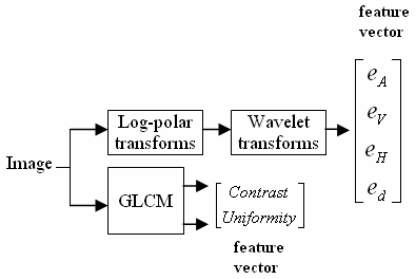

Figure 2. Feature extraction using GLMC and Wavelet transform

Wavelets transforms provide good multiresolution analytical tools for texture analysis and classification [3][4]. Experimental results show that this approach can achieve a high accuracy rate [5]. However, this approach assumes that the texture images have the same orientation and scale, which is not realistic for most practical application. A number works address the problem on rotation and scale on image. One on these works that shows promising results is using log-polar transforms on image [5][6] and combined wavelet packet transforms. Considered that image data in this research are obtained from scanning X-Ray analog image, which usually subject to certain random skew angles and scaling, we use this method prior to wavelets transforms on image texture-based feature extraction [6] (Fig. 2). Quantities calculated as features in this approach are the norm-1 *e* from all component of wavelet decomposed image (approximation, vertical, horizontal, and diagonal component).

$$e = \frac{1}{N^2}\sum_{k=1}^{N}|C_k|^2 \qquad (3)$$

Not all of the measure features above are considered as descriptor. In this paper, feature vector as descriptor is a two-dimension vector using combination of two features, one from statistical approach and another from wavelet transform. Defining which feature vector as descriptor is done by trial and error (Fig. 3).

Test on image classification is conduct on some sample data using each combination of two features. A simple minimum distance classifier method was chosen for this testing process. Feature vectors giving optimum accuracy on classification is selected. Feature vectors selected is used as descriptor for the systems and henceforth, system would only extract these features from images.

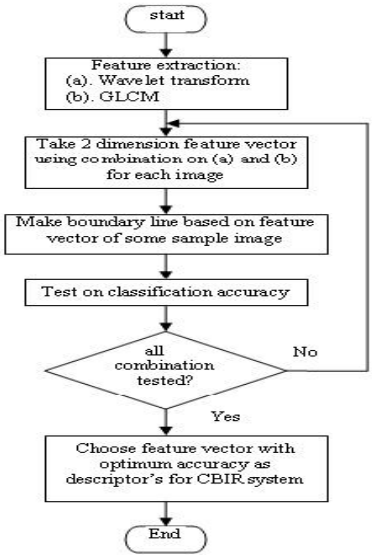

Figure 3. Flowchart on feature vector selection process

2.3 Similarity Measurements

Similarity measurement is conduct on image searching from database. The similarity of two images I_a and I_b is the distance between their descriptor $\mathbf{f}_a$ and $\mathbf{f}_b$. In this research, Euclidean distance $D(\mathbf{f}_a, \mathbf{f}_b)$ was adopted to measure the similarity between the query image and example (user's) image.

$$D(\mathbf{f}_a, \mathbf{f}_b) = \left[(\mathbf{f}_a - \mathbf{f}_b)^T(\mathbf{f}_a - \mathbf{f}_b)\right]^{\frac{1}{2}} \qquad (4)$$

The smaller distance is, the more similar the two images are. After calculating the distance, systems ranks similarity in descending order and then returns the top five images that are most similar to the user's image.

2.4 Software Implementation

Java RMI (Remote Method Invocation) is chosen in establishing systems based on Client-server architecture. We also used JAI (Java Advanced Imaging) library for image process supporting. On client side, we use Java Applet that runs in Internet browser. Important class developed in establishing this system shown in Table 1 below.

Table 1: Classes built in software implementations.

Class	Explanations
`OsteoObj`	Hold image data object.
`ImageRead`	Reading image in BMP format (grayscale), hold image in matrix forms.
`Convolusion`	Performing convolution operation, hold convoluted image in matrix form.
`Matrice`	Hold matrix data, perform operations used in this research.
`FilterRow`	Hold filter for wavelet transform.
`DBImageObjecs`	Hold all instance objects from OsteoObj.
`DBImagePane`	UI Panel to hold and display image databases
`RemoteInterface`	Remote interface for RMI Server
`ServerOsteo`	RMI Sever
`JApplletOsteo`	Java Applet for browser implementation

3. EXPERIMENTS AND PRELIMINARY RESULTS

3.1 Pre-process (Feature extraction and selection)

Experiment on feature selection shows that only four feature vectors (Table 2): $[e_A \ \textit{Contrast}]^T$, $[e_A \ \textit{Uniformity}]^T$, $[e_V \ \textit{Uniformity}]^T$, and $[e_D \ \textit{Uniformity}]^T$, that result in clustering in classification process. Among all those

combination, combination consist of *Contrast* on GLCM and Norm-1 on approximation component $[e_A \quad Contrast]^T$ is the best choice for image descriptors. Figure 4 shows classification based on this feature vector. Boundary lines are performed based on feature vectors (descriptor) of 37 images in databases.

Table 2: Classification accuracy achieved on classification process using four feature vectors

Classes	Classification acuracy using feature vectors: (%)			
	$[e_A \quad Contrast]$	$[e_A \quad Uniformity]$	$[e_V \quad Uniformity]$	$[e_D \quad Uniformity]$
Grade 3	91.67	75.00	66.67	75.00
Grade 4	70.00	80.00	60.00	30.00
Grade 5	83.33	83.33	66.67	25.00
Grade 6	100.00	100.00	100.00	100.00

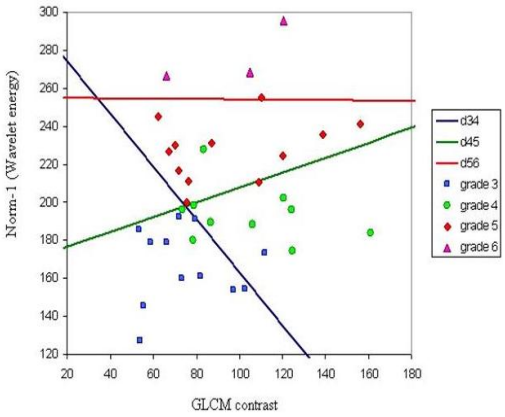

Figure 4. Decision boundary of minimum distance classifier based on $[e_A \quad Contrast]^T$.

3.2 Web-based implementation

Web-based implementation experiment shows that systems can perform image retrieval based on image contents. Previously, system presents user's example image and its features (Fig. 5). Furthermore, after conducting image searching, system present five images result from database (Fig.6). Those five images presented in Scroll Panel and accompany with some textual information (if any): feature vector, grade index, and some comment from expertise. The first order image present is the closest and the last image presented is the farthest to the user's example image.

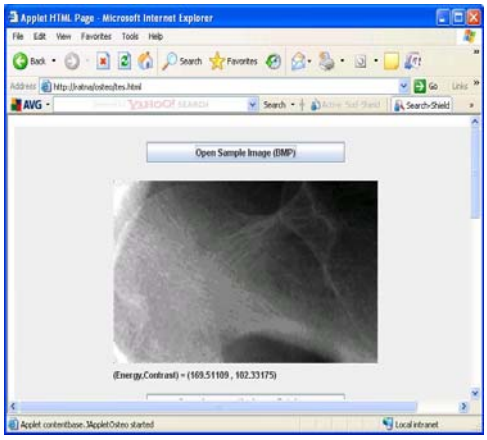

Fig.5. Presentation of user's image on user's screen.

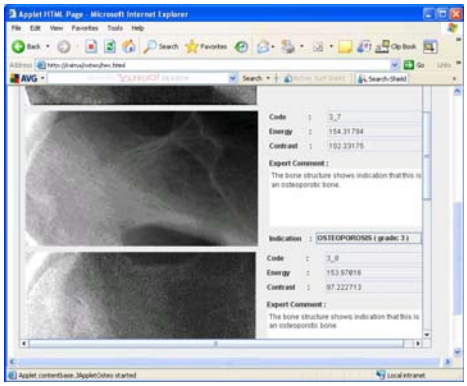

Fig.6. Presentation of retrieval image result in Scrolling Panel on user's screen.

3.3 Test on Log-polar transforms

Experiment for examine log-polar transform impact on image rotation and scaling effect shows that log-polar only reducing error in wavelet energy measured on rotated image (0.9% to 0.2%) and not on scaled image. Test conduct in classification process also shown that log-polar transform improving classification accuracy from 66.56% to 75.42 % (in average). However, on image retrieval process (on-line), although impact on image query result order, do not giving significant effect in image query result. This small impact is due not only on the use two-dimension vector, combination of wavelet energy and contrast on GLCM, but also from small images present on query results (only five images). When order is an important factor and more then five images result is to be presented, the use of log-polar transform prior to wavelet transforms is an important requirement.

4. CONCLUSION

Preliminary result in this works shows promising result in applying CBIR for osteoporosis X-Ray image databases. Combination on wavelet energy signature and contrast on GLCM as two-dimension vector descriptor, give sufficient accuracy for the CBIR purposes. Improvement in classification accuracy shown that, the use of log-polar transform prior to wavelet transform is useful in classification study. The log-polar transform is also become an important requirement if order in image query result is important and more than five image result is to be presented to the user.

However, only small database used for verification in this preliminary research, and most of data has already confirmed its index Sigh. Further works would be applying bigger database and more indistinct indicated data to the system. Moreover, feature vector dimension would need to be increased.

ACKNOWLEDGMENT

ABSTRACT

The vector control has become the first alternative in control of three phase induction motor. One of the vector control method which is commonly used is a direct torque control (DTC) method. However, this system has drawback as the existence of ripples torque. The addition of duty ratio control base on fuzzy logic can give better performance when is compared to conventional DTC. By doing an examination on DTC and duty ratio using small, medium and big capacities of three phase induction motors can be shown the influence from moment inertia to rotor rotation. This paper uses MATLAB SIMULINK for the simulation study with three types of motors power, for example 1, 10 and 50 hp. It is shown that using the same parameters, a motor with a larger moment inertia gives a better performance in comparison to a motor with smaller moment inertia.

Keywords : *induction motor, direct torque control, duty ratio,fuzzy logic, moment inertia*

1. INTRODUCTION

Direct Torque Control was introduced by I. Takahashi,T. Noguchi and Depenbrock as a new strategic in induction motor control, using inverter as voltage source [1-2].This method gives direct control torque and flux motor with to chose voltage vector, it used to limit the torque and flux error, is bounded in hysteresis band and to acquire the torque response at a short time. The DTC method does not use coordinate transformation as the *Field Oriented Control* method, not necessary voltage modulation block and torque, so that it has simple computation, the weakness of this method is torque ripple.

At steady state condition and constant torque, a voltage vector is applied to motor , so that gives torque response rise until end of switching period after that null voltage vector is applied for to drop the torque to reference value until end of the switching period, this event result torque ripple. The last research [3], had done the ripple torque using to give various *hysterisis band* value in hysterisis comparator, but the torque ripple motor as same as before.

The reasearch in this paper has goal , to do control simulation with to less torque ripple using DTC method and *duty ratio* . Simulation control torque ripple is applied to three phase induction motor using different power capacity, 1, 10 and 50 hp, and how the influence moment of inertia to motor's speed.

2 MODELLING

Three phase Induction motor model equations in αβ axis with parameter stator current and rotor flux is shown as below

$$\frac{d}{dt}i_{s\alpha}=\frac{L_r}{L_sL_r-L_m^2}\left(-R_s-\frac{L_m^2R_r}{L_r^2}\right)i_{s\alpha}+\frac{L_m}{(\sigma L_sL_rT_r)}\psi_{r\alpha}+\frac{L_m\omega_r}{(\sigma L_sL_r)}\psi_{r\beta}+\frac{1}{\sigma L_s}V_{s\alpha} \quad (2.1)$$

$$\frac{d}{dt}i_{s\beta}=\frac{L_r}{L_sL_r-L_m^2}\left(-R_s-\frac{L_m^2R_r}{L_r^2}\right)i_{s\beta}-\frac{L_m\omega_r}{(\sigma L_sL_r)}\psi_{r\alpha}+\frac{L_m}{(\sigma L_sL_rT_r)}\psi_{r\beta}+\frac{1}{\sigma L_s}V_{s\beta} \quad (2.2)$$

$$\frac{d}{dt}\psi_{r\alpha}=\frac{L_m}{T_r}i_{s\alpha}-\frac{1}{T_r}\psi_{r\alpha}-\omega_r\psi_{r\beta} \quad (2.3)$$

$$\frac{d}{dt}\psi_{r\beta}=\frac{L_m}{T_r}i_{s\beta}+\omega_r\psi_{r\alpha}-\frac{1}{T_r}\psi_{r\beta} \quad (2.4)$$

where $\frac{L_r}{L_sL_r-L_m^2}=\frac{1}{\sigma L_s}$ and $T_r=\frac{L_r}{R_r}$

Torque equation :

$$T_e=N_pL_m(i_{r\alpha}i_{s\beta}-i_{r\beta}i_{s\alpha}) \quad (2.5)$$

speed and rotor position equation :

$$\frac{d}{dt}\omega_r=\frac{(T_e-T_l)}{J} \quad (2.6)$$

$$\frac{d}{dt}\theta_r = \omega_r \qquad (2.7)$$

Equations (2.1), (2.2), (2.3), and (2.4) can be written in matrix form:

$$\frac{d}{dt}\begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ \psi_{r\alpha} \\ \psi_{r\beta} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & a_{14} \\ a_{21} & a_{22} & a_{23} & a_{24} \\ a_{31} & a_{32} & a_{33} & a_{34} \\ a_{41} & a_{42} & a_{43} & a_{44} \end{bmatrix} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ \psi_{r\alpha} \\ \psi_{r\beta} \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \\ b_{31} & b_{32} \\ b_{41} & ba_{42} \end{bmatrix} \begin{bmatrix} V_{s\alpha} \\ V_{s\beta} \end{bmatrix}$$

where :

$$a_{11} = a_{22} = \frac{L_r}{L_s L_r - L_m{}^2}\left(-R_s - \frac{L_m{}^2 R_r}{L_r{}^2}\right)$$

$$a_{13} = a_{24} = \frac{L_m}{(\sigma L_s L_r T_r)}$$

$$a_{12} = a_{21} = a_{32} = a_{41} = 0$$

$$a_{14} = -a_{23} = \frac{L_m \omega_r}{(\sigma L_s L_r)}$$

$$a_{31} = a_{42} = \frac{L_m}{T_r}$$

$$a_{33} = a_{44} = -\frac{1}{T_r}$$

$$a_{34} = -a_{43} = \omega_r$$

$$b_{12} = b_{21} = b_{31} = b_{41} = b_{42} = 0$$

$$b_{11} = b_{22} = \frac{1}{\sigma L_s}$$

Output vector is written

$$I_s = CX$$

$$\begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} i_{s\alpha} \\ i_{s\beta} \\ \psi_{r\alpha} \\ \psi_{r\beta} \end{bmatrix}$$

Induction motor parameters:

Rs, Rr = stator and rotor resistant (ohm)
Np = number of poles
Ls, Lr = stator and rotor inductance (henry)
Te = electromagnetic torque (Newton.meter)
Lm = magnetic inductance (henry)
ω_r = rotor speed (radian/second)

3. DIRECT TORQUE CONTROL

The Block diagram DTC consist of hysterisis comparator control, torque estimator, flux magnitude, stator flux position and voltage selector, are used as input voltage inverter (*Voltage Source Inverter* –VSI *)* [8].

Basic DTC block diagram can be viewed in Figure 3.1 below :

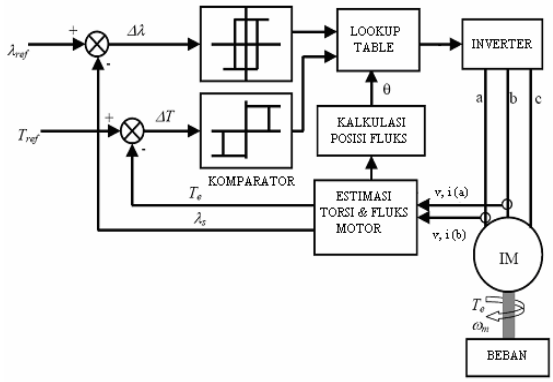

Figure 3.1 Basic DTC block diagram

Figure 3.1 describes DTC method uses hysteresis comparator, what will be compared between stator flux reference and torque with results of stator flux reference and torque motor estimate and stator flux position will be used to choose voltage vector.

3.1 Hysterisis Comparator

The torque control uses hysteresis comparator with three level torque conditions (cT_e). The value of (cT_e) is 1, if the torque must be raise, -1 if decrease and zero , if torque value is constant.

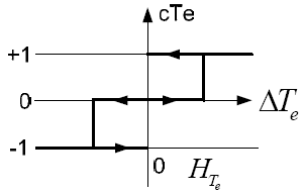

Figure 3.2 Hysteresis Comparator Torque Three Level

The flux controller uses hysteresis comparator with two level. Value of ($c\psi$) is 1, if the flux must be raise and -1 if decrease.

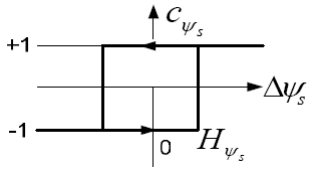

Figure 3.3 Hysteresis Comparator Flux Two Level

3.2 Choosing Voltage Vektor

The voltage vector has six sector and angle of each sector is 60º. The first sector begin -30º until 30º and second sector begin 30º – 90º, further each sector is added by interval 60º until sector 6th with angle between 270º - 30º. Figure 3.4 is chosen voltage vector at time the stator flux in first sector, the voltages V_1 and V_4 are not

used because parallel with normal line. In each sector has flux condition raise (FN) and decrease (FT), also torque condition raise (TN), constant and decrease (TT), what is seen from tangential axis (tan) and normal axis (n).

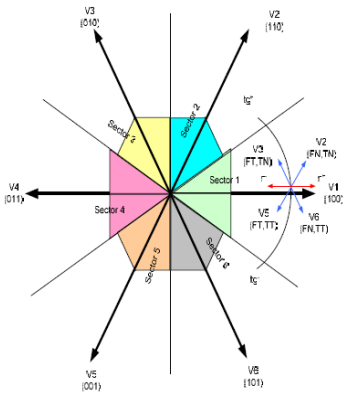

Figure 3.4 Voltage vector when flux at first sector

Voltage vector from each sector is written as switching below in table 3.1

Table3.1 The Choosing voltage vector [8]

φ	Te	Sector					
		1	2	3	4	5	6
cφ = 1	$c_T = 1$	V2	V3	V4	V5	V6	V1
	$c_T = 0$	V7	V0	V7	V0	V7	V0
	$c_T = -1$	V6	V1	V2	V3	V4	V5
cφ = -1	$c_T = 1$	V3	V4	V5	V6	V1	V2
	$c_T = 0$	V0	V7	V0	V7	V0	V7
	$c_T = -1$	V5	V6	V1	V2	V3	V4

The cφ = 1 means flux must be risen and if cφ = -1 , the flux must be decreased, and for the torque condition, c_T = 1 means torque must be risen, c_T = 0, the torque is constant and c_T = -1 the torque must be decreased

3.3 Inverter

Inverter voltage source has six switch or three couples, which each couple works to change over, means each couple of switch cannot work at the same time. If the value of Sa is 1 then the value of Sa' is 0.

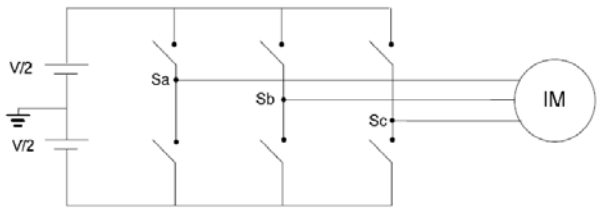

Figure 3.5 Inverter voltage source diagram

The inverter output is three phase voltage as input induction motor is written in equation:

Vn=(Sn–Sn')xVDC/2 (n=a,b,c) 3.1

Tabel 3.2 Switching base on voltage vector

	Sa	Sb	Sc
V0	0	0	0
V1	1	0	0
V2	1	1	0
V3	0	1	0
V4	0	1	1
V5	0	0	1
V6	1	0	1
V7	1	1	1

3.4 Estimate current model using *Observer*

For estimate values of stator flux, torque and stator flux position used the *observer* represents the estimate current model and rotor speed. [3].

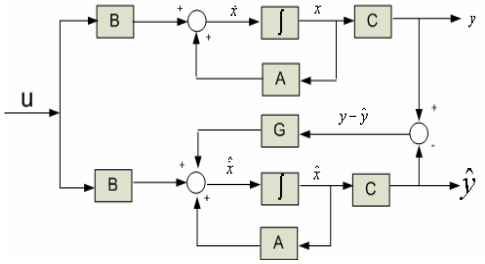

Figure 3.6 The Observer Block Diagram

3.4.1 *Full Order Observer*

The *observer* is designed base on three phase induction motor model using stator reference, stator current model and rotor flux. The *gain matrix full order observer* can be viewed as below:

$$G=\begin{bmatrix} g_1 & -g_2 \\ g_2 & g_1 \\ g_3 & -g_4 \\ g_4 & g_3 \end{bmatrix}=\begin{bmatrix} -(k-1)\left(\frac{R_s}{\sigma L_s}+\frac{R_r}{\sigma L_r}\right) & -(k-1)\hat{\omega}_r \\ (k-1)\hat{\omega}_r & -(k-1)\left(\frac{R_s}{\sigma L_s}+\frac{R_r}{\sigma L_r}\right) \\ c(k-1)\left(\frac{R_s}{\sigma L_s}+\frac{R_r}{\sigma L_r}\right) & (k-1)c\hat{\omega}_r \\ -(k-1)c\hat{\omega}_r & c(k-1)\left(\frac{R_s}{\sigma L_s}+\frac{R_r}{\sigma L_r}\right) \end{bmatrix}$$

The motor model estimate using *full order observer*, that the estimate current model is :

$$\frac{d}{dt}i_{s\alpha}=\frac{L_r}{\sigma L_s L_r-L_m^2}\left(-R_s-\frac{L_m^2 R_r}{L_r^2}\right)i_{s\alpha}+\frac{L_m}{\sigma L_s L_r}\psi_{r\alpha}+\frac{L_m\omega}{\sigma L_s L_r}\psi_{r\beta}+\frac{1}{\sigma L_s}V_{s\alpha}+g_1\left(\bar{i}_{s\alpha}-\hat{i}_{s\alpha}\right)-g_2\left(\bar{i}_{s\beta}-\hat{i}_{s\beta}\right) \quad (3.2)$$

$$\frac{d}{dt}i_{s\beta}=\frac{L_r}{\sigma L_s L_r-L_m^2}\left(-R_s-\frac{L_m^2 R_r}{L_r^2}\right)i_{s\beta}-\frac{L_m\omega}{\sigma L_s L_r}\psi_{r\alpha}+\frac{L_m}{\sigma L_s L_r}\psi_{r\beta}+\frac{1}{\sigma L_s}V_{s\beta}+g_2\left(\bar{i}_{s\alpha}-\hat{i}_{s\alpha}\right)-g_1\left(\bar{i}_{s\beta}-\hat{i}_{s\beta}\right) \quad (3.3)$$

$$\frac{d}{dt}\psi_{r\alpha}=\frac{L_m}{T_r}i_{s\alpha}-\frac{1}{T_r}\psi_{r\alpha}-\hat{\omega}_r\psi_{r\beta}+g_3\left(\bar{i}_{s\alpha}-\hat{i}_{s\alpha}\right)-g_4\left(\bar{i}_{s\beta}-\hat{i}_{s\beta}\right) \quad (3.4)$$

$$\frac{d}{dt}\psi_{r\beta}=\frac{L_m}{T_r}i_{s\beta}+\hat{\omega}_r\psi_{r\alpha}-\frac{1}{T_r}\psi_{r\beta}+g_4\left(\bar{i}_{s\alpha}-\hat{i}_{s\alpha}\right)+g_3\left(\bar{i}_{s\beta}-\hat{i}_{s\beta}\right) \quad (3.5)$$

3.4.2 Speed Estimate using Lyapunov

The speed estimate equation is written as below

$$\hat{\omega}_r=Kp\left(\hat{\psi}_{r\beta}e_{is\alpha}-\hat{\psi}_{r\alpha}e_{is\beta}\right)+Ki\int\left(\hat{\psi}_{r\beta}e_{is\alpha}-\hat{\psi}_{r\alpha}e_{is\beta}\right)dt \quad (3.6)$$

Where :

$\hat{\omega}_r$: rotor speed estimate (radian/second)

$\hat{\psi}_{ra}$: rotor flux estimate in α axis (Weber)

$\hat{\psi}_{rb}$: rotor flux estimate in β axis (Weber)

$e_{is\alpha}$: stator current error in α axis (Ampere), $e_{is\beta}$: stator current error in β axis (Ampere), Kp : proporsional contant and

Ki : integral constant

3.5 *duty ratio* controller design

The *duty ratio* controller uses two *rule base*. The first uses, when stator flux fewer than flux reference (error value is positif), and the second uses when stator flux greater than flux reference (error value is negatif). The membership function's input and output use triangular mode membership function , can be viewed in Figure 3.7 below :

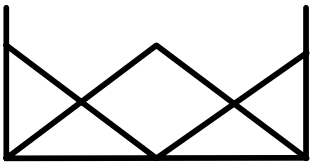

Figure 3.7 Membership function torque error

The values of A, B and C membership function torque error have various values depend on motor characteristic [8], and the values of A, B and C membership function stator flux position are 0, 0.517 and 1.047, base on stator flux position in a sector voltage vector [8].

The membership function stator flux position and duty ratio use as same as membership function torque error, only different in A, B and C values as is shown in figure 3.7

The values of A, B and C membership function *duty ratio* are adalah 0.55, 0.775 and 1, these values are acquired from simulation proses

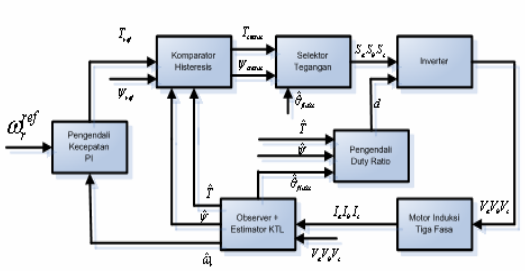
Application fuzzy rules is used to decrease ripple torque. The *duty ratio* proportional to torque error and stator flux position each its vector along torque deviation level proportional to angle between stator flux and voltage, which is supplied to motor, so that the d*uty ratio* also is influenced by stator flux in each sector. The application of two set the fuzzy set cause when the stator flux greater than stator flux reference , A voltage vector it leads stator flux vector in the two sector will be given by inverter then cause high difference torque level if is compared vector voltage it leads stator flux vector in a sector, when the stator flux less than reference value.

Table 3.3 Fuzzy Rule *duty ratio* Controller[8]

Kesalahan Flux			Kesalahan Torsi		
			Small	Medium	Large
Negatif	Posisi Fluks	Small	Small	Small	Medium
		Medium	Small	Medium	Large
		Large	Small	Medium	Large
Positif	Posisi Fluks	Small	Small	Medium	Large
		Medium	Small	Medium	Large
		Large	Medium	Large	Large

3.6 Block Diagram

The block diagram DTC using can be viewed in Figure 3.10



Figur 3.10 The DTC Syistem using *duty ratio*

The *duty ratio* controller acquires input from flux estimate and torque estimate, flux reference, torque and value of flux position estimate. The torque error and value of flux position error in a flux sector as input fuzzy logic controller The duty ratio is produced by proses fuzzification , infference and defuzzification process. .Nevertheless the *duty ratio* value which will be used depend on stator flux error. The *Duty ratio* will modulated triangular signal, then acquire a fixed width pulse .

4. SIMULATION

The results of the three phase induction motor control design using DTC and *duty ratio* is acquired from simulation method and SIMULINK MATLAB program with the various loads and speed. The research's first goal in this paper makes experiment DTC and *duty ratio* using three phase induction with various power, 1,10 and 50 hp is how influence of moment of inertia versus motor dynamic speed.

The sampling time is 10^{-4}seconds, and the modulation frequency in the *duty ratio* is 10^3 hertz.

Speed and Load Simulation

In this simulation the speed is given 100 radian/second at t = 0, then at t=10 second, it is risen till 140 radian/second, and reach nominal motor speed . At time t=0 second is given a balance load it match the motor charcteristic , and at t=14 second, the load is risen till the balance maximum motor torque.

4.1Simulation using Motor Power 1 HP

Table 4.1 The motor parameter 1, 10 and 50 hp is used in simulation program: [3][11][12]

Parameter	value		
Power hp	1	10	50
Num.o.poles Np	2	2	2
Stator Res Rs/Ω	2.76	0.6	0.087
Rotor Res Rs/Ω	2.9	0.4	0.228
Stator Indc.Ls/H	0.2349	0.123	0.0355
Rotor Indc. Lr/H	0.2349	0.127	0.0355
Magn Indc Lm/H	0.2279	0.12	0.0347
M.o.InertiaJ(kgm2	0.0436	0.05	1.6225
D.CoefD(N.msec)	0.0005	0.005	0.1

From this simulation is shown rotor speed ω_r, elektromagnetic torque T_e, single phase stator current i_a and *duty ratio* value. The torque hyteresis constant is 0.08, and flux hysteresis constant is 0.0173, The *observer* constants are acquired from experiment : K = 1.105 ; Kp = 8 ; Ki = 300, the speed control constant, it is used : Kp = 0.5 Ki = 1.2 and maximum torque = 7 Newton .meter.

4.1.1 Speed and Load's Motor

A. Motor Speed with Load variation

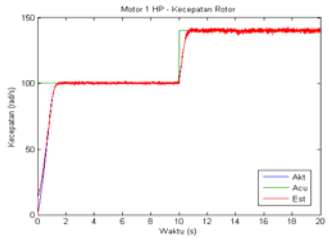


Figure 4.1 motor speed 1 hp with load variation

B. Electromagnetic Torque

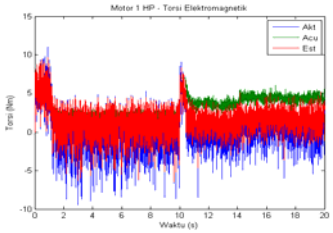

Figure 4.2 Electromagnetic Torque 1 hp with load variation

C. Single Phase Current

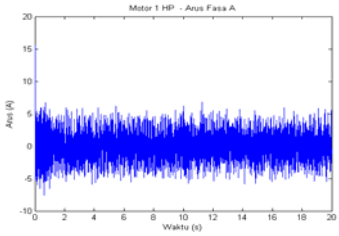

Figure 4.3 Phase A motor current 1 hp with load variation

D. *Duty Ratio*

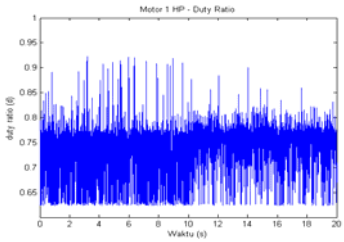

Figure 4.4 duty ratio 1 hp with load variation

4.2 Simulation using Motor Power 10 hp

Besides motor parameters, some constant must be initialized is observer constant gain K = 1.01, speed Kp = 0.8 and Ki = 60. The controller constant speed Kp = 0.1 dan Ki = 0.42. The hysteresis torque 0.1284 and flux 0.0173.

4.2.1 Speed and Load's Motor

A. Motor Speed with Load variation

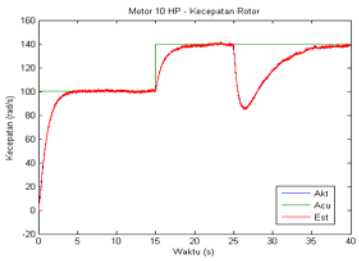

Figure 4.5 motor speed 10 hp with load variation

B. Electromagnetic Torque

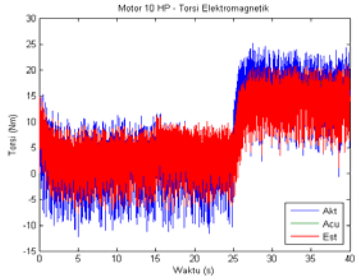

Figure 4.6 Electromagnetic Torque 10 hp with load variation

C. Single Phase Current

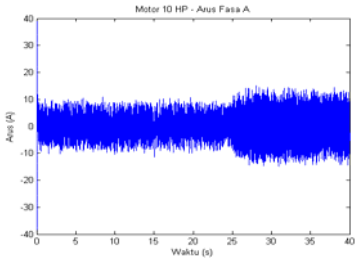

Figure 4.7 Phase A motor current 10 hp with load variation

D. *Duty Ratio*

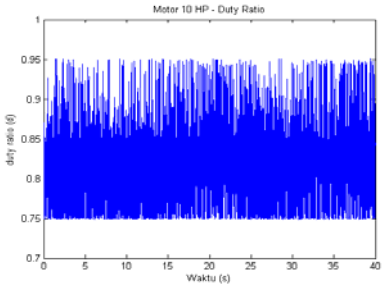

Figure 4.8 duty ratio motor 10 hp with load variation

4.3 Simulation using Motor Power 50 hp

:

The initialization constants are observer, gain K 1.3, *speed* Kp = 0.15 and Ki = 5.0, the controller. speed Kp = 50 and Ki = 50, the hysteresis torque 10 and flux 0.0173. For motor power 50 hp, the fuzzy logic's parameters input torque is 10 and 40 Newtonmeter, and flux position is 0 and 1.047, and output parameter is 0.7 and 1.

4.3.1 Speed and Load's Motor

A. Motor Speed with Load variation

.

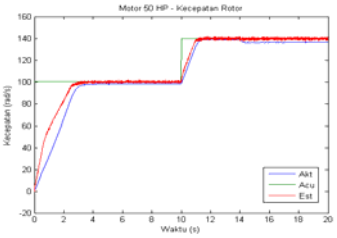

Figure 4.9 motor speed 50 hp with load variation

B. Electromagnetic Torque

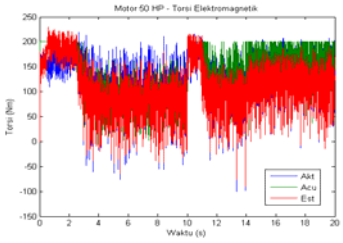

Figure 4.10 Electromagnetic motor Torque 50 hp with load variation

C. Single Phase Current

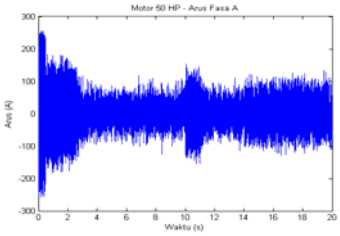

Figure 4.11 Phase A motor current 10 hp with load variation

D. *Duty Ratio*

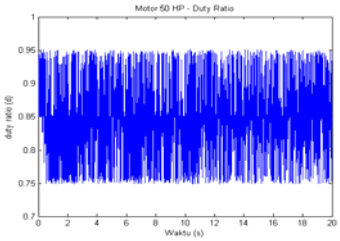

Figure 4.12 duty ratio motor 50 hp with load variation

4.4 Comparison Motor speed 1, 10 and 50 hp.

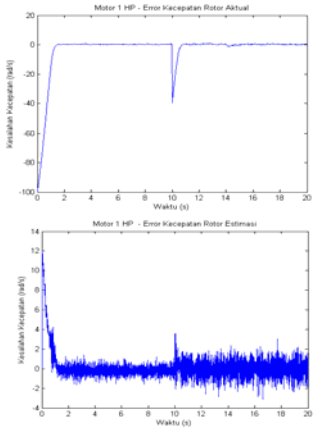

Figure 4.13 The rate actual speed error and estimate speed error motor 1 hp with load variation

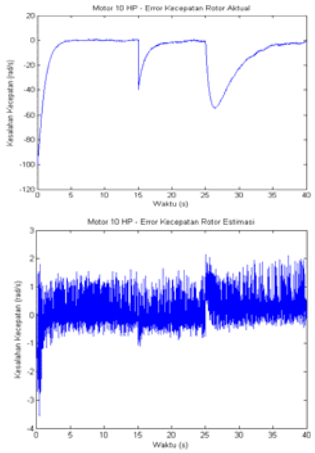

Figure 4.13 The rate actual speed error and estimate speed error motor 10 hp with load variation

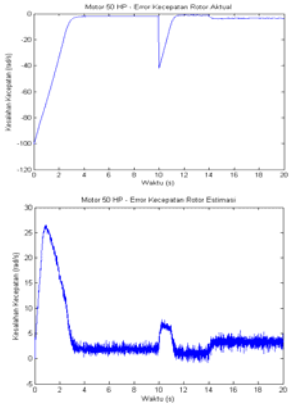

Figure 4.14 The rate actual speed error and estimate speed error motor 50 hp with load variation

Tabel 4.2 Motor speed for power 1, 10 and 50 hp (radian/second)

Power hp	speed err. rad/sec	No Load	Variable Load
1	Actual	0.38	0.317
	Estimate	0.54	0.56
10	Actual	0.93	1.01
	Estimate	0.35	0.33
50	Actual	0.65	2.52
	Estimate	1.22	2.3

The result of the rate actual speed and estimate speed error motor 1, 10 and 50 hp, show the actual motor speed 1 hp is the best, this matter depend on the observer design, it is very important to estimate torque, flux, flux position and motor speed.

4.5 Simulation using variation of Inertia Moment

Table 4.3 Variation of inertia moment induction motor with power 1, 10 and 50 HP

Power hp	1	10	50
time sec.	Moment of Inertia motor Kg.m2		
20	0.005	0.005	0.05
25	0.01	0.01	0.5
30	0.2	1	2.5
35	1	2	5
40	0.0436	0.05	1.622

Table 4.3 describes the variation of inertia moment induction motor with power 1, 10 and 50 hp, which is risen each 5 second begin 20th until 40th second .

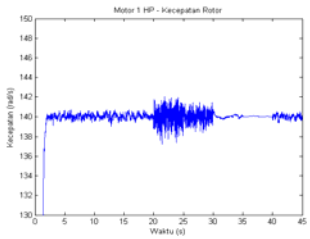

Figure 4.16 motor speed 1 hp with moment inersia variation

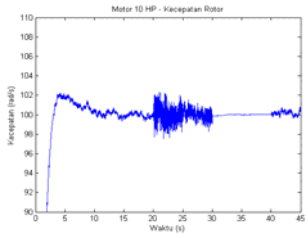

Figure 4.17 motor speed 10 hp with moment inersia variation

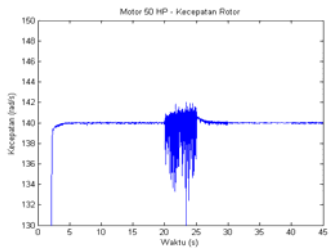

Figure 4.18 motor speed 50 hp with moment inersia variation

5 CONCLUSION

1. The motor with high inertia moment, has rotation more stable if be compared the motor, which has bila dibandingkan dengan motor dengan nilai momen inersia kecil.
2. DTC method using *duty ratio* control can decrease torque *ripple*
3. The *rate actual speed error* motor 1 HP with load variation is 0.317 rad/sec and *estimate speed error* 0.56 rad/sec, for motor 10 HP is 1.01 rad/sec and 0.33 rad/sec. , and for motor 50 HP is 2.52 radian/second and 2.30 radian/second.

ABSTRACT

This paper reviews the web extraction techniques for Web 2.0 to create a Mashup system to provide information on Indonesia academic citation index. Some web searching and crawling mechanism based search engine optimization system has created an environment for the democratization of information.

Presently the awareness for completeness of data in individual level, publications and to promote and guard the academic publication results have been enforced in order to encourage more publication and citations towards a paper/journal.

This paper describes the user requirement and application design, for the application of Mashup of Citation index for Indonesian Electronic Journal papers. We reviews the existance of personal blog of lecturers, digital online index, wrapper and tools for web extraction and digitalization of libraries in Indonesia. The intented system is expected to provide an award for research paper authors by providing the number of citation to his/her publication.

Keywords
Mashup, Web Extraction, Citation index.

1. INTRODUCTION

Information integration has been flourished during the last five years with the existence of Web 2.0 technologies. Some tools such as wrappers to collect online information on a timely manner have been available on the Internet.

In this work some infrastructure based on Extraction, Transformation and Loading (ETL) have been considered in designing a system to create the Index Citation Mashup. The system has been designed in the form of UML *(Unified Modelling Language)* diagrams, and the making of the prototype using robomaker REST based on OpenKapow. Subsequently the system should be implemented using PHP dan MySQL and web services based on XML standard for the Indonesian e-journal Mashup.

2. WEB EXTRACTION TECHNIQUES

Information technology infrastructure and the facilities development provided use with search engine and indexingsystem. The search engine is designed to make it easy for Internet user to get information from the world wide web. The system is based on the framework that information and knowledge are valuable things that should be used and shared by everyone.

2.1 Web Technologies

The new media has been widely developed with the development of Web 2.0. In order to become a new information society, our society has to change its characteristic and habit from a downloading society to become an uploading society, which provide and share information [2].

The authority to provide information has been moved from publishers, sites, or a knowledge based institution to a common citizen journalism and web based self publishing blog in the Internet. Knowledgeable person will be referred by the Internet users, therefore academician are required to provide complete and up to date information with a good analysis. Internet users will have the capacity to judge information. All information should be digested, analyzed, and evaluated from different perspective. Therefore it could lead to an improvement of human being's quality of life.

Academicians are in the forefront of the knowledge. Critical analysis and evaluation are the main requirement in academic world. A solid work will be based on deep literature review. A citation means an acknowledgement and a milestone in the research result towards a good and innovative research product.

ISSN 114-1284

Presently, there are some citation index tools currently available in the Internet which could provide the track record for academic authors [1, 3, 4, 5,9, 10, 11]. Google scholar [3] and citeseer are some of the indexing system in the form of softcopy which mostly are in English and acknowledge as an international standard of research result. Meanwhile some highly regarded journals is supported by professional organization, in addition to some journals owned by universities, faculties or study program.

International professional organization for researcher in the field of information and communication such as Institute of Electronics and Electrical Engineers (IEEE) and Association of Computing Machinery (ACM) is the highest authority and the most prestigious publication with the advancement of technology which could direct the future development of knowledge in the world. The publication can be searched from search engine, which usually needs a password and paid access to the journal or proceedings publication.

Meanwhile, in Indonesia some researchers and academician need to get the most current information of the citation to their publication. For example for the research publication which has been produced, how many researchers or academic article have referred to that research result. When an article is cited by other people or has been acknowledge as a contribution for the science, the author will be proud with his achievement.

Some places in the Internet has been prepared freely to show the full information such as in encyclopedia which can be updated by every one (note that the IP address of the machine which initiate the changing and adding information will be noted by the system, and when the update has been done). Wikipedia has been the place for the compilation of information which will be very useful, although the correctness of the information has been determined, due to the bias of information and the perspective of the writers. An academic article usually has a neutral characteristic, which is different from free information sources such as from Wikipedia.
The literature searching in the Internet should be carefully conducted to ensure that good quality of references can be gained. Open access journal in the Internet has been provided in the Internet, and many cyber library services have been provided by many universities to support academic communities to gain the most current resources in conducting research.

Web 2.0 technology is very usefull and cheap which can be deployed for the current non Web 2.0 product and services. The Web 2.0 environment enable user contribution to the system.

Search Engine Optimisation (SEO) can be performed better with the web 2.0 delivery mechanism such as Blogs and RSS which significantly can improve the search engine exposure thorugh a distributed mechanism. Wikis for example enable user to build documentation and knowledge based system, with a small investiment.

In Indonesian, a tradition of preservation of Information have come to a long history. The Indonesia National Archive Office kept the national archieval from hundreds of year back. For example many documents can be found from the time where the Malay language was first use in Voolkstraad (Representative Assemby). A Minangkabau Representative named Yahya datuk Kayo, was the first Indonesian member of Voolkstraad (51 members) who deliver his speech in Malay language in 1932.

Documentation and archieve have come to the time when digitalization and the electronic indexing system can help in making the search quicker.

Based on the literature study of the web extraction techniques which is related to the Mashup and its tools such such as Open Kapow, in this work we have created the fundament for a system to implement the system for the electronic journal citation indexing system [6].

Some problems such as the currently available existing standard of pdf files have been faced, which make it difficult to extract information and to evaluate the reference available in the background.

Our studies shows that using the currently available Wrapper such as Open Kapow is not straight forward considering that the reliability of the data extraction is very much dependent on the library at the server of Open Kapow.

2.2 Web Extraction Techniques

Web extraction is a method for mining core information from distributed documents in the Internet. This techniques can help to connect documents with high accuracy. This techniques can help to create a system which can provide credits for the academic paper authors in finding papers written by previous author [16, 17, 18, 19, 21, 22, 23, 24].

OpenKapow and Iopus are some tools which have been explored in this research [15, 16]. Some system such as Robomaker which took data in RSS, atom feeds, REST web extraction and web clip have been analyzed to implement the system. This system will be applied using Open Kapow services. This paper will present the design process of the creation of the Indonesian Electronic Journal Mashup System.

3. LITERATURE REVIEW

3.1. Mashup

Mashup is a hybrid web application which embed data and functionalities from more than one resources. The terminology of digital Mashup can be in the form of digital media file which consists of text, image, audio, video, animation recombined, or modify the result of digital work to create the derivative work. For music, mashup can consist of old songs which consist of other songs. Video Mashup is defined as a video which can be edited from different sources and will look like a complete video [7].

An example of mashup is a cartographic use of data from google maps to add location information to the real estate information, by adding new and different services from the currently available one.

Mashup content can be gained from a third party through public interface or API *(Web Services).* In addition to some method to get content from mashup, web feeds (RSS or Atom) and *screen scraping* can also be used. The term *screen scrapping, web extraction, web harvesting* will be described in more detail later on. Many people experiment using Amazon, eBay, Flickr, Google, Microsoft, Yahoo, or YouTube API, towards mashup editor.
A typical mashup web architecture consist of three part, i.e.:

1. Content Provider: data can be made using different API and web protocol such as RSS, REST, and web service.
2. Mashup sites: web application provides new services using some available data sources.
3. Web browser client: user interface from Mashup. Web content application can divided by web browsers using user language in web client side, for example JavaScript.

Tabel 1 describes the differences between a typical portal and mashup which describe the differences between portal and mashup.

Table 1: Comparison of Portal and Mashup

No	Features	Portal	Mashup
1	Classification	Older technology, using clearly defined approach for web server extension.	Web 2.0 techniques
2	Philosophy/ Approach	Aggregation approach by dividing web server into phases: markup generation and aggregation from markup fragment	Using APIs of available content sites for aggregation and reuse the content.
3.	Content dependent	Oriented towards markup fragment presentation aggregate (HTML, WML, VoiceXML)	Content aggregation can happen and content presentation orientation.
4	Location dependent	Traditional	On server and
5	Style Aggregation	Salad bar style (without overlap)	Melting point style (arbitrary structure)
6	Event Model	Read event model and update	CRUD operation based on REST
7	Relevant Standard	Portlet behaviour based on JSR. 168, 286, WSRP standards	Interchange data PeruXML with semantic REST. RSS and Atom are commonly used. Specific standard will be defined.

3.2. Workflow

Workflow is the description of the operation process which can be described as work result of the staff and machines in an organization, both in simple and complex form [8].

Workflow is a model to represent real time work to be evaluated, for example to describe recurrent operation. Workflow is an activity format which has been made possible by systematic organization of resources, which can be defined by flow of information.

3.3. Citation Index

Citation index is an index from citation on publication which enables user to define which document appears after other ones, from counting the citation of older documents [6].

Currently there are at least five publications of academic citation index available to be subscribed by libraries worldwide:

1. ISI (now part of Thomson Scientific).
   ISI citation index can be found in CD and web site format. The web version is called 'web of science' which is part of WoK data base.
2. Elsevier published Scopus, which is provided online with the same combination of searching subject by browsing citation and literature studies in natural and social sciences.
3. Citeseer system provided citation and other academic literature, particularly in computer and informatics.
4. RePec provided index in economics and other disciplines.
5. Google Scholars (GS) is a free of charge citation index which indexed new articles found in Google search. Currently Google scholar has enough features so that commercial products mention previously may no longer needed [10, 11].

ISSN 114-1284

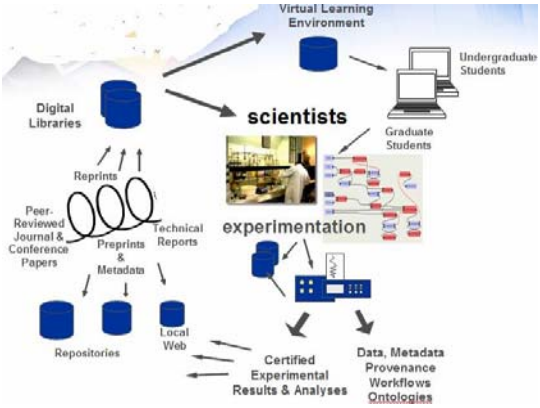

Figure 1: Social Process of Science [27]

Figure 1 shows the social and natural sciences processes, started from research experiment leading to search result repository. The result is published in peer reviewed journals and digital library to create a virtual learning environment.
Citation analysis (Scientometric) is normally conducted for the purpose of information retrieval, and many are used for bibliometrics and other studies for research evaluation [1, 2, 3, 13, 15]. Citation data is the basic information for journal impact factor.

3.4. Mashup Technilogy for Web Extraction

Web extraction is also called web harvesting, web farming, web mining, web scraping [1], dan screen scraping [2]. Extraction is a kind of information search to extract structured information, which is information defined in semantic approach, by context and particular categories of machine readable documents.

The aim of conducting web extraction is to collect information by integrated and automatic manner from heterogeneous resources [4]. The working method of web extraction is similar to the search engine process. Search engine provides information about pages and key words used by user.

The search engine phases conducting searching as follows:
1. *Scan* the web page to search for information.
2. Mark that information.
3. Copy that information.
4. Open other program such as spreadsheet or word processor and paste the copy result.

The limitation in using the search engine is recurrent daily changes of the web pages. To overcome this limitation, web extraction techniques have been created aiming to automate the process of read, copy and paste the information from websites

The web extraction is commonly used for particular information, as defined by web2DB for the following information [5]:
1. Create the contact list and market data.
2. Extract product catalogue.
3. Extract Real Estate information.
4. Automate the searching of advertisement list.
5. Clipping the latest news articles.
6. Automating auction.
7. Extracting betting sites.
8. Server migration.
9. Legal Notices
10. Military purposes

The following is the common extraction technique:
1. Extract information from defined document in a particular manner, such as HTML files, images, email messages, etc. First, the general structure of the document must be evaluated, images, and email messages. This is conducted by learning the general structure of the document, and mapped it with the data model or similar document. The alternative method is by adding more features to the search engine.
2. Conducting analysis to the document structure in relation with other documents. This is due to the fact that many related information can be found in the reference section of a publication.
3. Another alternative is by using recorded data by web server regarding the interaction of the user with a particular document or web page. From this data we can identified interaction pattern between the user and the web page. More over, the interaction pattern in a site can be customized dynamiccaly from the information shown, the depth of the site structure and the resources' format.

Data web extraction is an extraction process of structured data in a web site. The process consist of the following steps:
a. Find the HTML file from a site.
b. Extract relevant part of the data.
c. Process the data.

Most web extraction software is quick and easy to use. Some steps to crawl the designated site, extract structured and integrated data in the web data extraction. Some tools to extract web data have some features such as high speed, multi-thread and high accuracy. Due to the fact that many websites have been arranged with an HTML templates and database in the back, extraction tools must be able to find the information of the template and create an identical copy from the database.

Extracted data from a web site can provide the base for the information acquisition which shows the entity of the document or a web page. Data extraction created the platform for the document retrieval. Other web data extraction tools provided some equipment to generate some automatic

extraction procedure for the pages with repeating elements. Transformation mechanism chosen for this is called *Extensible Stylesheet Language Transformation* (XLST).

Web Content Extractor is an easy to use data extraction software for *web scraping*, *web harvesting*, and data extraction from the Internet. The most frequent changes in HTML design is the change of position of items in the web. The link is conducted by reinserting the page. Web data changes the way information extraction is conducted for business purposes. The combination of conditional statements, general statement, domain specific knowledge, web data extraction tools will eventually lead to intelligent way to find required information. It uses a general statement and contains mapping table to solve the differences between web resources [4].

3.5. Citation Extraction Techniques

Our aim is to create a design to create an application for web extraction in a form of a Mashup to count and update information of how many times citations have been made to a paper.
The following is the steps taken to count the citation to a journal paper [13, 14, 15].

1. Develop a *data-frame library* which consist of the previous information needed for data extraction. Therefore, *data-frame library* consist of historical detail of required information. For example by finding out all electronic journal sites in Indonesia and put the address to the web extraction tools such Open Kapow, Iopus, Lixto atau Marmite.
2. Creating a GUI (*Graphical User Interface*) to enable system users to gather all online paper required. Subsequently an *application-dependent forms*, and algorithm must be created to make sure that data has been gathered automatically from time to time.
3. Producing each component of application ontology (for example object and the connection between rules and bounds, extraction pattern, context, and keyword) by analyzing the page example of a journal and information list.
4. Providing a calculation of the citation number to a journal to evaluate the *ontology-generation system*.

Finding the journal citation is conducted by searching other papers which refers to that particular journal.

Challenges in web site scrapping are how to use the data. Data taken from web data extraction does not follow binary data and complex data format. To solve these problems, web site must provide access to the content through the API and web services.
Other challenge in finding references in Indonesian electronic journal is the fact that some systems prevent the extraction process. Screen/web scraping or web extraction are some method to solve the problem to find the web data by analyzing the structure of the data and wrapping the information.

Web extraction techniques are required to know the layout of the information both in metadata and it the document itself. Layout differences will create the problem to the accuracy of the extraction process. Therefore a model for the pattern should be created so that update and adoption of document manual template can help the process [16, 17, 18, 19, 21, 22].

There are some web extraction technologies to the open source tools. Some free software are available for this such as Yahoo pipes (pipes.yahoo.com), Microsoft popfly, Open Kapow (local computer application), Lixto (Austria), and Iopus [23, 24]. These tools are wrappers with web programming algorithm. The dycotomy of metasearch and google search (search all, including extracting the pdf) is the common problem. We need to also assess when a document received a Digital Object Indentifier (DOI) and where it was published [12].

4. REQUIREMENT AND ENVIRONMENTAL SETTING FOR INDONESIAN E-JOURNAL

The designated system is a web based system to automate the information search on citation of online journals belong to Indonesian universities. From the search result we can gather data and information citation indexing from many areas of knowledge to a database to store information.

Information can be processed so that the identification of the document relationship can be identified. The indexing result can be accessed by authors, researchers, and general public through the Internet. Automation can be done by system through auto update to ensure that the citation information is actual.

The intended system will be a web based system, and from the user side it will be similar to general search engine in which users can provide input in search query in search field provided. After the user executed the command to conduct search, system will search the data base of the processed information, which consist of the number of citation to that paper, the title, and author. The system is designed to provide links which is related to the document title which relate to the user query to be used for the future research.

Automatic web extraction will result ini a mashup. This mashup will integrate and provide relationship information and links between papers found. Figure 2, 3, and 4 depicted some diagrams which show the use case diagram, sequence diagram, and class diagram, of the intended system.

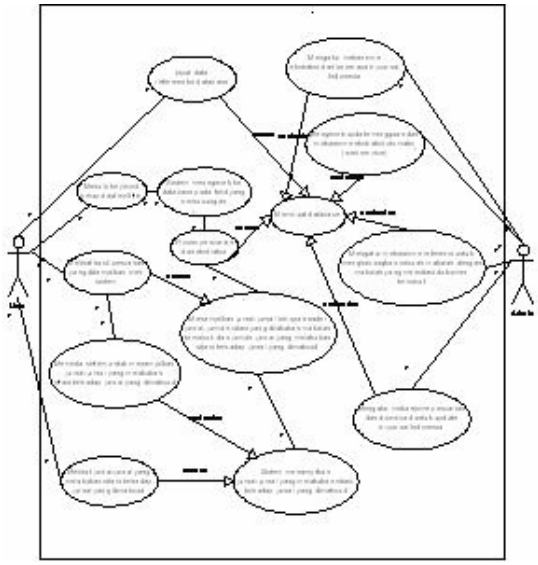

Figure 2: Use Case Diagram

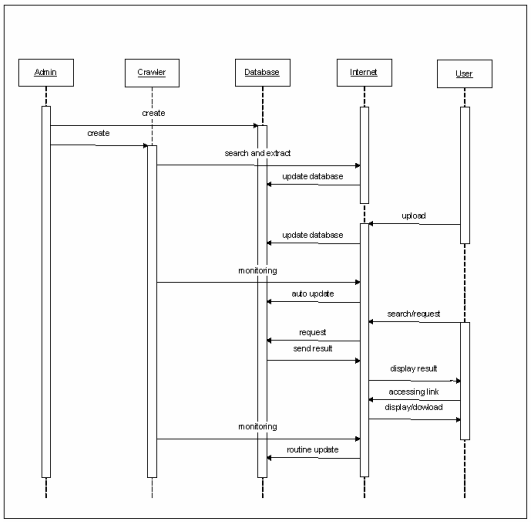

Figure 3: Sequence Diagram

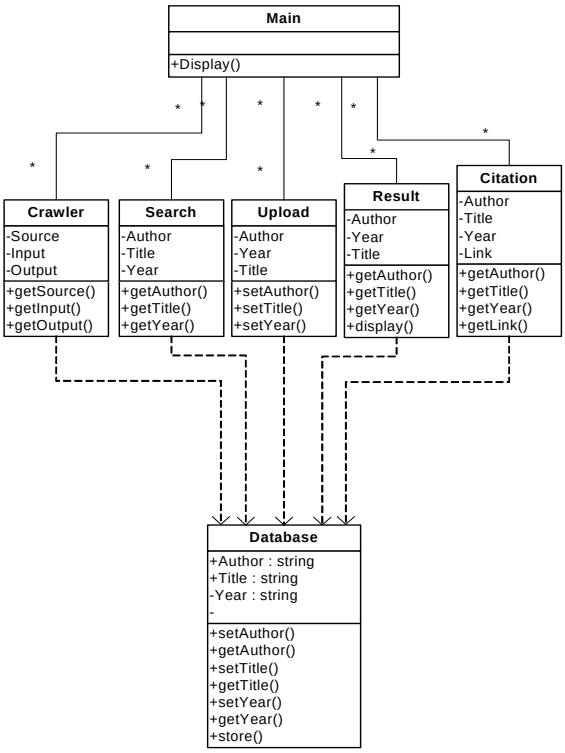

Figure 4: Class Diagram

5. INDONESIAN E-JOURNAL

From the web search of the Indonesian e-journal we have identified that some journals provided full text in the form of pdf file, some only provide abstracts. The following are the journals from Indonesian Universities portal, i.e. Universitas Airlangga (7 Journal), Universitas Negeri Malang (38), Universitas Udayana (31), Universitas Palangkaraya (1), Universitas Kristen Petra Surabaya (14), Universitas Paramadina (1), Universitas Indonesia (1), Universitas Gadjah Mada (5), Intitute Pertanian Bogor (10), Universitas Gunadarma (11).

7. CONCLUSION

Web extraction is a data mining method to retrieved information from distributed documents in the Internet. Using web extraction, user will be able to get the relationship between documents in an accurate manner. Some web extraction techniques will help to create a system to credit authors of research publications. This papers has shown the preliminary approach to design a Mashup for Indonesian electronic journal citation system. The future work will involved the implementation of the web based system using web 2.0 technology and the latest development in web integration methodology.

ACKNOWLEDGMENT

ABSTRACT

This paper presents the development of relatively new trend in communication technology addressing mobile ad-hoc network. To deploy the network with highly-mobile characteristic we are going to use distributed robots as media to carry information. The self-deployment algorithm is being constructed to support robots behavior in group. The adaptive method to deliver information within the network is being examined, that mobile robot network tends to suffer the rapid changes in configuration due to the movement of the robots.
The research has been conducted in several phase of implementation. In previous time, the algorithm for configuration process has been established, called self-deployment algorithm with connection priority criteria. In present time, we are going to observe a new way to optimize the algorithm in terms of the success rate of network deployment in minimum number of robots are used. Here we propose the use of artificial potential field method that once is developed to guide autonomous mobile robot in navigation planning.

Keywords
Distributed robot, mobile robot network, artificial potential field

1. INTRODUCTION

Mobile Robot Network (MRN) is relatively new trend in the communication technology development today. This application uses multiple robots as media to carry information throughout the network link which also enables the network with mobility characteristic. By implementing ad-hoc wireless technology and the form of Peer-to-peer communication, robots are capable to communicate each other in order to form network topology [1].
The present research will focus on the design of method to deploy Mobile Robot Network configuration in the given environment. The algorithm used in this research is based on self-deployment with connection priority criteria which supports decentralized and collective behavior among robots in group.
Communication between robots happens in two ways. The first is based on TCP connection as stable communication which is used for error-free data transfer and the second is based on UDP connection as unstable communication which is used to exchange location-information exchange between devices. Robots then need to establish stable connection in order to distribute information through network link [2].
The environment as robot working area is dynamic in which obstacle factors exist that obstruct robot movement. The definition of permitted and prohibited area are being made by using road-map input for each robot in order to model the simulation into the environment as close as the real world. Moreover, the solution for network configuration to be found is expected to be the most optimum solution from the given environment and obstacle definition. This to encounter the limitation often found in real life that the unlimited resource to build Mobile Robot Network is definitely not affordable, or even if we could, it will cost a lot of effort and expense.
The optimum solution of network configuration problem in this research is basically the trajectory with most minimum cost that connecting all given locations. Another requirement is that this trajectory may not violate the obstacles or prohibited area as stated in the road-map definition. For this purpose, we will then use the Artificial Potential Field method to find several possible trajectories. Robot is then to form the formation that follows the derived solution.
For routing problem in this research, we will use Ad-Hoc on Demand Vector Distance method to solve the requirement. This method is sufficient for mobile type ad-hoc network that it supports the capability for quick updating routing table that changes very often. The result that found from simulation activity is then to be evaluated from the sense of the algorithm's capability to find solution from minimum cost and resource in the given environment.

2. MOTIVATION

Artificial Potential Field (APF) is mostly used in several application that related to robot's navigation and motion plan [3][4][5]. The concept of this method is to build trajectory by generating potential-field map from the interaction of robots with its surrounding. Later, this map can be used to guide the movement of the robot. In other cases, this method is also applied for obstacle avoidance activity [6].

In this paper we will then utilize the APF method to find the propitious trajectories from the points that are going to be connected through the MRN communication link. This will provide the possible routes from each point to another within the given environment. By choosing the shortest path among all feasible trajectories, we can then determine the most optimum path to connect the intended points.

3. IMPLEMENTATION FRAMEWORK

Here will be explained how we are going to deliver the MRN application by using Self-deployment algorithm and Artificial Potential Field (APF) method to optimize network link deployment under the limited number of resources.

a. The Self Deployment Algorithm

In order to deploy MRN application, multiple number of mobile robots need algorithm that provide collective behavior to work in group. The self-deployment algorithm will then be capable to handle the decentralized activity of robots in delivering communication network. As this network link subjects to high mobility characteristic due to the movement of the robots, the self-algorithm needs to be adaptive with the changes.

Research in multiple robots' work in group is actually not a new problem to be examined. In several studies, the decentralized algorithm has successfully been implemented to solve hard problem in real life with the utilization collective robots behavior [7][8]. In this phase of research, we will then adapt the usage of self-deployment algorithm with connection priority criteria as this algorithm has successfully solved the cooperative object tracking with sensor network application [1]. This topic is quite similar with the problem we face in this research [2].

The self-algorithm with connection priority criteria treats all objects within the working environment with different priority that reflects the significance of the object for itself. From this priority, robot can decide what to do in the next step of its movement. Robot will then finish its work after all priorities have been fulfilled or whenever the main objective has been reached. To simplify the problem, figure 1 and 2 below will explain how this algorithm works to connect two points in the working environment.

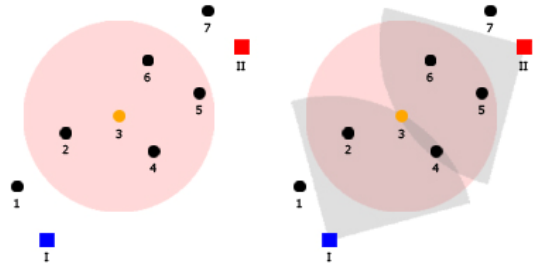

Figure 1 - Robot groups all other objects to determine the priority

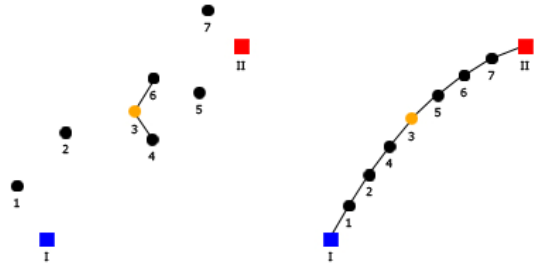

Figure 2 - Robot moves based on the priority

Figure 1 above shows that robot firstly group all other objects in the working environment to determine the priority of each to it. Since the capability of robot to recognize objects in its surrounding is limited, robot will just group objects within its sensing area. This is represented by red circle in left side of figure 1.

As there are two points to be connected through the communication link, robot will create two different groups; the first is the group that will help it connects the 1st target, and the second is the group that help it connects the 2nd target. This is represented in right side of figure 1.

The next activity to be done is deciding the value of priority for each object. This is determined by using distance heuristic that the closest object will be given highest priority. Robot will then approach the object with highest priority from each group, starting from the highest in the first group and then next to the highest in the second group. If there is no object that is grouped within the first or the second group, the priority will be the first or the second target points themselves.

In addition to this, robot also needs to maintain the connection after it is connected to its priority. This will help application to deploy the communication link between the target points whenever all robots have already reached their own movement priority. It is as shown in the right side of figure 2.

The self-deployment algorithm with connection priority criteria has successfully solved the MRN deployment. However, under certain conditions, this algorithm does not ensure the solution to exist; or if there is any solution exists, it is not guaranteed optimum. In other hand, the existence of any obstacle within the working environment will also obstruct this method to find the expected solution. That is why we will try to utilize APF method in order to solve this problem.

b. Artificial Potential Field

It is mentioned that Artificial Potential Field (APF) method has enormously used in term of robot navigation and motion planning. By building the potential-field map of the working environment, robot can then determine the best trajectory to be followed in order to reach the goal of its movement.
As the positions get closer to the goal, they will be given the lower potential value. However, when the positions get closer to the unreachable places or obstacles, they will be represented with the higher potential value. Then, the best trajectory to reach the goal position will be a trajectory that connects the current position of robot with the goal position that in the same time also contains the lowest potential value. It works since the low potential value in field will attract the robot, while the high potential value in field will distract the robot. Figure 3 and Figure 4 below will show the potential field map in case of one obstacle exist between robot and goal position [9].

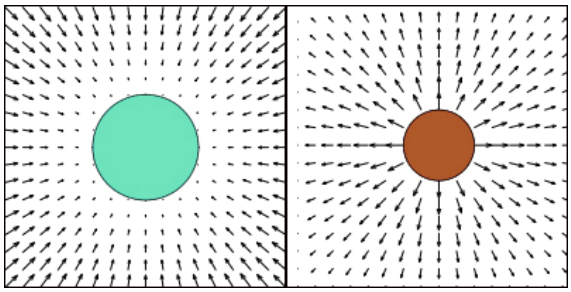

Figure 3 - Attraction from goal position (left) and distraction from obstacle (right)

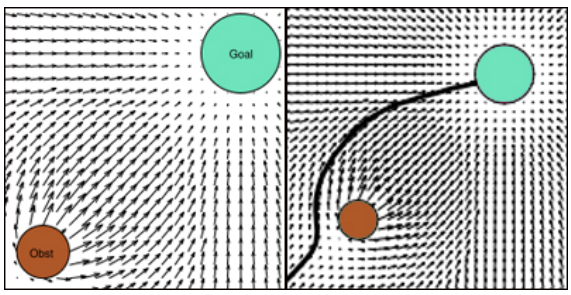

Figure 4 - Attraction and distraction from potential-field value will create directions as trajectories to guide robot's movement

From figure 3 we can see that since robot tends to follow the low potential value, it will create attraction force towards the goal position. It is represented in left side of figure 3 by the arrow that comes into the goal. In the contrary, the distraction force will be created avoiding the obstacles or unreachable position as shown in the right side of figure 3. It is represented by the arrow that comes out of the obstacle. By taking resultant from this both forces as the vector of robot's movement, we will get best trajectory to be followed by robot. It is shown as in figure 4 above.

c. Virtual Force Method

Even APF is expected to be able to find the shortest trajectory for the optimum solution; it still requires information about environment condition in order to generate potential field map. However, in this research we assume that robots do not work within a fixed environment. Therefore, robot first needs to explore its working area in order to get the representation of its circumstances. As the obstacles exist and can obstruct the movement of robots, we will use Virtual Force (VF) method to deal with the problem. This method is actually intended for obstacle avoidance. However, in this research we will exploit the usefulness of this method together with the technique to build the potential-field map in the same time. Figure 5 below is the graphical representation of how Virtual Force works [10].

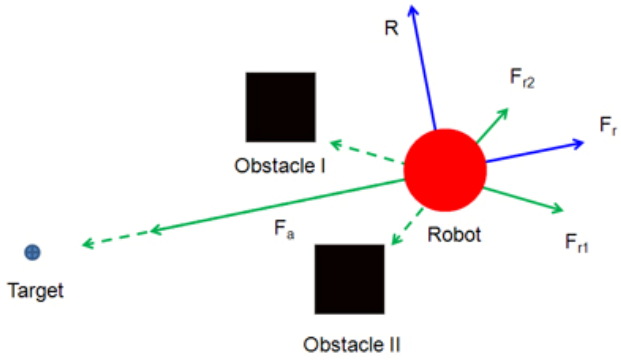

Figure 5 – Virtual force method to avoid obstacle within working environment

From the figure 5 above, robot decides that *R* will be the direction of its movement for the next step. By doing this, robot will be able to avoid obstacle and in the same time to build potential-field map to determine the attraction-distraction force from target and obstacles.

4. FUTURE WORK

This research is actually is still in the progress of development. Through this paper we propose new methods to upgrade the performance of old used method and uplifts the limitation of the research. Recently, the deployment of MRN application still faced the problem regarding to a few number of robot. Here we propose the method to increase the likelihood of finding solution by generating shortest path to be followed to configure the network topology. Therefore, MRN deployment can accommodate solution if the number of available mobile robots is limited.

For the future work, we still need to evaluate the performance of the self-deployment algorithm combined with the utilization of the APF method. In order to do that, we need to develop the simulation and implement the algorithm. Later, we can decide the goodness of this algorithm under several different parameter of experiment. This is expected to bring benefit for the research progression and later we can move on to MRN deployment for multi-points communication link.

5. CONCLUSION

The deployment of MRN application is being investigated through this paper. The research itself has been conducted in several phase of implementation. In previous time, the algorithm for configuration process has been established, called self-deployment algorithm with connection priority criteria. In present time, we are going to observe a new way to optimize the algorithm in terms of the success rate of network deployment in minimum number of robots are used. Here we propose the use of artificial potential field method that once is developed to guide autonomous mobile robot in navigation planning. The proposed method is expected to bring optimum solution.

ABSTRACT

GPS precision is excellent in long distance measurement, while it is poor in short distance measurement. IMU (Inertial Measurement Unit) has a different properties, it is excellent in short distance measurement, while it is poor in long distance measurement. Hence, the advantages of both sensors are being integrated by INS (Inertial Navigation System) algorithm using high speed microprocessor. Before being tested in a rocket flying, IMU v2.1 is tested in vehicle. IMU v1.2 has been integrated and a laboratory and field testing with vehicle. The result of this prototype for a while has shown that HPF could result in output stabilization to 0 g (gravity) or in 2.5 volt. Small value of capacitor in second version give fast response to steady position and the characteristics of sensor and signal condition are acknowledged. From this research are identified the amount of noise in zero g state with value ranging from 5 to 12 bit.

Keywords: *Accelerometer, Rate-Gyroscope, 6DOF IMU, INS Algorithm*

1. INTRODUCTION

Natural navigation has exists since thousands years ago in the life of animal or human. Bird, bee, fish and almost all kind of animal use their animal instinct for navigation to recognize their feeding ground and where their live and human who has the intelligence use sun and stars as natural navigation to know their direction and position. [7].

The aim of this research is to determine the level of accuracy between data from the GPS (Global Positioning System) and data from a prototype of IMU (Inertial Measurement Unit) which will be developed as a device for the INS (Inertial Navigation System) algorithm.

INS algorithm that will be developed use for rocket navigation. Later the testing phase in the rocket system, the algorithm testing is done first on the vehicle. Then testing is done using a vehicle with assumption that vehicles move on the surface of the earth that has matrix transformation in the coordinate of body or object reference , which then will be converted into account the reference system to change altitude or coordinate of earth reference .

Previous researches have been done by several people with the object and too many different of research focus. Walchko in 2002 write a paper, which title low cost inertial navigation: learning to integrate noise and find your way, the research has the accuracy of the GPS errors that can be used to reach 10-15 meters per second or equal to 95% in the second [4].

Real-time navigation, guidance, and control of a UAV (Uninhibited Aerial Vehicle) using low-cost sensor which write by Kim et.al on 2006 implemented INS/GPS for GNC (Guidance, Navigation and Control) system on UAV [3].

Design and error analysis of accelerometer-based inertial navigation system, Tan and Park (2002) design INS to computer linear and angular motions of rigid body uses only accelerometer on this paper [2].

Kumar 2004 write that Integration of INS and GPS using Kalman filter with a research focus on creating a INS simulator, where the output GPS processed on FPGA (Field Programmable Gate array) and integration IMU and GPS output processed on DSP (Digital Signal Processing) [10].

Simulation launch vehicle rocket AtlasIIAS also use the INS and the integration of GPS, such as in the paper written by Istanbulluoglu in 2002 [5].

Schumacher (2006) write about the Integration of a GPS aided Strap down INS for land Vehicle, The estimation accuracy and error state of INS be formed and analyzed by EKF (Extended Kalman Filter) [1].

Hjortsmarker (2005) write the experimental system for validating GPS/INS algorithm Integration, which aims to calibrate INS and GPS using the jet coaster so easily be described into three-dimensional space [6].

From some of the above research, this research attempts to analyze and compare the results of INS algorithm experiments testing to use the real-time rocket and a few test vehicles over the (pedestrian), the bicycle, and on the motorcycle with smallest estimation error. Long-term goal of this research is to give a large contribution to missile or guidance rocket at National Institute of Aeronautics and space (LAPAN).

2. INS ALGORITHM

INS or have also a call with INU (Inertial Navigation Unit) consists of several important components in the navigation, which are as Altimeter sensor altitude, GPS navigation as a reference, and IMU (Inertial Measurement Unit) which consists of a sensor and rate-gyroscope and accelerometer sensors added with one component that is most important algorithms Inertial Navigation System (INS), which function as our algorithm to combine the two navigation systems so that the speed and accuracy of the data navigation system can be more accurate. Two navigation systems are the combined GPS and IMU are both similar but not identical in terms sampling data. GPS is a tool for the navigation system based on satellite, while the IMU is not based on satellite but using the body frame and the navigation frame (earth). Altimeter on this research is not used with assume that using sensors accelerometer and three axis rate-gyroscope altitude will obtain from two sensors [8].

(Equation 1) is velocity equation to convert a velocity from body angle (p, q, r - deg / sec) to earth coordinate (– deg), where *c* is *cos* and *s* for *sin*.

$$\begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{bmatrix} = \begin{pmatrix} 1 & s\varphi\ tan\theta & c\varphi\ tan \\ 0 & c\varphi & -s\varphi \\ 0 & s\varphi\ sec\theta & c\varphi\ sec \end{pmatrix} \quad (1)$$

By integration of the above equations we can derive the Euler angles using initial conditions of a known attitude at a given time. But, for pitch angles around ±90°, the error becomes unbounded as tan tends to infinity. Quaternion algebra (equations 2-7) comes to the rescue here. We use four parameters, called the Euler parameters, which are related to the Euler angles as follows [10].

$$\dot{e}_0 = -\frac{1}{2}(e_1 p + e_2 q \quad (2)$$

$$\dot{e}_1 = \frac{1}{2}(e_0 p + e_2 r \quad (3)$$

$$\dot{e}_2 = \frac{1}{2}(e_0 q + e_3 p \quad (4)$$

$$\dot{e}_3 = \frac{1}{2}(e_0 r + e_1 q \quad (5)$$

with the parameters satisfying the following equation at all points of time.

$$e_0^2 + e_1^2 + e_2^2 + e \quad (6)$$

The above equations can be used to generate the time history of the four parameters e_0, e_1, e_2, and e_3. The initial values of the Euler angles are given which are used to calculate the initial values of the four parameters using the following equations.

$$\bar{e} = \begin{bmatrix} c\frac{\varphi}{2}c\frac{\theta}{2}c\frac{\phi}{2} - s\frac{\varphi}{2} \\ s\frac{\varphi}{2}c\frac{\theta}{2}c\frac{\phi}{2} - c\frac{\varphi}{2} \\ c\frac{\varphi}{2}s\frac{\theta}{2}c\frac{\phi}{2} - s\frac{\varphi}{2} \\ c\frac{\varphi}{2}c\frac{\theta}{2}s\frac{\phi}{2} - s\frac{\varphi}{2} \end{bmatrix} \quad (7)$$

Once we have calculated the time history of the four parameters, we can calculate the Euler angles using the following (equations 8-10).

$$\theta = sin^{-1}[-2(e_1 e_3 - \quad (8)$$

$$\varphi = cos^{-1}\left[\frac{e_0^2 - e_1^2 - e_2^2 + e_3^2}{\sqrt{1-4(e_1 e_2 - e_0 e_3)^2}}\right] sign[2(e_1 e_2 - \quad (9)$$

$$\psi = cos^{-1}\left[\frac{e_0^2 + e_1^2 - e_2^2 - e_3^2}{\sqrt{1-4(e_1 e_2 - e_0 e_3)^2}}\right] sign[2(e_1 e_2 - \quad (10)$$

The accelerations (*ax*, *ay* and *az*) of the aircraft along the three body axes, as read by the accelerometers, are given by the (equations 11-14). *U*, *V*, *W* and *p*, *q*, *r* are all available as states. If the acceleration dues to gravity (*g*) model which supplied as a function of location around the earth, then $\dot{U}, \dot{V}$ can be calculated.

$$\dot{U} = a_x + V_r - w_q + \quad (11)$$

$$\dot{V} = a_y - U_r + w_p - g\ cos \quad (12)$$

$$\dot{W} = a_z + U_q - V_p - g\ cos \quad (13)$$

The actual angular rates given by (equation 16), where and is given by (equation 14 and 15).

$$\Omega = \begin{bmatrix} \Omega \\ \_ \end{bmatrix} \quad (14)$$

$$\omega^{i} = \begin{bmatrix} \mu \\ \_ \end{bmatrix} \quad (15)$$

$$\begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} p \\ q \\ r \end{bmatrix}_{m} - DCM[i \quad (16)$$

DCM is the direction cosine matrix (transformation matrix), to converting from the local earth or navigation frame to the body frame, given by (equation 17), where *c* is *cos* and *s* for *sin*.

$$DCM = \begin{bmatrix} c\theta c\psi & c\theta s\psi \\ s\theta s\varphi c\psi - c\varphi s\psi & s\varphi s\theta s\psi + c\varphi c\psi \\ s\theta c\varphi c\psi + s\varphi s\psi & c\varphi s\theta s\psi - c\varphi s\theta \end{bmatrix} \quad (17)$$

$$\begin{bmatrix} \dot{X} \\ \dot{Y} \\ \dot{Z} \end{bmatrix} = \begin{bmatrix} V_N \\ V_E \\ V_D \end{bmatrix} - DCM \quad (18)$$

Let and *H* denote the latitude, longitude and height of the aircraft at any instant, then rate of change of latitude is given by (equation 19-21).

(19)

$$\mu = \quad (20)$$

$$\dot{H} \quad (21)$$

3. DESIGN OF SYSTEM

From previous section above diagram block can be described as found in the research (figure 1) following.

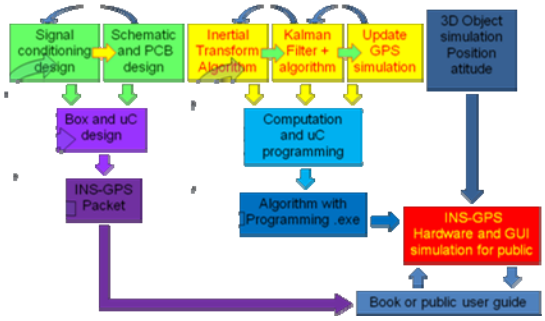

Figure 1: Research plan

This paper is a small part of the research and the beginning of the new algorithm to test the vehicle before entering the next stage in the test with roller coaster, aeromodeling, aircraft, and is implemented directly with the guided rocket at LAPAN. On this research, as there is on (Figure 1) is divided into several stages, including the hardware design, software design in the form of algorithms, box design, simulation software and user guide for public.

In the design of hardware system, IMU v2.1 is designed to experiment with the slow speed for pedestrian, bicycle, motorcycle or car. Previous version of the hardware has been tested and has been published [9].

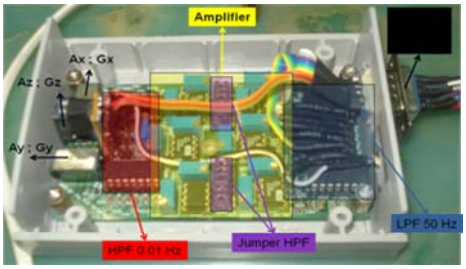

Figure 2: IMU v2.1 and signal processing board

For the data, the microprocessor is used to separate the IMU system because it is still in the experimental stage and should be used to replace the processor. Type of microprocessor used is ATMega8 and ATMega32, depending on the needs and the length of the algorithm is tested.

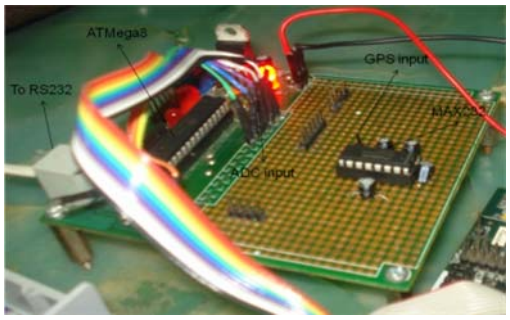

Figure 3: Microprocessor and Max232

Signal conditioning (figure 2) comprises two filters, LPF (Low-Pass Filter) and HPF (High-Pass Filter), which each has custom-made to the needs of the experiment on slow speed. While the amplifier used to increase the output of the sensor. Following (Figure 4) is a schematic of a series of HPF.

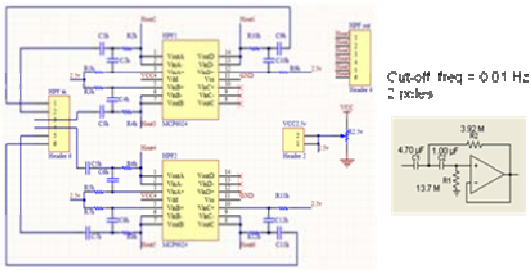

Figure 4: HPF schematic

HPF function to reinstate the position to state the value of 0 g in the system hardware is positioned on the 2.5 volt and also serves to identify the type of changes that occur on the sensors, motion sensors based on whether the real or move because there is a adjust in the position sensor on the body frame coordinate. While the LPF as a function of the output filter sensor. Output from the sensor is not pure value of the sensor but there is noise, bias, and drift of the sensor involved and strengthened, and also to the output system.

Noise, bias, and drift will be removed by digital filter with the following increase and provide initial value and some of the parameters in the algorithm so that navigation is no longer calculated the effects of the hardware system. Following (figure 5) is a schematic of a series of LPF.

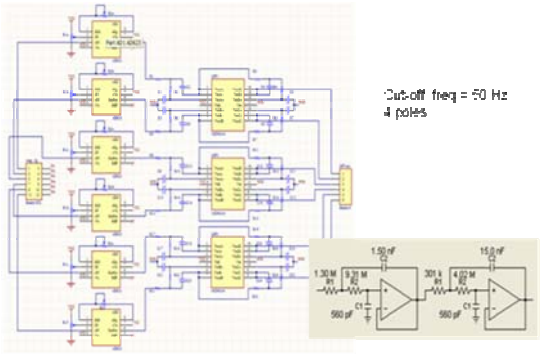

Figure 5: LPF schematic

4. RESULT AND DISCUSS

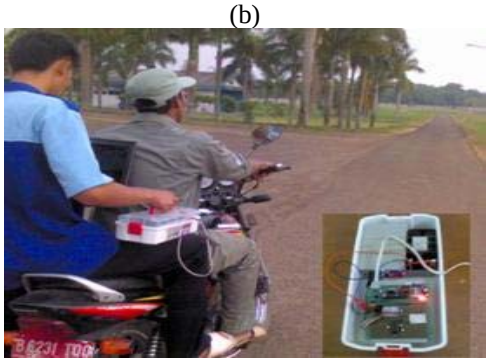
Research was conducted at guidance and control laboratory. The position of the data as indicated in (figure 6). The data begins when the GPS lock already, start from point 1 to point 2 and then back to point 1

Figure 6: Location collect data

The file saved with different name, this is meant to not only the data stored in each trial but the two data. Only changes the position change. Following (figure 7) is a 6DOF IMU and GPS v2.1 that have been equipped with the INS algorithm for the transformation matrix from body frame to inertial frame or navigation frame.

(a)

(b)



(c)

Figure 7: Testing 6DOF IMU+GPS with pedestrian (a), bicycle (b) and motorcycle (c)

In steady state conditions 6DOF IMU output range is between the following:

ax = 509 to 521 = 12 bit
ay = 511 to 516 = 5 bit
az = 759 to 769 = 10 bit
p = 508 to 515 = 7 bit
q = 484 to 531 = 47 bit
r = 508 to 517 = 9 bit

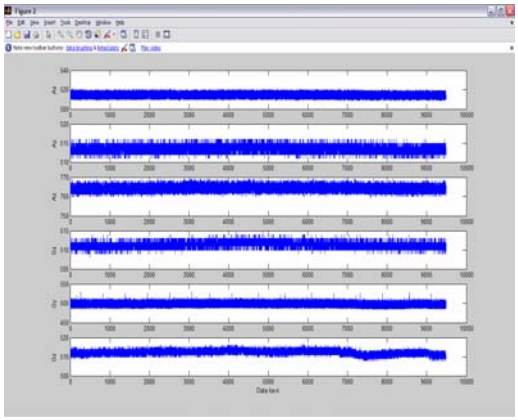


Figure 8: Output 6DOF IMU silence state condition

The value of voltage reference is set on the first, so that the reference voltage and balanced and are between 0 g (see section 3 paragraph 5). 6DOF IMU output value can be seen in (figure 8). Data from the noise, the noise and the big changes of each individual sensor will affect the size of the gain of the amplifier in the signal conditioning.

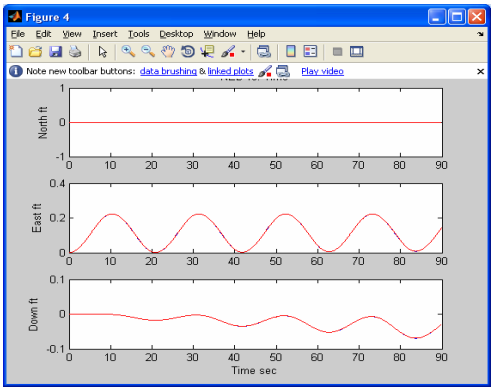

Figure 9: North East and Down Position

The collect data at the time of the vehicle generally will be shifting for initialization, because of the sensor effects. Data for test results by pedestrian, by bicycle and by the motorcycle, do not shown because it can still need to be developed with Kalman filtering. Analysis of data testing will result in the first study on the LAPAN progress report. Here is a picture of output of IMU is converted in the form of position. (North, East, and Down) (Figure 9) and (X, Y and Z) (Figure 10).

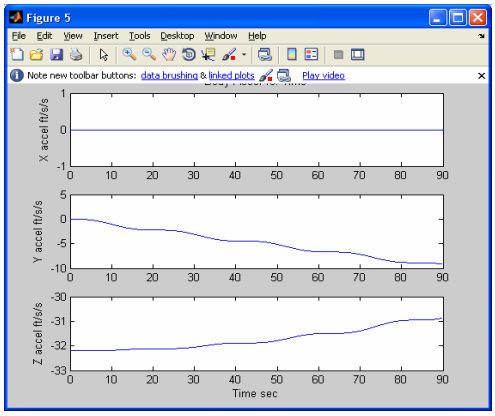

Figure 10: X, Y, and Z position

5. CONCLUSION

IMU v2.1 has been successfully developed and has been tested at low speed with three ways the data is different, with pedestrian, bicycle, and motorcycle. From the results of the experiment may be the characteristics of each and can be the difference in the gain amplifier for each series how the data. Strengthening pedestrian for more gain compared with the bike and compared with the motorcycle. Conclusions from this knowledge need to be research by changing the parameters of gain that have been done on this research and with the effect of noise, drift, and bias of sensor. Small value of capacitor in second version give fast response to steady position and the characteristics of sensor and signal condition are acknowledged. From this research are identified the amount of noise in zero g state with value ranging from 5 to 12 bit. Changes in output at the time the data was due to the effects of drift and bias on the noise.

ABSTRACT

Insulation issue is one of the most important things in electrical system distribution. Polyethelene Vynil Chloride (PVC) insulations are widely used as cable insulator in electrical installation because of its good characteristic especially for low voltage application. PVC is light and has high resistance which is suitable for insulator. However, PVC has limited working temperature. The working temperature of PVC is 70°C, its mean that if PVC cable is worked at high temperature (higher than 70°C) the PVC insulator will damage and furthermore it can melt.

We observe the degradation of PVC cable when it operates at high temperature and when the PVC cable starts to melt. We also investigate on what condition this melting may cause a fire. For that purpose, we conducted experiment by applying current to PVC cable 2 x 1.5 mm² using high injection current test. While applying current to the PVC cable, we monitor and record temperature rise on PVC cable every step of current level (every 5 ampere) and then examined the degradation and physical change that is happened to insulator material (PVC) and core.

The results show that the higher current flow is given, the faster cable insulation damage. Conditions in which the cable starts to melt down vary for each cable. For a straight cable, insulation start melt down at 56 A. For a curved cable, insulation start melt down at 54 A.

Keywords : *Insulator, thermal characteristic, PVC Cable, overload operation, maximum temperature.*

1. INTRODUCTION

Insulation issue is one of the most important things in electrical system distribution as its electical and mechanical functions. If the electrical functions break, the electricity supply would stop. Thus, it's necessary to use insulators that are qualified and reliable in an electric power systems to reduce the losses due to disfuction of insulator.

Polymer insulator has the characteristics which are suitable for the demand and fulfill the standard requirements. Besides, it is also having good mechanical and electrical properties,- like lightness, the low of dielectric loss, the low of dissipation factor and the high of resistivity volume. The other advatages of this kind of insulator are easy to be produced and quite cheap if compared with other kind of insulators.

However, the polymer insulators have also the limitations. One of them is its heat resistivity causing the insulator easy to melt down if it's operated on high temperature. At certain condition, the insulator applied in the cables will melt down and finally it will be burned. If arround the cable exists the burnable materials, it will initiate fire. This study investigates the assessment for PVC insulator above its current carrying capacity (CCC) to recognize the insulator degradation.

2. THEORETICAL OVERVIEW

If the temperature rise, the polymer insulator properties may change. This is because the temperature change causes molecular movement inside the insulator material. As the result, structural properties may be altered. If the oxygens and water exist, it will react each other and result in depolymerization, oxydation, and hydrolisys. These will of course change its mechanical, electrical and chemical properties. In this section, we investigate the thermal conductivity, thermal capaicty, heat rate, and expansion coefficient caused by the molecular movements due to increased glass transition temperature (T_g) which consists of melting point temperature (T_m), softing point, and thermal resistivity. Thermal resistivity of polymer material can be seen in Table 1 :

Table 1. Thermal resistivity of Polymers

Polymers	Thermal Resistivity (°C)
Polietilen(low specific mass)	80-100
Polietilen(medium specific mass)	105-120
Polystiren	65-75
Polyvinil chloride	65-75
Resin fenol	150
Resin melamin	160
Resin Urea	90
Polyetilen(high specific mass)	120
Polypropilen	120
Polycarbonate	120
Polyamid	80
Polysulfon	100

2.1 The effect of Curved angle and radius

Figure 1 shows the effect of curved radius R_o against conductor's maximum temperature. The conductor we used in this study was 1 mm in diameter. We got that the critical current (I_{cr}) we applied for straight conductors was 69 A. When the conductor was given 50 A, and curved angle α = 90° at curved Radius R_o = 2 mm, the maximum temperature (T_{max}) will be higher than that of straight conductor. As the curved radius R_o rises, the maximum temperature T_{max} will decrease. The T_{max} with curved angle 90o can be stated as equation below :

$$T_{\max,90}(^{o}C) = -20.56 \ln Ro + 283 \quad (1)$$

The equation (1) can be drawn as a graph below :

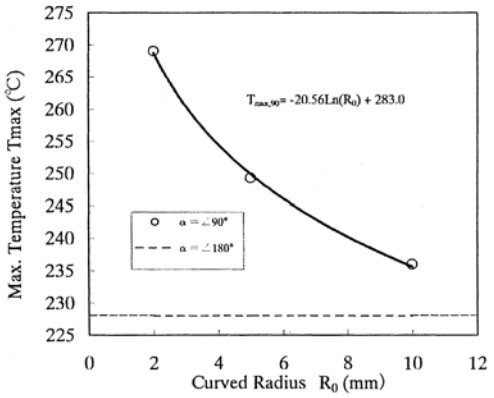

Figure 1. The Effect of R_o against T_{max}

Figure 2 shows the effect of curved angle against maximum temperature of conductor. As the curved angle rises, the maximum temperature decreases.

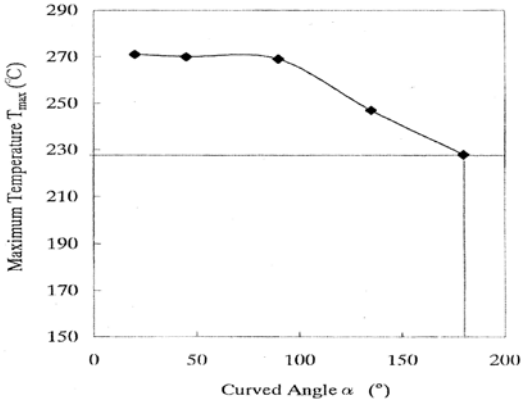

Figure 2. The Effect of α against T_{max}

3. METHODOLOGY

3.1 Measurement Equipments

The measurement equipments of this study consist of :

1) High Current Injector Test Set
2) Voltage AC 220 V
3) Ampere meter
4) Thermocouple
5) Stopwatch
6) Connector cable with capacity of 500 A

3.2 Measurement Circuit

In the experiment, we measured 3 kind of cables; straight cable, curved cable, and non-standard cable. The experiment was carried out by flowing current above its current carrying capacity (CCC). The temperature changes are measured by thermocouple. Figure 3 shows the measurement circuit for increased temperature.

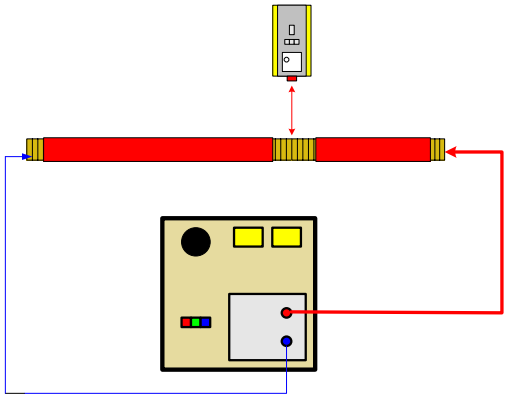

Figure 3. Measurement Circuit for Increased Temperature

4. RESULT AND ANALYSIS

Figure 4 shows the measurement for the straight cable including the temperature at surface insulator, core insulator, and core of conductor. Meanwhile, Figure 5 shows for the curved cable. Figure 6 shows the comparison of straight and curved cable current vs. temperature. We found that the curved cable will start to be smoked when it's given 46 A with the temperature of 156 °C and melt down at 54 A with the temperature of 295 °C. Meanwhile, the straight cable will be smoked at 48 A and melt down at 56 A. Table 2 shows the details of measurement.

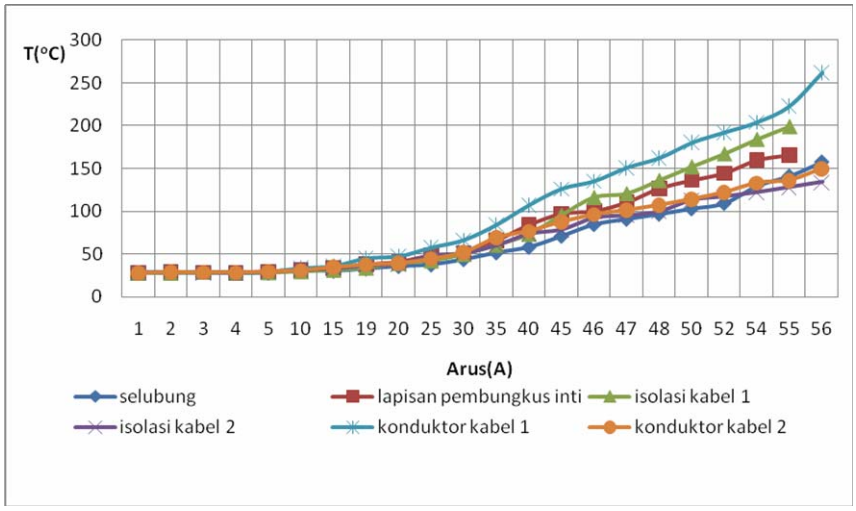

Figure 4. Current vs Temperature on the Straight Cable

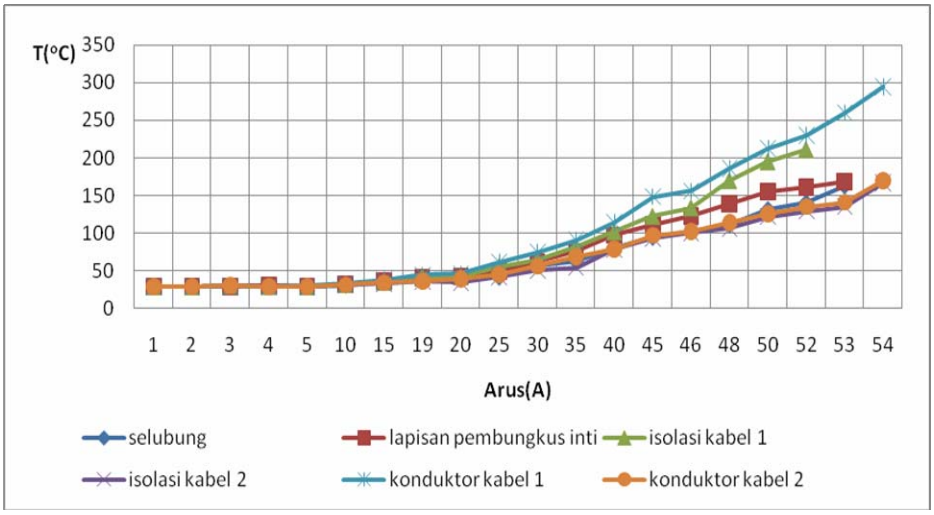

Figure 5. Current vs Temperature on the Curved Cable

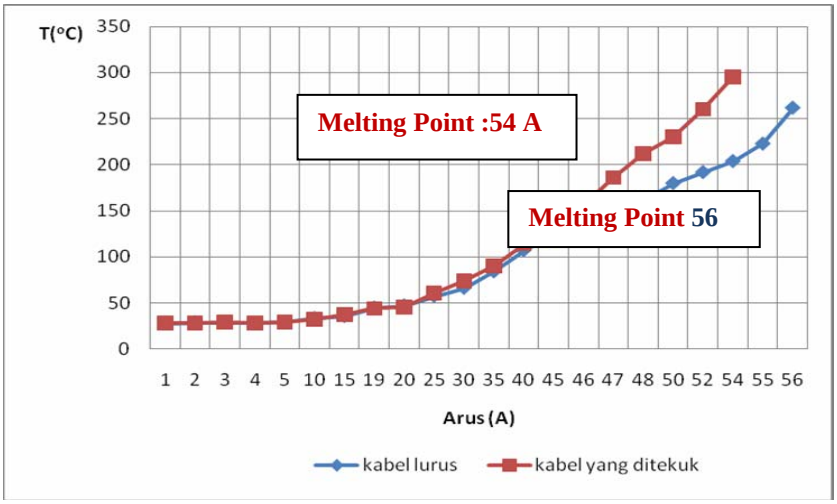

Figure 6. Comparison of Straight and Curved Cable Current vs. Temperature

Table 2. Comparison of Straight and Curved Cable

Current (A)	Tcr Straight Cable (^oC)	Cable Condition	Tcr Curved Cable (^oC)	Cable Condition
46	135	-	156	√
48	162	√	186	√
50	180	√	212	√
52	192	√	230	√
54	204	√	295	×

√ = Smoked × = Melting

According to the measurement, it can be seen that at the same current, the curved cable has higher maximum temperature than straight cable. The temperature distributions on the curved cable are not same. The temperatures are recorded high at the curved section.

5. CONCLUSION

The thermal characteristics of NYM 1.5 mm^2 cable has been investigated. The results show that the higher current flow is given, the faster cable insulation damage. Conditions in which the cable starts to melt down vary for each cable. For a straight cable, insulation start melt down at 56 A. For a curved cable, insulation start melt down at 54 A.

ABSTRACT

This paper introduces a low cost internet telemetry system for controlling and monitoring machines overseas. The system is developed to accommodate the needs of medium scale manufacturing companies so that the design must consider both technical and economical aspect. Unlike the common telemetry systems that implement a client - server communication model, this system uses a client – server – client model. This telemetry communication model is appropriate for controlling and monitoring many slaves that are located in different countries and it can be implemented using a low cost internet service such as a web hosting. Applying this system means creating a value added product and decreasing significantly the cost of after sales services.

Keywords

Internet Telemetry, Control, Manufacturing, SME, web-hosting

1. INTRODUCTION

Manufacturing is a type of industry that is capable to export products. That means a contribution to increase the foreign exchange for Indonesia. One of medium scale manufacturing companies develops machines for food and pharmaceutical processing. After being successful in the domestic market, those machines are exported to several countries such as ASEAN, Middle East and recently Turkey [1.]

Once a machine operates in a foreign country, the company needs to maintain an after sales service. The frequently task is to customize the parameters of the machine according to the demand of customers. Additionally, there is also a requirement that the parameters such as motor speed, gas pressure and chamber temperature need to be monitored all the time to prevent the failure of a product output. Then the company has to send the technicians overseas. According to the company record, there were 10 (ten) after sale services in 3 (three) months in the year 2008. Unfortunately it means a high cost for the company, especially if some machines from the different locations in overseas need to be customized in the same time. Another problem occurs when they apply for an entry permit. It may take several days until weeks to get it. This could affect the credibility of the company because clients need to be treated on time. Most of clients do not know even do not want to know about the permit processing for Indonesian.

A solution for the problem above is to develop a system that is able to monitor the machine parameters remotely. This system is usually called telemetry. A telemetry system is effective and beneficial since it enables 24/7 monitoring, the trend of the parameters of the machine can be online analyzed so that an anticipation against the failure can be taken immediately. For a specific case, a remote parameter setting can be done. However, to do this, a precaution must be taken, especially if the remote process could be danger for human being and environments.

Indonesia has already a national standard in telemetry. It can be seen for example in [4.] The standard is an adoption of the IEC. However, the application of this standard may focus on power distribution line. A publication of this topic can be seen in [5.]. The use of internet for telemetry in power distribution line was introduced in the work of Eichelburg [3.]. He proposed GPRS to connect outlying distribution station with the availability up to 99%. In the commercial area, a remote monitoring has been practiced for a vending machine [2.]. A device is embedded in the vending machine. The device sends machine's condition to a server that belongs to the vendor over GPRS. The owner of the vending machine now connects to the server via internet to check the condition of the vending machine. That inspired us to develop an internet telemetry system

The use of a telemetry system will benefit the company very much. It avoids sending technicians abroad which means reducing the operational cost significantly. In addition, the after sales service can be done on time. However, a cost reduction through the implementation of the telemetry system should not significantly increase the price of the machine and the cost for operating the telemetry system. Otherwise, the

ISSN 114-1284

system would be unused. According to that, the design of a telemetry system must consider both technical and economical aspect.

2. METHODOLOGY

The challenge in the development of this telemetry system is the necessity to consider both technical and economical aspect at the same time. From the economical aspect, it requires the acceptable ratio between the prices of the machine with telemetry system with that of the machine without it. From the technical aspect, the master controller and the controlled slave machine are separated in a very long distance and are not located in the same country. Furthermore number of exported machines may increase.

For the reason above, it is almost impossible to establish a private communication infrastructure. The possible connections are the public phone line and internet. However the use of a direct phone line is not economical solution because the connection is an international connection. So, the internet would be the possible connection.

.There is different kind of internet services. Two of them are the virtual private network (VPN) and web hosting. Technically, the VPN is the most appropriate service for this telemetry system. It offers direct connection to the machine and the machine can be treated as a slave. However, the VPN is still not economical. The price increases with the increasing of the number of connections. For the connection overseas, some internet service provider charge more.

The low cost solution is the use of web hosting as the service. The company needs only to purchase a space and database at ISP's server. The size of it depends on the number of controlled machines. We must assume that the customer overseas has already a local area network so that the machine can be connected to the internet without an extra expense. Web hosting is used for instance in mail server such as yahoo™. Two parties that want to communicate each other must put and take the message in the web server. Since the machine can not be approached directly as a slave/server, then we have to modify the communication model as the client – server – client as can be seen in the following figure.

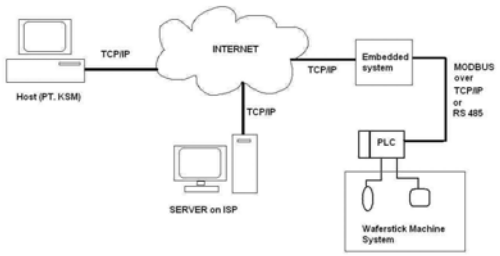

Figure 1: Internet Telemetry Design

Both controllers (in Indonesia) and the machine (overseas) act as a client. In the monitoring process, the machine (as slave client) puts the data into the web server and the controller/observer (as the master client) takes those data and display it. In the setting process the controller/observer puts the data into web server and the machine takes the value and set the parameter according to data. Both clients (controller and machines) initiate the connection. It has an advantage comparing to the client – server model. The local area network where the machine is located does not need to reconfigure the firewall setting because the initiation does not come from outside the network but from the machine itself inside the network.

To implement the client – server – client model through a web hosting service, an interface between the machine and the web server must be developed. The interface can be a single personal computer, an industrial single board computer or even an embedded system. But more important is the development of a program that seeks the address of the web server automatically.

2.1 Sections and Subsections

3. EXPERIMENTS

We limited the experiment so that there is no operating machine because there was no machine available at the moment. Instead of it, we used only a PLC that controls the machine locally. It is justified because the value of the speed of the machine is determined by the PLC.

In the experiments, a system according to the Figure 1 is implemented. All operating systems including the web hosting is a free open source such as Ubuntu©. At the master client a personal computer/notebook with a common specification is used. The function is to display the monitored machine's parameters.

The web server belongs to an internet service provider. Although there are many international ISPs that offer web service cheaply, however an ISP in Indonesia is preferred. When there is a problem with the server/connection, then it is

more convenient and also inexpensive to contact the ISP in Indonesia. The web hosting provides a customized database system. A relational database is programmed using Mysql. An example of the database is shown in the table below:

Table 1:Information about the machine

Field	Type	Null	Key	Default
IDMesin	varchar(12)	NO	PRI	Null
Location	varchar(50)	NO		Null
Other info				

Table 2: Machine's parameters

Field	Type	Null	Key	Default
IDMesin	varchar(12)	NO	FK	Null
DateRead	Date/Time	NO		Null
DateRecv	Date/Time	NO		Null
RpmAdonan1	int			
RpmAdonan2	int			
Other params				
….				
TimeStamp	Date/Time UTC			
Counter	int			

The primary key is the ID machine. There are 23 parameters to be controlled, such as the speed of motors, pressure and temperature. This set of parameters will be sent together. A counter differentiates a set of message and another. Time stamp can be defined by users to determine how often the machine will update its parameter.

At the slave client, an embedded system connects the machine to the internet. In the practice, the machine is controlled locally with a programmable logic controller (PLC). In the experiment a PLC M340 from Schneider Electric is used. The embedded system talks to the machine via PLC using a Modbus protocol. At the early stages of experiments a personal computer substituted the embedded system.

The scheme of the implementation program can be seen in the following figure:

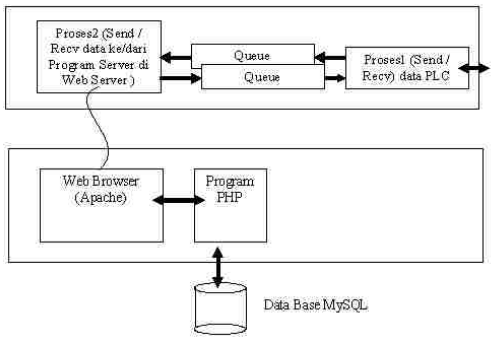

Figure 2: Program scheme

The first block is the program that is developed in the embedded system. There are two sections in the program. The first section communicates with the PLC and the second one connects to the web server. The web browser itself connects data base using PHP.

In the experiment, we developed a simple program that the output of PLC increased its value every 2 minutes and after a defined threshold it reset the value and began to count again. The outputs simulate the speed of motors. Time stamp of telemetry system was set to 1 minute. Then the telemetry system began to monitor and occasionally a parameter change was conducted

4. RESULT AND DISCUSSION

To access the web server, we connect directly to the ISP's web address. In the real application it is strong recommended that the company purchase a domain name so that the access to the web server independent on the change of IP server of the ISP. The picture below shows the connection to the web server that was done by the master client. Values in the left column indicate the value of the output of PLC. For example the speed of 1st motor for *adonan* is 5 rpm at 12:39 pm. The values at the right are the last setting.

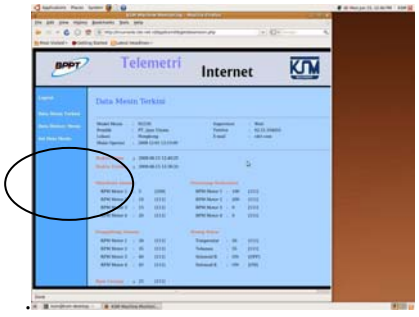

Figure 3: Monitored data at master client (bottom picture was zoomed).at 12:39 pm

To approve the consistency between a monitored value and the real value inside PLC, then we displayed the parameter of PLC using a Unity© vendor specific software.

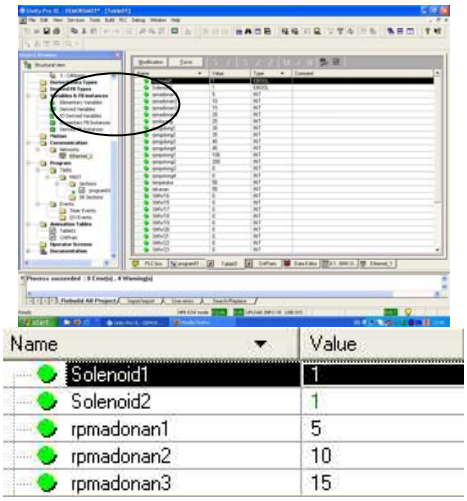

Figure 4 real values inside PLC at 12:39 pm

As can be shown in the picture above, all the real and monitored values are the same. Then in next 2 minutes (12:41 pm) the PLC increased the values as is shown below:

Figure 5: real values inside PLC at 12:41 pm

The speed of motor of *adonan* became 7 rpm. In the master client through web server, all monitored values changed.

Figure 6: Monitored data at master client .at 12:39 pm

Setting process was conducted by the master to specific motors, for instance the speed of 4 motors for cutting (Indonesian: *pemotong*). For setting up parameter, the value must be placed first in the memory address before being transferred to the output. This is important because in the practice, the machine is not in view. There is a risk that the setting may cause an unexpected activity. To minimize the problem, the value must be change gradually and placed in another address other than of output. After the PLC sends back the value to the server, then a real setting can be applied.

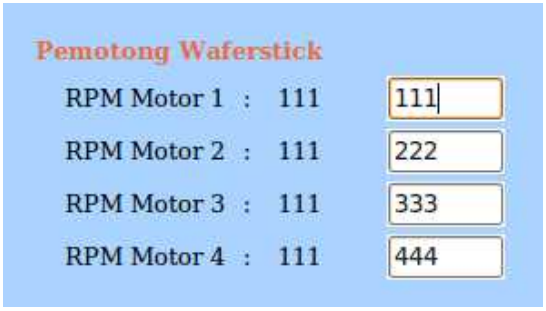

Figure 7: Parameter setting at the master client

As can be seen in the picture using Unity software, the set values were placed in a memory address in the PLC (%MW24 -27).

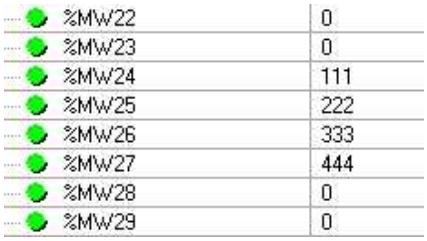

Figure 8: the real value inside PLC

Finally, the process inside the embedded system is documented and for the analysis can be accessed, as shown in the picture below:

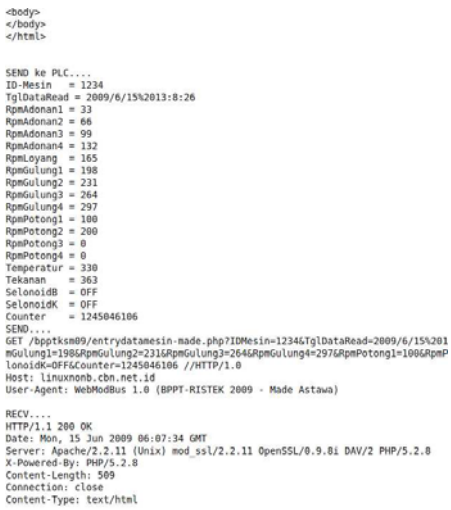

Figure 9 The process inside the embedded system

5. CONCLUTION

Web hosting, as an internet service, can be adapted to implement a low cost telemetry system. With the system, one can monitor and control every where as long as there is an internet connection. A new approach of communication model is a client – server - client model. According to the result of the experiments, the system works properly.

This application has advantages. Firstly, it reduced significantly the cost of after sales services. Secondly, the company has a competitive value added product. Finally all machines can be 24/7monitore so that an early anticipation can be made against the failure. It increases the level of client's satisfaction.

Even though there are some issues that still need to be considered and to be worked out. They are the security and reliability measurement of data. It needs some intensive work in the next step of the research.

ABSTRACT

This paper introduces a self developed prototype of ADSB receiver. According to International Civil Aviation Organization (ICAO), ADSB technology is considered to substitute radar systems. The purpose of the development of this ADSB receiver is to assess the new technology and to endorse domestic industries. The work includes building the down converter, signal conditioning and message decoding. Since there is a large amount of messages, this paper it does not describe message decoding. At the end it can be concluded that it is highly possible for domestic industries to develop such an ADSB receiver.

Keywords:

Surveillance, broadcast, radar, extended squitter.

1. INTRODUCTION

Radar systems will be substituted by an Automatic Dependent Surveillance Broadcast (ADS-B) system. In contrast to radar system where an aircraft will be scanned and identified by radar, in this new system, an aircraft sends signals (ADSB signal) to the ATC tower actively. It has an advantage that below a certain flight level the aircraft still sends information while radar can not detect it because radar has a fix angle position. In addition, the aircrafts are able to communicate to each other. Furthermore, the operational cost of ADSB is much lower than that of a radar system.

South East Asia nations and Australia are committed to implement the ADSB system. Indonesia needs to adopt this new aviation system. Otherwise the air space over Indonesia is going to be controlled by another country that has implemented the ADSB system. Additionally, Indonesian aircraft may have low priority of service when entering the ADSSB ready country.

Indonesia has relative bigger airspace than all South East Asia nations. To cover the airspace, Indonesia needs to provide a large number of ADSB systems. In a report [1.] of ICAO meeting, 30 ADSB stations will be installed in 2010. Thus it is a potential market for ADSB system providers. All providers are from foreign countries. A problem may occur if their systems are not interoperable. This could happen, since each provider has their own protocol communication in the end system. Additionally, it is important to endorse domestic industry to have knowledge about this new technology so that they are capable develop such system and to maintain the system operation.

Considering the problem above, it is important to assess this new technology, before its implementation. Beginning with study of aviation standard documents, working papers of ICAO workshop we develop such system as a test bed.

ADSB system may include three sub-systems. Those are transmitter-receiver, data link, and network sub system. Since the scope of works is so wide the first approach is focused on an ADSB receiver as the front end system

2. THEORY AND SPECIFICATION

ADSB message [2.] is encoded in 112 bits with the format that is shown in the table below.

Table 1: ADSB Message Format.

Downlink Format (bits)	Target Address (bits)	Message (bits)	Parity Check (bits)
8	**24**	**56**	**24**

First five bits in the downlink format field indicate either the data is an ADSB message or another one. The ADSB message is encoded in “10001” and “10010” or equal to 17 and 18 decimal respectively. A 24 target address is an address that is assigned by the aviation authority as can be seen in the ICAO document [4.] Next field consist the information of the flight. Since there is only 56 bits for message encoding, the complete information must be divided into groups and then transmitted separately. There are 32 groups of message including position, velocity and aircraft status. The determination of 32 groups is accommodated in first five bit of 56 bits message field. The last field contains 24 bits for error detection. It is done by using CRC. The polynomial for the divisor can be found in [3.].

The format of transmitted ADSB data stream according to RTCA document is shown in the picture below. It consists of 4(four) pulses as the preamble and 112 pulses as data. All pulses have duration of 0.5 us with the tolerance at 0.05 us. The second, third and forth preamble pulses are spaced 1.0, 3.5 and 4.5 us respectively from the first preamble pulse. The data block begins 8 second after the beginning of the first preamble's pulse. Like the preamble, the length of a pulse is 0.5 $\pm$ 0.05 us. The data is encoded as using pulse position modulation (PPM) that is often called Manchester encoding. A pulse is transmitted in the first or second half interval of one microsecond tome interval. A time interval consists of a pulse in the first half assigns a “ONE” while in the second half a” ZERO”.

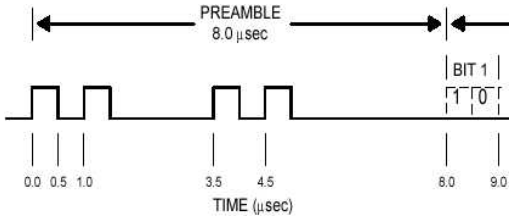

Figure 1: The format of ADSB pulse stream. The preamble.

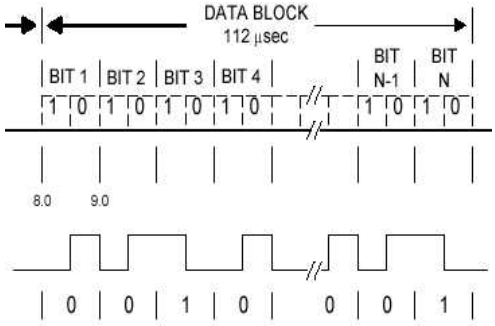

Figure 2: The format of ADSB pulse stream. The data block. PPM encoding.

This data stream is modulated with the frequency at 1090 MHz. A transponder at the aircraft will broadcast the so called the extended squitter.

There are some criteria for the squitter. The important one is the spectrum as can be seen in the Figure 3.

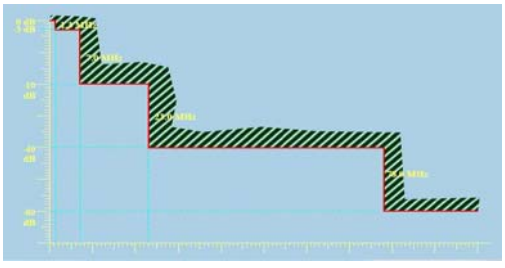

Figure 3: The spectrum of ADSB squitter.

3. DESIGN AND IMPLEMENTATION

To extract and decode the data, a design of the receiver is developed as can be seen in the picture below:

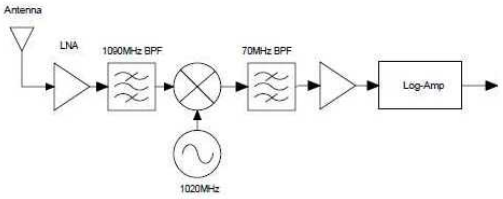

Figure 4: The bock diagram of the receiver (analog section).

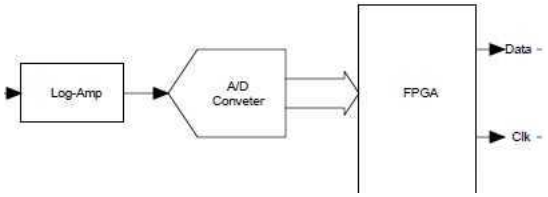

Figure 5: The bock diagram of the receiver (digital section).

The block diagram can be divided into two sections, namely the analog and digital section. The analog section contains a down converter that demodulates the signal. The digital section processes the incoming analog signal so that the ADSB message is validated.

After passing trough a low noise amplifier the 1090 MHz signal will be converted down to an intermediate one. According to the typical spectrum (Figure 3) the signal is demodulated using 1020 MHz signal produced from an oscillator. It represents a bandpass filter with 70 MHz bandwidth inside that is the data signal. The data signal that is still the analog signal is amplified.

Then digital processing begins. The process includes bit confidence determination, preamble detection, retrigerring and ADSB data recognition. First of all, the signal is sampled at 10 MHz. Since a period is one microsecond, then there will be ten sampled value in a period and consequently five sampled value of a pulse. This sample rate is beneficial to determine the bit confidence of PPM code. An alien signal could be superposed to the squitter. It may makes two pulses each in the first and second half interval. In the PPM code that is forbidden. We set so that a valid pulse position (high bit confidence) contains at least 4(four) consecutive sampled values in a half period within a threshold. The threshold is $\pm$ 3 db from the peak. It is under assumption that the interference signal has a short duration of peak time. This has advantage comparing using only peak detection

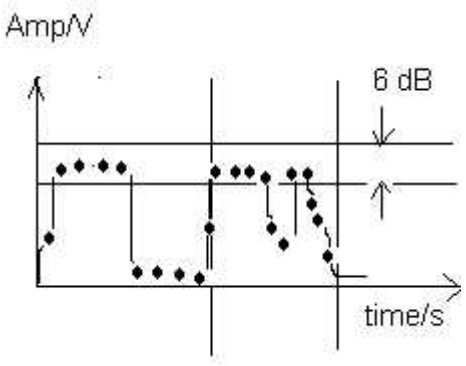

Figure 6: Bit confidence

We can see in the figure that in the first interval the code is clearly ONE. In the second interval, there are two pulses in a period. Using only peak detection, the bit confidence is low so that the data is not valid. However using 10 sample/us, the bit confidence is high. The code is assign as ONE.

Then begin the process to detect the preamble. The process need to recognize the relative transmit time between 4 pulses as it is stated in Figure 2. The pulses must be high confidence. In addition, at least two pulses have a leading edge. It is defined that two consecutive sampled value must be at least 4.8 dB difference for 10 MHz sampling.

It must be reminded that the message from a transponder is a broadcast. It is possible during current preamble recognition, a new but stronger preamble than previous one is detected. Then the new coming preamble must be processed an. If it is valid then the previous message will be discharged. This is a retriggering process that is shown in the Figure 7

Figure 7: The retrigerring

The new coming preamble pulses must be above the threshold area. That is at least 3 dB from the currently being processed preamble pulse. When it is valid then a new threshold must be defined.

The last process is to determine whether the message is the ADSB message or not. According to the previous section, the ADSB message is determined by first five bits of the data. The decimal form of it is 17 or 18. Rather then translating to decimal, it is more efficient if we only inspect the pulses. The binary form of this number has only two bits that its value is ONE. It is the forth and the fifth for 18 and 17 respectively.

After the PPM encoded ADSB message is valid, then the data is converted to a binary stream. The output data is sent in an SPI like protocol. While in the SPI the length of the data usually 16 bits long, in this receiver the data is 112 bit long.

4. RESULT AND DISCUSSION

The result of the ADSB receiver system can be seen in the Figure 8. In the experiment, the data signal was transmitted by an ADSB transponder and the output signal of the ADSB receiver was measured using an oscilloscope of 200MHz bandwidth and with sampling rate 2Gsa/second.

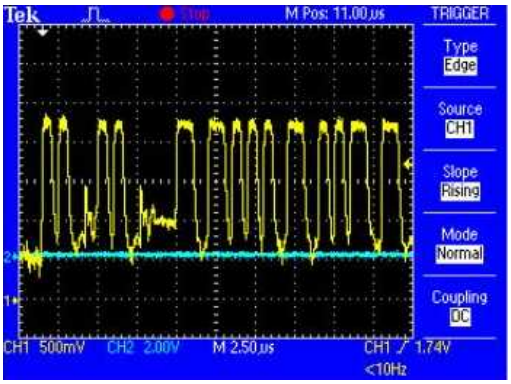

Figure 8: The measured ADSB pulse stream at the receiver.

As the theory said, the demodulated signal contained a preamble that consists of 4 pulses and followed by data. We can see from the oscilloscope display that the difference between second and forth preamble pulse is one division. Since one division is 2.50 microsecond, then the time distance between them is 2.50 microsecond. It is exactly correct according to the standard that is shown in the figure above. It was also said that the data come 8 microseconds after transmitting first preamble pulse. However, the data are encoded in PPM format that has been describe above. It means, the first pulse of data could be 8 or 8.5 microseconds of the first transmitted preamble pulse, depending on the decoded datum is “ONE” or “ZERO” respectively. The picture below is the expanded version of the figure above where the time scale is one microsecond per division. The first pulse of data came 3.50 microseconds after forth preamble pulse that means 8 microseconds from the first transmitted pulse. It indicates us that first datum is a ONE, because the pulse is in the first half interval of one microsecond time period.

ISSN 114-1284

Figure 9: The ADSB first five data in PPM format.

Since the first datum is a ONE, then next four data pulses need to be analyzed, to detect whether the squitter is an ADSB message. The rising edge of the next pulse is about 1.50 microseconds. It indicates us that the pulse is in the second interval of next time period. Thus the second datum is "ZERO". So are the third. The forth pulse may longer than other pulses. Since the maximum accepted length of a pulse is 0.50 + 0.05 microseconds, then it indicates us that the fifth pulse is in the first half interval of a time period what means a "ONE". It concludes that first five bits of data is a consecutive 10001 or in decimal form is 17 (seventeen). According to the standard in figure above, the message is exactly the ADSB message with downlink format 17 (DF 17).

The analysis of the analog signal is proven using the digital signal processing inside the FPGA[5.]. The picture below shows the output of the processing block inside FPGA.

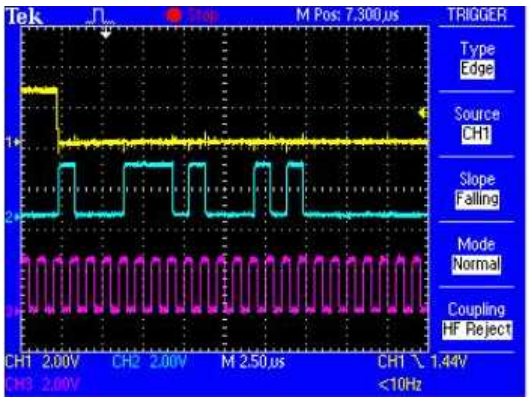

Figure 10: The decoded ADSB data.

There are three output channels. First is a strobe. Second is binary data where high amplitude is ONE and low is ZERO. Last one is the clock with the pulse length of 0.50 microseconds in one microsecond period. After a falling edge of a strobe signal, the data is valid and it is indicated with a rising edge of a pulse. Then in the picture, we can see that the first datum is valid 0.50 microseconds after falling edge of the strobe signal. The first datum is a ONE. The second, third and the forth datum is ZERO and the fifth is already ONE. Thus the code is 10001 what means the DF 17. It concludes that the result from analysis and measurement conform each other.

5. CONCLUTION

The idea of conducting this device engineering is to assess a new technology in civil aviation and to introduce this technology to the domestic electronic industry. Begin from studying the civil aviation standard documents and conducting the experiment, it can be concluded that it is highly possible to develop commercial ADSB receivers in a mass product in Indonesia.

Since the process is a real time and very high speed, then it is highly recommended to use FPGAs as the tools since those are is price competitive in compare with very high digital signal processor.

Finally, the system is still a basic design yet. There are some improvements that must be done, especially in the determination of the bit confidence. A fast but reliable process need to be developed.

ACKNOWLEDMENT

In this occasion, the authors want to thanks PT. compact Microwave Indonesia (CMI) for the collaboration in the development of this receiver, especially for the development industrial standard hardware and packaging.

ABSTRACT

VoDSL is a fixed line technology that enables true convergence between multi broadband services and multi voice services into the same pair cable. Actually now, POTS revenue is significantly decreasing in Indonesia, so that the network and feasibility analysis is needed to examine implementation of VoDSL technology especially in PT. Telkom's network. In this paper, the demand projection is developed and analyzed for VoDSL implementation over existing Telkom customers using three models, they are pessimistic, moderate and optimistic. The investment cost, feasibility and payback period during 2008-2013 is analyzed and seek which models suitable for existing infrastructure and demands. The results show that using pessimistic model, VoDSL worth implement as its IRR 6% higher than assumed discount rate and has 80% of CAPEX efficiency that compared to copper investment. From the analysis, VoDSL is supported by existing ATM and IP Network and take in to account for PT. Telkom benefit with seamless migration to broadband services. To guarantee IP quality network implementation, a new strategy with placing voice gateways on intersect locations is needed. VoDSL for both ATM and IP backbone area is feasible that it has positive NPV and IRR above discount rate and payback period from 1 to 2 years.

VoDSL, Voice over DSL, G.SHDSL, Voice over ATM, Voice over IP

1. INTRODUCTION

Facing the facts that voice revenue over wireline is decreasing[1]. There are three reasons that PT Telkom should implement VoDSL as a new service with low cost technology. [2] [3]. It could efficiently optimize the copper wired network and generate new services. Some problems in the existing condition of telecommunciation infrastructure and services in Indoensia, they are: First one, there are millions of people in the waiting list asking for cable services, but only thousands of available copper network and the remaining cables are reserved for broadband services such as : IPTV, VoD and high speed internet. VoDSL efficiently could use few cables to answer many demands in telecommunication servcies. Second one, the phone lines requires new copper lines to connect to customers. For every single SOHO or corporate customers and even residentials there are more than one pair of copper supplying phones, faxes, dial-up servers, credit card applications and so on. VoDSL only employs one pair of cable to support all this services up to 16 lines with the same quality as POTS (without compression). And third one, the existing leased lines cannot provide voice services in the same copper wired. VoDSL enables it and can be used to solve te above problems [2]-[5].

In this paper demand projection for VoDSL implementation over existing Telkom customers using three models, they are pessimis, moderat and optimis is developed. In addition, this research is also to build business assessment on VoDSL over existing copper wired network. The investment cost, feasibility and payback period during 2008 – 2013 is calculated and seek which models should be suited to existing infrastructure and demands. Some implementation scenarios consist of topologies of existing and new services that could be served by VoDSL are also to be described and analyzed.

2. VODSL TECHNOLOGY AND NETWORK PLANNING

As shown in Figure 1, VoDSL topology is the same as DSL topology with some added devices, such as IAD (at customer premise) and Voice Gateway (operator site).

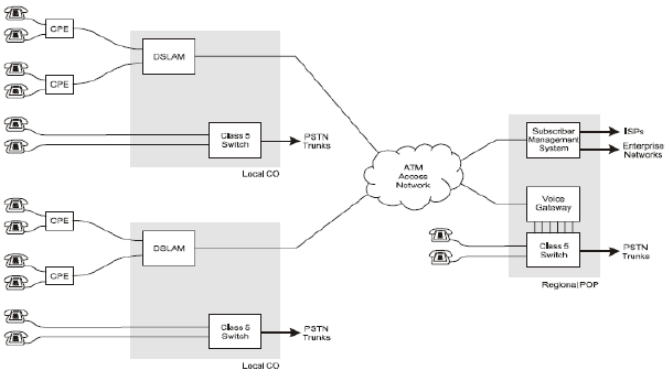

Figure 1. Centralized VoDSL over ATM

Voice Gateway could be located centralized or distributed. Centralized means that only single Voice Gateway serves to all DSLAMs, gives operator low investment and operation cost but QoS guarantee must be well calculated and prepared for end to end network. Distributed means Voice Gateway per DSLAM while Semi Distributed means Voice Gateway for few DSLAMs.

The transport technologies include ATM and IP and use the standardization for voice codecs G.711 or G.726. POTS is to be used in 64kbps and can be compressed to 32kbps. For IP backbone, distributed topology is needed to ensure QoS issues over IP network.

Based on ITU presentation [3], based on derivation from simple IPO (Input Process Output), the network planning model is proposed as shown in Figure 2.

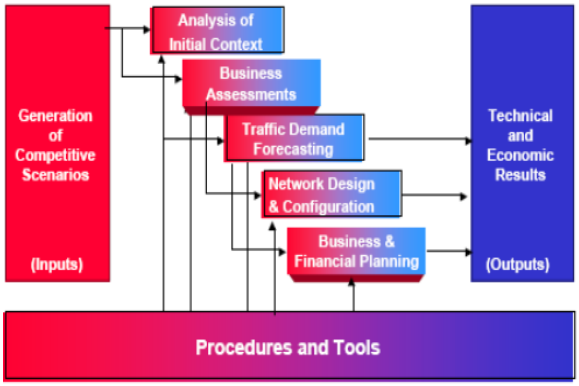

Figure 2. Network Planning Model

1. INPUT
   a) *Generation of Competitive Scenarios* consists of scenarios based on various technology standards.
2. PROCESS
   a) *Analysis of Initial Context*, the basic analysis of scenarios is analyzed using simple tools. In this paper we analyze existing infrastructure and its support for VoDSL.
   b) *Business Assessment*, is used to evaluate the business opportunity on each scenarios.
   c) *Traffic Demand Forecasting*, demand projection and network capacity issues regarding each scenarios.
   d) *Network Design & Configuration*, network reengineering and topology review as required by scenarios.
   e) *Business and Financial Planning*, includes investment and operation cost and feasibility analysis
3. OUTPUT
   a) Economic and Technology Result

This model will be used to analyze VoDSL implementation in Jabodetabek area.

3. Network Architecture

Network utilization in cable networks reach 70% with penetration only 11% of total population JABODETABEK (Jakarta Bogor Depok Tangerang Bekasi) [4]-[5]. Cable network with "ready to broadband" status range between 127 K and 304K for each DATEL (Daerah Telekomunikasi). Total number of DATEL is 8 that serve in JABODETABEK area. The condition of existing condition and the ready to broadband condition is shown in Figure 3.

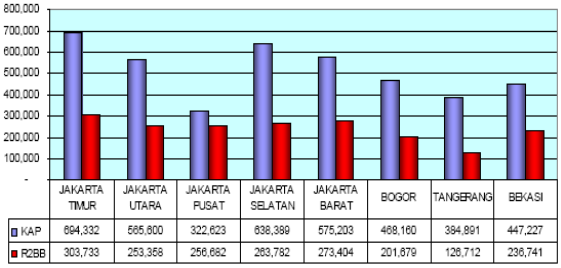

Figure 3. R2BB (Ready to Broadband) vs Existing

There area various access technology employed by Telkom such as : POTS, ADSL, G.SHDSL and backbone technology such as: NG-SDH backbone, SDH backbone, Metro Ethernet backbone and IP Transport. POTS provides the basic telephony services such as phone, fax, dial up access for remote application or credit card payments, and PBX. ADSL supply high downstream bandwidth to customers and one analog phone while G.SHDSL meets corporate customer demand for symmetric bandwidth. VPN or Internet access without any phone services could be delivered over the same copper pair. The demand from POTS waiting list, ADSL office segmen, and G.SHDSL customers are derived in this paper.

4. Demand Projection

The demand projection is built in three models, they are: pesimis, moderat and optimis and consist of POTS, ADSL and G.SHDSL demand combinations.

POTS Waiting list condition is shown in Figure 4. We will calculate status of UN, SI, RE, UO as demands. The UN (Unavailable) means that the network capacity is full; SI means that is is impossible regarding primer cable; RE means that it registered for new cable; UO means that is Unfeasible. POTS growth reach CAGR 10,65% as reported by government in [6]. We will use this as growth condition for POTS projection.

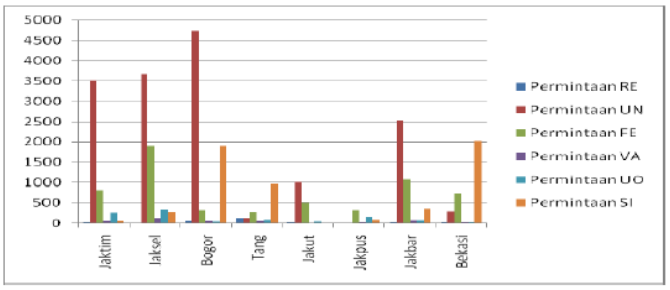

Figure 4. POTS Waiting List

ADSL Network – ADSL services have three base customers, they are residential, office and warnet (internet café). The office customers is focused in the research because they need more than one phone lines for faxes, PBX, and dial-up transaction applications. The office customers are ranging from 2% - 10% of all ADSL customers. From the same source as POTS, 24% of CAGR is used for ADSL.

G.SHDSL network – G.SHDSL customers have more than a pair cable because no phone services could delivered over basic G.SHDSL. G.SHDSL customers pay the higher bill than ADSL office customers for they have symmetric private access in their offices conectivities. G.SHDSL has the same growth as ADSL.

From the data some variables are assumed in the models, they are:

Pesimis – Focusing VoDSL implementation on POTS demand. 10% of growth is sued for POTS, 2% for ADSL and G.SHDSL customers.

Moderat – Focusing on average between POTS and corporate customers. 17% and 5% of growth are used for ADSL and G.SHDS, respectively.

Optimis – Focusing on the higher of POTS and Corporate Customers demand. 24%, and 10% of growth are used for ADSL and all G.SHDSL, respectively. The demand projection is show in Table 1.

The service areas as Telephony based customers (Phone majority), Internet based customers (warnet majority) and Corporate based customers (Office building majority) are classified in the analysis. The samples from phone and corporate based is used and from the data, **BOGOR** area is for the most phone customers and **JAKBAR** area is for the most office buildings.

5. Results and Analysis

For calculations, we have to use assumed service rate because VoDSL hasn't delivered elsewhere in Indonesia. Tariff that is used in this analysis is assumed as follow :

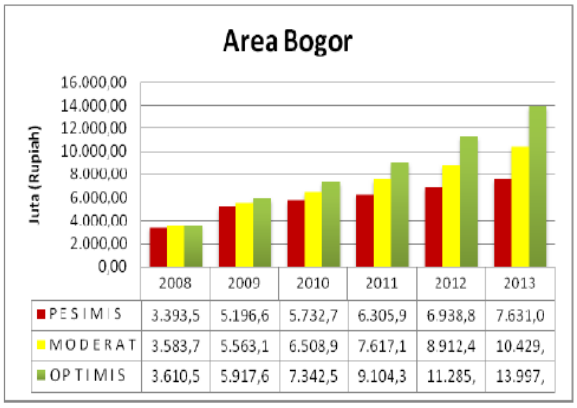
- IAD installation : IDR 200K
- Added Voice lines : 0
- Abonemen VoDSL : 80% POTS or IDR 24K
- ARPU per line : IDR 60K
- VoDSLto VoDSL Call Unlimited

We use two scenarios, they are VoDSL over ATM as scenario-1 and VoDSL over IP as scenario-2. Location for both scenario is explained as follows:

Scenario-1 – VoDSL over ATM, Centralized
GW BOGOR : GATOT SUBROTO
GW JAKBAR : SLIPI
Customer ask for 1 phone lines
Scenario-2a – VoDSL over IP, Distributed
GW BOGOR : 10 Locations
GW JAKBAR : 8 Locations
Scenario-2b – VoDSL over IP, Semi Distributed
GW BOGOR : 3 Locations
GW JAKBAR : 2 Locations
Customer ask for 3 phone lines

Revenue Projection

From these assumption we could calculated revenue projection different services as shown in Figure 5 and Figure . We choose as case area is Bogor and Jakarta Barat.



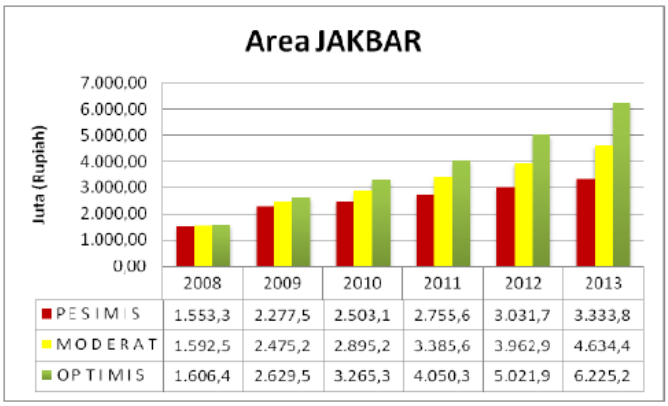


Figure 5. Revenue Projection VoATM

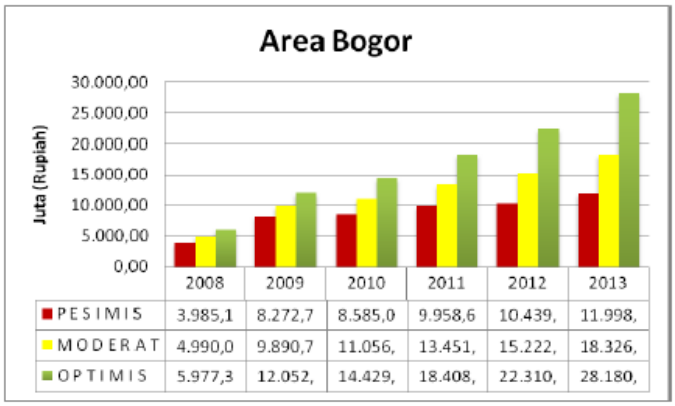

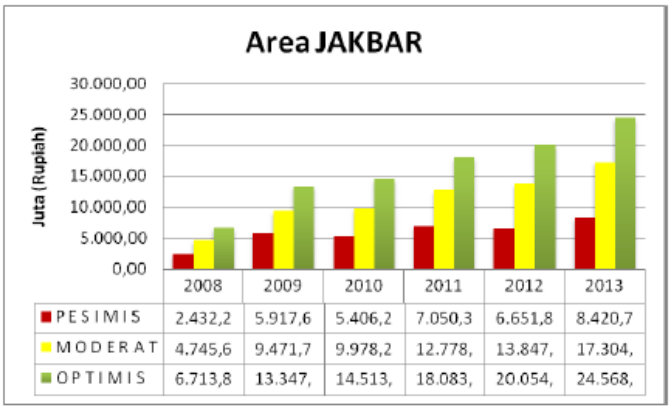

Figure 7. Revenue Projection VOIP

Analysis of Initial Context

For each scenarios, Telkom has all basic network required for copper infrastructure, ATM and IP. Bandwidth available in existing network suits demand calculations with some relocation needed in ATM networks between DSLAM-rich but low demand area and DSLAM-poor but high demand such as : JAKBAR and BOGOR area respectively. The result shot that no investment needed in primer copper, ATM switches and routers.

Table 2. Analysis of Initial Context

Materi	ATM backbone	IP backbone
Konteks Dasar	- ATM-DSLAM mendukung protokol AAL2, AAL5 dan IP - ATM Switch mendukung multi pvc - Dukungan line VoDSL : VoATM codec G.726 : 38.750	IP-DSLAM mendukung protokol AAL2, AAL5 dan IP - Dukungan line VoDSL : VoIP codec G.711 ~ 70.000 ssl
Desain/ Konfigurasi Jaringan	Centralized	Distributed
Demand vs Bandwidth (Bogor + Jakbar) kompresi G.726 (32Kbps)	**1 line telepon/ demand** VoDSL Jakbar *over capacity* : permintaan 8.789 sst dukungan bandwidth 31.000 ssl voDSL- Bogor kapasitas kurang : permintaan 19.753 sst dukungan bandwidth 7.750 ssl	**3 line telepon/ demand G.SHDSL, 2 line telepon/ demand ADSL, 1 line telepon pelanggan baru.** Jakbar : permintaan 35.910 sst Dukungan bandwidth 66.664 ssl Bogor : permintaan 41.811 sst dukungan bandwidth 49.998 ssl

Investment Calculation

Investment cost consist of some parameters as shown in detail price in table 3)

- Voice Gateway (G.711, G.726, VoATM, VoIP)
- Jumper cable

- Optical Patchcord
- IAD
- DSLAM relocation cost

Table 3. Investment Cost

				kurs : 9300	
	Satuan	Vol	Harga	$	Rp
Voice Gateway Cisco MGX8880-CHCL (Chassis and Cooling)	Unit	1	23.465	23.465	
AXSM-32-T1E1-E (32 E1)	Modul	1	30.875	30.875

Jasa penarikan E1/patchcord	STO	28	500.000		14.000.000
				Total Dollar	1.203.733
				Konversi Rupiah	11.194.712.250
				Total Rupiah	20.500.000
				Jumlah Total	11.215.212.250
				PPn	1.121.521.225
				Total Investasi	Rp12.336.733.475

Copper investment per user reach US$1000. Compare to this VoDSL investment, 80% saving of CAPEX can be achieved and more than copper with lower copper's capacity utilization. One pair cable could serve up to 16 lines (uncompressed). Investment chart year of year is describe in Figure 8.

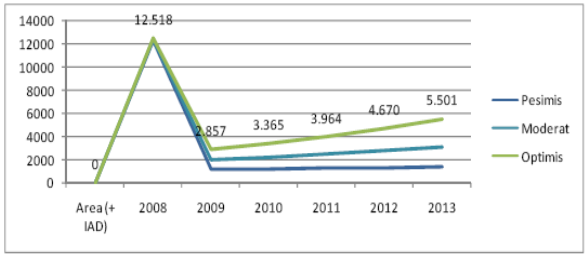

Figure 8. Investment Chart

Operation Calculation

Operation is calculated nd the results is shown in Table 5. Compare to existing condition, OPEX by VoDSL saves 23% from 30% to 7% OPEX.

Table 5. Opex Structure

Feasibility Calculations and Analysis

We use NPV, IRR and Payback Period to measure feasibility. NPV includes investment cost, operational expenditures, maintenance cost and revenue projection. NPV is calculated as follows:

$$NPV = \frac{\text{Kas Bersih } 1}{(1+r)^1} + \frac{\text{Kas Bersih } 2}{1+r)^2} + \cdots + \frac{\text{Kas Bersih N}}{(1+r)^n} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad (4.1)$$

Dimana : r = discount rate, dalam satuan '%'

N = umur investasi, dalam satuan 'tahun'

Payback Period is calculated to get how the project could reach break even for investment.

For IRR, we use discount rate 20%, and calculation result is shown in table 6-8.

Table 6. VoDSL over ATM

		NPV	IRR	Payback Period
Pesimis	Bogor	18.139.521.420	22,30%	1 Tahun 9 Bulan 8 Hari
	Jakbar	7.988.462.408	19,22%	1 Tahun 9 Bulan 12 Hari
Moderat	Bogor	21.364.415.383	17,93%	1 Tahun 9 Bulan 22 Hari
	Jakbar	9.498.931.989	14,86%	1 Tahun 9 Bulan 26 Hari
Optimis	Bogor	24.981.187.464	11,56%	1 Tahun 10 Bulan 8 Hari
	Jakbar	11.110.718.142	8,98%	1 Tahun 10 Bulan 11 Hari

Table 7. VoDSL over IP, Distributed

		NPV	IRR	Payback Period
Pesimis	Bogor	27.050.247.130	12,20%	1 Tahun 9 Bulan 21 Hari
	Jakbar	18.158.318.068	10,10%	1 Tahun 9 Bulan 20 Hari
Moderat	Bogor	36.167.577.392	12,06%	1 Tahun 9 Bulan 29 Hari
	Jakbar	33.829.291.434	17,81%	1 Tahun 9 Bulan 18 Hari
Optimis	Bogor	48.982.180.917	-13,38%	1 Tahun 11 Bulan 10 Hari
	Jakbar	74.246.194.785	1,76%	1 Tahun 10 Bulan 13 Hari

Table 8. VoDSL over IP, Semi Distributed

		NPV	IRR	Payback Period
Pesimis	Bogor	27.050.247.130	27,05%	1 Tahun 8 Bulan 29 Hari
	Jakbar	18.158.318.068	20,28%	1 Tahun 9 Bulan 5 Hari
Moderat	Bogor	36.167.577.392	12,06%	1 Tahun 9 Bulan 29 Hari
	Jakbar	33.829.291.434	20,76%	1 Tahun 9 Bulan 14 Hari
Optimis	Bogor	48.982.180.917	-13,38%	1 Tahun 11 Bulan 10 Hari
	Jakbar	74.246.194.785	2,89%	1 Tahun 10 Bulan 12 Hari

From table 6, Scenario-1 is feasible for BOGOR and JAKBAR with notes, some DSLAM on JAKBAR relocated to BOGOR because phone demand for BOGOR is higher than JAKBAR. While no VoDSL over IP Distributed models is above discount rates on table 7 and therefore scenario-2a not feasible.

We couldn't calculated centralized topology on VoDSL over IP because of QoS issue. Figure 9 and Figure 10 shows the VoDSL for Bogor area and Jakarta Barat area. We could see in Figure 8, why we have to use 10 voice gateways in BOGOR.

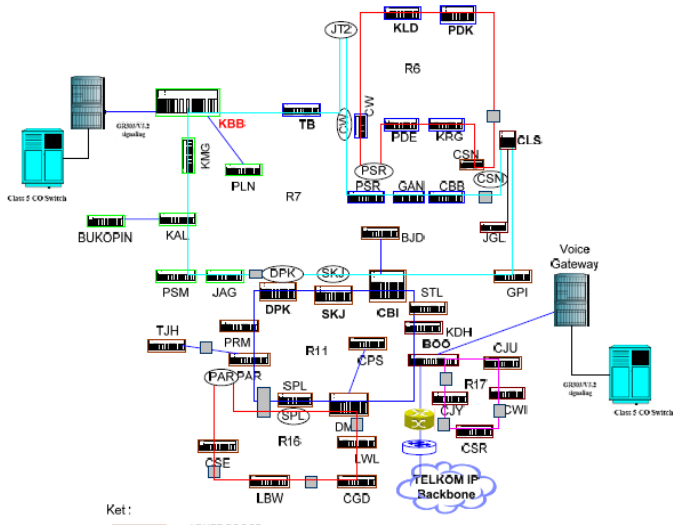

Figure 9. VoDSL BOGOR

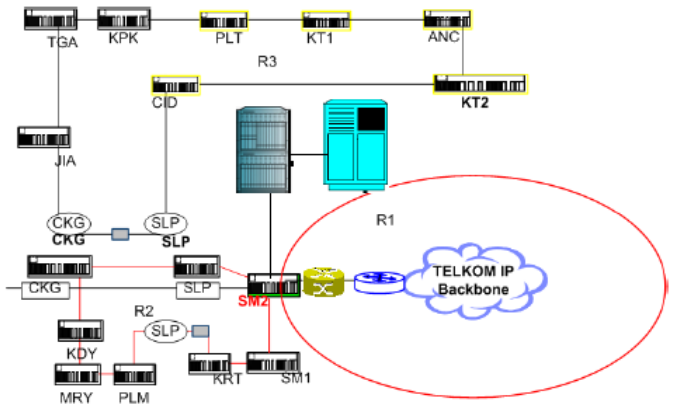

Figure 10. VoDSL JAKBAR

To overcome the problem, we could use semi distributed by "centralized traffic" from buildings across BOGOR and JAKBAR, related to scenario-2b. For example, Buildings across JAKBAR are centralized in SM2 and Slipi area and prposed as redundancy. These two location also intersect locations. That is a location which is part of more than one area. So traffic from other locations within the area directed to these locations. If we applied the same reason to BOGOR, we would have 3 Gateways for BOGOR, the are Cibinong, Depok and Bogor and 2 Gateways for JAKBAR, they are Slipi and Semanggi.
For pesimis model, VoDSL implementation in Bogor and Jakbar over IP is feasible.

Targeted Applications

Residential Connection

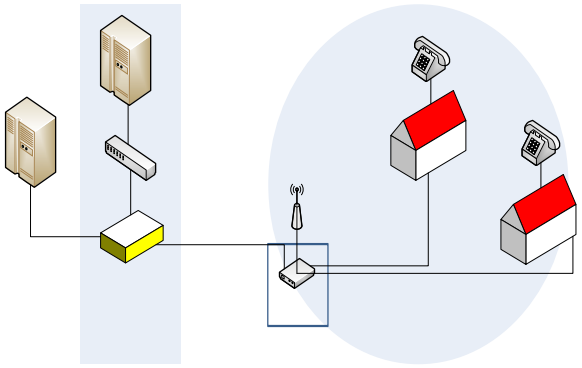

Figure 11. Residensial connection

This architecture as shown in Figure 11 is used to save copper and prepare for broadband connection for customers. IAD is installed in Cable House (no in customer's house) and supply phone lines to several houses. One port of data is connected to

WIFI access Points as a value added for VoDSL. Phone based customers would be educated to use broadband through this connection.

Corporate PBX

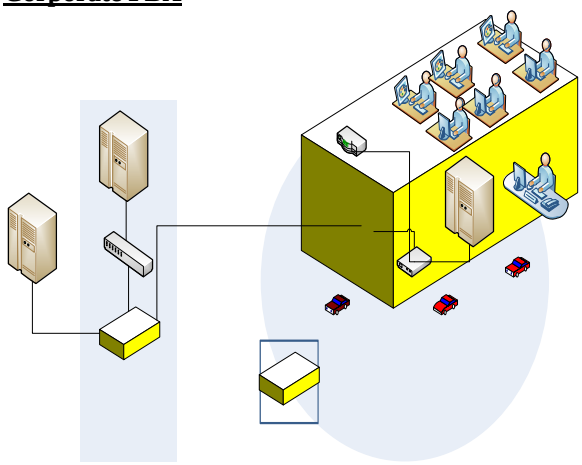

Figure 12. Corporate PBX

This architecture in Figure 12 is used to integrated coppers to a corporate customers. IAD is installed in building and supply phone lines to the company. One port of data is connected to router. By this topology only single copper cable is supplied to building with reduced service rate. Customers will be pleased.

SOHO

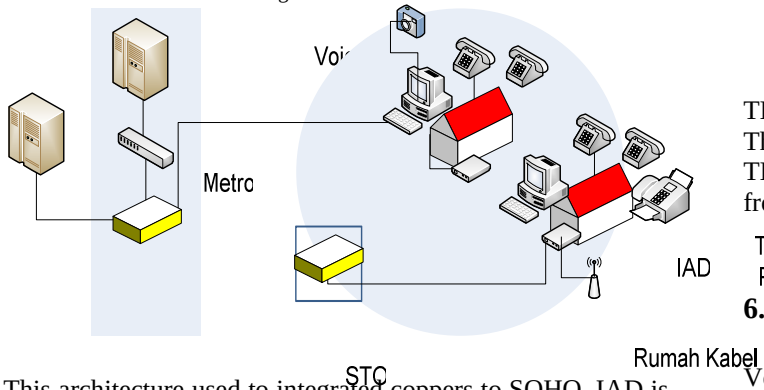

Figure 12. SOHO

This architecture used to integrated coppers to SOHO. IAD is installed in customer premises and supply phone lines to the them. One port of data is connected to access point for internet access. SOHO usually used phone lines for credit card transaction, several bank need several copper lines. By this topology only single copper cable is needed plus lower rate.

WARTEL SPEEDY

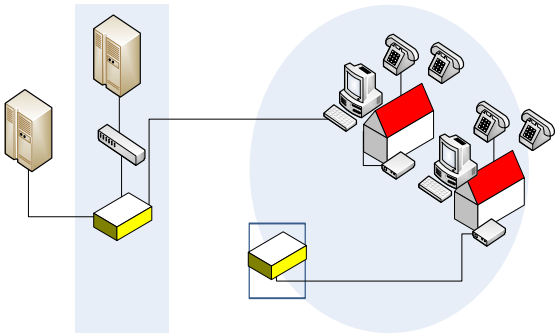

Figure 13. WARTEL SPEEDY

This architecture as shown in Figure 13 is used to integrated coppers to WARTEL and add one internet connection as value added service. By this topology WARTEL partner could reduced opex and monthly cost and even change profit proportion between them and TELKOM.

TELUM

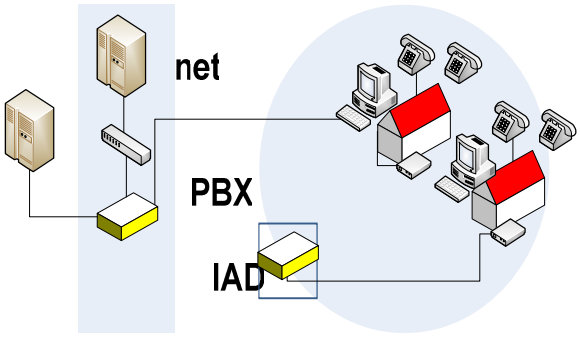

Figure 14. TELUM

TELUM means TELEPON UMUM or Public Telephone. This architecture is used to save coppers supplied to TELUM. TELUM rate could be reduced, and would increase revenue from TELUM. The architecture for this is shown in Figure 14.

6. CONCLUSIONs

VoDSL is supported by existing ATM and IP network own by PT Telkom. POTS waiting list could be served by VoDSL with CAPEX efficiency 80% and payback period of 1 year. This would benefit Telkom with seamless migration to broadband services because IAD has installed in customer premises. VoDSL enables G.SHDSL provides phone-based services; this would efficiently saves copper lines and increase revenues over existing corporate customers. To guarantee IP quality network, implementation strategy is

needed such as placing voice gateways on intersect locations. VoDSL for both ATM and IP backbone area feasible with recommendation, it has positive NPV and IRR above discount rate and payback period from 1 to 2 years.

ABSTRACT

Nowdays, a handphone becomes a multipurpose equipment. User can use it to communicate, to capture image or event, as well as to transfer data to another device. Its bluetooth availability increases the inter-device wireless connection usability.

This research design and implement a client-server streaming content constructor over a piconet network in a point-to-point connection using a handphone as client. As an alternative way in recording and delivering data in video format, which is bandwidth consumptive, this paper proposed the recording and sending data in image and video format. The JAVA API JSR-82-based connection is choosen because of its portability. Experiments were done to analyze the camera and voice recording, as well as sending data from client handphone to computer server.

Experiments on camera recording indicated that JPEG encoding of 160x120 pixel resolution produces the highest data transfering speed. The result of voice recording experiment showed commit time to reputed as the best result of audio recording is 5 second. The sending data from client to server experiment showed that delay of sending voice data is bigger than that of image data for similar time. The limitation on processor speed and memory size of the mobile phone influence the delay result while sending image and voice at the same time.

Keywords: *bluetooth, distance learning, piconet, point-to-point, JSR-82*

1. INTRODUCTION

The *handphone* technology increases fastly on the realibility, capability and fetures to satisfy the user [1]. Recently, *handphone* is equipped by additional features such as camera, bluetooth, etc. to meet the user needs. User use h*andphone* not only for voice communication purpose, but for voice recording, photo capture, video player and other purposes. Now, *handphone* becomes a multipurpose equipment. On the other side, long-distance learning also implemented widely. Learning activity does not limited in physical classroom anymore. Using the streaming technology, physical classroom can be replaced by a virtual classroom. A virtual classroom environment aims at simulating a real classroom for remote participants [2]. Then they don't have to meet physically in a classroom. The streaming can be broadcasted through a LAN/PAN/Internet network.

Bluetooth is a flexible and capable technology for providing short-range radio communications between devices in an ad-hoc manner using the 2.4GHz band [3]. Although the bluetooth technology has been established for a long time, there are less applications developed based on it. The common applications are apllications to connect the handphone to the headset or computer [4]. At advanced the audio streaming over bluetooth has been implemented over ACL Links [3] as well as the video streaming [5].

The last two research implemented the bluetooth technology on the computer-based. However implementation of bluetooth-based network on limited device is more complicated. This research proposed an alternative way in feeding the real time video server streaming, by recording the event in image and voice format instead of in video format. Recently, the camera availability together along the bluetooth technology bundled in a handphone provide a challange to use them as streaming content development tools for any purpose, such as long distance learning system as in this research.

In this paper we show how to design and implement streaming content constructor module as part of web-based long-distance learning system. The module consist of two submodules, the client-side (handphone) module and the server-side (computer) module. In supporting that modul development we analyze the file size and the delay information produced by the data recording-and-transfering. This analyzis are needed to choose the right image encoding as well as the voice recording commit time to apply in this application development.

The rest of this paper is organized as follows. Section 2 provides some backgrounds of bluetooth technology. Section 3 presents the design and implementation of streaming content constructor module over a piconet network using JAVA API JSR-82 in a point-to-point connection. Section 4 presents the result of our experiments. Finally Section 5 concludes this paper.

2. BLUETOOTH TECHNOLOGY

2.1 Bluetooth Connection Type

The basic bluetooth network is a piconet, whic is a dynamic ad hoc network. A device calling another to join the piconet is a master and the calee is a slave. The connection can be established through one of three : point-to-point, point-to-multipoint, and scatternet.

Point-to-point connection is established while one *master* and one *slave* perform a communication. When the slave connect to the master are more than one, the connection becomes a po*int-to-multipoint* connection. A device in a piconet can communicate to another device in another piconet to build a scatternet. These type of connections are showed in Fig.1 and Fig. 2 [6].

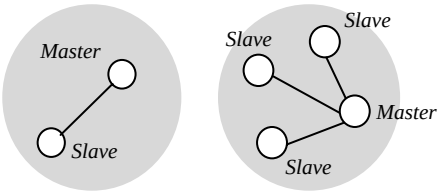

Figure 1: Piconet (a) point-to-point and (b) point-to-multipoint.

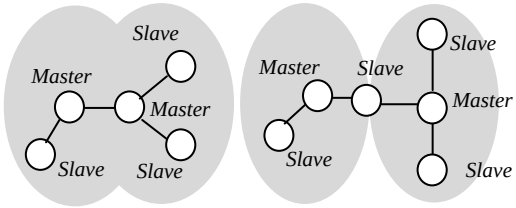

Figure 2: Piconet scatternet.

2.2 Handphone-Computer Bluetooth Connection on JAVA

There are two techniques to build a bluetooth connection between computer and handphone, they are [7] :

a COM-Port-based technique

This technique uses virtual COM-Port as a communication media as shows in Fig. 3

b JSR-82-based technique

The two techniques are similar. The only difference is the API JSR-82 implementation needs additional component that is separated from bluetooth software and operating system. The JSR-82-based architecture is showed in Fig. 4

The mechanism of *Java API JSR-82* implementation includes (Ericsson 2004) : bluetooth stack initialization, in-the-range service and device searching, waiting of connection initialization, connection opening/closing, and running Input/Output operation.

Bluetooth connection created by Java API JSR-82 implement Serial Port Profile (RFCOMM), L2CAP, and OBEX protocols. The JAVA API JSR-82 connection based on Generic Connection Framework (GCF). Fig. 5 shows the state diagram of bluetooth communication mechanism on JSR-82 [8].

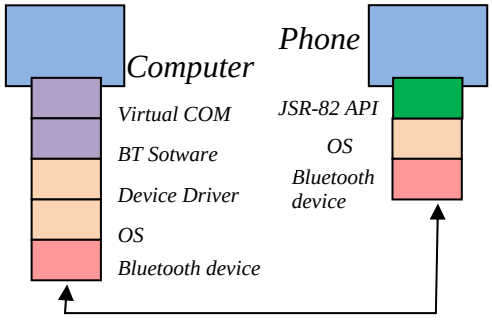

Figure 3: COM-Port-based technique.

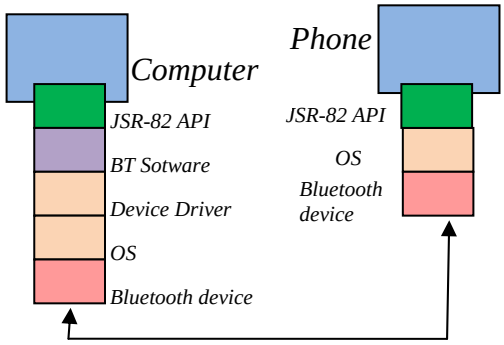

Figure 4: JSR-82-based technique.

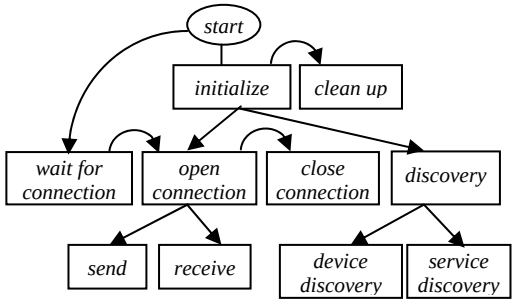

Figure 5: State diagram of Java API Bluetooth (JSR-82) –based connection.

2.3 Mobile Media API (JSR-135)

Mobile Media API (MMAPI) JSR-135 is an optional API packet that application developer has to deploy to access multimedia capability of a JAVA-support handphone. *MMAPI* based on *Java Media Framework* concept in *Java 2 Standar Edition (J2SE)*, built specially for handphone with limited audio/video, processing power, and memory. The *MMAPI* architecture is showed in Fig. 6 [9].

2.4 Video Frame Rate

Video uses frame concept to display a number image per second [10]. The more frames will produce better object movement. For web based application the minimum frame rate is 12 frame per second.

3. DESIG AND IMPLEMENTATION

3.1. Design and Implementation of Streaming Content Constructor Module

There are two submodules in the streaming content constructor module, client-side (handphone) submodule and server-side submodule (computer). The client-side submodule captures image sequence, via handphone's camera, and also records the voice, via handphone's microphone, as specify by user. By the time, this submodule sends the data to the server-side submodule periodically over bluetooth connection.

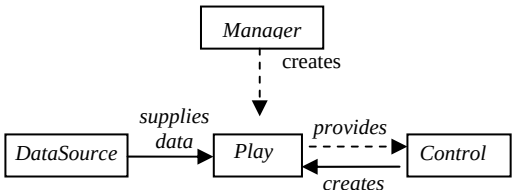

Figure 6: Mobile Media API architecture.

As soon as the data are received by the server, the server-side submodule processes the data to produce a video file and transfering the file to the streaming server.

Based on some literature studies the bluetooth connection is implemented on the JSR-82-based for portability reason.

3.1.1 Design and Implementation of Client-side submodule

Unless configure some connection parameters before sending the data, user open the connection directly using the default configuration. Once the opening connection is established the client will search an available bluetooth service (provide by server).

After the successful opening connection, the client-side submodule will activate a connection handler to control the data sending specified. The available data to send is image, voice, or both of them. Under the control of connection handler client sends the data specified to the server periodically. The process flow is showed on Fig. 7

This submodule is implemented using Java programming language supported by JSR-82 optional package and JSR-135 MMAPI. As pictured in Fig. 8 there are nine section in this submodule, they are :

a Controller, to configure the connection, camera used, and type of data to be transferred,
b Image Capturer, to capture the image and forward it to the image-sender section,
c Bluetooth module, the interface to perform a bluetooth connection,
d Sound Recorder, to capture voice from microphone and forward it to the voice-sender section,
e Device detection, to search in-range another bluetooth device,
f Service detection, to detect a bluetooth service,
g Image-sender, to forward image captured to the server,
h Connection Handler, interfacing communication between bluetooth module and image/voice-sender
i Voice-sender, to forward voice recorded to the server.

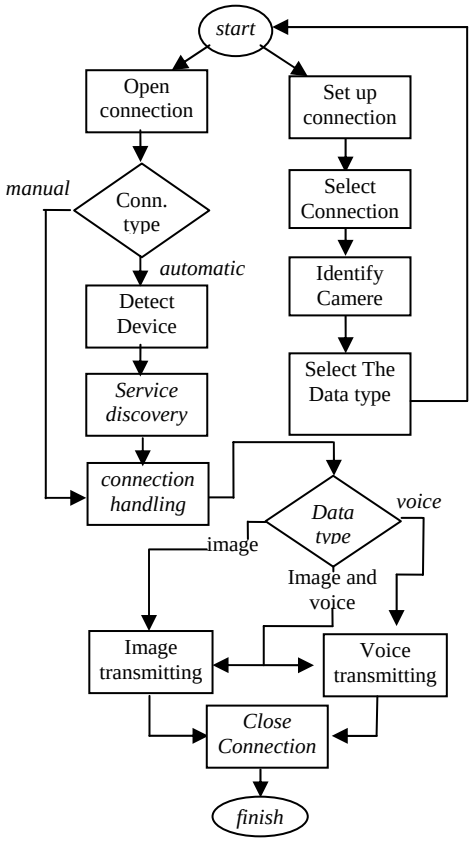

Figure 7: Workflow of client-side submodule.

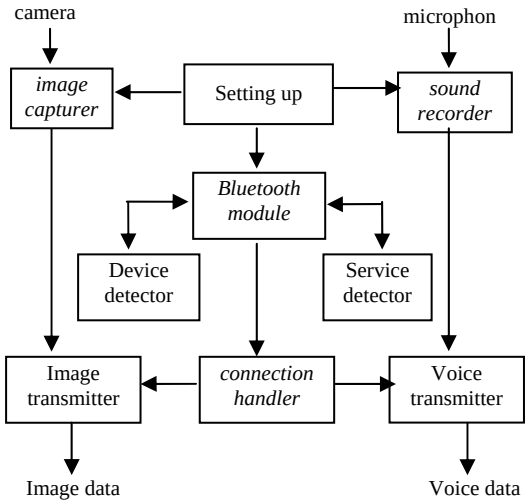

Figure 8: Implementation modules of client-side submodule.

3.1.2 Design and Implementation of *Server-side submodule*

User has to configure teh server before data receiving process, unless he/she activates the server using default

configuration. The server activation is suited to the accepted data type image data, voice data, or both of them. Once the activation is successful, the server-side submodule perform a listening process to capture the connection request from a client. When the connection is established, the server activate a connection handler to save the received data temporarely in the temporary folder.

A special thread is generated to collect the image and voice and merge them altogether into a new file periodically. The next step is transcode the merged file into mp4 format and hintrack it. The last step is move/copy the streaming content file to the root of movie folder of the Darwin streaming server to stream to over the network/internet. Fig. 9 pictures the flowchart of the serve-side (computer) submodule.

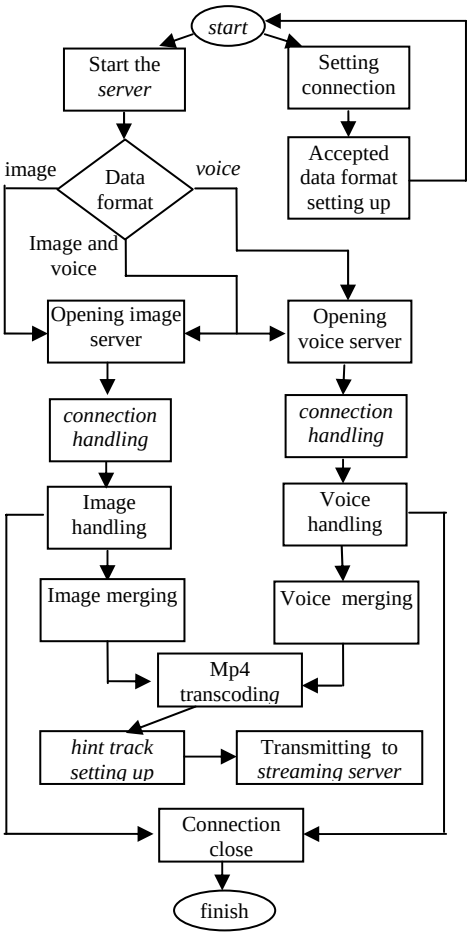

Figure 9: Workflow of server-side submodule.

Server-side submodule implemented using Java programming language supporting by bluecove-2.0.2 library, tritonus share-0.3.6.jar, ,java-getopt-1.0.13.jar, and *Java Media Framework 2.1.1e*. There are seven section in this submodule as pictured in Fig. 10:

a Controller, to configure the accepted data type,
b Connection Handler, to activate the server and to interface to the image/voive receiver,
c Image receiver, to receive image sending by the client,
d Voice receiver, to receive voice sending by the client,
e Display, to display the received image/voice on monitor,
f Video Processing, to process the received file to become a straming content file,
g Streaming content file-sender, to send the streaming content file to the root of movie folder of the Darwin Streaming Server.

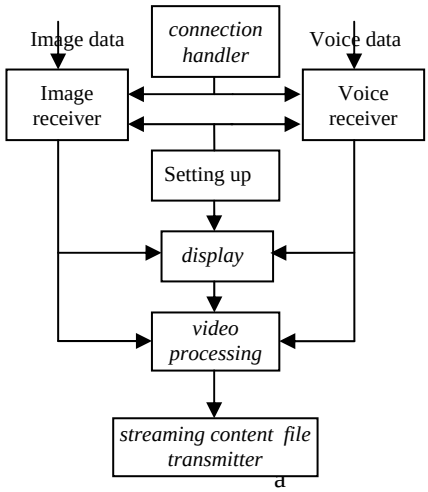

Figure 10: Implementation modules of server-side submodule.

4. PERFORMANCE EVALUATION

The first two experiments are performed to get the best image format and commit time to use in the following tranfering data performance experiments.

4.1 Image Capturing Evaluation

From the various image-encoding capturing in one minute, the result shows that the highest maximum frame number provides by JPEG and BMP encoding. While the best dimension to produce the maximum frame is 160 x 120 pixels as pictured in Fig. 11. Another parameter to analyze is the file size produced by each image encoding for each dimension. Fig. 12 shows that the JPEG encoding has the smallest size for various dimension, while in the contrary for the BMP encoding.

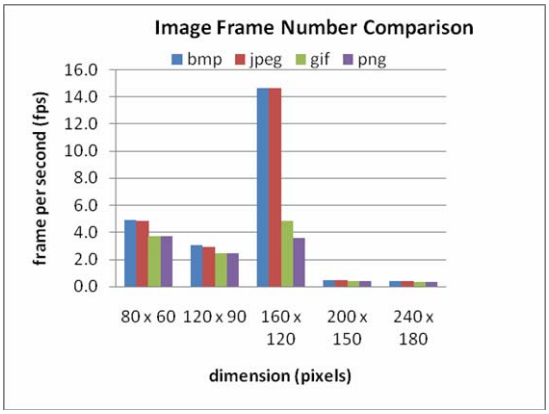

Figure 11: Image frame number for various encoding and dimension.

.As video streaming is a delay-sensitive application, the file to stream should be in minimum size with maximum frame number. The image encoding that meets this requirement is JPEG encoding in 160 x 120 pixels imension.

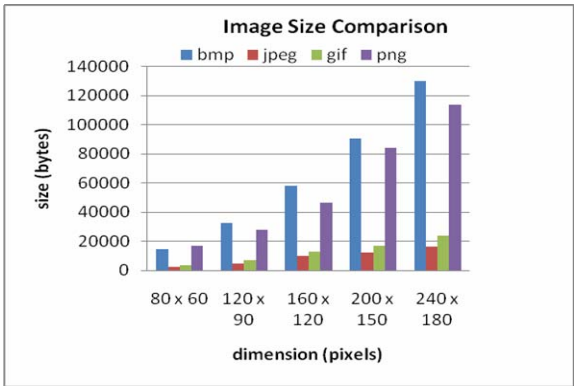

Figure 12: Image file size for various encoding and dimension

4.2 Voice Recording Evaluation

Fig. 13 presents the file size of voice recorded for various commit time, whic is showing the linear relation between them. Other parameters measured in this experiment are recorded file duration and the number of file produced in one minute.

The maximum duration of recorded file provided by voice recording with commit time 5 second as presented in Fig. 14. On the other hand, the number of file produced is less for the longer commit time as presented in Fig. 15.

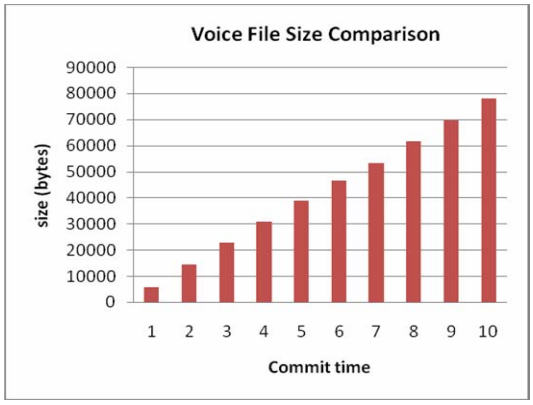

Figure 13: Audio file size for various commit time.

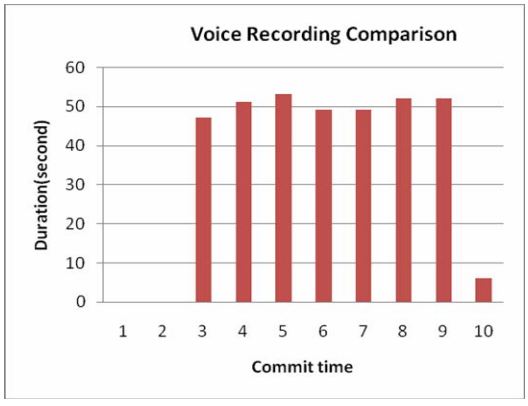

Figure 14: Duration of one minute voice recording for various commit time.

From these experiments the commit time choosen for data transfering is 5 second. This commit time produces the fine combination of duration and number of file.

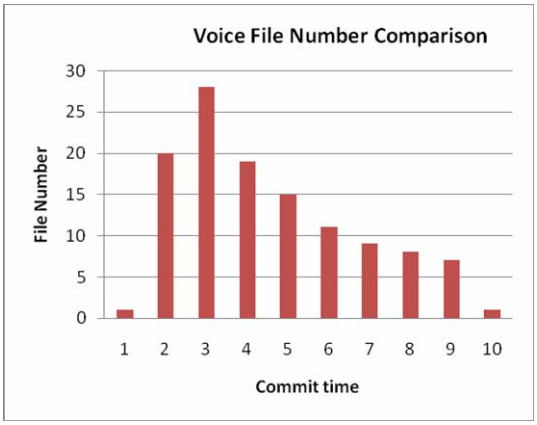

Figure 15: Number of file produced of one minute voice recording.

4.3 Image Transfering Evaluation

The image transfering delays for one minute image recording are 1390-1440 milisecond as pictured in Fig. 16. The delay variation is caused by the various number and size of image file for each capturing.

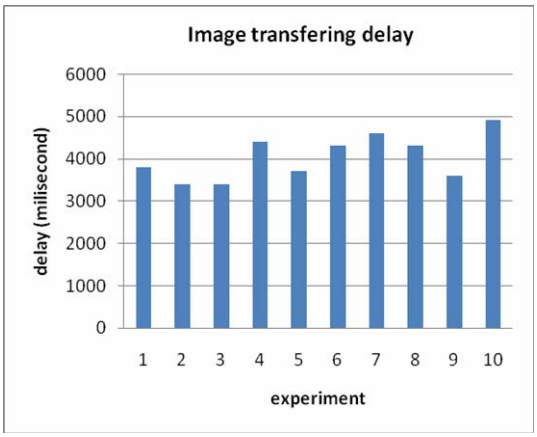

Figure 16: Image data transfering delay

4.4 Voice Transfering Evaluation

Fig. 17 presents the experiment results of one minute voice recording. The transfering delays are 1950-2150 milisecond. In comparing to image transfering delay, the voice transfering delay is higher, because the voice file size is bigger than that of image file. And the voice processing time is longer than that of image.

4.5 Image-Voice Transfering Evaluation

In this experiment, the voice and image transfering is carried out simultanously in one minute period. The transfering delays produced by the both of data are almost the same as pictured in Fig 18. The values are 3000-5000 milisecond, much higher than transfering delay produced

by separated transfering data. This situation is caused by the limited resources of the device.

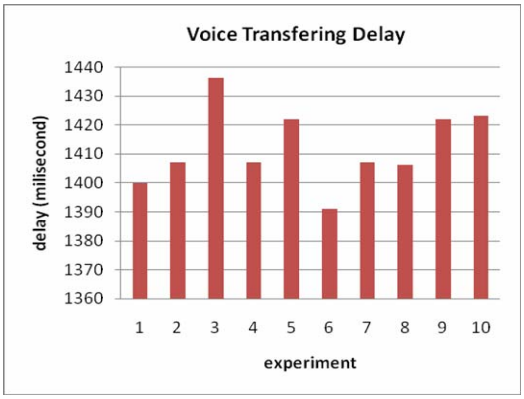

Figure 17: Voice data transfering delay

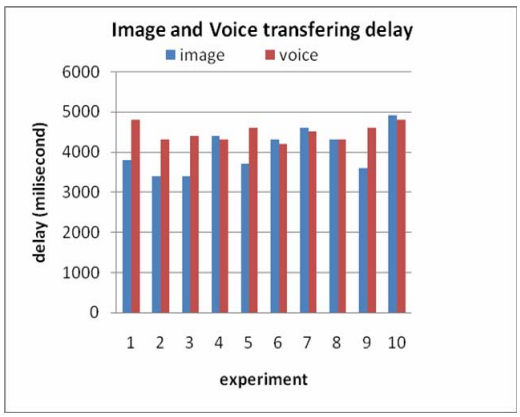

Figure 18: Image-voice transfering delay.

5. CONCLUSION

The handphone equipped with camera and bluetooth connection provides a challenge to build a streaming content for any necessity, such as web-based long-distance learning.

For limited device and connection, the streaming content file can be build from image and voice recorded separately, not as a video file. The image format best suited is JPEG encoding format because of its maksimum number of frame in minimum file size. For this encoding, the recomended dimension is 160 x 120 pixels. While the best commit time for voice recording is 5 second.

Our short-term future involves using point-to-multipoint connection in capturing the image to get the better view of a recorded object.

ABSTRACT

Computation and regeneration of CRC code in each router may cause slower IPv6 packet transmission. Utilizing advantages of IPv6 features namely IPv6 extension header and fiber optic medium, we proposed CRC extension header (CEH) to do error control in Network layer rather than in Data Link layer. The purpose is to reduce error checking process in IPv6 packet transmission over high speed networks. The CEH will utilize CRC-32 to do error detection. This paper investigates which CRC-32 generator polynomial would be suitable for CEH. To find out the answer we developed a simulation program in Java that generates IPv6 packet and CRC-32 code. The simulation produced CRC processing time both at the sender and receiver. The result showed that CRC-32 generator polynomial proposed by Castagnoli is the fastest generator polynomial to generate CRC code. We then conclude that Castagnoli generator (CRC-32C) is the best generator to apply in CEH on IPv6 transmission over high speed networks.

CRC-32, error, generator polynomial, transmission

1. INTRODUCTION

Internet has been connecting million people in the world. They use Internet not only to communicate each other but also military, business and administration purposes. Sending information from one side to another via Internet is fast and easy but may get some changes on the data due to weakness of the medium or noise affecting the channel. To ensure the data is accurate and free from error, designers have already equipped the protocol stacks such as TCP/IP with error control mechanism.

Error control in TCP/IP is divided into two types: error control in upper layer and lower layer. Upper layer is Transport layer that employ TCP or UDP checksum for segment data. While lower layer is Data Link layer that handle transmission error. This paper focuses on lower layer error control that ensures link by link data transfer of adjacent node is free from error. Transmission errors which change one or more bit of data may be caused by medium used in data transmission. Following the OSI reference model, data from Network layer will be added with header and trailer at the Data Link layer. Trailer is actually frame check sequence (FCS) that contains cyclic redundancy check (CRC) 32 bits to do error checking for the whole fields of link layer frame.

The traditional protocol stacks such as TCP/IP does error checking process by calculating and regenerating the CRC code in each intermediate node. It has to calculate CRC-32 of each IPv6 packet in incoming port of router and regenerate CRC-32 code before forwarding to the next hop. In response to increasing network speed and advance of fiber optic technology, the error checking mechanism in each router eventually become a bottleneck [1]. This study addresses improving IPv6 packet processing by eliminating CRC computation in each router. We proposed a new IPv6 extension header called CRC Extension Header (CEH) to do error checking in Network layer. The CEH uses the same CRC-32 algorithm which is table lookup algorithm. Format of CEH can be seen in figure 1 [2] below.

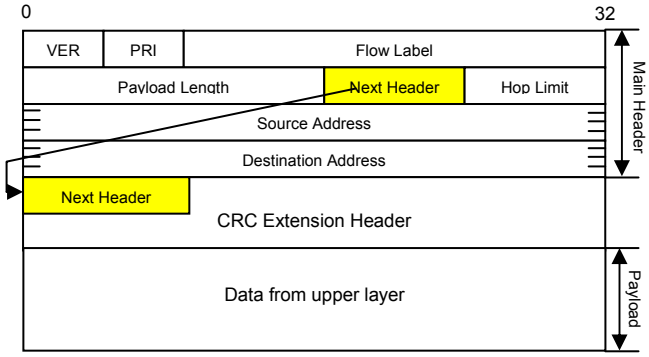

Figure 1 IPv6 packet with CEH

To generate CRC-32 code, it needs certain generator polynomial g(x). There are many generator polynomial have been proposing by researchers. This paper intends selecting the best generator polynomial to be used in CEH. The rest of this paper is structured as follows. Section 2 describes the work by explaining overview of CRC operation. Section 3 discuses the candidates of generator polynomial that will be used in CEH. In Section 4, method of the selection is presented followed with result and discussion in section 5. The end of this paper is conclusion.

2. OVERVIEW OF CYCLIC REDUNDANCY CHECK

Cyclic redundancy check (CRC) is a code that used to detect errors that occur during transmission or storage of digital data information. Error detection is conducted by adding a code on the data transmitted and check the code at the receiver. There are various lengths of CRC codes such as 16 bits (CRC-16) [3] and 32 bits (CRC-32) [4]. This paper focuses on CRC-32 to be used in CEH to detect transmission error in Network layer. This section gives overview of CRC algorithm.

There are many algorithms utilized to generate CRC-32 code. This section introduces the simplest algorithm in order to understand the concept easily. Furthermore, it discusses the fastest algorithm which is table lookup algorithm that widely used today. The simplest way to know CRC code generation is algebraic approach as discussed in [5] and more explanation in [6]. We present a short overview of the algorithm.

In the algebraic approach, an information or message is interpreted as coefficient of polynomial called data word d(x). The data word is divided by pre determined CRC generator polynomial g(x) using equation 1 giving a code word c(x).

$$c(x) = q(x).g(x) + r(x) \quad (1)$$

The operation called modulo two division, meaning that all of the term on equation 1 is base two. q(x) is quotient of the division and r(x) is remainder of the division. CRC operation concerns on the remainder rather than quotient q(x). The remainder also could be obtained using equation 2, which m is the number of bits of the generator polynomial g(x) used or the highest degree of its polynomial. Data word d(x) is appended by 0s and represents with multiplication x^m.

$$r(x) = d(x).x^m \bmod g(x) \quad (2)$$

This operation to obtain r(x) is performed at the transmitter side. Code word c(x) which is d(x) + r(x) is transmitted along the network to reach a destination. Let say the receiver gets a code word c'(x) from the sender. Receiver conducts similar operation using the same generator.

$$c'(x) = c(x) + e(x) \quad (3)$$

There are two ways to justify whether there is an error in the code word received. Firstly, divide c'(x) using the same generator, if c'(x) is divisible by g(x) meaning there is no error or the error is undetected. Secondly, extract r(x) from the code word. Do operation of equation 2 using the same g(x) to get a new CRC code (remainder) r'(x) and then compare the r'(x) obtained with original r(x) extracted from the code word. If the two remainder is the same, there is no transmission error otherwise there is an error in the packet received.

Modulo 2 division generally could be performed by a sequence of shifts register. The division process makes addition and subtraction equal to bitwise XOR. Bitwise XORs are performed for all data including 0s appending till finish and obtain the remainder. The process is equal to shift bit by bit data to register from left most bits. In the hardware implementation uses LFSR (linier feedback shift register) of length m.

The process of bit by bit register needs more time and make it inefficient. To address the problem, engineers implement CRC operation in software using table lookup algorithm. The algorithm processes byte by byte instead of bit. The algorithm proposed by Sarwate [7]. *Firstly*, the CRC value is set to an initial value. Then data word is inputted to data stream byte by byte. *Secondly*, every byte of input stream is performed an XOR operation with the least significant byte of initial value. The result is used as index to access a 256 entry table. *Thirdly*, the value from the table is XORed with the rest of initial value by shifted byte by byte to the right. The result is CRC value to the next iteration.

In term of Ethernet, data word is the whole frame except frame check sequence field (FCS). As shown in figure 2, a standard Ethernet frame consist of destination and source Ethernet address, Ethernet type, data from upper layer and FCS.

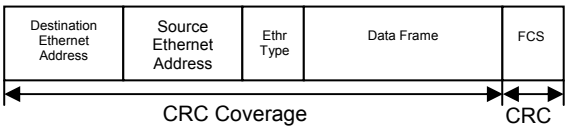

Figure 2 Standard Ethernet frame format

CRC coverage area in figure 2 is data word and FCS is remainder of modulo two division in equation 1. Hence, the whole frame is code word that actually transmitted into the networks.

3. IMPLEMENTATION CRC-32 FOR CEH

Implementation of CRC-32 in CEH uses the same algorithm with the existing CRC in Data Link layer which is table lookup algorithm. The differences of the

new mechanism are coverage area and field of the CRC-32. As mentioned previously, the CRC-32 is used as IPv6 extension header thus it placed between IPv6 main header and upper layer data *(see figure 1)*. The coverage area of CEH is the whole IPv6 packet excluding hop limit and CEH itself as shown in figure 3. From the figure, the size of CEH coverage area consist of 40 bytes IPv6 header minus 2 bytes hop limit field and upper layer data with maximum value 65,535 bytes. However the implementation is adapted with the maximum transmission unit (MTU) of the widely used Data Link layer technology which is Ethernet. Hence, the maximum MTU is 1500 bytes.

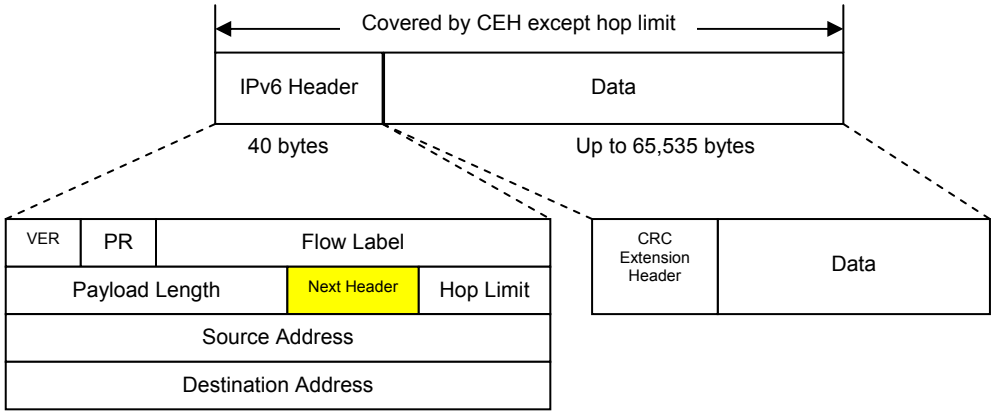

Figure 3 CEH coverage areas for error detection

Using equation 2, the coverage area is divided by g(x) to obtain r(x). r(x) is remainder of the division and represents of CRC code. Then, it is placed in the extension header field as shown in figure 4. Accordingly, pass the IPv6 packet to Data Link layer as usual to transmit through Physical layer without generate link layer trailer.

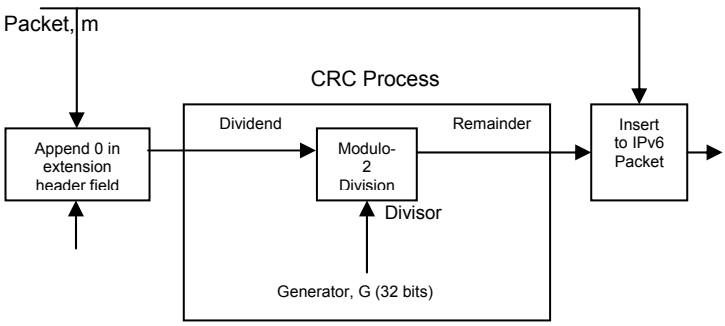

Figure 4 Generation of CEH in transmitter

At the receiver, Data Link layer captures the transmitted packet and pass the packet into Network layer directly. The layer does not compute CRC code any more. In the Network layer of the final destination, the packet will be processed as figure 5. It extracts CEH field from IPv6 packet. The other parts of the packet are divided by a generator to get a new CRC code. The new CRC code is compared with the original CRC inside CEH. If the result is similar, meaning no error. Thus, forward the packet to Transport layer, otherwise reject the packet.

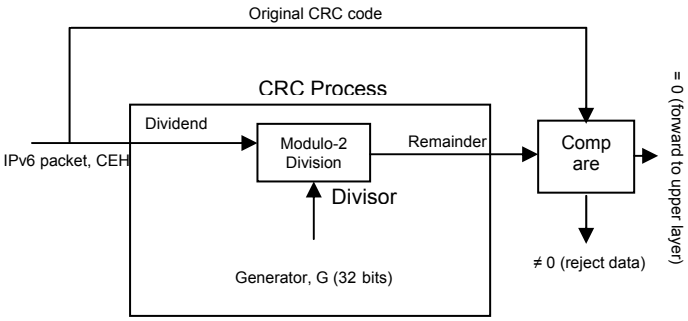

Figure 5 CEH processing in receiver

4. CANDIDATES OF GENERATOR POLYNOMIAL FOR CEH

Generator polynomial is the most important part of CRC code generation. It influences to the result of error detection. Hence selection of the best generator polynomial is also very important. This section discuses three candidates of generator polynomial that will be used in CEH they are standardized generator in IEEE 802.3 (CRC-32E), generator suggested by Guy Castagnoli (CRC-32C) and generator introduced by Philip Koopman (CRC-32K).

4.1 Generator used in Ethernet (CRC-32E)

This generator is widely used in data communication and data storage today. It was standardized by project IEEE 802.3 [8]. It is a polynomial with highest degree 32 and shown as

$$g(x) = x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^{8}+x^{7}+ x^{5}+x^{4}+x^{2}+x+1 \quad (4)$$

This polynomial can be formed as binary number as 10000010011000001000111010110111. The left most 1 is coefficient of x^{32} and following bits correspond to coefficient of the polynomial. The number of bits in a generator polynomial is equal to m + 1. The generator can be represented as 32 bit hexadecimal number 0x04C11DB7. However, some CRC implementations use its reverse as 0xEDB88320.

Based on [9], this generator satisfies for 4096≤codeword≤12144 bits. The interval is equal to the size of Ethernet frame (512 – 1518 bytes). For this implementation, it has Hamming distance, HD = 4 meaning the generator are able to detect all 3 bits error and lower.

4.2 Generator Proposed by Castagnoli (CRC-32C)

The name Castagnoli refers to the author of [10]. Castagnoli, Braurer and Herrmann evolved technique of constructing dual code polynomial belong to Fujiwara. They built special purpose hardware to find out new generator to improve performance of IEEE 802.3. Several factorization classes of generator polynomial of size 24 and 32 were evaluated. The evaluation yielded four optimum classes of 32 bits polynomials. *First*, CRC-32/8 code whose factors into $(x + 1)^2$ and three distinct irreducible polynomials of degree 10. The generator equivalent to codes of data length 1023 bits with HD = 8. *Second*, CRC-32/6 is the code of CRC-32 whose factors into $(x + 1)^2$ and two distinct primitive polynomial of degree 15. This generator similar with CRC-32 code for data length 32767 bits and HD = 6. *Third*, generator CRC-32/5 whose consists of one polynomial of degree 32. It gives HD = 5 to 65535 bits data. And the last is generator CRC-32/4. It was resulted from 47000 such codes that factors into (x + 1) times a primitive polynomial of degree 31. This generator keeps HD = 4 but it covers at data words sizes in excess 64 Kb. This generator is represented as

$$g(x) = x^{32}+x^{28}+x^{27}+x^{26}+x^{25}+x^{23}+x^{22}+x^{20}+x^{19}+x^{18}+ x^{14}+x^{13}+x^{11}+x^{10}+x^{9}+x^{8}+x^{6}+1 \quad (5)$$

In the hexadecimal form is 0x1EDC6F41 or 0x82F63B78 in its reverse. RFC 3385 [11] proved this generator to be used in iSCSI (Internet Protocol Small Computer System Interface). Thus we choose the code as a candidate to be used in CEH.

4.3 Generator Proposed by Koopman (CRC-32K)

Koopman did experiment to search a generator polynomial that covers larger data length [4]. He criticized the widely used generator polynomial that is IEEE 802.3. The standard only achieved Hamming Distance (HD) 4 for maximum packet length 12144 bits (Ethernet MTU). Whereas, theoretically it possible to detect HD = 6. The author searched a new generator polynomial that could to be used on HD = 6 for larger data length.

The evaluation was done for several generators including IEEE 802.3 and Castagnoli. The conclusion of the study is a 32 bits generator polynomial whose factors $(x+1)(x^3+x^2+1)(x^{28}+x^{22}+x^{20}+x^{19}+x^{16}+x^{14}+x^{12}+x^9+x^8+x^6+1)$. It constructs a full 32 bits generator represents as

$$g(x) = x^{32}+x^{30}+x^{29}+x^{28}+x^{26}+x^{20}+x^{19}+x^{17}+x^{16}+x^{15}+ x^{11}+x^{10}+x^{7}+x^{6}+x^{4}+x^{2}+x+1 \quad (6)$$

In binary form is 0x741B8CD7 or 0xEB31D82E of its reverse. The authors claimed the generator achieves HD = 6 for 16360 bits data length and HD = 4 to 114663 bits data length.

5. METHOD OF SELECTING GENERATOR POLYNOMIAL

We use two parameters to select the generator suitable for CEH based on previous work and our experiment. The two parameters are error detection capability and processing time to generate CEH in IPv6 packet transmission. The first parameter is analyzed by reviewing previous work on it and the latter analyzed by experiment. We configure small network to do the test bed in order to obtain particular data regarding processing time and delay transmission. The network is shown in figure 6.

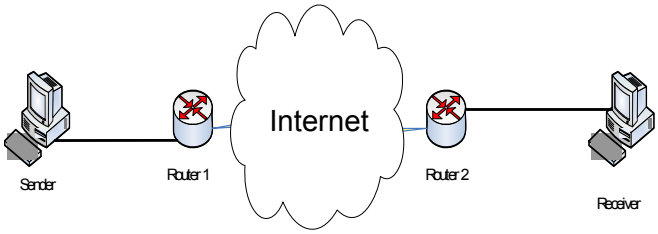

Figure 6 Topology of CRC Generator Polynomial Selection

We develop a program in Java that generates IPv6 packets with CRC extension header. The CRC code is generated from coverage area in figure 3. It is placed between IPv6 main header and TCP header and payload. The complete IPv6 packets are sent through the network. As common extension header, the CEH will not be processed in each router instead of in destination node indicated by destination address field. Another program is run in receiver side to compute the CRC code following figure 5.

6. RESULT AND DISCUSSION

In this section, we present result of our study on data length scope of the three candidates. Capability of generator polynomial to detect transmission error can be measured by its probability of undetected error [9], [10], [12]. This is summarized in table 1.

Based on table 1, HD = 4 and 6 whose available on the three candidates states obviously. This refers to the existing widely generator polynomial which is Ethernet. It uses HD = 4 with minimum data length 4096 (512 bytes) and maximum 12144 (1518 bytes). The data length interval is used in standard IEEE 802.3 for all type of Ethernet. For CEH implementation, we chose to use HD = 4. It means all burst error with 3 bits and below is able to be detected by the generator polynomial.

Table 1 Summary of Data Length

Generator	Factor	HD	Data length (bit)
CRC-32E	32	3	$2^{32} - 1$
		4	**4096 – 12144**
		5	512 – 2048
		6	204 – 300
CRC-32C	1,31	3	-
		4	**5276 – ($2^{31} - 1$)**
		5	-
		6	210 – 5275
CRC-32K	1,3,28	3	-
		4	**16361 – 114663**
		5	-
		6	153 – 16360

Consider to RFC 2460 [12], the minimum MTU in IPv6 transmission over Ethernet is 1280 bytes or 10240 bits. This minimum length is able to be covered by CRC-32E and CRC-32C and it is not covered by CRC-32K. The maximum length of IPv6 MTU over Ethernet is 1518 bytes or 12144 bits. This value is also covered by CRC-32E and CRC-32C. However, for the CRC-32E this value is its maximum. Hence, it is difficult to use for the future because of increasing Ethernet MTU such as jumbo frame implementation. CRC-32C is suitable for larger MTU in the future.

Our experiment used topology in figure 6 to note processing time of each generator polynomial. Processing time of the first packet is different from the following packet. In case of the first packet, it runs full algorithm to generate a table 156-entry. Thus, time processing for the first packet is the biggest one. While other following packets consume fewer time to generate the CRC code. This is because it utilizes the preceding table lookup generated by the first packet.

We sent various sizes of IPv6 packet from sender to receiver: 64, 128, 25, 512, 1024, 1280 and 1492 bytes. The data documented are processing time in sender, receiver and total processing time. Processing time is the time required to generate CRC 32 code and insert it in IPv6 packet as extension header. With an assumption time of IPv6 packet generation is constant value, the processing times represent time to generate CRC code. The result is shown in figure 7, 8 and 9 respectively.

Figure 7 shows graph processing time (ms) vs packet size (bytes) at the sender side. The processing time increases with increasing packet size. This is inline with nature of CRC code that is linier code. Three generator polynomials show tight competition. All of packet size demonstrates small differences. However, the average processing time of CRC-32C is the lowest value that is 0.900 ms compare to CRC-32K 0.918 ms and CRC-32E 0.912 ms.

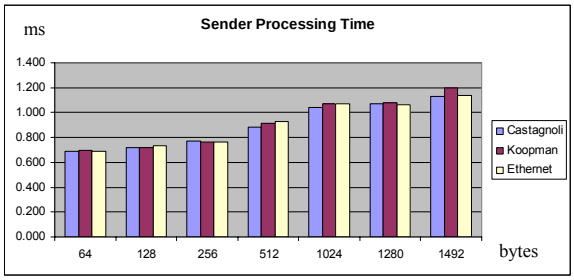

Figure 7 Sender Processing Time

Figure 8 shows processing time (ms) vs packet size (bytes) at the receiver side. The graph also demonstrates similar inclination with sender side. The processing time for the first IPv6 packet in receiver side increases with packet size increasing. However, receiver processing time is smaller than sender side. This is because in the receiver, there is no IPv6 packet generation.

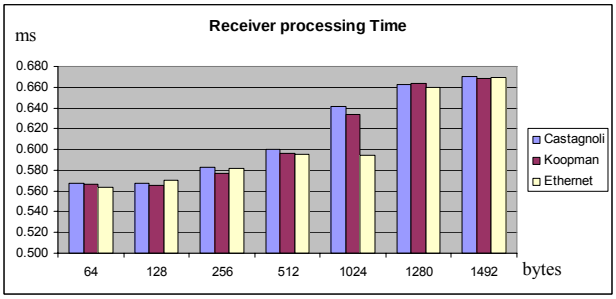

Figure 8 Processing Time in Receiver Side

The smallest average receiver processing time is belonging to CRC-32E that is 0.605 ms and 0.613 ms for CRC-32C and CRC-32K is 0.610 ms.
Total processing time of CRC code generation is shown in figure 9. Similar to previous processing time, the figure also illustrates that the three candidates are homogeny. It means the three generator polynomials are applicable in CEH from processing time point of view. Hence, capability of error detection that is analyzed in early of this section is a good way to determine which polynomial suitable for CEH.

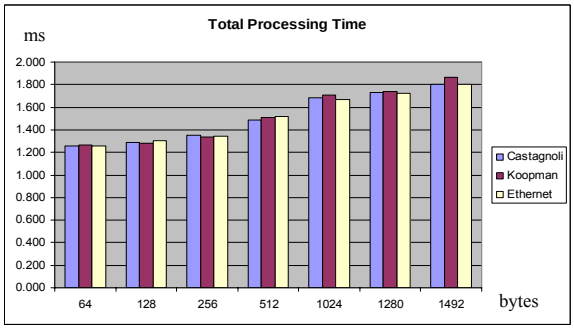

Figure 9 Total Processing Time

As stated earlier, the processing time is based on the first packet. The other following packet need smaller time processing to generate CRC code. This is because there is a CRC code stored on table from the first packet. Figure 10 demonstrates processing time for common Internet packet size that is 1518 bytes. The graph shows time processing for the following packet in exponentially decrease. The three generators shows their trend line enumerated below

$$\text{CRC-32C} = 0.7601x^{-0.9562}$$
$$\text{CRC-32K} = 0.7626x^{-0.9422}$$
$$\text{CRC-32E} = 0.7612x^{-0.9554}$$

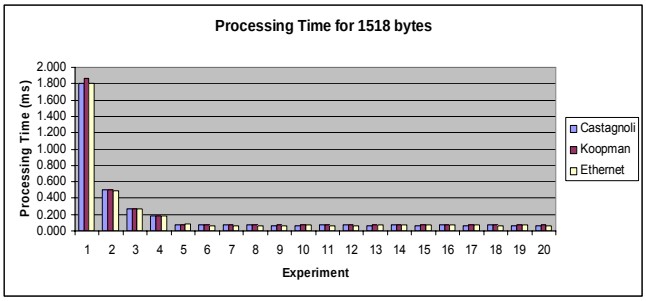

Figure 10 Time Processing for 1518 bytes packet size

The three exponential trend lines demonstrate that CRC-32C has smallest coefficient and power. This means the CRC generator polynomial has the best trend line. The processing time decreases toward smallest value.

7. CONCLUSION

We proposed CRC Extension Header (CEH) as a new mechanism to reduce duplicate error detection in intermediate node. CEH is applied to perform error control in the Network layer. With Network layer error control, we can eliminate error control in each intermediate node which possible to reduce the transmission time. CEH generation needs a generator polynomial. This paper described CEH and how selection of most suitable CRC-32 code generator polynomial for CEH was done. Among the generator used in existing Ethernet (CRC-32E) and two other generator suggested by Castagnoli (CRC-32C) and Koopman (CRC-32K), CRC-32C showed the best result. Its data length range covers larger data and at the same time the minimum data length also smaller than minimum MTU of IPv6 packet. The trend line of CRC-32C has smallest coefficient. We then conclude that CRC-32C suggested by Castagnoli is the most suitable generator polynomial for CRC extension header. Our future works will be implementing the CEH and analyzing its efficiency in handling the error detection in the high speed network.

ABSTRACT

Power quality is an issue that is becoming increasingly important to electricity consumers at all level of usage. These result from with increasing use of electronic equipment in several sectors for the reason to improve energy efficiency. Almost all power quality issues are closely related with power electronic. Equipment using power electronics in low voltage environments for examples are television, microwave ovens, personal computers, printer, lighting, heating ventilation air conditioners, etc..Using with high efficiency fluorescent lighting with electronic ballast, adjustable speed drive for air conditioning and single phase switch mode power supplies for computers. These equipments are characterized as harmonic sources and also highly susceptible to voltage sag. Harmonics and voltage sags are most frequent among various types of power quality disturbance faced by many consumers. Sources of power quality problems, such as harmonics caused by electronic equipments are characterized as non linear load, whereas voltage sags generally as result from faults (short circuit) in transmission or distribution line. Voltage sags normally do not cause equipment damage, but can easily disrupt the operation sensitive load. Effect produced by voltage sags are variable in generally depending on the magnitude and duration of the sags and type of equipment. A Shaffner "Profline2100" has used for measuring harmonics source and load sensitivity test to voltage sags.

Keywords

Power quality, Harmonics, Voltage Sags, Low voltage consumer loads.

1. INTRODUCTION

With the increasing use of electronic equipment in office buildings and household, power quality issues in low-voltage distribution systems have received much attention from utilities, building owners, tenants and manufacturers. The problems in power quality appeared for the first time in the beginning of the 1980s with the introduction of non linear loads like computers, power electronics, internet, etc [1]-[2]. The power quality problems is defined as any power problem manifested in voltage, current, or frequency deviations that result in failure or disoperation of customer equipment [2].

Many electronics equipment systems are susceptible to disturbances come from the input power supplied to them. Some of the common power disturbances are voltage sags caused by fault in power system, transient over voltage created by the switching of the utility's capacitor banks, voltage waveform distortion generated by the injection of harmonic currents from nonlinear loads is propagate to all distribution circuits [2]-[3].

The harmonic currents interact with the power system impedance creates harmonic voltage distortion on the system. The voltage distortion will continue to increase in the electrical environment as more electronic loads are connected to the power system. For examples the equipment which dominant harmonic sources in commercial building are computers, etc [2]-[5], fluorescent lamps and adjustable-speed drives (ASDs) for heat ventilation AC (HVAC) system and control motor, associated with the diode bridge rectifier circuit having a constant high fundamental power factor [2]-[3]-[4]-[6].

Almost all power quality issues are closely related with power electronic. Equipment presents different levels of sensitive to power quality issues, depending on type of both the equipment and the disturbance. Several surveys have been carried out to determine the relationship between perturbations and damage. The results are not always comparable due to discrepancies in the definition of perturbation characteristics [2].

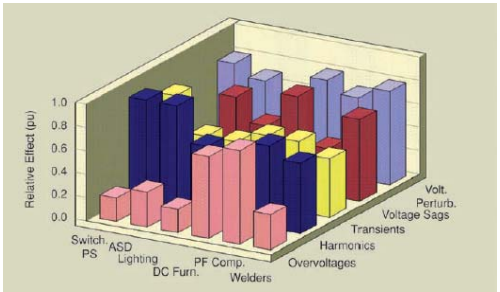

Figure 1(a). PQ issues caused by electronic equipment

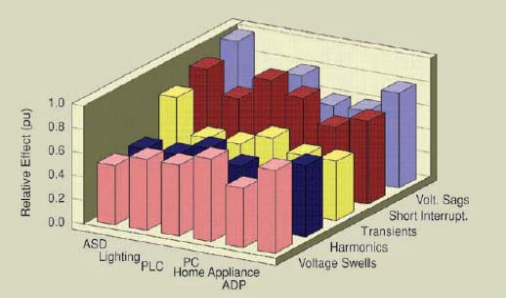

Figure 1(b) Effect of PQ issues on electronic equipment.

The relationship between a typical equipment sensitive and disturbance is shown in Figure 1(a). Furthermore, the effect on power quality of electric power systems due to presence of power electronic equipment, depends on the type of power electronic used. Figure 1(b) shows typical effects of the most common electronic equipment application. From the both of figure, ASDs are extremely sensitive to power quality problems and it's also creates power quality problem.

2. SOURCES OF POWER QUALITY PROBLEMS

2.1. Electronic Power Supplies

Electronic power supplies single phase electronic power supplies are becoming a dominant load in commercial buildings. Personal computers, printers, copiers, and most other single-phase electronic equipment now almost universally employ switch-mode power supplies. The key advantages are the light weight, compact size, and efficient operation. All contain power supplies with similar characteristics [1]-[2]. The personal computer is identified as the most prominent source of harmonics distortion [5,6]. PCs cause power related problems due to the electronic switch mode power supply. They are typical single phase and require low voltage power supply. Almost all electronic power supplies contain a diode bridge rectifier, which supplies d.c power to large d.c filter capacitors. The rectified filter d.c potential is then electronically regulated by a switch mode dc/dc converter before it is passed to micro electronic circuitry.

The percentage of load that contains electronic power supplies is increasing at a dramatic space, with the increased utilization of personal computers in every commercial sector. Commercial loads are characterized by a large number of small harmonic-producing loads.

There are two common types of single-phase power supplies. Older technologies use ac-side voltage control methods, such as transformers, to reduce voltages to the level required for the dc bus. The inductance of the transformer provides a beneficial side effect by smoothing the input current waveform, reducing harmonic content. Newer-technology switch-mode power supplies use dc-to-dc conversion techniques to achieve a smooth dc output with small, light weight components. The input diode bridge is directly connected to the ac line, eliminating the transformer. This results in a coarsely regulated dc voltage on the capacitor. This direct current is then converted back to alternating current at a very high frequency by the switcher and subsequently rectified again.

Figure 2 shows the current and voltage waveforms for a personal computer from laboratory measurement result. It can be shown that the current is pulsed around the peak of the voltage. Odd harmonics have percentage harmonic distortions are much larger than even harmonics. Odd harmonics created are significant until nineteenth harmonics and become small gradually. From harmonic spectrum result obtained the value of total harmonic distortion (THD) of current is 189.4 percent and crest factor (CF) is 5.9. It shows that the computers are a significant as source of harmonics and also generate high crest factor.

2.2. Fluorescent Lighting

The typically accounts for 40 to 60 percent of a commercial building load and it's supplied through low voltage. According to the 1995 Commercial Buildings Energy Consumption study conducted by the U.S. Energy Information Administration, fluorescent lighting was used on 77 percent of commercial floor spaces, while only 14 percent of the spaces used incandescent lighting [3]. Fluorescent lights are a popular choice for energy savings.

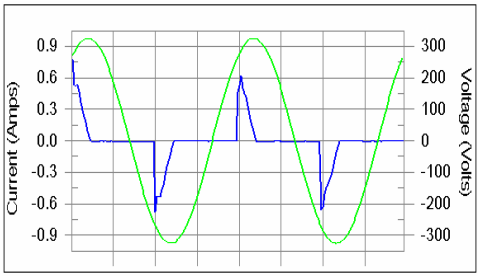

Figure 2(a). Current, voltage waveforms for personal computer.

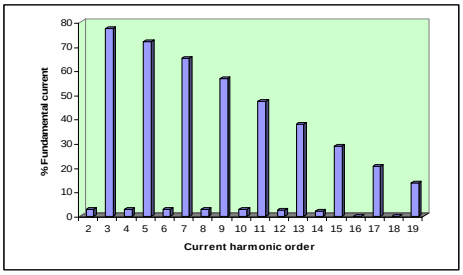

Figure 2(b). Harmonics spectrum for personal computer

Fluorescent lights are discharge lamps which require a ballast to provide a high initial voltage to initiate the discharge for the electric current to flow between two electrodes in the

fluorescent tube. Once the discharge is established, the voltage decreases as the arc current increases. It is essentially a short circuit between the two electrodes, and the ballast has to quickly reduce the current to a level to maintain the specified lumen output. Thus, ballast is also a current-limiting device in lighting applications.

There are two types of ballasts i.e. magnetic and electronic and it does can be supplied at either: 120 volt, 220 volt or 240 volt. Standard magnetic ballast is simply made up of an iron-core transformer with a capacitor encased in an insulating material. Single magnetic ballast can drive one or two fluorescent lamps, and it operates at the line fundamental frequency, i.e., 50 or 60 Hz. The iron-core magnetic ballast contributes additional heat losses, which makes it inefficient compared to electronic ballast.

The lamp voltage and current are at the same frequency of the input ac source, as shown in Figure 3(a). Conventional magnetic ballasts are rapidly being replaced by electronic ballast [3]. Electronic ballast employs a switch-mode–type power supply to convert the incoming fundamental frequency voltage to a much higher frequency voltage typically in the range of 25 to 40 kHz, as shown Figure 3(b). This high frequency has two advantages. First, a small inductor is sufficient to limit the arc current. Second, the high frequency eliminates or greatly reduces the 100 or 120-Hz flicker associated with iron-core magnetic ballast.

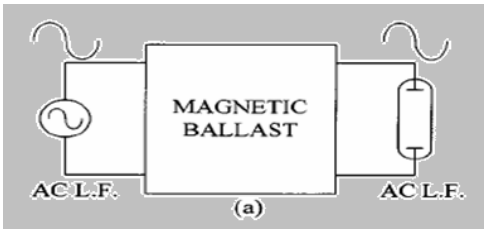

Fig. 3(a). Low-frequency (L.F.) magnetic ballast

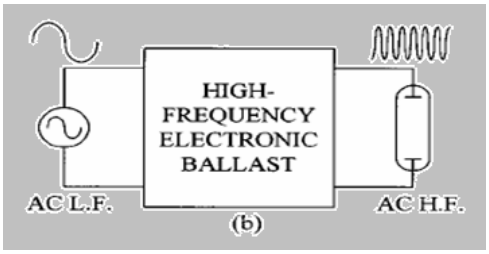

Fig.3(b) High-frequency (H.F.) electronic ballast.

Standard magnetic ballasts are usually rather light source of additional harmonics themselves, because the main harmonic comes from the behavior of the arc [2]. Figures 4 and 5 show a measured fluorescent lamp with magnetic ballast and electronic ballast, respectively. They draw non-sinusoidal current in power system.

The fluorescent lamp with magnetic ballast, the current THD is 17.85 percent and crest factor is 1.6. As a comparison, electronic ballast has current THD of 209 percent and crest factor is 4.3. The both of the lamps generate odd harmonic currents only. Because the fluorescent lamps are significant source of harmonic in commercial buildings, they are usually distributed among the phases in a nearly balanced manner.

2.3. Adjustable speed drive (ASD) for HVAC applications

Common applications of adjustable-speed drives in commercial loads can be found in elevator to control motors and in pumps and fans in HVAC systems. An ASD consists of an electronic power converter that converts ac voltage and frequency into variable voltage and frequency. The variable voltage and frequency allows the ASD to control motor speed to match the application requirement such as slowing a pump or fan. Figure 5 illustrates the current waveform and harmonic spectrum for a typical adjustable-speed-drive (ASD) input current [3]. The ASD gives high crest factor too and the current THD of 41.1 percent.

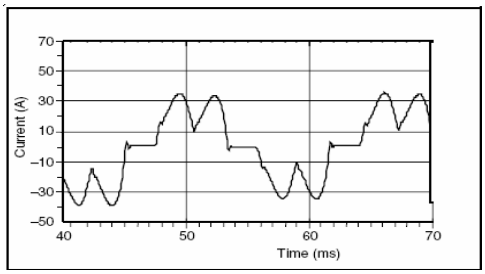

Figure 5(a). Current for an ASD input current

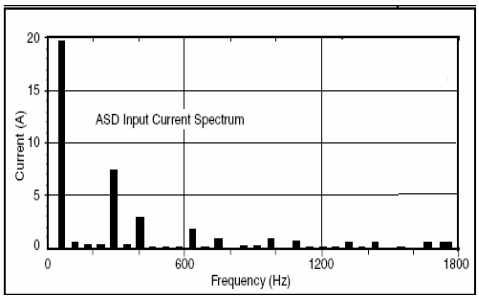

Figure 5(b). Harmonic spectrum for an ASD input

2.4. Voltage sags

Voltage sags are usually associated with system faults but can also be caused by energizing of heavy loads or starting of large motors. The faults on transmission/distribution system can affect even more customers. The customers hundreds of miles from the fault location can still experience voltage sag such as Figure 6, resulting in equipment miss-operation even shutdown [5]. During voltage sag, the voltage is below normal for some period of time that reduces the power and energy delivered to load by the system. The energy lost during a voltage sag event is a function of voltage and the time duration of the sag event.

Voltage sags and momentary interruptions are two of the common power quality concerns for utility customers with sensitive electronic equipment. In power system, disturbances for example voltage sags and service interruptions inevitably occur on some occasions.

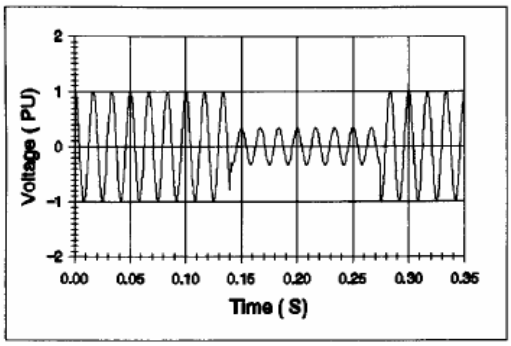

Figure 6. Voltage sag waveform caused by remote fault condition

Customers usually can tolerate complete outages or blackouts since faults in the power system are inevitable. However customers are intolerant if their equipment frequently malfunctions due to voltage sags and momentary interruption in power system. Faults resulting in voltage sags and interruptions can occur within the building installation or on utility system. The voltage sag usually lasts until the fault is cleared by a protective device. This device can be fuse, circuit breaker, re-closer. Table 1 shows types of the protection system used for low voltage system [4].

Table 1. Types of the protection system

Protection Scheme	Sag duration
Fuse	5 to 10 ms
Breaker	80 to 150 ms
Auto re-closing	300 to 700 ms
Back up protection	300 ms to some seconds

3. EFFECT OF POWER QUALITY PROBLEMS

3.1. Effect of Harmonic distortion

The harmonic currents to flow from the harmonic producing load to the power system. The impedance of the power system is normally the lowest impedance seen by the harmonic currents. The harmonic currents interact with the impedances to give rise to harmonic voltage distortion. IEEE Standard 519 [7] provides guidelines for acceptable levels of voltage distortion on the utility system. Evaluations of harmonic distortion are usually performed at a point between the customer and the utility system where another customer can be served. This point is known as the point of common coupling (PCC). The recommended limit the harmonic voltage distortion level for system below 69 kV should be less than 5 percent. If it exceeds the recommended standard limit can influenced on equipment.

The presence additional losses significantly cause increased heating on transformers and motors [3]-[8]. Hysteresis and eddy current losses in the core increase as higher frequency harmonic voltage are impressed on the windings. Hysteresis increase with frequency and eddy current losses increase as the square of the frequency. The current harmonic increases produce additional I^2R losses in the windings. This additional I^2R loss also happened on cables and neutral wires to operate at excessive temperature level. The effective resistance of the cable increase with frequency because of the phenomenon known a skin effect. These increased heating effects can shorten equipment operating life.

The other equipment can be affected by harmonics distortion such as circuit breakers to fail prematurely or malfunction [4]. Capacitor can experience overload and subsequent failure because of absorbe harmonic current. Harmonic currents and highly crest factor influence the operation of protective device [5]-[8]. Fuse and thermal overload relays are prone to nuisance operation when subjected to non linier currents. The relays can operate faster or slower than the expected times for operation at the fundamental frequency alone. Reading error in kWH meters. Computers may exhibit data errors or loss of data and electronic process control may operate out of sequence [4].

The large third harmonic currents in the neutral conductor of rising bus-bar may lead to vibration of joints and cable terminations. If the neutral fails on rising bus-bar system serving single phase loads, over voltage can occur on each single phase board is connected across two phases. Hence, failure of equipment will occur that most common problem is burnt out switch mode power supplies [5].

3.2. Effect of Voltage Sag

Voltage sags normally do not cause equipment damage, but can easily disrupt the operation of sensitive electronic equipment. The voltage sag can be characterized by their magnitude and their duration. The equipment sensitive is determined by the both of values. The sensitivity of the equipment to voltage sags can be expressed by the tolerance curve. Two popular equipment tolerances curve namely the information technology industry council (ITIC) curve and the SEMI F47 curve. Based on reference [9] states more than 62% of disturbance recorded were voltage sags with duration of less than 0.5 s (30 cycles). The effects produced by these disturbances on the equipment are variable depending on equipment types.

3.2.1. Effect on computers.

Voltage sag is normally not a significant problem to single computers unless they are used as servers. In such cases it is relatively easy to protect them, for minor cost by using backup power supply. The problem is not very significant to ordinary single PCs since the lost work not often exceeds 1-2 hours work and often there is a back up or automatic restore of the file. However, there are some PC based offices where disruption will costly greatly. Financial trading and telecommunication offices are typical examples [9]. Two different computers are test to study the effect of voltage sag with specifications of them are shown in Table 4.

Table 4 Specification of the tested computer

	Computer 1	Computer 2
CPU	Intel Pentium III	Intel Pentium IV
RAM	64 MB	512 MB
Hard disk	40 GB	80 GB
Monitor	Dell	Dell
Operating system	Windows 98	Windows 2003

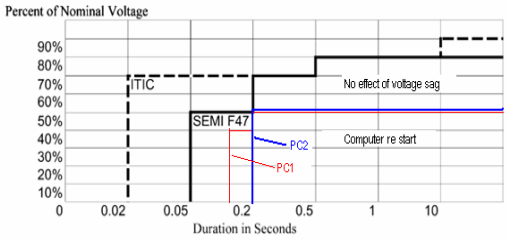

Figure 7. Sensitivity curves for computer

From the Figure 7 for sag of depth 90% to 55%, there are no effects on the both of computers observed during period. However, for sag of depth 50% with duration of 0.2s or more, the both of computers showing restart. For sag of 40%, duration of 0.1s the both of PCs have different sensitive. The 1st computer restarts, while the 2nd computer still in normal operation. Computer 1 shutdown for sag of depth 30% or less, duration 0.1s or more, whereas computer 2 shutdown for sag of 20% or less. It means computer 1 is slightly more sensitive than computer 2. And also can be seen in Figure 7, sensitivity curve for the both of computer is much lower than standard ITIC and SEMI F47 curves. The part above of computer curve denotes that computers do not re start caused by voltage sag.

3.2.2. Effect on Lightings loads

Voltage sags may cause lamps to extinguish. Light bulbs will just twinkle; that will likely not be considered to be serious effect. All lamps, except incandescent lamps, require high voltage across the electrodes during starting. This voltage is essential to initiate the arc. The lamp starting voltage is affected to a large extend by the ambient temperature and humidity levels as well as the supply voltage [9]. Experiments were done two of the most common categories of lightning loads: Fluorescent lamps and Mercury vapor lamp. The specifications of the lamps tested such as in Table 5.

Table 5 Specification of the tested lamp

	Lamp 1	Lamp 2
Type	FCL with magnetic ballast	Mercury vapor lamp
	240 VAC/18 Watt/ 0.37A/PF=0.32	240 VAC/250Watt/ 2.10A/ PF=0.52

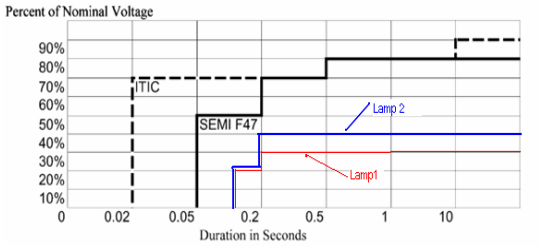

Figure 8 Sensitivity curve for lamps

The Figure 8 shows impact voltage sag on the lamps. Sensitivity of the lamps has response not similar. For examples, for sags of depth until 40% do not cause lamp 1 switch off; whereas lamp 2 when subjected for sag of depth 60 and duration of 10s above will switch off. Its light becomes weaker during the sag period. Sag duration does not affect fluorescent lamp's lightness. The lighting weakness caused by sag depth.

In Figure 8, curves of the fluorescent lamp (lamp 1) and mercury vapor lamp (lamp 2) are much lower than the standard ITIC curve and SEMI F47 curve. Above the line curve, the lamps do not switch off. There may be visible effects like flickering. However, below the line curve the lamps switch off. From this figure also can be shown that the lamp 1 switch off for sags of 30%, duration of 0.2s above. The lamp 2 switches off for sags of 40% and duration of 0.2s above. It's mean that lamp 2 more sensitive than lamp 1.

7. CONCLUSION

Personal computers, adjustable speed drives can be found in elevator to control motors and in pumps and fans in heat ventilations (HV) AC systems, fluorescent lamp with electronic ballast are significant a source harmonics. They inject non sinusoidal current propagate to all circuit of power systems. Interaction of the current with impedance cause harmonic voltage distortion. It can cause detrimental some of equipment in power system and also in consumer.

The computers show almost same affect on the occurrence of voltage sags. The both of computers restart for sag of depth 50% below and duration 0.2 seconds or more. The computers even can shutdown for lower voltage sag.

In the case of lightings show difference behavior on the occurrence of voltage sags. Mercury vapor lamp (lamp 2) more sensitive than fluorescent lamp (lamp 1). They will switch off for voltage sag of 40% and voltage sag 30%, respectively and duration 0.2 seconds or more.

ABSTRACT

Nowadays, it is difficult to access radio spectrum because of complicated radio regulation. Large parts of our radio spectrum are sent to licensed radio services. As a matter of fact, a free access to open spectrum, is generally not permitted. However, only some small fractions of the radio spectrum are openly available. These are the unlicensed frequency bands, which build a tiny fraction of the entire radio spectrum, where overlay sharing is commonly used. Spectrum access remains to be a restricting obstacle that may even slow down the development of new radio services that can substantially improve our health, safety, work environment, education of people, and quality of leisure time. This study aims at solving the problem of the difficulty of accessing radio spectrum suffeciently by using the new communication paradigm; cognitive radios. The definition of cognitive radios, system requirements, system architecture and system functions will be discussed.

Cognitive Radios are capable of sensing their spectral environment and locating free spectrum resources. Radios perform local spectrum sensing but Primary User detection and channel allocation is performed in a coordinated manner. This collaborative effort increases the system's ability in identifying and avoiding Primary Users. A group of Cognitive Radios forms a Secondary User Group to coordinate their communication. Each member of this group senses the Spectrum Pool, which is divided into sub-channels. A pair of Secondary Users picks a set of sub-channels spread over multiple Primary User frequency bands to form a Secondary User Link. Sub-channels are picked based on estimated channel gain of a sub-channel and the user's requirements. For group management a number of underlay control channels exists. A Universal Control Channel is used by all groups for coordination and separate Group Control Channels are used by members of a group to exchange sensing information and establish Secondary User Links.

The commercial success of wireless applications in the unlicensed bands indicate that it may be helpful to change our established radio regulatory regime, towards an open spectrum access. We may just want to let radio systems coordinate their usage of radio spectrum themselves, without involving regulation. Cognitive radios overcome this problem as they autonomously manage the usage of spectrum.

In this paper the cognitive radio system which is used to regulate unoccupied frequency bands for the creation of virtual unlicensed spectrum is presented.

1. INTRODUCTION

This paper presents a Cognitive Radio approach for usage of Virtual Unlicensed Spectrum (CORVUS), a vision of a Cognitive Radio (CR) based approach that invests allowed spectrum to create "virtual unlicensed bands" i.e. bands that are shared with the primary (often licensed) users on a non-interfering basis. Dynamic spectrum management techniques are used to adapt to immediate local spectrum availability. The system requirements for this approach will be presented, as well as the general architecture and basic physical and link layer functions of CORVUS. This system has been designed by a group of scientists from Berkeley Wireless Research Center, University of California at Berkeley, USA and Telecommunication networks Group, Technical University of Berlin, Germany.

It is commonly believed that there is a crisis of spectrum availability at frequencies that can be economically used for wireless communications, which indicates that a new approach to spectrum licensing is needed. What is clearly needed is an approach, which provides the incentives and efficiency of unlicensed usage to other spectral bands, while accommodating the present users who have higher priority or legacy rights (**primary users**) and enabling future systems a more flexible spectrum access.

An approach, which can meet these goals, is to develop a radio that is able to reliably sense the spectral environment over a wide bandwidth, detect the presence/absence of legacy users and use the spectrum only if communication does not interfere with any primary user. These radios are lower priority **secondary users,** which exploit cognitive radio (CR) techniques, to ensure non-interfering co-existence with the primary users**.** The sensing function is one of the most important attributes of cognitive radios - as it ensures non-interference to licensed users - and should involve more sophisticated techniques than simple determination of power in a frequency band. A CR must sense across the multiple signal dimensions of time, frequency and physical space, of a wireless channel and user networks**. B**est CR operation will allow sensing of the environment and transmission optimized across all of these dimensions and thus allows a truly revolutionary increase in the capacity of spectra to support new wireless applications.

2. COGNITIVE RADIOS

2.1. The Definition of Cognitive Radios

Cognitive radio is a paradigm for wireless communication in which either a network or a wireless connection changes its transmission or reception restrictions to communicate efficiently avoiding interference with licensed or unlicensed users. This alteration of restrictions is based on the active monitoring of several factors in the external and internal radio environment, such as radio frequency spectrum, user behaviour and network state.

2.2. History

The idea of cognitive radio was first presented officially in an article by Joseph Mitola III and Gerald Q. Maguire, Jr in 1999. It was a novel approach in wireless communications that Mitola later described as:

The point in which wireless personal digital assistants (PDAs) and the related networks are sufficiently computationally intelligent about radio resources and related computer-to-computer communications to detect user communications needs as a function of use context, and to provide radio resources and wireless services most appropriate to those needs.

It was thought of as an ideal goal towards which a software-defined radio platform should evolve: a fully reconfigurable wireless black-box that automatically changes its communication variables in response to network and user demands.

Regulatory bodies in various countries (including the Federal Communications Commission in the United States, and Occam in the United Kingdom) found that most of the radio frequency spectrum was inefficiently utilized.[3] For example, cellular network bands are overloaded in most parts of the world, but amateur radio and paging frequencies are not. Independent studies performed in some countries confirmed that observation,[4][5] and concluded that spectrum utilization depends strongly on time and place. Moreover, fixed spectrum allocation prevents rarely used frequencies (those assigned to specific services) from being used by unlicensed users, even when their transmissions would not interfere at all with the assigned service. This was the reason for allowing unlicensed users to utilize licensed bands whenever it would not cause any interference (by avoiding them whenever legitimate user presence is sensed). This paradigm for wireless communication is known as cognitive radio.

3. SYSTEM REQUIREMENTS

The basic premises of the CORVUS system are as follows:

1) Abundance of spectra, which is available and used for spectrum sharing by Secondary Users (SU).

2) SUs use cognitive radio techniques to avoid interfering with Primary Users (PU) when they are present.

We define a PU as an entity that has a high priority in a given frequency band (e.g. cell phone provider, TV station, emergency services, etc). PUs are not cognitive radio aware, i.e. there are no means to exchange information between primary and secondary users provided by a primary system. Specifically, PUs do not provide special signaling in order to access their frequency band. We assume all SUs having cognitive radio capability, i.e. the system only consists of Primary Users and Cognitive Radio capable SUs. Cognitive unaware Secondary Users are treated as noise by this system. In this heterogeneous network, it is assumed that a PU can tolerate interference for no more than at time units. Note that this interference time is dependent on the primary system and may be different for different PUs. After this interference time all SUs have to clear the frequencies belonging to the frequency band of the respective PU. Also, even if a SU is currently using parts of a primary user frequency band, the PU of that band may start the transmission at any time. In case the PU is using a carrier sense access scheme, an SU operating in that band thus has to operate below the carrier sense sensitivity of the PU.

From the above, it is clear that a fundamental requirement for the Secondary User is to continually monitor the presence of Primary Users (or at least every Δt_x). In order to reliably detect primary users, SUs use information based on the Primary User Footprint, which is assumed to be available to the SU System. The primary user footprint includes - but is not limited to - the information from FCC's spectrum inventory table [1]. Additional information could be maximum interference time Δt_x, and local characteristics of PUs such as minimum communication times or time of use.

4. System Architecture

In our system model, SUs form Secondary User Groups (SU Groups) to coordinate their communication. Members of a SU Group use a common control channel for signaling and might communicate with each other in a distributed ad-hoc mode or through a centralized access point. In either mode we assume only a unicast communication, either between a pair of SUs or between a SU and the access point. Direct point-to-point communication between Secondary Users from different SU Group's or broadcast is not supported.
The traffic pattern for the SUs will be initially assumed to have the following characteristics:

1. Centralized, infrastructure based where there has to be a base station or access point providing connection to a backbone connection, as typically found in Internet access networks.
2. Ad hoc networking covers all kinds of ad-hoc traffic that does not assume any infrastructure. Main purpose is to communicate with each other and exchange information within a SU Group.

To support this traffic CORVUS operates over a Spectrum Pool, which could cover from tens of MHz to several GHz creating a "virtual unlicensed band". It is not necessarily a contiguous frequency range and Spectrum Pools of different SU Groups may overlap which implies that SU Groups will compete for the available resources. Each Spectrum Pool will be further divided into N Sub-Channels, which will be the basic resolution used for sensing and transmission.

Figure 2 shows the principle idea of a Spectrum Pooling system in CORVUS. Primary Users own different parts of the spectrum but may not be active at a particular time. The shaded frequency bands indicate that the PU is currently using its spectrum and consequently this frequency band cannot be used by any SU. The figure also shows three different active Secondary User communications. For each communication a pair of SUs picked a pattern of sub-channels to form a Secondary User Link (SU Link). The number of sub-channels in a SU link may vary depending on the quality of the sub-channels, the bandwidth of a single sub-channel and QoS requirement for that connection.

Sub-channels selected to create a SU Link should be scattered over multiple PU frequency. This principle has a double significance. On one hand it limits the interference impact of a SU on a re-appearance of a PU, while on the other hand if a PU appears during the lifetime of a SU Link it would impact very few (preferable one) of the Sub-Channels used by the SU Link. The communication peers using that link would have to immediately clear the affected sub-channel and find a new free sub-channel. In order to maintain QoS, SUs should always have a redundant number of sub-channels for their SU Link.

Within CORVUS, SUs use dedicated logical channels for the exchange of control and sensing information. We envision two different kinds of logical control channels, a Universal Control Channel and Group Control Channels. The Universal Control Channel is globally unique and has to be known to every SU operating in the relevant frequency bands, since access to that channel is pre-requisite for initiating communications. The main purpose of the Universal Control Channel is to announce existing groups and to give the relevant transmission parameters to enable newly arriving users to join a group. Additionally SUs, which want to create a new group can request the local primary user footprints on that channel. Although globally unique the communication range should be locally limited as SU Groups are limited to a local area. In addition to the Universal Control Channel each group has one logical Group Control Channel for the exchange of group control and sensing information.

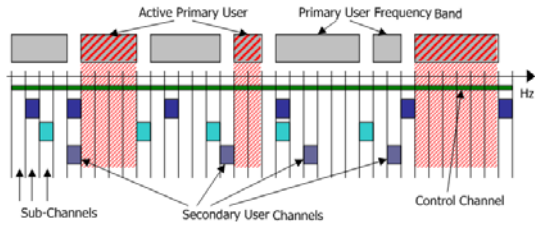

Figure 2. Spectrum pooling idea

Control channels will carry a limited load of low-bit rate signaling which could be located in:

a) dedicated spectrum for this purpose
b) an unlicensed band such as the ISM/UNII bands
c) unlicensed UWB (Ultra Wide Band)

We believe the UWB option is especially attractive if we are considering use of the 3-

10GH band. UWB control channels would be unlicensed but with low impact on other types of communication and with the possibility to operate independently using different spreading codes. There are severe limitations on the power of UWB emissions limiting its range, but the control channel requires very low data rates, so spreading gain will increase the range to be adequate for most applications (more than 10,000 times lower datarate than the commercial UWB systems being envisaged in this band). Note that the Universal Control Channel and the Group Control Channels are logical concepts, which might even be mapped to a single physical channels.

5. SYSTEM FUNCTIONS

Our system design only covers the ISO/OSI layers one (physical layer) and two (link layer). Higher layers will implement standard protocols not specific to cognitive radios and thus are not relevant to our discussion. Figure 3 shows the main building blocks for the deployment of a Cognitive Radio system. We identify six systems functions and two control channels that will implement the core functionality.

5.1. Physical Layer Functions

5.1.1. Spectrum Sensing:

The main function of the physical layer is to sense the spectrum over all available degrees of freedom (time, frequency and space) in order to identify sub-channels currently available for transmission. From this information, SU Links can be formed from a composition of multiple sub-channels. This will require the ability to process a wide bandwidth of spectrum and then perform a wideband spectral, spatial and temporal analysis. Sub-Channels currently used for transmission by SUs have to be surveyed at regular intervals – at least every Δt_x – to detect Primary Users activity on those Sub-Channels ("reclaiming the usage of their Sub-Channels") and if there is activity then those Sub-Channels must be given up.

It will be necessary for the SUs to exchange and merge their local sensing information in order to optimally detect presence of PUs and avoid the hidden terminal problem. This cooperation between SUs within a communicating group will be important to realize adequate accuracy of interference activity. Spectrum sensing is best addressed as a cross-layer design problem since sensitivity can be improved by enhancing radio RF front-end sensitivity, exploiting digital signal processing gain for specific primary user signal, and network cooperation where users share their spectrum sensing measurements.

5.1.2. Channel Estimation:

In order to set up the link, channel sounding is used to estimate the quality of sub-channels between SUs that want to communicate. The transmission parameters (transmit power, bit rate, coding, etc.) are determined based on the channel sounding results. After the setup, the physical layer continuously estimates the quality of sub-channels analyzing the data packets received during ongoing communication.

5.1.3. Data Transmission:

CR's optimally uses the available spectrum as determined by the spectrum sensing and channel estimation functions. Therefore it should have the ability to operate at variable symbol rates, modulation formats (e.g. low to high order QAM), different channel coding schemes, power levels and be able to use multiple antennas for interference nulling, capacity increase (MIMO) or range extension (beam forming). One possible strategy would be based on an OFDM-like modulation across the entire bandwidth in order to most easily resolve the frequency dimension with subsequent spatial and temporal processing.

5.2. Link Layer Functions

5.2.1. Group Management:

We assume that any secondary station will belong to a SU Group. A newly arriving user can either join one of the existing

groups or create a new one through the Universal Control Channel.

5.2.2. Link Management:

covers the setup of a link in order to enable the communication between two SUs and afterwards the maintenance of this SU Link for the duration of the communication. The link layer will initially choose a set of Sub-Channels in order to create a complete SU link subject to the considerations described previously.

5.2.3. Medium Access Control (MAC):

As long as it can be assured that all Sub-Channels are used exclusively, i.e. all Sub-Channels used by one SU Link cannot be used by any other SU Link this problem comes down to a simple token-passing algorithm ensuring that only one of the two communication peers is using the link. However, when considering a multi-group, multi-user system, which may not be centrally organized, making the assumption of exclusively used Sub-Channels is not realistic. So the MAC has to provide means to concurrently access a SU Link by SUs or even to manage the concurrent access of individual Sub-Channels by different connections of different SUs.

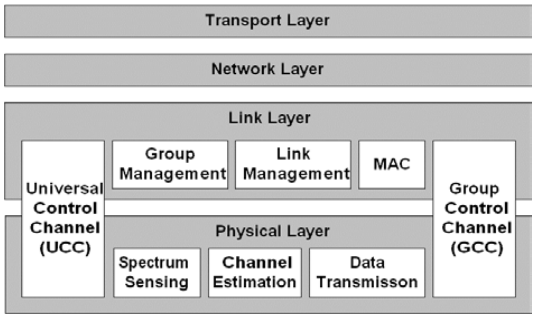

Figure 3. General ISO/OSI Stack for a Cognitive Radi

6. CONCLUSION

In this paper the CORVUS system concepts to harness unoccupied frequency bands for the creation of virtual unlicensed spectrum is presented. The motivation for this approach comes from the enormous success of unlicensed bands and the realization that the present strategy of allocation has resulted in much under-utilized spectra.
Cognitive Radios are capable of sensing their spectral environment and locating free spectrum resources. In CORVUS, these radios perform local spectrum sensing but Primary User detection and channel allocation is performed in a coordinated manner. This collaborative (either centralized or distributed) effort greatly increases the system's ability in identifying and avoiding Primary Users.

In the CORVUS architecture, a group of Cognitive Radios forms a Secondary User Group to coordinate their communication. Each member of this group senses the Spectrum Pool, which is divided into sub-channels. A pair of Secondary Users picks a set of sub-channels spread over multiple Primary User frequency bands to form a Secondary User Link. Sub-channels are picked based on estimated channel gain of a sub-channel and the user's QoS requirements. Furthermore, chosen sub-channels are scattered over the frequency bands of multiple Primary Users to reduce disruption when a Primary User reappears. For group management a number of underlay control channels exists. A Universal Control Channel is used by all groups for coordination and separate Group Control Channels are used by members of a group to exchange sensing information and establish Secondary User Links.

ABSTRACT

On this paper being analyzed the optical link of Palapa Ring Project in the Region 10 that clustering in the arroud Maluku islands. From the numerical simulation by employing single channel with capacity of rate transmission is 10 Gbps, the maximum of span fiber length is 6 Km while to reach 679 Km away between those cities need 64 EDFA's. By this scheme, regarding combination to Radio over Fiber to reach the rural area so minimum 1 EDFA is also required.

Keywords: *Palapa Ring Project, Radio over Fiber, optical power budget, EDFA*

1. INTRODUCTION

The needs of optical link network that could linking-up the whole region of Indonesia is very essential in order to develop integrity and nationalism. Those whole regions are spread between 5 main islands and 17.000 islands. By looking closer, the many type of social conditions among them not all of them having access to global internet up to date information. The open or free access to information or internet only exist in the main regency such capital of province or center of industry area. This condition influences the economic growth of each region relatively has a great distinction. As an example west region relatively has highest growth that east region. Also the education factor has been influenced by this factor. Internet, communication, and information access is become the fundamental needs to develop the capacity of those region in order to enhance their capability in education and economic.

Palapa Ring Project is the main solution to provide its problem. This project is optical network between 440 Residents (Kabupaten) that launched by Information and Communication Department of Republic Indonesia, also supported by some of telecommunication operator in Indonesia [1]. The launching of this project has begun in 2009 and realizing in the east region first that targeted finish in 2011. The existing of optical network only exist in the west region that connected to Singapore and Hongkong access. This would be integrated with the entire developed network of Palapa Ring. The region of optical link is divided into 11 regions that consist of:

1. Region 1 = West Sumatra
2. Region 2 = Riau, Jambi
3. Region 3 = South Sumatra
4. Region 4 = West Borneo
5. Region 5 = East & South Borneo
6. Region 6 = North Sulawesi
7. Region 7 = South Sulawesi
8. Region 8 = West Papua
9. Region 10 = Bali & Mataram
10. Region 9 = Maluku
11. Region 11 = Java

Those regions would be integrated with optical link via optical communication link. This communication has to consider with the network topology in order to enhance the reliability and access performance. Optical transmission planning is the key to make up those planning. This planning include some optical components (active/passive; laser transmitter, optic receiver, optical amplifier, optical fiber, connector, MUX/De-MUX). Also the heart of optical transmission planning is considering with bandwidth of transmission and parameters that determining the performances and reliability of this network. The main parameter of optical transmission planning are BER (bit error rate) and time of (jitter/wander).

The mature development of communication sytem has reached the broadband scheme. This scheme could be combined in optical fiber communication system called Radio over Fiber [2]. The demand for broadband access has grown steadily as users experience the convenience of high-speed response combined with always-on connectivity. A broadband wireless access network (BWAN) is a cost-effective alternative to providing users with such broadband services since it requires less infrastructure compared to wire-line access networks such as xDSL and cable modem networks [3]. Thus, these days the so-called wireless last miles has attracted much attention. However, it has been concerned mainly with densely populated urban areas. Recent survey shows that although penetration of personal computers in rural areas is significant in some countries most of the users still use low-speed dial-up modem for the Internet access [2] [3]. Since in such case broadband services based on wire-line networks are prohibitively expensive, wireless access network might be the best solution. On the other hand, a radio over fiber (ROF) based wireless access network has been proposed as a promising alternative to BWANs due to its cost-effective network architecture [4]. Hence this scheme could reach the entire region of 440 residents not only restricted to main resident but also could reach the

whole regencies. This hybrid scheme could overcome the geographic condition that has already become main problem to broadcast and open access of communication and information.

On this paper being analyzed the optical power budget that could provide information about the needs and requirement of optic components to build those optical links. Also this analyzes is regarding the possibility to merit with the broadband wireless access network (BWAN).

2. METHOD OF EXPERIMENT

The numerical simulation is taking into account by below diagram:

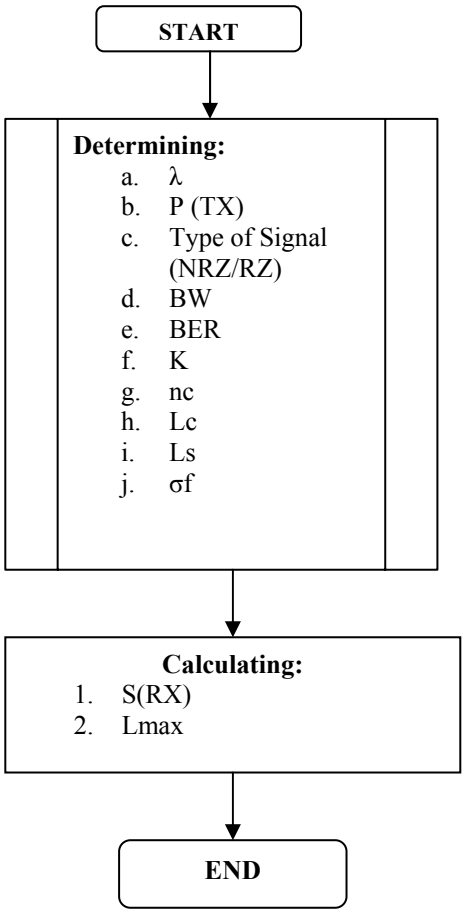

Figure 2.1 Diagram of numerical simulation to find S(RX), L

a. λ the wavelength is chosen at 1300 nm and 1550nm (S and C band)
b. P (TX) is the power of semiconductor laser sources as transmitter in dBm
c. Type of Signal (NRZ/RZ) is the type of digital signal that modulated into laser sources
d. BW is bandwidth of information being broadcasted into network
e. BER is bit error rate
f. K is Excess Noise Factor
g. M is margin of optical link
h. nc is number of connection
i. Lc is loss of connection
j. Ls is loss of splice
k. σf is fiber dispersion factor

The numerical simulation is finding the values of **S(RX)**; sensitivity of photodetector in dBm, **Lmax**; the span of fiber length.

3. RESULT & DISCUSSION

The model of optical link for repeatered submarine fiber optic in the Region 10 (Maluku) as backbone is outlined as figure 3.1.

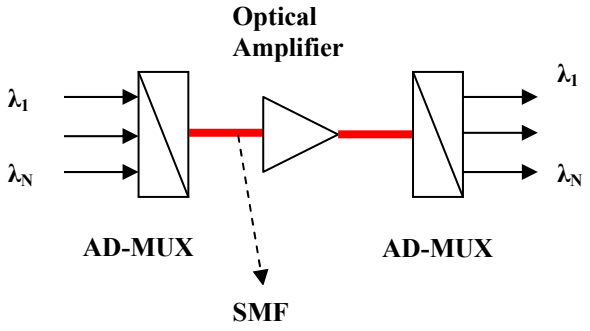

Figure 3.1 The model of Passive Optical Network as backbone.

Figure 3.2 Map of Region 10.

Table 3.1 Span maximum of fiber length for all channel.

λ (Channel)	BW (Gbps)	Lmax (Km)
1	1	6
2	2	6
3	3	6
4	4	6
5	5	6
6	6	6
7	7	6
8	8	6
9	9	6
10	10	6
11	20	6

The calculation as shown as Table 3.1 assumed that channel input to the Add MUX is 10 channels that consist of single wavelength and based on standard ITU - T G.984 Series dan IEEE 802.3ah. Regarding those results if the implementation took place to connecting Kendari City and Ambon City where the total length of span fiber needed is 679 Km then it must use an optical amplifier. The choice of an optical amplifier is EDFA Erbium Doped Fiber Amplifier [5].

Based on numerical simulation of EDFA on the scheme of two level system where the pumping wavelength is 980nm and Pumping power is 20 mWatt, could acquired Gain Spectrum of C-Band wavelength as function of EDFA Length [6]. The maximum Gain is resulted from 1530 nm and 12 m of EDFA length. The minimum case is acquired at the 1560 nm near L-Band for all length (8 m, 9 m, 10 m, 11 m and 12 m).

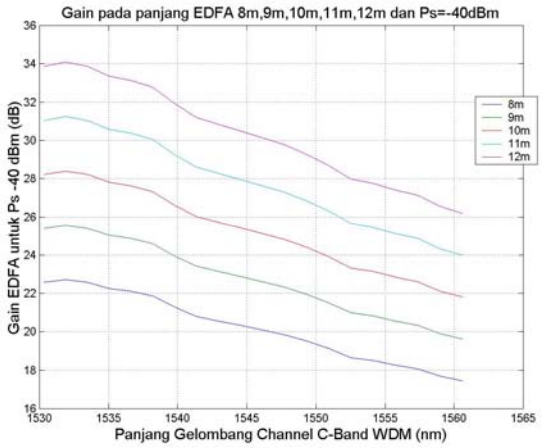

Figure 3.3 Gain profile of EDFA on -40dBm of input signal as function of wavelength (5 channel of C-Band) and length of EDFA.

By assuming the length of EDFA is 8 m based on gain profile of C-Band as shown in figure 3.3, the signal input is -40 dBm and considering the absorption loss is 0.16 dB/Km. Hence the number of EDFA required is 64 one and the power output after traveling 679 Km is -40 dBm. In order to combine those results with Radio over Fiber to reach the rural areas hence minimum 1 EDFA is required to feed the antenna remote unit as outlined in figure 3.4. Each remote unit antenna will share 1 Gbps of via BWAN to user.

The bandwidth that has been planned on Region 10 is 80 Gbps and using 10 channel wavelengths hence each channel wavelength will carry 1 Gbps of rate transmission. If the channel is using C-Band the problem that may arise is fluctuation of gain for every channel. It will arise because each channel has a specific gain for every signal input. The solution to anticipate this problem is using gain flattening method using Bragg Grating Filter. Since the bandwidth doesn't degrade with this method.

The splitting channel then performed in order to feed to antenna remote unit. Each remote unit will receive 1 Gbps data that would already share to user. This technique will overcome the variety of topography in rural area. Hence the high speed connection could be established.

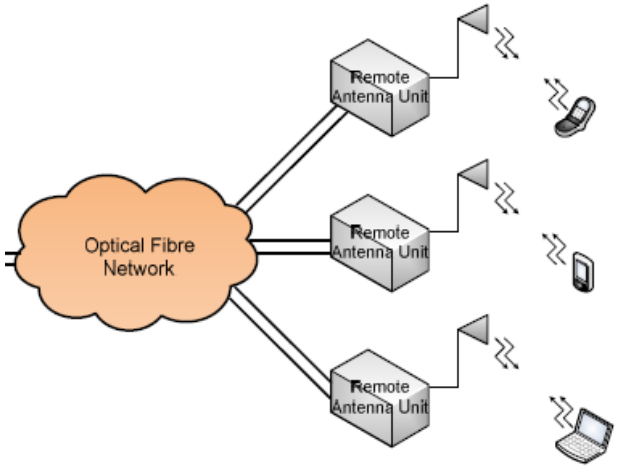

Figure 3.4 Scheme of Radio over Fiber to reach the rural areas [7].

4. CONCLUSION

From the simulation if each single wavelength channel is contained 10 Gbps the maximum span fiber length is 6 Km while to reach 679 kilometer away between Kendari and Ambon Cities within Region 10, so each 10.5 Km need an EDFA.

ABSTRACT

The accelerometer is an acceleration sensor that signal output in voltage/g, where g is the earth gravity. The acceleration is the rate of change of the velocity of an object and the velocity is the rate of change of the position of the same object. The position is the integration of velocity and the velocity is the integration of acceleration. If the data of the acceleration of an object is known, the data of the position can be obtained by applied a double integration. The output of accelerometer has noise and to remove this noise is not enough only use the analog filter but also the digital filter. This paper presents the comparison of two methods of digital filter, they are an exponential filter and a Finite Impulse Response (FIR) filter. The exponential filter is a recursive solution to the process filtering problem, but the FIR is a moving average or nonrecursive filter. A good filtering algorithm can remove the noise from signal, then give the valid information and minimum of error. The estimating of position using the exponential filter is similar to using the FIR filter. The results show that the error average on three axis of position estimation using the FIR filter is 3.0136% and the error average of position estimation using the exponential filter is 3.0087%.

Keywords: *exponential filter, FIR filter, accelerometer, double integration, and position.*

I. INTRODUCTION

An IMU (Inertial Measurement Unit) is the main component of inertial guidance systems used in aircraft, spacecraft, and watercraft, including guided missiles. An IMU works by sensing motion , including the rate and direction of that motion, using a combination of accelerometers and gyroscopes. The data collected from these sensors allows a computer to track a craft's position, using a method known as dead reckoning. An IMU works by detecting the current rate of acceleration, as well as changes in rotational attributes, including pitch, roll, and yaw. This data is then fed into a computer or a microcontroller, which calculates the current speed and position, given a known initial speed and position.[8] On this paper, we done the aquisition of position data from accelerometer on three axis using microcontroller. The goal of this paper is applying the second order of the exponential filter and FIR filter on position estimation use the accelerometer sensor (MMA7260Q) base on microcontroller ATmega 8535. MMA7260Q has three internal accelerometer are placed in a similar orthogonal pattern, measuring position in reference to an arbitrarily chosen coordinate system.

II. THE BASIC OF THEORY

The basic FIR (Finite Impulse Response) filter is characterized by the following two equation, i.e., the FIR difference equation and the transfer function of the filter as below.[1]

$$y(n) = \sum_{k=0}^{N-1} h(k)x(n-k) \qquad (1)$$

$$H(z) = \sum_{k=0}^{N-1} h(k)z^{-k}$$

Where h(k), k=0,1,…,N-1, are the impulse response coefficients of the filter, H(z) is the transfer function of the filter and N is the filter length, that is the number of filter coefficients. It is a time domain equation and describes the FIR filter in its non recursive form: the current output sample, y(n), is a function only of the past and present value of the input, x(n). The exponential filter is a simple IIR (Infinite Impulse Response) filter. Realizable IIR digital filter are characterized by the following recursive equation.

$$y(n) = \sum_{k=0}^{N} a_k x(n-k) - \sum_{k=0}^{M} b_k y(n-k) \qquad (2)$$

Where h(k) is the impulse response of the filter which is theoretically infinite in duration, a_k and b_k are the coefficients of the filter, and x(n) and y(n) are the input and output to the filter. The transfer function of the IIR filter is given as below.

$$H(z) = \frac{\sum_{k=0}^{N} a_k z^{-k}}{1 + \sum_{k=0}^{M} b_k z^{-k}}$$

An important part of the IIR filter design process is to find suitable value for the coefficient a_k and b_k such that some aspect of the filter characteristic, such as the frequency response. Exponential Filter is a simple recursive filter. The first order of exponential filter is shown as below.[2]

$$y(t) = (1-a).y(t-1) + a.x(t) \quad (3)$$

Where $x_{(n)}$ and $y_{(n)}$ are input and output of filter, the value of coefficient α is between 0 to 1. The value of coefficient α can be calculated as below.

$$\alpha = \frac{1}{(1 + 2\pi.\frac{f_c}{f_s})} \quad (4)$$

Where f_c is the cutoff frequency and f_s is the sampling frequency. The second orde of exponential filter is shown as below.

$$y(t)^{[2]} = (1-a).y(t-1)^{[2]} + a.y(t) \quad (5)$$

The features of MMA7260Q are low cost, low current consumption, integral signal conditioning with low pass filter, high sensitivity temperature, selectable sensitivity (1.5g/2g/4g/6g), and low voltage operation. Output of accelerometer is voltage/g that show the acceleration of an object. The functional block diagram is shown in Figure 1[6].

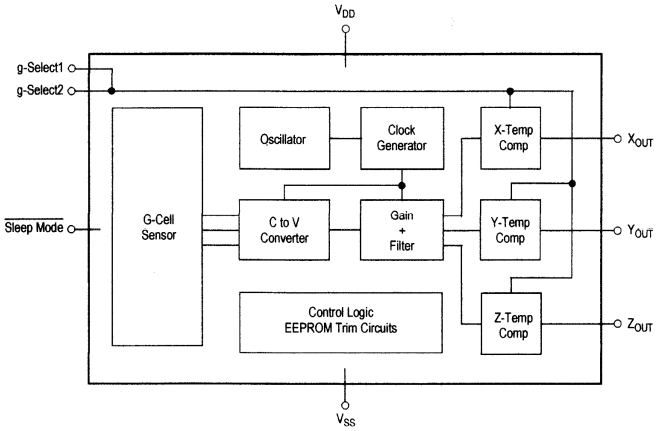

Figure 1 Functional block of MMA7260Q.

The acceleration is the rate of change of the velocity of an object. At the same time, the velocity is the rate of change of the position of that same object. In other words, the velocity is the derivative of the position and the acceleration is the derivative of the velocity, thus:

$$\vec{a} = \frac{d\vec{v}}{dt} \text{ and } \vec{v} = \frac{d\vec{s}}{dt} \text{ or } \vec{a} = \frac{d(d\vec{s})}{dt^2} \quad (6)$$

The integration is the opposite of the derivative. If the acceleration of an object is known, we can obtain the position data if a double integration is applied (assuming initial conditions are zero).

$$\vec{s} = \int \vec{v}dt \text{ and } \vec{v} = \int \vec{a}dt \text{ or } \vec{s} = \int (\int \vec{a}dt)dt \quad (7)$$

One way to understand this formula is to define the integral as the area below the curve, where the integration is the sum of very small areas whose width is almost zero. In other words, the sum of the integration represents the magnitude of a physical variable. The sampling of accelerometer sensor is shown in Figure 2[4].

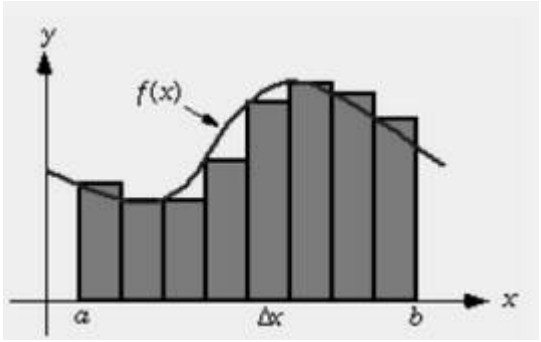

Figure 2. Sampling of gyroscope signal

$$\int_a^b f(x)dx = \lim_{n\to\infty} \sum_{i=1}^{n} f(x_i)\Delta x \quad (8)$$

where $\Delta x = \frac{b-a}{n}$

With the previous concept about "areas below the curve" a deduction can be made: Sampling a signal gets us instant values of its magnitude, so small areas can be created between two samples. In order to create a coherent value, sampling time must always be the same. Sampling time represents the base of this area while the sampled value represents its height. In order to eliminate multiplications with fractions (microseconds or milliseconds) involving floating points in the calculation we assume the time is a unit. Now we know each sample represents an area whose base width is equal to 1. The next deduction could then be that the value of the integral is reduced to be the sum of samples. This assumption is correct if the sampling time tends to be zero. To get the position data, we use the second order of integration trapezoidal method (Runge-Kutta Method) as below.[3]

$$x_k = x_{k-1} + \frac{h}{2}[f(x_k, t_k) + f(x_{k-1}, t_{k-1})] \quad \text{.....(9)}$$

III. DESIGN OF SYSTEM

The microcontroller uses three pin of port A, A.4 A.2 A0, for three inputs from output of accelerometer. Pin A.4, A.2, and A.0 are used as x axis, y axis, and z axis. Output voltage of accelerometer is represented the acceleration and converted to digital data by internal ADC on microcontroller. The accelerometer data is transmitted from microcontroller to personal computer via the serial port RS232. Block diagram of system is shown in Figure 3.

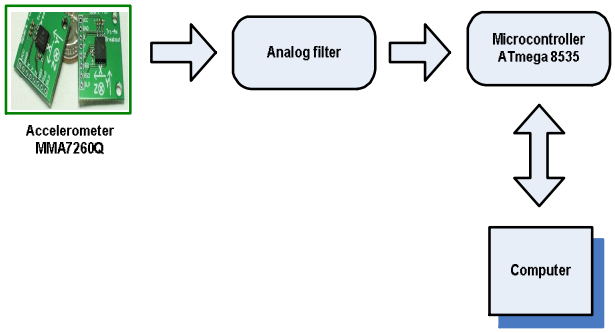

Figure 3 Block diagram of system.

The sub-routine code to get gyroscope data can be exited from CodeWizardAVR as below

```
#define ADC_VREF_TYPE 0x60
// ADC interrupt service routine
interrupt [ADC_INT] void adc_isr(void)
{
unsigned char adc_data;
//Read the 8 most significant bits
//of the AD conversion result
adc_data=ADCH;
//Place your code here
}
Void main(void)
{
// ADC initialization
// ADC Clock frequency: 62,500 kHz
// ADC Voltage Reference: AVCC pin
// ADC High Speed Mode: Off
// ADC Auto Trigger Source: None
// Only the 8 most significant bits of
// the AD conversion result are used

ADMUX=ADC_VREF_TYPE;
ADCSRA=0x86;
SFIOR&=0xEF;
}
```

The design process of FIR filter is to find suitable value for the impulse response coefficients of the filter ,h(k), using the Mathlab FDA Tools. This design use the cut off frequency and sampling frequency of the filter. The cut off frequency of filter is 350 Hz and the sampling frequency is 11 KHz. Block parameter of digital FIR filter design is shown in Figure 4.

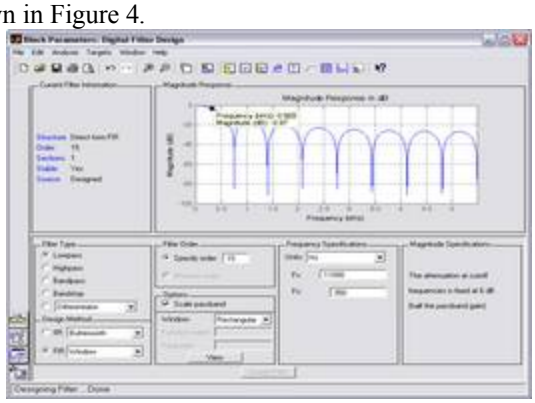

Figure 4 The block parameter of digital FIR filter design.

The impulse response coefficients that obtained from FDA tools is realized for x axis on microcontroller as below.

```
// program FIR x axis
unsigned char FIR_x (unsigned char input)
{
static float
z0x,z1x,z2x,z3x,z4x,z5x,z6x,z7x,z8x,z9x,z10x,z11x,z12x,z
13x,z14x,z15x;
        float output_x,rx,ox,hx;
        z15x=z14x;
        z14x=z13x;
        z13x=z12x;
        z12x=z11x;
        z11x=z10x;
        z10x=z9x;
        z9x=z8x;
        z8x=z7x;
        z7x=z6x;
        z6x=z5x;
        z5x=z4x;
        z4x=z3x;
        z3x=z2x;
        z2x=z1x;
        z1x=z0x;
        z0x=input;
        output_x=(0.0470*z0x+0.0533*z1x+0.05829*z2x
+0.06262*z3x+0.06621*z4x+0.06898*z5x+0.07087*z6x+0
.07182*z7x+0.07182*z8x+0.07087*z9x+0.06898*z10x+0.0
6621*z11x+0.06262*z12x+0.05829*z13x+0.0533*z14x+0.
0470*z15x);
        hx=floor (output_x);
        rx=output_x-hx;
        if (rx<0.5)
        {
        ox=floor (output_x);
        }
        if (rx>=0.5)
        {
```

```
        ox=ceil (output_x);
        }
        return ox;
}
```

The design process of exponential filter is to find parameter (α). A filter parameter (α) can be obtain using equation 4. The exponential filter is used on the cutoff frequency 350 Hz and the sampling frequency 11000 Hz.

$$\alpha = \frac{1}{1 + 2.\pi.350/11000} = 0.83$$

This is a program listing of an exponential filter on microcontroller.

```
float filter_x (char in) //function of exponential filter
{
float ym1,ym2,A1,A2;
static float y1,y2,y12,y22,out1,out2;
A2=0.83;//value of parameter filter
A1=1-A2;
//single exponential filter
y1=A1*in;
y2=A2*out1;
ym1=y1+y2;
out1=ym1;
//double exponential filter
y12=A1*ym1;
y22=A2*out2;
ym2=y12+y22;
out2=ym2;
return ym2;
}
```

IV. EXPERIMENT AND ANALYSIS

The experiment data of position restimation is obtained by using exponential filter and FIR filter. We compare this result on error of estimate position at three axis. Table 1 and Table 2 are the experiment data of x axis using FIR filter and exponential filter.

Table 1. The experiment data of x axis using FIR filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	16.664	15	1.664	11.0933
2.	30.732	30	0.732	2.44
3.	44.425	45	0.575	1.2778
4.	60.651	60	0.651	1.085
5.	78.579	75	3.579	4.772
Average				4.1336

Table 2. The experiment data of x axis using exponential filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	15.207	15	0.207	1.38
2.	30.483	30	0.483	1.61
3.	46.86	45	1.86	4.1333
4.	60.539	60	0.539	0.8983
5.	73.407	75	1.593	2.124
Average				2.0291

Teble 1 and Table 2 show that the average of error using FIR filter more large than using the exponential filter. The average of error using FIR filter and exponential filter are 4.1336 and 2.0291. Table 3 and Table 4 are the experiment data of y axis using FIR filter and the exponential filter.

Table 3. The experiment data of y axis using FIR filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	14.924	15	0.076	0.5067
2.	31.298	30	1.298	4.3267
3.	44.141	45	0.859	1.9089
4.	62.13	60	2.13	3.55
5.	74.107	75	0.893	1.1907
Average				2.2966

Table 4. The experiment data of y axis using exponential filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	14.62	15	0.38	2.5333
2.	30.085	30	0.085	0.2833
3.	43.948	45	1.052	2.3378
4.	61.979	60	1.979	3.2983
5.	73.896	75	1.104	1.472
Average				1.9849

Table 3 show that the average of the estimate distance error is 2.2966%. The average error on y axis using exponential filter that shown in Table 4 is 1.9849%. Table 5 and Table 6 are the experiment data of z axis using FIR filter and the exponential filter.

Table 5. The experiment data of z axis using FIR filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	15.344	15	0.344	2.2933
2.	20.062	20	0.062	0.31
3.	26.768	25	1.768	7.072
4.	29.172	30	0.828	2.76
5.	39.753	40	0.247	0.6175
Average				2.6106

Table 6. The experiment data of z axis using exponential filter.

No	Estimate distance (cm)	True distance (cm)	Error (cm)	Error (%)
1.	15.92	15	0.92	6.1333
2.	20.094	20	0.094	0.47
3.	22.531	25	2.469	9.876
4.	29.357	30	0.643	2.1433
5.	37.425	40	2.575	6.4375
Average				5.0120

From Table 5 and Table 6, we know that average of the error of estimate distance using FIR filter smaller than using exponential filter. The average error on z axis using FIR filter that shown in Table 5 is 2.1606 and the average error on z axis using exponential filter that shown in Table 6 is 5.0120.

V. CONCLUSION

Design of digital filter in three axis of accelerometer system has been develop to build IMU system. The design process of FIR filter is to find suitable value for the impulse response coefficients of the filter using the Mathlab FDA Tools. The filter characteristic to design FIR filter are the cut off frequency of filter and the sampling frequency. The design process of exponential filter is to find parameter (α).The exponential filter is used on the cutoff frequency 350 Hz and the sampling frequency 11000 Hz. The estimating of position using the exponential filter is similar to using the FIR filter. The results show that the error average on three axis of position estimation using the FIR filter is 3.0136% and the error average of position estimation using the exponential filter is 3.0087% .

Abstract - All parts of our body protected by skin tissues. There are many way to measure glucose rate in a blood for non invasive on this skinned tissue, but one of a part becomes focus which is on fingertip part. A part of fingertip has skin tissue that modestly and comprise of 3 layers which are epidermis, dermis, and subcuttant. This each tissue has a function and existence in the body. Needs to knows to sense glucose rate in blood just looks for part on this tissue that one has vein tissue which is on dermis's layer. On this skinned tissue needs to be analogized into an electronic circuit so is gotten an electronic properties point which is applicable to make a blood glucose sensor. The research done for modeling of tissue electronic circuit to get an electronic properties point (permittivity). The result of electronic properties of skin tissue that will be measured is equivalent by assesses permitivity which is a part of a capacitance point. Using RC circuit will get a permitivity value to figure out an analysis of glucose. Outgrow of permitivity value of glucose that increases in a blood figure out how increase blood glucose rate step-up in a body. To know blood glucose rate that equals to assess permitivity of detectable glucose on fingertip, a RC model that simulate into a graph that figured by matlab programs. Expected by this model can add a scientific contribution for measuring instrument more blood glucose sensor accurately.

Key words: Blood glucose, monitoring tool, non-invasive blood glucose sensor, skinned tissue, modeling of permitivity blood glucose, Matlab Graph

I. INTRODUCTION

As many scientist to research in blood glucose monitoring, there is just for commercial used and not so opened for research in public. So in this research for beginning of all the project were try to describe any blood glucose model at finger skin. Finger skin was choose because it were usuall part wich blood taken for blood glucose invasive methode to measure. There is seen for literatur that describe any analysis of biomedical within electronical engineering that first is blood glucose properties were dielectric equivalent [13]. The second is blood glucose were in β dispersion of dielectric that mean of blood glucose permittivity at of permittivity value [4]. The thirdth is blood glucose were a molecular pyhsically that bond of carbon material ($C_6H_{12}O_6$) [5].

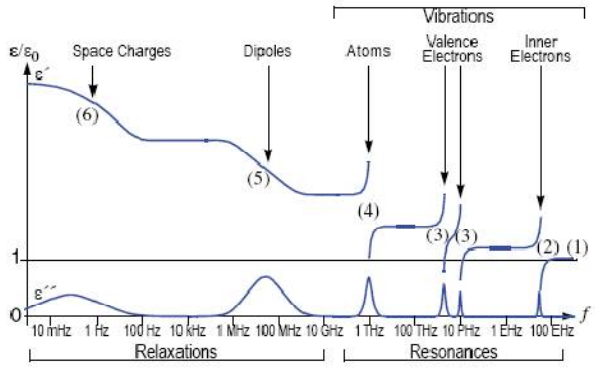
Based on three of literatur to describe what properties of glucose within biomedical and electronic engineering, glucose were described as a capacitive component that equal to permittivity value. If we discuss about dielectric and capacitive there is some of frequency dependent to measure blood glucose. And its permittivity that made of material were diferrences each other. So in this research were make 2 models that can be analysis any changed of glucose effect within dermis or blood parts. Its a simple to analysis if we had a lot of any properties that glucose were been effected it. From any literatur that giving any data of some properties that we need as epidermis, dermis, and blood were giving as seen at Table 1. The data at Table 1 is a constant. In this research we assume that epidermis were human skin dry because part of physically is dead tissue. Assume Dermis were human skin wet that parts of pyhsically is life tissue or life cell that with water concentrated.

Table 1. Data of skin & blood properties [4]

Layers of Skin	(Tipe Data 1)	(Tipe Data 2)	
Epidermis (Human skin Dry)			80
Dermis (Human skin Wet)			30
Blood			20

In dielectric dispersion, there is a point there will be important point that is a relaxation point. The dielectrics will become relaxation when it range between 0-10GHz and will become resonances when it range more than 10GHz. It graph on Graph 1. Resonances in dielectric

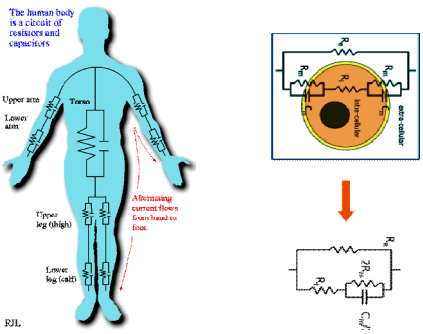
means the phase between imaginary part (conductivity) and real part (permittivity) is same or we can assume for 0 and ∞ .



Graph 1. Relaxation & Resonance [22]

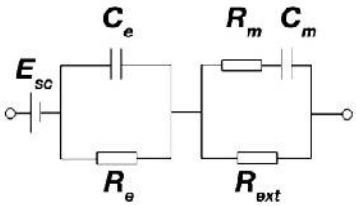
II. BODY EQUIVALENT MODEL

Let's we discuss about a common model for macroscopic of body that means our part of body. The circuit model equivalent is RC model circuit with series between every part of our body. It's were drawn on Graph 2. For every cell that our body have, the circuit equivalent is RC model but it more complex than macro's model. For every microscopic model that we must categorize it between intracellular cell or extracellular cell. So model equivalent for extracellular cell is resistance that resist a current that will get into intracellular cell. Capacitance is a model equivalent for intracellular cell that were had a value properties of materials that will permit any of energy to stored. All macroscopic and microscopic model were drawn on Graph 2.



Graph 2. Circuit Model of Macroscopic [23] and Microscopic [4] Equivalent

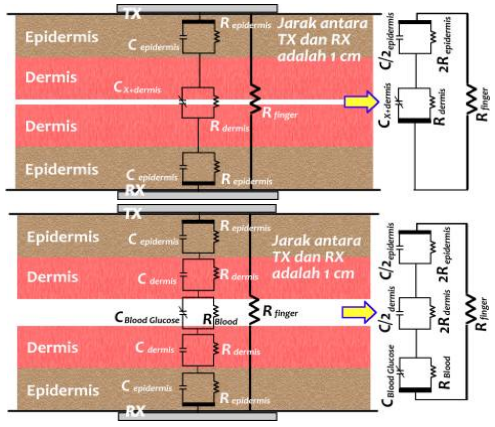
Many research that do for measure blood glucose at any parts of human body. Harman-Boehm were take their research on ear skin. The model were present at Graph 3. The model were using maxwell-wagner model for two layers. [11]



Graph 3. Harman – Boehm Model [11]

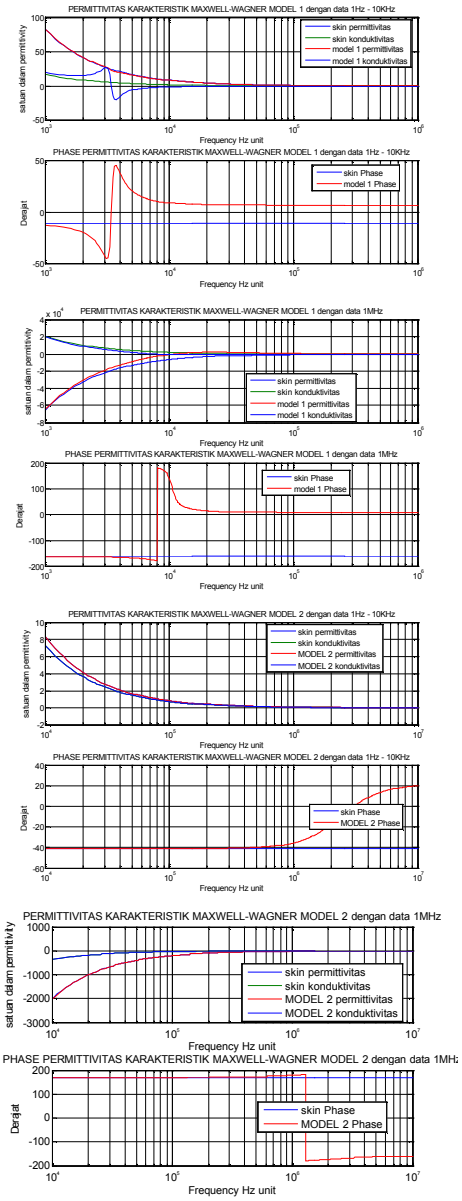
III. GLUCOSE AT FINGER SKIN MODEL

Based on Graph 2, we try to make 2 models of finger skin at fingertip. First concept of model were made for describe of glucose change at dermis of skin that had a lot of a tiny blood vessel at dermis of skin. Second concept of model were made for describe of glucose change at blood parts that were the third layer of skin. Both of model were drawn at Graph 4.



Graph 4. (a). Model 1 (b). Model 2

Simulate both models properties of permittivity with Matlab programming. We can get some of properties like a range frequency of change and relaxation point or resonance point. There is based on maxwell-wagner model to analize both of models and Logarithmic Statisctic that we have a result for permittivity of each which drawn into Graph 5.



Graph 5. Result of Simulation with Matlab.

IV. CONCLUSION

Based on both of model equivalent, model 1 similar with Harman-Boehm Model that used for ear skin. At model 1 with 1 MHz, it were dispersion relaxation point at 22 KHz frequency. The effect of glucose were relaxation of permittivity at 25 and 0,75 at model 1. The permittivity point of relaxation were describe for a point of glucose value change towards to skin.

ABSTRACT

The switched beam antenna is one type of the antennas, which consists of the microstrip antenna array and the switch beam network. This feature can help users pointing directly to target or signals direction. In this research, novel design of wideband switched beam microstrip antenna array using a modified 3 dB hybrid coupler in the single layer substrate has been proposed. The results have been achieving a good performance. The return loss is achieved below -25 dB at 9.4 GHz. A wideband characteristic can achieve up to 1 GHz at the center frequency (9.4 GHz)

Keywords
3 dB Hybrid Coupler, switched beam linear array microstrip antenna, wideband

1. INTRODUCTION

Nowadays the need of a broadband channel becomes the most important things in providing wireless infrastructure. Several services in set of devices becomes a absolutely needed for supporting the mobility of wireless telecommication services. The antenna is one of device of wireless system with the fuction is receive and transmit the electromagnetic wave.

Switched beam antenna or so called fixed beam antenna is one kind of the smart antenna which needed more than one beam to select the course of the strongest signal among the exsisting several radiation pattern. With that mentioned ability, the antenna is capable to radiated his energy to appropiate user course. So it is hoped to reduce the interference problem that caused by multipath fading effect.

Switched beam antenna has the ability to reduce of radiation pattern swith the desired target. For that reason, many author has been research the switched beam antenna array because this kind of antenna has the ability of reducing existing interference beside it improved the capacity.

For achieving the switched beam antenna, the simple form to achieve two beams that can be switched according with port that exitate is the integration between array antenna with the hybrid coupler. Array antenna arranged two elements.

Antenna element has an important role in forming and acquiring radiation desires. One type of an antenna element that can be used is by using microstrip antenna.

Antenna microstrip which is arranged in linear array becomes one of the right choice because microstrip antenna has high performances beside easy to combine with active MMIC (Miniatured Microwave Integrated Circuit). So it can be integrated with control system and signal processing.

A linear array antenna consists of identic elements located finite distance apart along a straight line. The total field from the array described by the equation above is made up of an element pattern $f(\theta,\phi)(e^{-jk_o r/4\pi r})$ and the array factor (AF). This is know as pattern multiplication.

Hybrid coupler does make an important role in the design of microwave circuits and their applications are various. It, however, has narrow band characteristic and requires a large circuit area. Now, wideband circuits are in demand.

In order to reduce the size, many authors have suggested several solutions [1] – [3]. Samsinejad et al [1] was resulting in reducing dimension by substitution two pieces of stub which put on an oblique position, an inductor and capacitors. Using this method reduced the size into 27%, however the bandwidth is narrow and by the structure becomes complicated. To achieve a wide band coupler, Chun et al [2] used a cascaded branch line coupler with mixed distributed and lumped distributed elements and Cho at al [3] used N section tandem connected structure. By such methods are resulted a wide bandwidth as wide as 56% and 42% respectively. In fact, it would be desirable to develop an alternative hybrid that can achieve a better tradeoff between bandwidth, size and power handling.

2. NOVEL DESIGN WIDEBAND 3 DB MICROSTRIP HYBRID COUPLER USING CURVE LINE AT THE SERIES ARM

Normally, hybrid coupler consist of a main line which is coupled to a secondary line by two quarter wave length long section spaced one quarter wavelength apart, thus creating a square approximately one wavelength in circumference[4]. The coupling factor is determined by the ratio of the impedance of the shunt and series arms according to Figure 1.

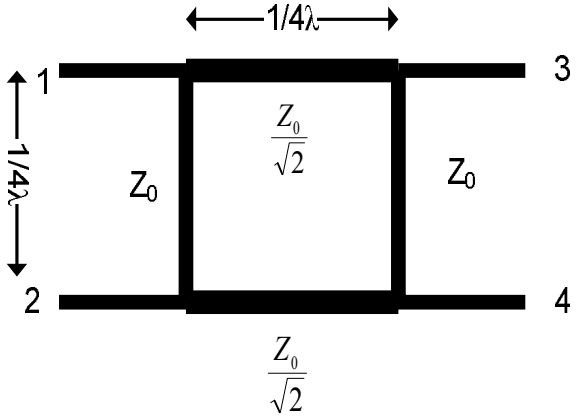

Figure 1: The normal structure 3 dB hybrid coupler

When signal is introduced at a port 1 the signal at the two output arm (port 3,4) are equal in amplitude but have a 90 degree phase difference between each other. Ideally, no signal should appear at the fourth port. The same thing happens of course if a signal enters one of the others port. For 3 dB coupling, the characteristic impedances of the shunt arm is $Z_{sh} = Z_o$ and the series arm is $Z_{se} = Z_0/\sqrt{2}\ \Omega$ respectively for optimum performance of the coupler. The characteristic impedance of input and output port Zo is normaly equal to 50 Ω for microstrip line.

One method to obtain a wideband characteristic was use a thick substrate [5]. Working at high frequency requires proper selection of the substrate. For the new design of hybrid coupler, a substrate with thickness 1.57 mm and dielectric constant (ε_r) 2.2 was selected. This substrate can be categorized as a thick substrate with low permittivity. With increasing in the thickness of the substrate will give higher radiation losses but otherwise it would acquire a wideband characteristic

A novel design of wideband 3 dB microstrip hybrid coupler was proposed which use a substrate with thickness 1.57 mm and dielectric constant (ε_r) 2.2 [6]. The desirable 3dB hybrid coupler should have a good performance such as return loss and isolation loss, wideband characteristic, and a small size on a single layer circuit.

Figure 1 shows the structure of the proposed novel design 90° hybrid coupler with curve line at the series arm.

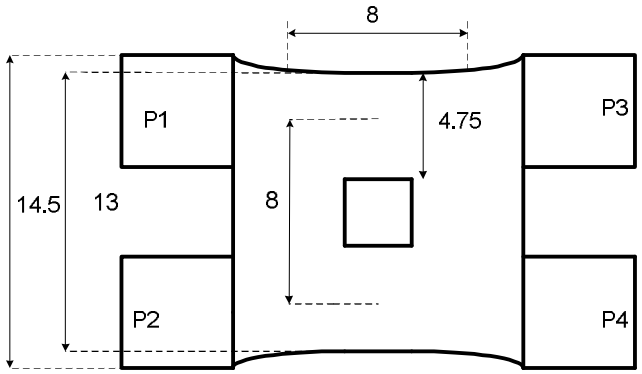

Figure 2 : A New Design 3 dB Hybrid Coupler With Curve Line For f_r = 9 Ghz

A novel design wideband 3 dB hybrid coupler using curve line at the series arm has been simulated. The result takes all the coupling allowing high performance. At 9 GHz, the simulation result shows -3 dB coupling ± 0.3 dB with phase error 3°, return loss below -22.56 dB and isolation below -25.11 dB

3. DESIGN OF SINGLE ELEMENT PATCH ANTENNA

In designing antenna, the first is to decide the working frequency, a bandwidth impedance and the design gain. Further, to select a substrate specification which will used. In designing high frequency antenna which is using microstrip, the kind of selected substrate must according with the requirement [7] those are :

$$f[\text{GHz}]\ h\ [\text{mm}] > 2.14\ \sqrt{\varepsilon_r} \qquad (1)$$

That has been done because the beginning of radiating at high frequency, the course of radiation at the antenna is curved and causing loss. To protecting radiation condition so the selected must conform with (1).
The purpose of the design is the feed line want to located at the same level as the antenna on the single layer, the substrate of antenna used substrate with thickness 1.57 mm and dielectric constant 2.2 .

After gaining the substrate specification, further designing the patch of antenna microstrip. The antenna which is designed here will work at 9.4 GHz .

The design of antenna patch begins with calculate the dimension of the microstrip patch. The designed antenna patch is rectangular shaped. After the calculation, iteration and analysis based on moment method , the effective dimension of patch antenna is resulted, where the length (L) is 10 mm and the width (W) is 12.8 mm as depicted in Figure 3.

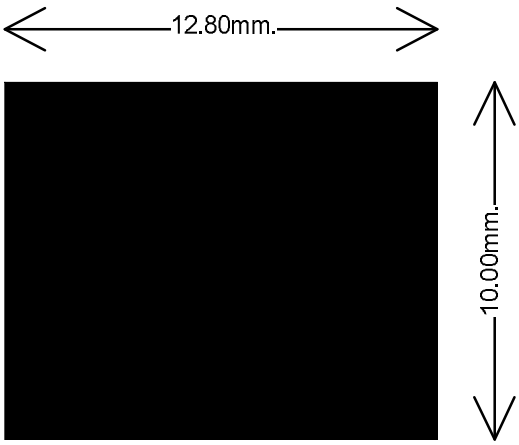

Figure 3: Design of Microstrip Patch Antenna

Resulting from simulation of single element is presented at Figure 4 to Figure 6. It is shown the simulation result at 9.4 GHz.

The return loss for single element achieve below -32.25 dB, The bandwidth achieve 800 MHz from 9.0 GHz to 9.8 GHz. That's mean a good performance for single element can be achieved.

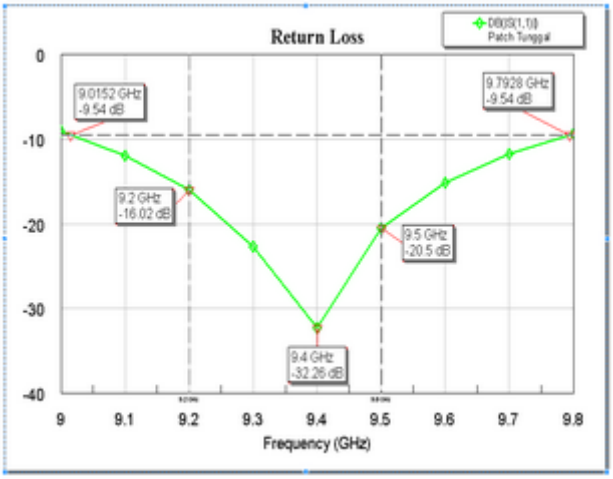

Figure 4 : Return loss for Single Element

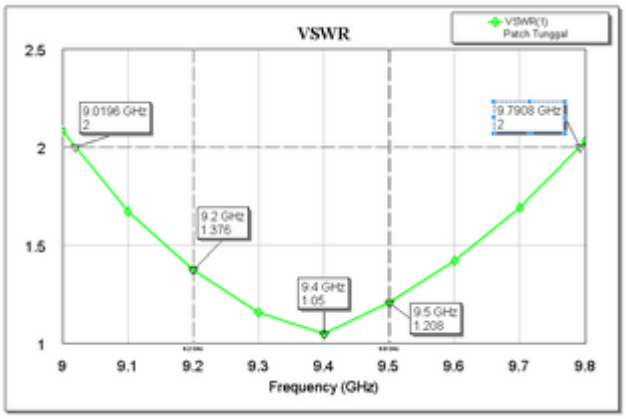

Figure 5: VSWR for Single Element

Figure 6 shown the radiation pattern from the single element. That's not yet produce the required radiation pattern for the swithed beam.

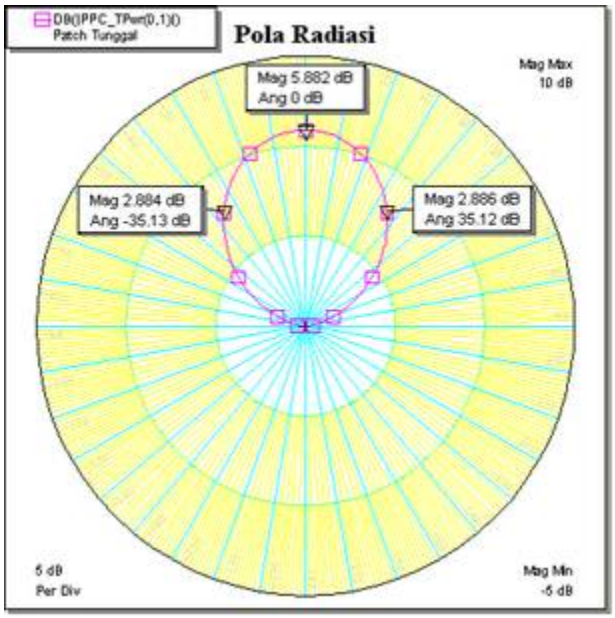

Figure 6: Radiation Pattern for Single Element

4. DESIGNING OF THE SWITCHED BEAM ARRAY ANTENNA

The result of the simulation of single element in question provide a reference to patch that will be integrated with hybrid coupler, that's mean it achieve a microstrip switched beam antenna.

For achieving the switched beam antenna, the simple form to achieve two beams that can be switched according with port that exitate is the integration between array antenna with the hybrid coupler. Array antenna arranged two elements.

Figure 7 shown the design of switched beam antenna array with two radiation patterns that can be changed to diffrent beam. Amount of beam according the amount of port. The distance between the element is ½ λ. This distance is the efficient enough for the effective dimension and it is not make overlapping the other patch element .

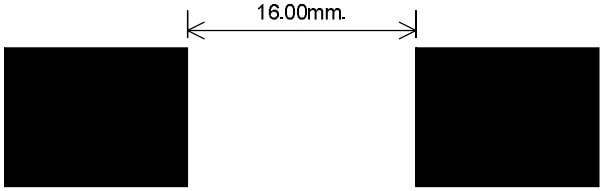

Figure 7: Distance of array antenna 2 elements for f = 9.4 GHz

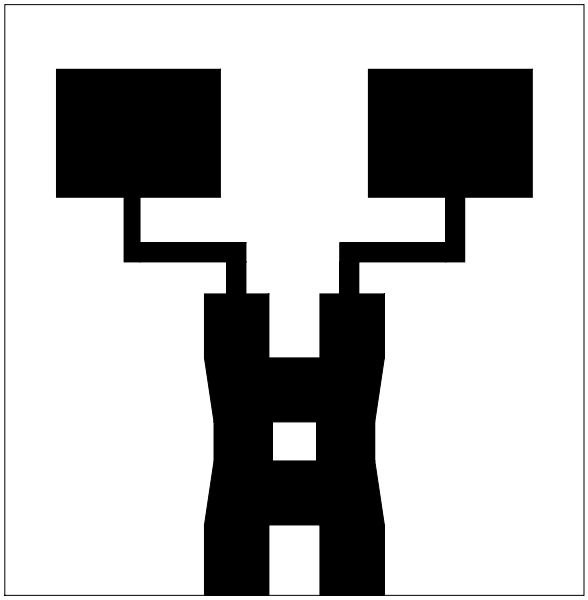

Figure 8: Design of array antenna 2 elements with a hybrid coupler for f = 9.4 GHz

5. RESULT AND ANALYSIS

In this section, simulation results for a novel wideband switched beam antenna array using modified 3 dB Hybrid Coupler are presented. Simulation tools have been used to calculate return loss, VSWR, and radiation pattern, based on the Method of Moments. Simulation results as depicted in Figure 8 are presented in Figure 9 to Figure 11. The ground plane dimension is 45 mm x 46 mm.

5.1. Return Loss

Corresponding to previous port assigning, S_{11}, S_{22}, are the return loss factors. The coupler is designed to keep return loss factor at acceptable level. For the structure forms of a new design are symmetrical so the value of the four ports should be equal. The return loss factor vs frequency is depicted in Figure 9. The reflection coefficient is achieved below -25.29 dB at 9.4 GHz.

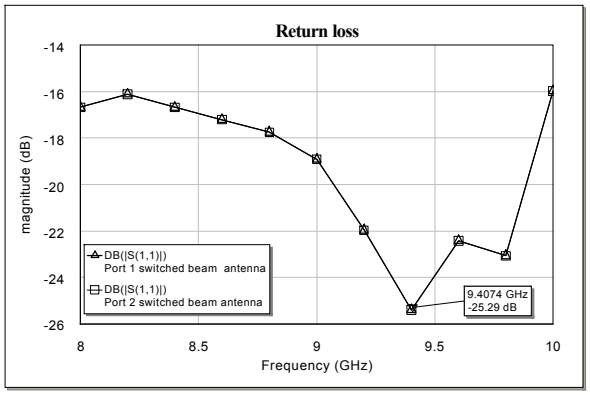

Figure 9: Distance of array antenna 2 elements for f = 9.4 GHz

5.2. Wideband the Switched Beam Array Antenna

Design of the integration between array antenna with a new design of hybrid coupler achieve a wideband characteristic up to 1 GHz, which around 10.6 % the center frequency (9.4 GHz) as shown in Figure 10.

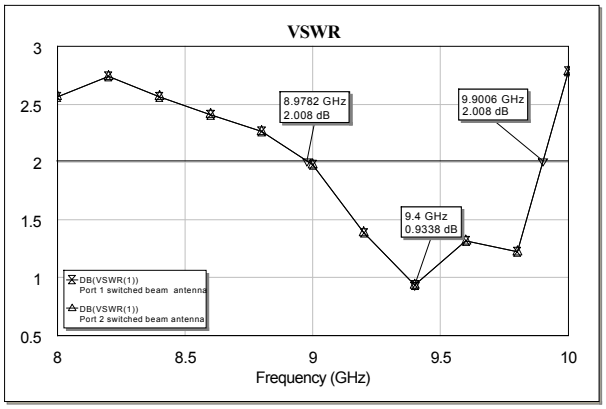

Figure 10: with a hybrid coupler for f = 9.4 GHz

5.3. Switched Beam Antenna Array with Two Radiation Patterns

Figure 11 illustrates the radiation pattern of the switched beam antenna array respectively. From the radiation pattern, it is shown that the angles of the two beams associated with the 2 inputs are -13.5° and 14°.That's mean two beams can be switched according with port that exitate.

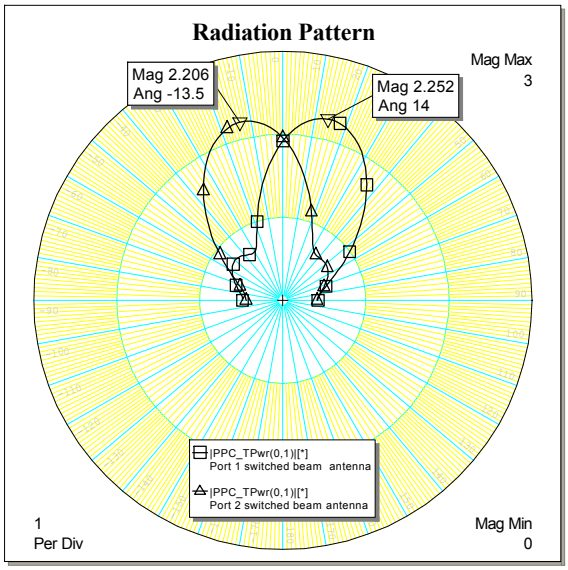

Figure 11: Radiation Pattern of switched beam array antenna for f = 9.4 GHz

6. CONCLUSION

A novel design wideband switched beam antenna array using modified 3 dB hybrid coupler has been studied and simulated. The result takes all the parameters allowing high performance. At 9.4 GHz, the simulation result shows return loss below -25 dB. By printed on the same layer, the integration between array antennas with a new design of hybrid coupler with a curve line at the series, can achieved the excellent bandwidth, up to 10 % centered at 9.4 GHz on a single layer circuit.

ABSTRACT

Mobile Ad hoc Network (MANET), can be implemented in area that have no telecommunication infrastructure due to its limitation. With MANET, the need for communication in that area can be serviced. For communicating with internet, the MANET must be connected with the nearest telecommunication infrastructure via Gateway. For implementing this, a routing protocol a such as AODV++ has been introduced. This protocol is modification of AODV that was originally designed for only routing packets within the MANET and not between a MANET and a wired network. For measuring performance we use three performance metric packet delivery ratio, end to end delay, and overhead.

In this work, we evaluated the performance comparison between two queuing mechanism that can implemented on a MANET, i.e. Drop Tail and RED. Performance, our hypothesis is that RED perform is better than Drop Tail. To prove this, a scenario has composed as follow; 20 mobile nodes, two gateways, two routers and two hosts. The topology is a rectangular area with 1300 m length and 800 m width. A rectangular area was chosen in order to force the use of longer routes between nodes, compared to a square area with the same node density. The two gateways were placed on each side of the area; their x- and y-coordinates in meters are (200,500) and (1100, 500). All simulations were run for 1000 seconds of simulation time. Since we were interested in studying the behavior of the network in steady state, the first 100 seconds of the simulation were ignored. Ten of the 20 mobile nodes are constant bit rate (CBR) traffic sources sending data packets with a size of 512 bytes, to one of the two hosts, chosen randomly. The sources are distributed randomly within the MANET. The transmission range of the mobile nodes is 250 meters. For overcoming congestion RED Drop Tail queuing algorithm has been used.

Our Simulation result shows that, with adding more mobile nodes, congestion will increased the congestion, and than in comparing both of the queuing mechanism on a MANET, the RED mechanism shows is a better performance than Drop Tail. The AODV ++ evaluation proves that RED is better in management buffer mechanism.

1. INTRODUCTION

A mobile ad hoc network (MANET) can be formed without the need for any established infrastructure or centralized administration. It normally consists of mobile nodes, equipped with a wireless interfaced, that communicate with each other. Due to the fact that kinds of networks are very spontaneous and self-organizing, they are expected to be very useful. It is also highly likely that a user of the network will need to connect to the Internet. There are several routing protocols for MANETs, such as Ad hoc On-Demand Distance Vector (AODV), Dynamic Source Routing (DSR), Optimized Link State Routing Protocol (OLSR) and Topology Dissemination Based on Reverse-Path Forwarding (TBRPF). These protocols were designed for communication within an autonomous MANET, so a routing protocol needs to be modified in order to achieve routing between a mobile device in a MANET and a host device in a wired network (e.g. the Internet). The AODV routing protocol is one of the most developed and implemented routing protocols investigated by the IETF MANET working group. In this work AODV has been modified to achieve routing of packets towards a wired network, which is referred to as AODV+ [1].

ISSN 114-1284

2. AD HOC ON-DEMAND DISTANCE VECTOR (AODV)

Ad hoc On-Demand Distance Vector (AODV) is a reactive MANET routing protocol [1], where the reactive property implies that a mobile node requests a route only when it needs one. Consequently, the node maintains a routing table containing route entries only to destinations it is currently communicating with. Each route entry contains a number of fields such as Destination IP Address, Next Hop (a neighbor node chosen to forward packets to the destination), Hop Count (the number of hops needed to reach the destination) and Lifetime (the expiration or deletion time of the route). AODV guarantees loop-free routes by using sequence numbers that indicate how fresh a route is.

There are two buffer management mechanisms in AODV such as RED (Random Early Detection) and Drop Tail. Floyd and Jacobson introduce RED, a technique implemented at gateways to achieve improved congestion avoidance. The primary goal of RED is to detect and avoid incipient congestion. Essentially, RED monitors and controls the average queue size in order to detect incipient congestion. This reduces the average delay across the gateway. Floyd and Jacobson's algorithm aims to eliminate global synchronization and avoid bias against bursty traffic. TCP senders respond to dropped packets by reducing their window. When the gateway's queue is full, all packets are dropped, and all senders reduce their windows at the same time. This global synchronization results in a loss of throughput and decreased network utilization. Additionally, RED attempts to avoid the bias against bursty traffic inherent to Drop Tail gateways. With Drop Tail gateways, connections with more bursty traffic are more likely to have dropped packets even if they have the same average traffic.
The RED algorithm accomplishes these goals by randomly marking packets such that packets from a particular source are marked with a probability proportional to that connection's share of the bandwidth through the gateway. The algorithm sets up a minimum and maximum threshold for the average queue length (AQL). When the AQL is less than the minimum threshold all packets are forwarded. If the AQL is between the minimum and maximum thresholds, packets are marked with a probability proportional to the AQL. Thus, more packets are marked when the average queue length is longer. For AQLs greater than the maximum threshold, all packets are marked. Marking a packet alerts the sender of congestion and should result in some reduction from the sender. Packets may be marked either by setting a bit in the header or simply dropping the packet.

The former approach requires the recipient to recognize the "congestion" bit and relay this knowledge to the sender. The latter method implicitly alerts TCP of congestion since TCP responds to dropped packets by reducing the window. The goal is for RED gateways to mark packets in fairly even intervals instead of all at once like Drop Tail gateways. This technique avoids biases and global synchronization.

2.1. Operation of RED

RED monitors the average queue size, and checks whether it lies between some threshold minimum and maximum. If it does, then an arriving packet is dropped or marked with probability, p, where p is a function of the average queue size. Several researchers have studied early Random Drop gateways as a method for providing congestion avoidance at the gateway. In the implementation of Early Random Drop gateways in, if the queue length exceeds a certain *drop level*, then the gateway drops each packet arriving at the gateway with a fixed *drop probability*. The drop level and the drop probability should be adjusted dynamically, depending on network traffic.

2.2. The RED algorithm

The algorithm for RED gateways can be explained that the RED gateway calculates the average queue size, using a low-pass filter with an exponential weighted moving average. The average queue size is compared to two thresholds, a *minimum* threshold and a *maximum* threshold. When the average queue size is less than the minimum threshold, no packets are marked. When the average queue size is greater than the maximum threshold, every arriving packet is marked. If marked packets are in fact dropped, or if all source nodes are cooperative, this ensures that the average queue size does not significantly exceed the maximum threshold. The general RED gateway algorithm is as follow [2]:

for each packet arrival calculate the average queue size avg

if min_{th} < = avg < max_{th}__
    calculate probability p, with probability
    p : mark the arriving packet
else if max_{th}_<=_avg
    mark the arriving packet

2.3. Drop Tail

In this gateway mechanism, each congestion period introduces global synchronization in the network. When the queue overflows, packets are often dropped from several connections, and these connections decrease their windows at the same time. This results in a loss of throughput at the gateway [7].

3. SIMULATION RESULTS

For simulating the network, in this work we use ns-2 simulator. This simulator covers a large number of applications of protocol, network types, and network element and traffic models. NS-2 simulator is based on two languages: an object oriented simulator, written in C++ and OTcl (an object oriented extension of Tcl), with one to one correspondence between them. The compiled C++ hierarchy allows us to achieve efficiency in the simulation and faster execution times. This in particular is useful for the detailed definition and operation of protocols and allows one to reduce packet and event processing time.

TCL (Tool Command Language) is used for millions of people in the world. It is a language with a very simple syntaxes and it allows a very easy integration wit other languages. The characteristics of this language are enabling fast development, provide a graphical interface, compatible to many platforms, flexible for integration, easy to use and free [3].

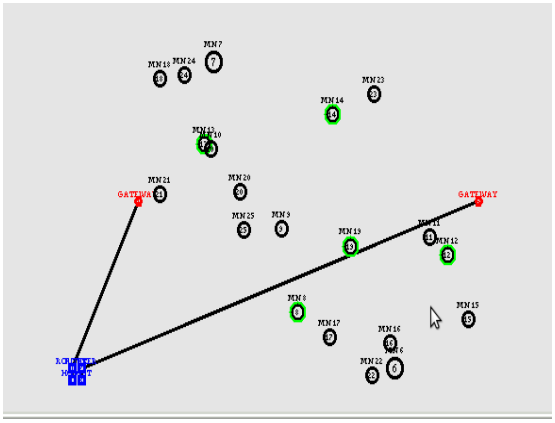

Figure 1 : Scenario of the AODV++ Simulation on Network Animator (NAM)

In analyzing the result we used the fallowing formula that implemented in AWK, this formula are as follow :

1. PDF (Packet Delivery Fraction)
   PDF = (Receive/Send) * 100 %
2. NRL (Normalize Routing Load)
   NRL = Routing Packet/Receive packet.
3. End to end delay

The result of AWK used for analyzing, these result is composed in table 1 and table 2. Table 1 is result of RED queuing mechanism, beside it, table 2 is result from Drop Tail queuing mechanism. Subsequently, using Xgraph these results are displayed. with using Xgraph on NS. The following subsections explain the results.

3.1. Packet Delivery Fraction (PDF)

Table 1 and Table 2 show that PDF values always 100 %, this means that all packets can be delivered to destination. Both Table 1 and Table 2 also show that RED and Drop Tail mechanisms do not influence PDF values. This is confirmed with Casey experiment [5]. Base on these tables using Xgraph tools, we produced Figure 2 which shows that in all time intervals will produce fix PDF. This condition occurred on both of queue mechanism, RED or Drop Tail. This condition occurred because in scenario congestion does not occur, so that all of packets sent, are delivered to MN destination.

The result of this scenario confirmed with the previous hypothesis, because in scenario congestion does not occur because this traffic is lower than the capacity of the network.

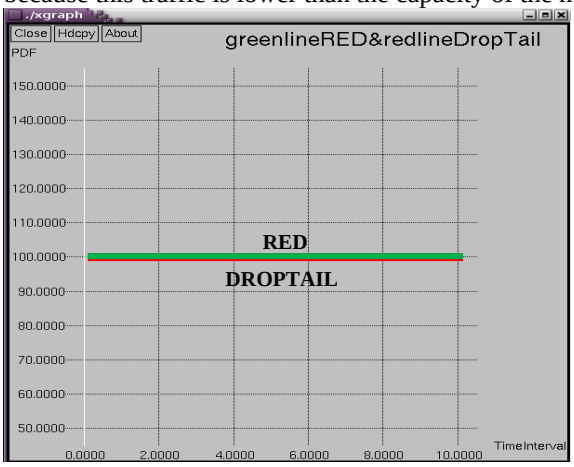

Figure 2: PDF graph for Drop Tail and RED queuing Mechanism.

3.2 Normalized Routing Load (NRL)

The NRL values from simulation result are shown in Figure 3. This graph is made base on both table 1 and table 2. In this graph, green line indicates NRL for RED mechanism, and red line indicate NRL Drop Tail mechanism.

Table 1: The result of simulation with RED Mechanism

Time Interval Traffic (S)	METRIC		
	PDF	NRL	e2n
0.01	100	0.03	265,37
0.1	100	0.03	265,37
0.2	100	0.62	387.58
0.3	100	0.93	383.81
0.4	100	1.21	539.13
0.5	100	1.54	514.13
0.6	100	1.87	489.13
0.7	100	2.13	648.77
0.8	100	2.42	648.77
0.9	100	2.73	648.77
1	100	3.01	648.77
1.1	100	3.01	648.77
2	100	6.03	648.77
4	100	12.06	648.77
6	100	18.05	648.77
8	100	24	648.77
10	100	29.98	648.77

Table 2: The result of simulation with DROPTAIL Mechanism

Time Interval Traffic (S)	METRIC		
	PDF	NRL	e2n
0.01	100	0.03	265,37
0.1	100	0.03	265,37
0.2	100	0.62	387.58
0.3	100	0.62	387.58
0.4	100	0.62	387.58
0.5	100	1.54	514.13
0.6	100	1.87	489.13
0.7	100	2.13	648.77
0.8	100	2.13	648.77
0.9	100	2.73	648.77
1	100	2.73	648.77
1.1	100	3.34	648.77
2	100	3.34	648.77
4	100	12.06	648.77
6	100	12.06	648.77
8	100	24	648.77
10	100	24	648.77

The graph indicates that RED mechanism have NRL is higher then DROPTAIL mechanism. Graph for RED mechanism is indicated with Green line have more overhead then DROPTAIL (red Line). And also is indicated that this trend will increase if rate sending of packet go down (time interval for sending packet go down). Especially for DROPTAIL mechanism, at point time interval 8 s and more, NRL trend to fix.

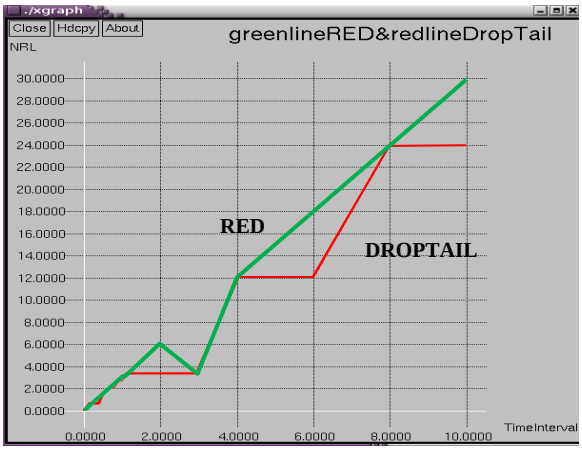

Figure 3: NRL with Time Interval Function

3.3. End-to-end delay

As well as PDF and NRL, End to End Delay for RED and DROPTAIL have different value on time interval low, but if time interval is increased, both queuing mechanism have same value. This is showed in Figure 4. These result can be explained that on Time interval 0.6 s, end to end delay have fix value because on this condition end to end has achieve maximal value. If delay more increase then packet will be discarded (drop).

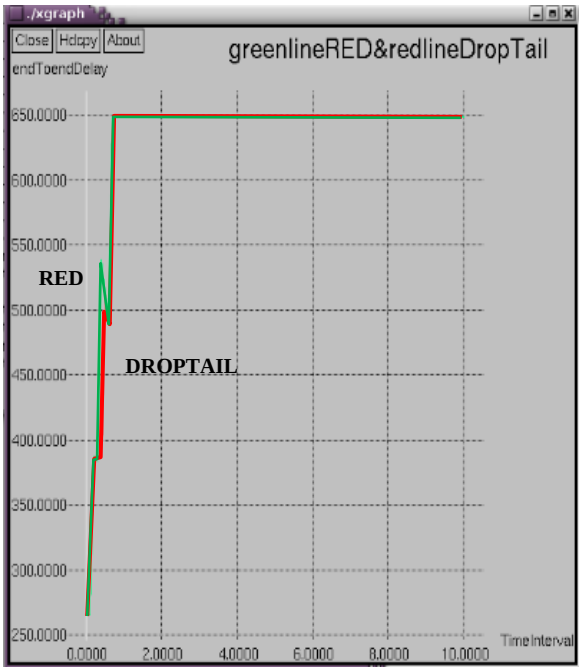

Figure 4: End to end Delay with Time interval Function

4. CONCLUSION

In terms of Normalized Routing Load, in lower time interval data rate, RED mechanism is superior than Droptail, because sending more packet will increase the packet received. On medium time interval data rate, Drop Tail mechanism is superior than RED mechanism, because there are less overhead in Drop Tail mechanism. In the occasion where time interval data rate decreased, both RED and DROPTAIL mechanisms have the different NRL trend, RED mechanisms tends to increase, while DropTail mechanism tend to have a fix NRL.

For Packet Delivery Fraction (PDF), both queue mechanism, RED and Drop Tail have 100% PDF, which indicate that all of packets have been sent, and arrived at destination. This fact indicates that both queuing mechanism do not influence PDF, because in these scenario congestion did not occur.

For end to end delay, in low time interval low, RED's delay is higher than Droptail. In higher time interval both RED and Drop Tail, resulted in similar end to end delay.

for Sustainable Development

Symposium B

PT. NUSANTARA DAYA TEKNOLOGI atau NUSANTARA TECHNOLOGIES didirikan di Jakarta oleh orang-orang yang berkomitmen untuk memajukan pendidikan dan ketrampilan khususnya kejuruan dan kampus-kampus ataupun tempat-tempat pelatihan.

Kami mendedikasikan diri dalam menyediakan jasa layanan dan peralatan praktek. Sebagai perusahaan yang relatif baru, kami memiliki fokus pada bidang pendidikan dan pelatihan:

- Biologi, Kimia dan Farmasi, Fisika,
- Kesehatan dan Kedokteran,
- Industri dan Pabrikasi,
- Komputerisasi.

Kami merupakan pemegang lisensi langsung dari beberapa produsen alat-alat peraga pendidikan dan
ketrampilan dari seluruh dunia, seperti:

- Altay Scientific
- Elettronica Veneta dari Italia
- Cusson Technology dari Inggris
- 3B Scientific dari Jerman.

Visi dan Misi

VISI dari perusahaan kami adalah menjadi partner yang terdepan dan terpercaya dalam memajukan pendidikan dan pelatihan anak bangsa.

MISI kami untuk mencapai VISI tersebut adalah:

- Kami senantiasa mengikuti dan berusaha untuk selalu mengaplikasikan teknologi terkini
- Menjadikan klien sebagai mitra bisnis dan selalu mengedepankan layanan terbaik
- Kami senantiasa memberikan edukasi kepada masyarakat dalam bidang yang sarat dengan Teknologi untuk kepentingan bersama dalam tahun-tahun mendatang

ABSTRACT

The implementation of High Speed Railway (HSR) networks involves a large amount of financial support imposing, at the conception and design stage, a complete and rigorous estimation of the total costs involved in the lifecycle of the system. Using appropriated tools for HSR lifecycle costs (LCC) estimation, it is possible to minimize the final cost and, at the same time, to identify the most important aspects, and parameters, that influence the cost evaluation. Research is required not only on LCC modelling but also particularly on the estimation of major degradation factors and on the assessment of its impact on maintenance needs. This paper, which based on the on going doctoral research, will address these objectives by developing improved performance indicators as well as creating a system dynamic for cost effective maintenance strategies.

Keywords:
Track Degradation Model, Dynamic Analysis, Transition zones, train-track interaction, maintenance optimization

1. INTRODUCTION

In recent years, the study on the track degradation in the area of railway has attracted a great deal of attention. The intensive research activity has been carried out by many organizations with aims to secure a high level safety and reliability of the infrastructure system. New technologies and stringent safety standards thus constantly being introduced for several reasons, not only to prevent the assets from failure/damage but also to diminish the risk of loss of human life. Further to that, the other reason is to minimize the main source of problems associated to the performances degradation in terms of ride quality, comfort and etc.

Since failure on the high speed railway system can cause a significant economic losses, many railway infrastructure managers (IMs) thus spent a substantial proportion on the maintenance budget with 60 percent of the total being for track and structure maintenance [1]. Therefore, to have an optimization on track laying and track maintenance is a significant challenge for rail players around the world. The reduction on the maintenance cost would impact to the overall life cycle cost expenditure that can remain rail transport more competitive with respect to road and air transport.

One of the best way to pertain this substance would be by understanding the degradation process of the railway track. Recognizing any changes on the track condition over time and consequences maintenance actions on the track performance enable us to predict residual life time of the asset. The accurate life cycles including any maintenance activities that need to be carried out throughout useful life thus can be drawn and by doing so, the railway company could reduce the operation and maintenance expenditures in the systematic way without endangering the traffic safety.

For this reason, this research aims to develop an approach to predict track degradation in the area of railway infrastructure. The predicted model will be based on the investigation of the dynamic response generated by interaction of vehicle track coupled system and its contribution to the rate of track degradation. Since the major irregularities of the railway track has been revealed in the transition zone, therefore, the adjacent between track embankment and bridges, that represents the stiffness variability, will be served as the places of investigation. Variables that influence the rate of degradation such as traffic characteristics, track parameters and track quality will be analyzed, leading to the development of correlation between the effective parameters and the track degradation. These constructed correlations will define the most influence parameters in the global deterioration model. Furthermore the efforts also will try to identify the threshold value in the general deterioration model that should be kept the performance indicator (vibration, train acceleration etc.) in the range of safety standards, reliability and passenger comforts. This reminder of performance indicator together with predicted degradation model and any other aspect relating to the maintenance activities will be analyzed in order to develop system dynamic for cost effective maintenance.

2. TRACK DEGRADATION CONCEPT

There are many factors that are interconnected and interfaced which may influence track degradation rates. For instance, the interaction between track and train generates the effect of dynamic forces which produce the vibration at many points along the track. As the track growing older, factors such as weather, track condition and component decay rate interact with these forces lead to the track deterioration. Several parameters therefore have been identified as the main contributors on this rate of track degradation. These parameters can be categorized in three areas which are track condition quality (TQI's), traffic and maintenance [2]. Track Quality indices is defined as quantities value that describe the relative condition of the track surface geometries [3]. Sadeghi & Akbari [4] distinguished Track Quality indices to be two dependent variables; Track Geometry Index (TGI) and Track Structure Index (TSI). The TGI indicates only the geometry parameters of the track, such as profile, twist, gauge and alignment that have a direct influence on track riding comfort. This TGI is resulted from the statistical analysis of track geometry data recorded by track inspection cars. The other one, TSI expresses the structural condition of the track, which include the condition of rail, fastening system, sub-grade, and drainage systems. This index refers directly to the actual condition of the track and indicates the track's potential for degradation.

Ferreira and Murray [5] split traffic related deterioration factors into three groups; dynamic effects, speeds and loads. The dynamic effects vary with the type of traffic on the track. Accelerations, retardations, lateral forces in curves, vibrations, and the condition of the rolling stock are examples of factors that affect the track bed. The dynamic forces contribute to the deterioration process as the speed increase while the rates of degradation decrease at low speed. When the train passing along the track, loads give rise to rail wear and fatigue, wheel wear, and increase the strain in rails and sleepers. As a consequence, cracks in the rail appear, the railhead is worn out, sleepers crack, rail fastenings loosen, ballast is redistributed leading to reductions in travel comfort, reduced speeds, increased energy and fuel consumption, higher risks for derailment and delays, and increased needs for maintenance.

The last parameter, maintenance action which involved tamping, grinding, ballast cleaning, lubrication etc, are influencing the quality condition of the track. For instance when the tamping action is performed, the ballast under the ties is re-compacted to provide the proper load bearing. The ties thus distributes the weight of the rail and rolling stock, and keep the track properly aligned, that in turn impede the acceleration of rail degradation rate. As well as tamping, preventive grinding also leads to a significant increase in the service life of rails, slow down the growth of rail corrugation and decrease the traffic noise [6].

3. TRACK SETTLEMENT

Trains, subject to the track structure, are repeated its' loading and unloading as they pass [7]. When the track is in loading cycle, especially to high frequency load variations, the ballast and the layers below can undergo a non elastic displacement. When unloading take a place, the initial geometry does not return exactly and leave a small residual displacement. After several cycles, different parts of the track will accumulate these small settlement lead to a modification of the geometry of the track.

There are two major phases occurs in track settlement. First, its occurred directly after a major maintenance action of the ballast. In this phase, the settlement is relatively fast until the ballast is well compacted and density of the ballast particles is increased. The second phase, the settlement is slower and increases regularly with the number of cycles. In this phase, the settlement mainly governed by several mechanism of ballast and sub-grade behavior for instance continued volume reduction due to the particle rearrangement, sub-ballast or sub-grade penetration into ballast voids, and volume reduction caused by particle breakdown and abrasive wear [8].

The study of track degradation process due to the dynamic load resulted in different track degradation models. Some reviews of them include the modeling of train track interaction are given in Lundqvist and Dahlberg [9], Ishida et al. [10], Iwnicki et al. [11]. However only few papers in this respect modeling the track settlement in transition zone, the places where the stiffness changes are revealed. Therefore, it is important to have a further insights on the mechanism of track deterioration and predict track settlement particularly in the adjacent between two different zones in order to optimize the maintenance decision that respected to the structural safety, track safety and passenger comfort. Beside of this, the improvement of computer capacity and use of numerical methods have made it possible to make more detailed models of train track structure and more reliable prediction on the track settlement.

Thus, there are three main aspects that have been considered important as this research objectives, namely:

A. Identifying the key influencing parameters that may have a great impact on the railway track degradation model.
B. Developing the track degradation model due to the dynamic load in the transition zone
C. Optimizing the way of maintenance strategies (in economical and /or technical way) by developing the system dynamic for cost effective maintenance that leading on the reduction of Life Cycle Cost (LCC).

4. METHODOLOGY

A combination between statistical and engineering approach are adapted for this research equipped by comprehensive track field data with measurement made on the track Porto-Lisboa railway line during the last nine years. The engineering approach consists of establishing the mechanical properties of the entire element that make up the track and the railroads vehicles. By doing so, the appropriate methods of modeling and numerical analysis can be developed to determine the dynamic load that the vehicle will impose on the track as function of train characteristic and track profile. Further to that, the predicted track settlement in the transition zones caused by this load also can be determined. The advantage of this approach is that it gains a deeper insight to understand the interaction between vehicle and track and identify the role of each track and train parameter to the rate of track degradation. The statistical approach involves the analysis of many observations of actual track performance and the corresponding causal parameter. This analysis is used to calibrate the adopted methodologies in engineering analysis by comparing analytical solution with the results presented in the case study. Finally the creation of system dynamic for cost effective maintenance strategies will be carried out in order to find a balance between the maintenance cost (inspection, tamping, grinding activities) on one hand and the consequential cost of failed operation on the other.
With the result of the predicted track degradation model, a general degradation curve will be formed that can be used to optimize the maintenance decisions.

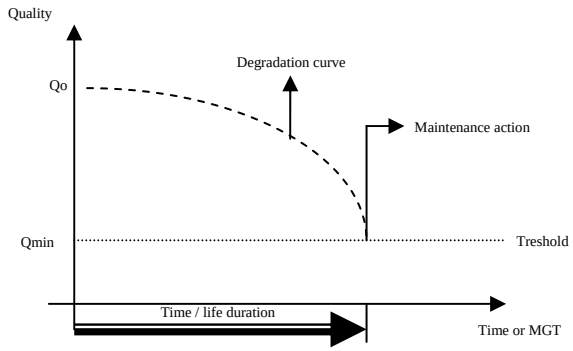

Fig. 1 : Diagram showing general degradation curve

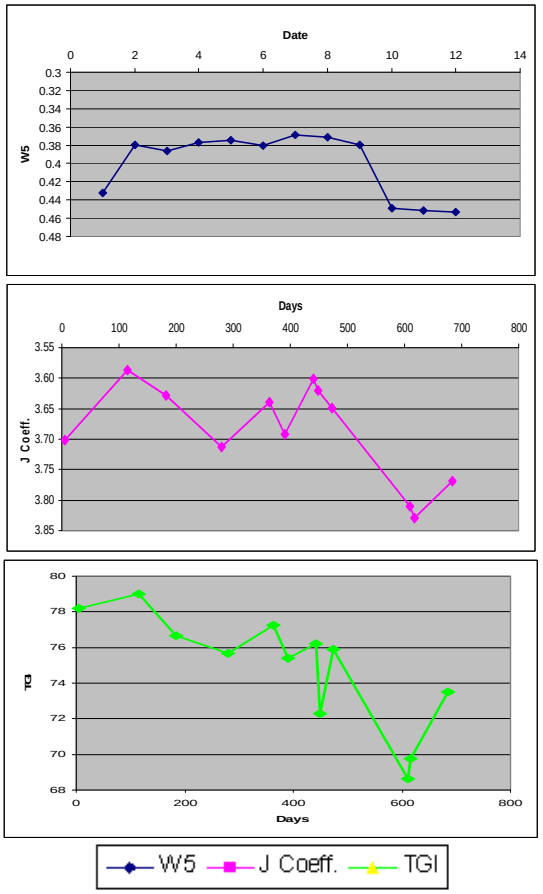
The railway track has initial value or track settlement Qo. During the train operation it degrades/settles because the cumulative of the track loads. If the minimum quality (Qmin) or an intervention level is almost reached, maintenance action (tamping) are carried out.

5. DISCUSSION

In order to quantify the track condition in numerical value, the terms of Track Quality Indices (TQI) is used [12]. This index is defined as a function of one or more of the main geometry parameters such as profile, alignment, gauge, and cant that is obtained from automated geometry vehicles. Profile and alignment are delineated with the track geometry of each rail projected onto the longitudinal vertical and horizontal plane respectively. Gauge is defined as a range between two rails measured at 16 mm below the top surface of the railhead. Cant is used as indicator deviation between the top surfaces of two rail at a given location [13].

By assessing the track condition using TQI formula applied in various countries, the results of trend degradation model on the particular segments of North Line of Portuguese Railways are shown in the following figures. As it can be seen, the trend of degradation is varied between different models. Based on the Five Parameter defectiveness (W5) graphic, the tendency of degradation is quite different with figures presented in J track quality indices (J-coefficient) and Track Geometry Indices (TGI). However, the trend of degradation illustrated in both J-coeff. and TGI even are not totally same but expressed the similar characteristic. This differentiation has been caused due to each of the model employs different weighted values for its particular geometry variables. The other reason is the difference of mid chord measurement that has been conducted by various railway companies to measure the deflection of geometry parameter, for instance the mid chord measurement that has been used by Indian Railway company (TGI) is different with others.



Thus, there are some research priorities that have been revealed concerning this track degradation model:

1. The best track quality indices that represented the true condition of railway track.
2. Mechanism of transmitting these track geometry indices to a value that could assess degradation in terms of track settlement.
3. The level of importance of each particular effective parameters contributing to degradation rates.
4. The minimum quality (threshold value) that should be kept the railway track in the range of safety standards, reliability and passenger comforts, and
5. A mechanism to develop a predicted degradation model and methodology for using it in order to optimizing the maintenance decision.

6. CONCLUSION

This research aims to develop new lifecycle costing models and infrastructure and risk management programs to effectively derive design and maintenance strategies for high-speed rail infrastructures and operations. Some of the future agendas would be developing a Maintenance Management System adapted to HSR and integrating the necessary information from track state, from behaviour models for the life cycle, and from the organization as an active part of the process and assessing the impact on LCC of different design and maintenance strategies for high-speed and very high-speed lines in different operational scenarios.

Sustainable Housing Practices in Malaysian Housing Development: Towards Establishing Sustainability Index

Abu Hassan Abu Bakar,PhD[1], **Khor Soo Cheen[2] and Rahmawaty[3]**

School of Housing, Building and Planning
Universiti Sains Malaysia
[1]abhassan@usm.my, [2]s_cheenk@hotmail.com, [3]wawa_archies@yahoo.com

ABSTRACT

This paper presents a study on various sustainable rating systems on sustainable housing that had been developed by various countries around the world. The objective of this study is to develop a framework for a rating system for housing development for Malaysia by taking into account the local requirement. There are numerous sustainable rating systems on building and group of buildings being developed in the built environment around the world. Rating tools like CASBEE, LEED, BREEAM, GB Tool, Green Star to name a few, have great influence over the development of other rating tools over the world. Malaysia too has recently launched a rating system for buildings called Green Building Index (GBI). However, Malaysia is yet to introduce a rating system for measuring the sustainable practices in housing development. Hence, this paper reviews some key available tools that related to the rating of housing developments for the purpose of developing one for Malaysia. Some important factors used for developing a tool for measuring sustainability practices should include sustainability criteria that are related to environment, society, economics, site/land use, communication, transportation and many more. An index for measuring sustainability in housing development will be developed to suit the local context. The formulated index will take into consideration the parameters in sustainable housing developed by various systems around the world. The index that called A Comprehensive Assessment System for Sustainable Housing will be available for further testing.

Keywords: *Sustainable Housing Development, Urban Development, Building (Housing), Sustainability Index, Malaysia.*

1.0 Introduction

Nowadays, sustainable development is a common goal of many worldwide urban (re)development policies (Shutkin, 2000; Berke, 2002; Chan and Lee, 2006). The development of housing sector also include in the policies of urban development. There are many housing schemes have been developed in Malaysia since housing is prerequisite for human habitat settlements. Housing is also a major concern for all people in every corner of the world. In the present context, housing is developing in line with the goals of Habitat Agenda as well as the principles of Agenda 21 which is a blueprint for sustainable development in the 21st Century adopted by 179 nations including Malaysia in Rio de Janeiro in June 1992. (Tosics, 2004) stated that housing is one of the most important public policies affecting urban development and, as such, it has significant potential to contribute to sustainability. Various aspects of housing construction, design, use and demolition can have significant impacts on the environment (Huby, 1998)

According to Islam (1996), the well accepted definition of sustainability was defined by the World Commission on Environment and Development. It is conceived as development "which meets the need of the present without compromising the ability of future generations to meet their needs" (WCED; 1987). This concept must recognize as a safe, secure and universally designed (A Sustainable Housing Forum Report, 2003).

Sustainable development is essential for human settlement development and gives full consideration to the needs of achieving economic growth, social development and environment protection. It is increasingly linked with the concept of quality of life, well being and livability (Moore and Scoott, 2005). It also a dynamic process in which communities participate and accommodate the needs of current and future generations in ways that reproduce and balance local social, economic, and ecological systems and link local action to global concern (Berke and Conroy, 2000). Being sustainable is as much about efficient profit-oriented practice and value for money as it is about helping the environment (BRE Report, 2002)

Sustainable development is unattainable without sustainable building and housing. Chougill (1994) stated that the sustainable housing may be understood in terms of ecological sustainability, economic sustainability, technological sustainability, cultural sustainability and social sustainability. According to Edwards and Turrent (2000) housing is sustainable if everyone has the opportunity of access to a home that is decent; if it promotes social cohesion, well-being and self-dependence.

The aim of this research is to develop a guideline for assessing the residential development in respect to sustainable housing concept for improving the level of sustainable practices in housing development. The formula of sustainability index in housing development will be developed based from the critical factors to the success of

ISSN 114-1284

a sustainable building / housing and the rating system that apply in Japan, United Stated, United Kingdom and else available in others country.

Sustainable housing development should measure the area development within sustainability criteria namely as environmental, society, economics, site/ land uses and facilities of communication and transportation and include the assessment of building forms particularly for housing performance. Therefore, it is possible using two tools separately, independent of the two tools but in simultaneous assessments of the project with the same purpose. For example in Asia, Japan had designed standards and guidelines for sustainable building and urbanization sustainability; it is called as Comprehensive Assessment System for Building Environmental Efficiency (CASBEE for an Urban Area+ Building). These system tools refer to CASBEE for Urban Development and CASBEE for building scale. In the United Stated, a rating system called LEED (Leadership in Energy and Environmental Design) for Neighborhood Development Rating System has been developed. This system is used to evaluate the urban development for sustainability with integrated LEED for building scale assessment system for sustainable building.

1.1 Statement of Problem:

The issues of sustainable housing are still new and still unfamiliar to the public in Malaysia. According to Mohd Jasan (2004) the houses being built in the past decade was not meeting the essential criteria of sustainability and the problem detailed out as follow:

a) The building design do not takes into account of energy efficiency and building green with affordable housing. As building green housing will require specialize design of the building such as materials used either in construction work progress or for building installation purpose, structure of the building and the calculation of energy use of the building. To build the green houses, we need to employ building related professionals with 'extensive residential construction experience, drafting experience, building science backgrounds, indoor air quality investigation training, mechanical ventilation training and much more' (Kibert C., 2005). The problem is we are lack of the green house expertise builders or consultancies in Malaysia.
b) The sustainability of housing development will give greater emphasis on environmental, economic and social issues. The building itself will incur variety of environmental problems such as greenhouse gas emission. The implication of construction activities do cause environmental pollution, mainly because of 'the materials used, nature of design, methods of construction, locations and layout, physical structure and the use to which buildings are put', Ramachandran (1990).
c) The awareness of our public on the important of sustainable housing concept is obscurity. This may result in the difficulty to achieve the objectives of the projects if without the public participation and cooperative in the whole process as they are the end users of the products.
d) The objective of sustainable housing is to make the projects more valuable. With reducing the criteria of building usage such as energy consumption, water and materials used, life cycle cost plus decreasing in the accidents occurrence on sites will improve the quality of life, productivity and user accessibility.
e) The countries of North America, Europe and developed country in Asia do practice the sustainable building with establishment of sustainable rating systems for evaluating each phase of building work of the project. Malaysia does implement the tasks of Agenda 21 as an effort with respond to the sustainable development; however, Malaysia is yet to practice the sustainable building construction, particularly for *residential building*. Recently a green rating tool called the Green Building Index (GBI) of residential was developed, however is yet to be launched.
f) Furthermore, the development of housing sector or housing schemes development, do cover groups of buildings. Not only the building itself but also the whole housing scheme will affect the environmental performance. CASBEE for Urban Development has formulated a tool for this purposed. However, Malaysia is yet to introduce the tool for rating the practice of the sustainable housing development in both urban and suburban.

1.2 Objectives:

The objectives of this paper are as follows:

1. To develop a framework for a comprehensive assessment system for sustainable housing.
2. To identify factors affecting sustainability performance in Housing Development.
3. To formulate a Comprehensive Assessment System for Sustainable Housing (CASSH) for Malaysia.

2.0 The Existing Sustainability Assessment Systems around the World.

Recently, Malaysia has published its own first edition (version 1.0) of Green Building Index (GBI) Assessment Criteria for Non-Residential which measures new building construction since April 2009. The outline for key components of the Green Building Index (GBI) for Residential purpose is yet to be published. The intention of the GBI for Residential is to assess the building and its external area. This system is similar to that of the BREEAM for EcoHomes in the U.K., the LEED for Homes in the U.S., and the CASBEE for Home (detached houses) in Japan, Green Star for Multi-Unit Residential in

Australia and Green Mark for Residential Building in Singapore

This research is conducted with the objectives to establish a sustainability index for rating the housing development in Malaysia. A model for rating the housing development in Malaysia will be established. It will cover a wider scope covering a group of buildings which is similar to that of the assessment of urban development that in practiced in other countries such as Japan (CASBEE for Urban Development) and the U.S. (LEED for Neighbourhood Rating System).

2.1 The currently available building assessment tools around the world

There are several systems for evaluating environmental performance of buildings being developed and established currently. The growth and the use of buildings' environmental performance assessment methods has given great contributions to the building sustainability practices in various stages of building performance. The assessment tools that had been developed worldwide built upon the different evaluation criteria that were based on conditions to suit the countries' own characteristics. The objectives of the tools are to measure the practice of the sustainable building towards realization of sustainable development worldwide. Followings are some of the key assessment systems for buildings developed by various countries around the world such as shown in table 2.0.

Table 2.1 shows the Primary issues of concern identified in each building assessment tool for various countries around the world. Some key issues were identified as among the most popularly used by these assessment tools are site, indoor environment, energy, material resources and water. Below are summaries of some of the systems that being implemented in various countries.

ISSN 114-1284

1) The BREEAM Method
The BREEAM method is an environmental assessment method developed by the BRE Ltd (Building Research Establishment Limited), in England. It evaluates the environmental performance of buildings in both the design phase as well as the existing buildings in the UK. It is separated according to the building type to BREEAM for offices, Ecohomes, BREEAM retail, industrial BREEAM, BREEAM schools and health buildings. Credits are awarded to each issue according to their performance and are then added together to produce a single overall score. The building is rated on a scale of pass, good, very good or excellent. The method is not available to the public and it involves the participation of the company and the licensed assessors.

2) The GBTool Method
The GBTool is a software system for assessing the environmental and sustainability performance of buildings. It is an implementation of the green building challenge (GBC) assessment method that has been under development since 1996 by a group of more than a dozen teams. The GBC process was launched by Natural Resources Canada, but responsibility was handed over to the International Initiative for a Sustainable Built Environment (IISBE) in 2002.

The method comprises two parts, Module A which includes benchmarks and weights, Module B which results to the sustainability performance of the building. The assessment can be carried out at various phases of the life cycle of a project. The system carries a wide range of issues related to sustainable design. Four phases are included in the tool: pre-design, design, construction and operations. A scale ranging from -1 to +5 is used to express the evaluation in any case. The scale is interpreted as 1 negative performance, 0 minimum acceptable performance (usually but not always defined by regulation), three good practice and five best practice.

3) The LEED Method
The LEED system, developed by the US Green Building Council, is a national standard for developing sustainable buildings. LEED applies to new commercial construction and major renovation projects (LEED-NC), existing buildings operations (LEED-EB), commercial interiors projects (LEED-CI), core and shell projects (LEED-CS), homes (LEED-H) and neighbourhood development (LEED-ND). A number of parameters are evaluated and result to a score, which gives a certification of certified, silver, gold and platinum construction.
The LEED method involves several parties along the process of the evaluation and certification. The verification process consists of four phases, namely inspection, performance testing, rating and certification. In all the phases, the participating of the provider is mandatory.

4) The CASBEE Method
CASBEE is a Japanese environmental labeling method for buildings, based on assessment of their environmental performance. CASBEE is developed based on three major concepts. Firstly, it is designed for the assessment of buildings which corresponds to their lifecycle. Secondly, it is based on a concept that early distinguishes environmental load (L) and quality of building performance (Q) as the major assessment targets. Thirdly, it introduces a new indicator, namely BEE (building environmental efficiency) based on the concept of eco-efficiency. BEE is defined as Q/L to indicate the overall result of environmental assessment of buildings.
CASBEE can be applied to both private and public buildings, which are broadly divided into residential and non-residential and further into building types. The tool comprises of a set of four basic assessment tools, namely CASBEE for pre-design (CASBEE-PD), CASBEE for new construction (2004) (CASBEE-NC), CASBEE for existing buildings (CASBEE-EB) and CASBEE for renovation (CASBEE-RN), which correspond to the individual stages of the building's lifecycle. The tool has introduced a labeling classification of five areas, where class C is regarded as poor in terms of sustainability, class B + , class B - , class A, are regarded as average and class S as excellent.

5) The HQE® method
The HQE® (High Quality Environment) project methodology was developed in France and presents a mostly open character. It integrates a great number of parameters, requires a mode of management of the operations inspired by the international standard ISO 14001, and consists of a project methodology instead of a simple ex-post certification like the majority of the other existing methods. Launched in 1996, the HQE® programme enables developers and project owners to adopt construction options appropriate to sustainable development at all stages of a building's life cycle (manufacture, construction, use, maintenance, conversion and end of life). The HQE Association defined 14 targets specifying the particular environmental requirements that a building, whether new or rehabilitated, must satisfy. The method is applicable in all phases of design. The Environmental management system (EMS) is needed to implement the HQE® method. In fact, most of the builders in France refer to a general declaration without an operative EMS. Few of them are developing a specific approach based on an environmental policy, objectives and targets, requirements and evaluation.

6) Green Building Index
Green Building Index (GBI) is developed by Pertubuhan Akitek Malaysia (PAM) and the Association of Consulting Engineers Malaysia (ACEM). It is a profession driven initiative to lead the property industry towards becoming more environment-friendly. The rating system gives opportunity for developers and building owners to design and construct green, buildings that can provide energy and water savings, a healthier indoor environment, better

connectivity to public transport and the adoption of recycling and greenery for their projects. Buildings are awarded GBI Malaysia Platinum, Gold, Silver or Certified ratings depending on the scores achieved.

2.2 The available assessment tools for sustainable urban/ neighborhood development

Several environmental assessment tools for evaluating environmental performance on development of the designated areas are being developed and established currently. The main purpose of establishing these assessment tools is to improve the environmental performance in developed area. It measures the environmental design in multi-angles that are possibly contributed by a group of buildings. Nevertheless, the sustainable urban assessment tool includes the measurement in term of economic and social sustainability level in the development of designated area (housing sector). These assessment tools are built upon different evaluation criteria which based on the countries' conditions to suit the local contents. Followings are some of the key assessment systems developed by various countries around the world such as shown in table 2.2:

1) CASBEE for Urban Development

Initially, CASBEE is a Japanese environmental labeling method for evaluating and rating the environmental performance of individual buildings. In year 2007, CASBEE has developed another tool which called CASBEE for Urban Development where the assessment tool covers groups of buildings (urban scale) in a designated area. When a project is planned and implemented that comprises multiple buildings and other elements on a single, large-scale site under a unified design concept, assessment can go beyond the environmental design of each building. It also covers identification of new or expanded environmental measures, and their effects, that are made possible by the building group, and thereby contribute to the comprehensive improvement of environmental performance in urban renewal.

Urban Scale

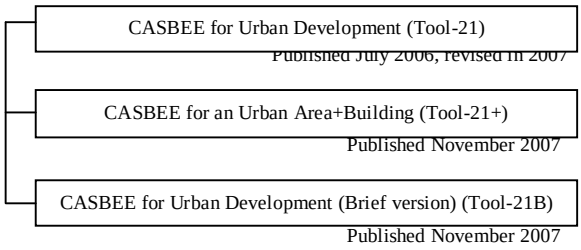

Figure 2.0 The CASBEE expanded tools for specific purposes

(Sources: CASBEE for Urban Development, Technical Manual 2007 Edition)

According to CASBEE for Urban Development, the center of the assessment designation is not the building but the space that surrounds the group of buildings. A hypothetical boundary is set around the area development project to be evaluated. The assessment then addresses both the environmental quality within the boundary and environmental load beyond the boundary. The assessment of buildings themselves is covered by CASBEE (building scale) and is not covered by CASBEE for Urban Development. The figure 2.1 below shows the basic concept of the hypothetical boundary.

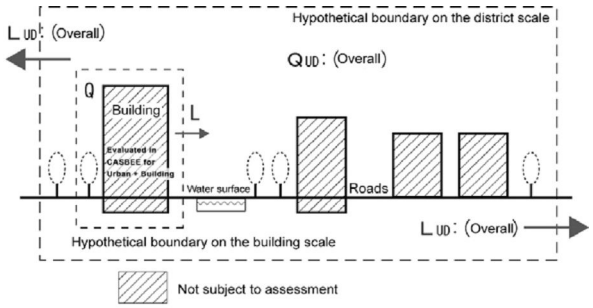

Figure 2.1 Concept of Assessment subjects for CASBEE for Urban Development.

(Sources: CASBEE for Urban Development, Technical Manual 2007 Edition).

Under the CASBEE methodology, which evaluates both environmental quality (Q) within the hypothetical boundary and the environmental load (L) acting outside the boundary, the site boundary is the same as the hypothetical boundary on the building scale. That leads to the approach that "space inside the site" is the environment as a private property under the control of the building owner, designer and the other parties involved in the building, while "space outside the site" is a public property (the public environment), which the building owner cannot control but should consider.

In the same way as the CASBEE (building scale), both Q (environmental quality) and L (outdoor environmental load) are evaluated and scored separately. Q_{UD} (environmental quality in urban development and L_{UD} (outdoor environmental loads in urban development) each comprises three main categories. Table 2.3 below shows the composition of assessment items for both Q (environmental quality) and L (outdoor environmental load).

Table 2.3 Composition of assessment items

Assessment field	Medium-level	Minor category
$Q_{UD}1$ Natural environment (microclimates and ecosystems)	5	17
$Q_{UD}2$ Service functions for the designated area	6	11
$Q_{UD}3$ Contribution to the local community (history, culture, scenery and revitalization)	4	6
$LR_{UD}1$ Environmental impact on microclimates, facade and landscape	6	16
$LR_{UD}2$ Social infrastructure	6	14
$LR_{UD}3$ Management of the local environment	4	13

(Sources: CASBEE for Urban Development, Technical Manual 2007 Edition)

The major categories from $Q_{UD}1$ to $LR_{UD}3$ each comprise 4-6 medium-level categories, and each medium-level category is further divided into minor categories. Each minor category is scored on five levels, according predetermined criteria, and weighting coefficients are applied between assessment fields to calculate the results The tools has introduced a labeling classification of five areas, where class C is regarded as poor in terms of sustainability, class B-, class B+, class A are regarded as Average and class S as excellent.

Table 2.4 The correspondence between ranks based on BEE values and assessments.

Ranks	Assessment	BEE value, etc.	Expressions
S	Excellent	BEE=3.0 or more, Q=50 or more	★★★★★
A	Very Good	BEE=1.5~3.0	★★★★
B+	Good	BEE=1.0~1.5	★★★
B-	Fairly Poor	BEE=0.5~1.0	★★
C	Poor	BEE=less than 0.5	★

(Sources: CASBEE for Urban Development, Technical Manual 2007 Edition)

The assessment procedures are using both of the system tools; there are CASBEE for Urban Development and CASBEE (building scale) to evaluate the target project. While evaluating the building scale with multiple designated buildings, recording the assessment results (point scores) for each building under "Assessment of

ISSN 114-1284

multi-use buildings" using CASBEE for New Construction, then take a weighted average according to the ratio of their floor areas.

2) LEED for Neighbourhood Development

LEED for Neighborhood Development (LEED-ND) is a rating system that integrates the principles of smart growth, new urbanism, and green building into the first national standard for neighborhood design. LEED-ND recognizes development projects that successfully protect and enhance the overall health, natural environment, and quality of life of our communities. Points are available within the LEED for Neighborhood Development rating system for including LEED Certified buildings and for integrating green building practices within the buildings on the project site. These credits relate to energy efficiency, reduced water use, building reuse, recycled materials, and heat island reduction.

According to LEED for Neighborhood Development is a rating system that integrates the principles of smart growth, new urbanism, and green building into the first national standard for neighborhood design. It is being developed by USGBC in partnership with the Congress for the New Urbanism (CNU) and the Natural Resources Defense Council (NRDC).

The rating system encourages smart growth and new urbanizes best practices, promoting the location and design of neighborhoods that reduce vehicle travel that provides work places and public services which are accessible in a walking distance. It promotes more efficient energy and reduced the use of water which is important in urban areas where infrastructure is often overloaded.

Credits are given in the LEED for Neighborhood Development rating system and labeled the LEED Certified buildings for integrating green building practices within the buildings on the project site. These credits relate to energy efficiency, reduced water use, building reuse, recycled materials, and heat island reduction."

Table 2.5 Composition of assessment items

Assessment Field	Prerequisite Assessment	Measurement Criteria Credit (Medium-level)
Smart Location & Linkage (SLL)	6	9
Neighborhood Pattern & Design (NPD)	3	15
Green Infrastructure & Building (GIB)	3	16
Innovation & Design Process (IDP)	NIL	3

(Source: LEED for Neighborhood Development Rating System)

Table 2.5 shows the LEED-ND that comprises four major categories of the assessment field. Each of the main categories has medium level assessment criteria, which the composition distinguished into prerequisite measurement and normal credit measurement in respectively. For the medium–level of prerequisite assessment of each classification comprises a minimum of three to six categories. Then the normal credit measurement can be comprised as maximum as 16 categories.

3) Ireland- A rural housing sustainability index (RHSI)

The rural housing sustainability index is developed by the Minister of the Environment, Heritage and Local Government of Ireland. While the objective of the rural housing sustainability index is to ensure that better-quality and more sustainable housing is constructed in rural areas, while also minimizing the effect of such housing on the rural environment. The index uses 70 criteria or indicators categorized into site, design, construction and social indicators. A score is allocated for each indicator with higher scores allocated for more sustainable actions or options. Threshold scores are set for each category from which the sustainability of the proposed development is determined. This allows planners to more accurately assess the impact of rural development as well as increasing the sustainability of the housing stock. The concept of a trade-off, by allowing more sustainable and sensitive housing in areas where normal housing is inappropriate, is explored.

A detailed list of potential indicators was drawn up from the existing literature and subsequently categorized under four broad groupings, there are: site or environmental indicators, design indicators, building or construction indicators, and finally, social indicators. Thus, as a result the sustainability index is established by comprise 70 indicators of the total of four broad groupings. The criteria used in the selection of sustainability indicators including: policy relevance, simplicity, validity, affordable data, reality, adequate scope and openness. Indicators selected for inclusion in the index had to be policy relevant and satisfy as many of the remaining criteria as possible. The composition of four categorizes of assessment criteria was shown as table 2.6 below:

Table 2.6: Composition of assessment criteria

Assessment Indicator	The quantity of assessment criteria in per categorize
Site (environment)	39
Design	35
Building (construction)	21
Social	13

(Source: A rural housing sustainability index)

4) FGBC-Green Development

The synopsis of the FGBC with stand for Florida Green Building Coalition organization had briefly depicted at the section 2.1 for building assessment tools which currently available around the world. The many resources had offered by the FGBC for green building standards of the certification programs and five in total. Except the developed programs for building's certification, FGBC do develop the assessment program for green development in the designated area, and the certification program is called Green Development Designation Standard Reference Guide.

ISSN 114-1284

The purpose of Green Development Reference Guide is to serve two purposes: to provide information on green development practices and to provide details on how to earn points for complying with the Florida Green Development Designation Standard. The standard requires substantial environmental stewardship beyond typical practice, yet it allows for developers to choose how to meet the standard from a variety of methods. There are enough items to choose from that every developer, through planning and dedication to green development should be able to comply with the standard. This level of planning can only be done through knowledge of the site as well as applying best management practices regarding wildlife preservation, stormwater, transportation, landscaping, and utilities.

The standard was developed by the Florida Green Development Working Committee of the Florida Green Building Coalition, Inc. The committee had active participation from one or more architects, builders, consultants, developers, ecologists, educators, energy raters, government agencies, landscape architects, planners, Realtors, researchers, and water-management district personnel. A number of parameters are evaluated and result to a score, then give the certification based on the score level achieved over a minimum threshold points. It gives the certification of Bronze, Silver, Gold, and Platinum.

The FGBC Green Development Designation Standard of Reference Guidelines does comprise six categories of the main assessment elements. Each of the categories does have the sub-assessment criteria for evaluation. The composition of assessment items are shown in table 2.7:

Table 2.7: Composition of the green development guideline

Category	Assessment criteria	Quantity of sub-assessment items
1	Protect Ecosystems and Conserve Natural Resources	14
2	Circulation	10
3	Green Utility Practices	7
4	Amenities	8
5	Covenants and Deed Restrictions	3
6	Provide Educational Information to Help Achieve and Promote Green Living Practice	10

(Source: FGBC for Green Development)

5) DDC-Sustainable Urban Site Design

The synopsis of the DDC background with stand for Department of Design and Construction had briefly depicted at the section 2.1 for building assessment tools which currently available around the world. As leaders in design and construction, it is DDC responsibility to provide New Yorkers with buildings and services that are socially responsible, progressively designed and environmentally sound. The DDC had published the reference guidelines for building practices and also sustainable urban site design with a purpose of guiding the consultants to successfully navigate the City's design and construction requirements; detail important sustainable strategies; showcase of Design and Construction Excellence policies; and review valued information essential to the design of public facilities.

The Sustainable Urban Site Design Manual offers an introduction to more environmentally, economically, and socially responsible urban site design practices for New York City capital projects. It is conceived as a resource handbook, featuring chapters that marry the unique site conditions encountered on many City projects with appropriate sustainable site design strategies. The contents are addressed to the whole rainbow of NYC DDC project participants, from City administrators to architects and their consultants, to construction managers, contractors, and facility personnel.

The DDC Sustainable Urban Site Design Manual of Reference Guidelines does comprise five categories of the main guidelines in difference aspects. The composition of reference manual is shown in table 2.8:

Table 2.8: Composition of DDC Sustainable Urban Site Design

DDC Sustainable Urban Site Design Manual
1. Sustainable Sites for DDC
2. Maximize Vegetation
3. Minimize Site Disturbance
4. Water Management on Urban Sites
5. Materials in Site & Landscape Design

(Source: The DDC Sustainable Urban Site Design Manual of Reference Guidelines)

6) SURPAM-HK

The SURPAM from Hong Kong is an assessment model developed by Lee and Chan (2007) which is called Sustainable Urban Renewal Project Assessment Model (SURPAM). This assessment model is attempts to generate the most sustainable urban renewal design for an area undergoing urban renewal. The objectives of the model comprised of three aspects namely economic sustainability, environmental sustainability and social sustainability. The design criteria level consists of 17 criteria which are the most important urban design considerations highlighted in previous studies (Chan and Lee, 2007a; Chan and Lee, 2007b; Chan and Lee, 2008). The assessment tool is composed of 34 indicators for 17 design criteria and the composition of the assessment criteria are shown in table 2.9 below:

Table 2.9: Composition of assessment criteria

Assessment element of SURPAM	The quantity of assessment criteria per element
Environment Sustainability	6
Social Sustainability	6
Economic Sustainability	5

(Source: Journal of Facilities "A sustainability evaluation of government-led urban renewal project")

Table 2.10 shows the Primary issues of concern identified in each building assessment tool for sustainable urban development for some countries around the world. Some key issues were indentifies as among the most popularly use by these assessment tools are site, indoor environment, energy, material resources, water, transport, health, social and services.

3.0 Establishing of the assessing model

The assessment model for housing sustainability index will be addressed as a Comprehensive Assessment System for Sustainable Housing (CASSH). It is made of a hierarchy of three major levels, that is, the outcome, design measurement indicators, and sustainability criteria level. The schematic diagram is as shown below in the theoretical framework in Figure 3.0. The goal level describes the ultimate achievement of the model. It attempts to generate the most sustainable housing development for an area either undergoing new development or renovation. The assessment model is try to evaluate an area of development as a whole, plus evaluates the environmental performance of individual buildings within the designated area as well. The framework requires the assessment method that integrates the neighborhood of building group constructed in the designated area and also consider the assessment of the interior environment performance of the building (housing) itself. The overall format for assessment result is as defined by CASBEE as "Urban Area + Buildings" for the developed area.

The sustainability criteria comprised multiple variables to be evaluated as leverage for achieving housing sustainability in the develop area. They can be categorized in six categories namely; Environment, Society, Economics, Building Forms (Housing), Site/ Land uses, and Communication & Transportation. The design indicators consist of 30 measurement criteria which are important in urban design development or neighborhood development plus building performance considerations highlighted in many other assessment systems. Through the literature review, a total of 131 short listed considerations can be incorporated in the model of assessment after verification through a pilot test for reliability and validity, to suit the local context.

3.1 Toward Establishing a Rating System for Housing Development in Malaysia

Indices are widely used in performance evaluation and have proven useful in locating weaknesses in overall design and system (Bell and Morse, 1999). The index is generally a number that is derived from the collection of a broad range of individually generated values or indicators that are used to characterize or evaluate specific aspects of the system (Gray and Carton-Kenny, 2004).

Rating system (1)

In the building scope Gray and Carton-Kenney (2004) has studied the sustainability index for rural housing. The objective of the study is to ensure a better quality and more sustainable housing is constructed in the rural areas. The sustainability index comprises 70 indicators categorized into site, design, construction and social. The criteria used in the selection of sustainability indicators including: policy relevance, simplicity, validity, affordable data, reality, adequate scope and openness (Gray and Carton-Kenney, 2004).

For example:

$$RHSI = \sum_{i=1}^{n} qi\ wi$$

Where RHSI is the Rural Housing Sustainability Index
n is the number of indicators,
qi is the score of the ith indicators
wi is the weighting attributed to the ith parameter

Rating system (2)

The CASBEE of Urban Development, both Q_{UD} (environmental quality in urban development) and L_{UD} (outdoor environmental loads in urban development) are evaluated and scored separately.

All the categories are also compounded using the formula below to generate BEE_{UD}, and indicator for Building Environmental Efficiency in Urban Development.

Building Environment Efficiency in Urban Development (BEE_{UD})

$$BEE_{UD} = \frac{Q_{UD}}{L_{UD}} = \frac{25 \times (SQ_{UD}-1)}{25 \times (5-SLR_{UD})}$$

Where Q_{UD} is Environmental quality in urban development
L_{UD} is Environmental load in urban development

First the numerator Q_{UD} is defined as $Q=25(SQ_{UD}1)$ to convert the SQ_{UD} scores (1~5 points) for the environmental quality in urban development into the Q_{UD} scale of 0~100. Then the denominator L_{UD} is defined as $L=25(5-LR_{UD})$ to convert the SLR_{UD} scores (1~5 points) for load reduction into the L_{UD} scale of 0~100

Rating system (3)

Lee and Chan (2007) have illustrated the assessment mechanism of the model of the Sustainable Urban Renewal

ISSN 114-1284

Project Assessment Model (SURPAM) on the basis of Hong Kong context to evaluate the sustainability level of individual urban renewal project by assessing the design quality of the projects. The formula for SURPAM as shown below:

$$P_k = jW_j \times S_{kj};$$

where P*k* is the overall score of an urban renewal project *k*,
W*j* is the final weight of criterion *j* in third level,
S*kj* is the score of project *k* on criterion *j*, and *j* is the 17 design criteria.

Proposed an Assessment Model for CASSH

The sustainability level of housing development is represented by the overall score of using formula of CASSH (Comprehensive Assessment System of Sustainable Housing) model. The calculation method is similar to that of the CASBEE for Urban Development and SURPAM of Hong Kong measurement. The calculation of the formula is proposed by multiplying the score indicating the performance of the designated area of each sustainability criterion indicator with the defined weighting of each of the same indicator as well. The weighting coefficients between the assessment criteria will determined by conducting a questionnaire survey to ask the experts who involved in the related fields. It is then use the Analytic Hierarchy Process (AHP) to defining the weighting in numeric which is being done by CASBEE.

The overall score of the sustainable development area is calculated using the formula as shown below:

$$CASSH = \sum SCn \times Wn$$

Where CASSH is Comprehensive Assessment System of Sustainable Housing
n is the numeric indicator for each of the sustainability criteria parameter
SCn is the score of the Sustainability Criteria of each of the n indicator
Wn is the weighting attribute to the n indicator to each Sustainability Criteria

The calculation of final score of CASSH on particular project is as listed below:

$$CASSH = \sum EnxW_{En} + ScxW_{Sc} + EcxW_{Ec} + BxW_B + SxW_S + CTxW_{CT}$$

Where En is represent Environmental criteria
Sc is represent Society criteria
Ec is represent Economics criteria
B is represent Building Forms criteria
S is represent Site/ Land uses criteria
CT is represent Communication & Transportation criteria

In order to calculate the overall score, it is necessary to define the value of the component of each indicator. However, the scores of each criterion will not identify firmly because it vary with performance of the designated area development.

ISSN 114-1284

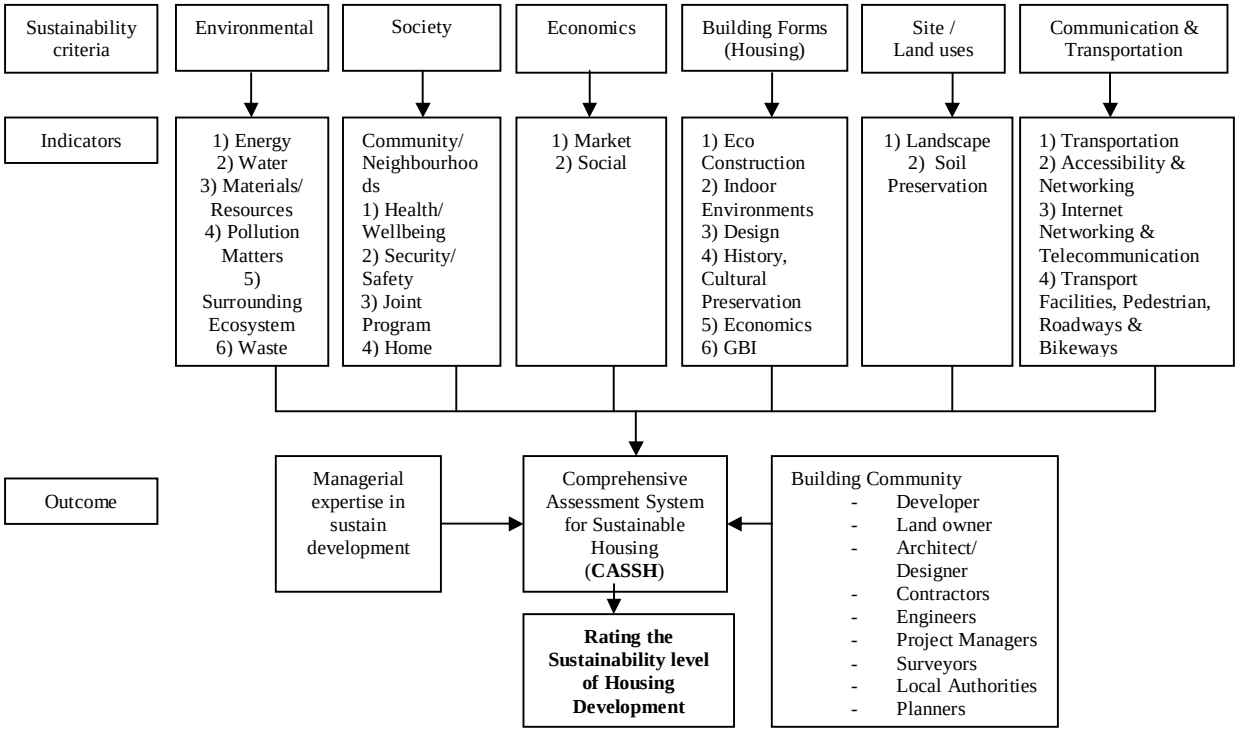

Figure 3.0 Conceptual Frameworks for Comprehensive Assessment System for Sustainable Housing (CASSH)

4.0 Conclusion

Basically, the assessment systems for sustainability from various countries are used to evaluate the building performance. Majority of countries, especially those developed countries, do have their own established building assessment system. For example BREEAM in UK do evaluate buildings by its' type, the BREEAM had formed up the multiple tools for different buildings' design such as, Ecohomes, Healthcare, Industrial, Multi-residential, Prisons, Office, Retail and Education Buildings. However, it is also important to evaluate environmental performance for a group of buildings. This mean evaluation include the surrounding of the designated area, as the assessment activity in Urban Area or in other words, the assessment on the buildings' neighborhood. The common district on buildings within a district can raise environmental quality and performance throughout the area. Thus, the establishment of Comprehensive Assessment System for Sustainable Housing (CASSH) to assess in a wider scope of housing sector development, "encompassing measures deliver through urban renewal and district-wide effort covering multiple buildings", as stated in CASBEE for Urban Development.

The analysis of the existing assessment tools and design methodologies has shown that there is emphasis on environmental issues. However, in the holistic approach, all of the tools will have to consider every aspect of the sustainability parameters and that will result in a more pragmatic effort in preservation of the environment. However, the implementation of the evaluation system will become more complicated and sophisticated.

The assessment tools are intended to be used as guidelines during the design process and as a more general sustainability assessment rather than a more specific architectural evaluation tool. The evaluation of housing sector development not only evaluate the surrounding of building being developed but also should include the assessment of building performance, since the buildings performance also will have significant impact on our environmental. Therefore, the establishment of CASSH, the housing sustainability index, is an assessment tool to evaluate the designated area (exterior spaces on the district scale (roads, plazas and other public spaces, and exterior spaces within building sites) identified by CASBEE Urban Development) and the buildings themselves within the hypothetical boundary of the defined area.

By improving the level of sustainability practices in housing development, this will require to shape up a guideline for rating the residential development in respect to housing sector by using the measurement of housing sustainability index. The formula of sustainability index in housing development will be produced based on adapting the critical factors to the successful practice system tools developed in Japan, United State and United Kingdom. These indicators for sustainability parameters should be recommended to be incorporated in the policy on sustainable built environment and should take into account criteria that compatible to local context.

Lastly, to achieve the sustainability development, it is significant for the development to consider many indicators which includes the following three cores: the Environmental, Social and Economic efficiency.

ABSTRACT

In construction project, bidding process is important because it represents early starting construction project. All government bidding projects is executed based on Presidential Decree Number 80/2003 and Region Government Law. In Brebes region, there is incident that bidding process is influenced by Contractor Associates involvement. Contractor Associates links the entire member to get opportunity in following tender with limited emulation.

The aim of this paper is to describe the trigger of Contractor Associates involvement in infrastructure construction bidding process in Brebes Region.

This is a case study research that gather respondent in form of survey and interview with related parties. Data is analyzed with descriptive statistical analysis by using frequency distribution method. The validity and reliability are analyzed with Corrected Total Item Correlation Test and Kruskal Wallis Test.

The results indicate that Contractor Associates involve in bidding process because there are certain work packages requested by government employee, the quality of work is low in terms of low competitiveness in price, the probability to sell the projects is high as a result of few resources, companies have low education background expertise and low skill resources, and the company financial ability is unsteady during tender.

Keywords

Bidding process, contractor associates, involvement

1. INTRODUCTION

Construction projects in both the provincial and district or city, consists of private and government projects. Private sector projects can be conducted through auction or direct appointment and the work is financed with private funds. Meanwhile, the government project, the financing comes from the APBN or APBD, where the responsibility may be attempted carefully and must follow the outlined, because the transparency factors in its implementation is highlighted.

Auction services for government construction projects is technically set in the decree the Presidential Decree No. 80/2003, which refers to the Law No 18/1999 and Law No 5 / 1999, so that it is expected to encourage the creation of a healthy competition, the use of products in the country, reduce the costs, and expanding business opportunities [1].

However, apart from imperfect legislation, and in fact there is behavior controversy contrary to the principles of healthy business competition. Implementation of Presidential Decree No. 80/2003 and Law No. 5/1999 is not realized, this is because there are many cases that occur related to the suspected violations in business competition [2]. Based on the reports, about 60% of reported cases are cases of conspiracy auction construction services suspected. Practices cartel or conspiracy auction often coloring activities auction services in the construction of a number of government institutions [1]. The same phenomenon also occurs in Local Government Brebes Kabupaten (Pemkab Brebes), the violation suspection in the procurement of health equipment Brebes District hospitals in the year 2006. In addition, there is also involvement suspected of individual House of Representatives District Regional Brebes (Brebes DPRD) in the direct appointment of the project [2].

Association of Construction Services is a role in encouraging the creation of business services and construction of health professionalism. Therefore, the association as a delivery vessel communication, coordination, and consultation between public service providers with the construction of construction, are required to improve the capability and professionalism of its members. This is to prevent the occurrence of competition that is unhealthy, because it can often make all parties and rarely cause problems in its implementation, and low quality construction of the resulting [3]. Thus, the associations are expected to play an active role in distributing the aspirations of members to organize and develop the work climate better, which allows the

participation of members in national development [4]. With the opening of the community in the role of business development services result in the construction many associations appear in the construction services sector, which one of them is the Association of Construction Services with the authority to implement the main providers of construction companies. However, often in practice in the field, the authority made it back to the emergence of behavior as opposed to the Law No. 18/1999, which is the difficulty in obtaining a certificate of business and individuals for the construction services business, and many other issues related to business competition in the field of construction services [5].

Association of Construction Services in the Brebes District has an important role, because of suspected involvement in the auction service on the construction of Public Works Brebes District. The indication is the emergence of symptoms similar the cases of prominent auction line-up in the last few years. The involvement of the association is conditioning auctioned, which is coordinating the auction members in construction services. This problem comes from the existence of the association itself, of companies engaged in the construction services sector. This is certainly not going to happen, when service providers compete for construction professionals in an effort to get a project.

In addition, the association is also expected to not get stuck in routines certification members, as a result of many other functions and tasks that have not been optimally implemented. As one of the authorized organization of the setting, guidance, supervision, business development and construction services, the Association of Construction Services in Brebes District not optimal in the running of its duties and functions. In addition, many cases of business competition are not healthy in the construction services sector continues to appear, which usually appear in the form of a conspiracy auction. This can be seen from the establishment that has not been a healthy business competition in the auction service construction, in which associations bridge the interests of its members to create a pseudo-competition condition. Devices such as contract documents and packages prepared in auction are being conditioned with the purpose of the project.

This condition is set in an effort to get the project desired by the members. Due to the involvement of the Association of Construction Services is significant, it should be special attention for the auction as the committee representing the owners to implement the project activities of the goods or services the construction, so it can be expected construction service providers get the best work to given implementation.

2. LITERATURE REVIEW

In project construction, the auction is one important part of a series of project activities. This is because of the success of the auction is the beginning of the start of the implementation of the project construction work. In addition, the auction is also the stage for a very important provider of construction services, as living dead: the company's success depends not in the auction [6]. Given the resources involved and the risk faced, in an effort to obtain the services of construction is expected to carry out work which needs to be done given the tight selection. Auction services are a set of construction activities to provide goods or services in a way to create a healthy competition among providers of goods or services that are equivalent and are eligible, based on the method and procedure which has been set and followed by the parties related to the rule, so that selected service provider is the best construction [7].

Therefore, in this case it is said that the main purpose of the auction is to provide a balanced opportunity for all bidder, resulting in the most affordable price with maximum results. Although generally acknowledged, that cheap is not the sole measure to determine the victory in the auction. However, the mechanism through auction bidding, avoided wherever possible the opportunity to make a conspiracy between competitors or the bidder and the auction committee. Based on Presidential Decree 80/2003, that in every activity of the goods or construction services are required to apply the principles below are efficient, effective, open and competitive, transparent, fair or not discriminatory, and accountable [1].

The selection procedure of service construction process is a series of activities that begins with identifying the needs of service of construction by the owner to prepare and package up to the auction contract for the implementation of physical projects. This process includes research and evaluation work that often reach the internal organization and financial service providers from the construction. This needs to be done, because it will affect the success of the project and the quality of the project [1].

The prequalification process designed correctly should meet things like this. First, ensure that the construction of service is quite competent, responsible, experienced, and have sufficient resources to complete the project. Second, service providers are able to eliminate the construction that has limited resources, over-commitment, and companies that are less or not very experienced, so that reduces the administrative burden and to prevent the owner of difficulty determining the winner. The third is to maximize competition among providers of construction objectives [8].

In the process of decision making on the stage prequalification, project owners must do the steps as follows. First, determine the criteria to be used in the assessment of the participants, of course it depends on the needs of the project. Second, find the data provider of construction services that will be evaluated. This can be done with the construction of service request to submit the data or the way the service providers for the construction or to answer questions that have been prepared. If necessary the data provider of construction services that are less, then be found from other sources. Third, evaluate the data from data-service providers in the construction. Fourth, make the assessment of the data providers with the construction criteria that are used,

already sufficient for decision making. Fifth, if it turns out from these assessments still require additional data, then the next step is the search for additional data, so it is sufficient for decision making. Sixth, decision-making at this stage is a critical step, because the errors in the decision will bring a big impact with the implementation of the project. So in the stages of decision-making, should the data required must be sufficient available [9].

Based on Presidential Decree No. 80/2003, the assessment criteria for construction services performed by the auction committee includes three aspects, namely administrative, technical, and price [1]. System assessments of evaluation service providers should consider the construction of minimum standards for each category, where bid or proposal to auction the documents submitted will be disqualified if it does not meet the standards set. In general, the sale or importation document should include information related to categories such as, the following of the technical approach, management ability, financial capability, personnel qualifications, experience of, the performance of the past, the method of execution, and price information project [10].

Racketeering conspiracy in the auction or services defined as the construction of the cooperative agreement between bidders, which should compete with the goal of winning particular auction participants. This agreement may be made by one or more of the auction participants that are not agree to submit bids, or by auction that a participant with a lower price and then make a bid with a price above the bid price of the company as the winner. The agreement of this kind against the auction process is fair, because the public auction procedure is designed to create equity and to ensure a result with cheap price and most efficient. Therefore, the line-up in the bidding auction is considered inhibit the creation of a healthy competition among the bidder [11].

3. RESEARCH METHODOLOGY

The chosen method of research is survey method with the quantitative approach. The research is based on a theory of reference or some of the literature relevant to the research problems. The category variables are consisting of three criteria as follows, administrative, technical and financial. Meanwhile, to check the validity of research variables, validation is done by specialist construction services by the competent services in the areas of construction and set of research variables used.

Research data collected using the questionnaire as research instrument. The questionnaire was designed in the form of a Likert Scale with the choice of alternative answers to choose one of them as the most appropriate answers. Collecting research data carried out by distributing questionnaire and direct interviews with the respondents.

Methods used to analyze the research data are consists of several methods such as the following statistics. First, test the reliability and validity of the method corrected Item Total Correlation. Second, comparative analysis with the Kruskal Wallis Test methods. Third, the analysis of descriptive statistics with frequency distribution method based on the value of the mode.

After analyzing the research data, then the next stage is to validate the research results to the specialist construction services by the competent services in the areas of construction to ensure that research results are relevant to the facts that occurred in the field.

4. RESULTS

Test results show the validity and reliability Cronbach's Alpha value of 0.479 that is greater than the value for r table df = 23, namely 0.265 and tested questionnaire are proved reliable enough with the reliability level of 47.9%.

Based on the survey that was done, the answers obtained from respondents who agree on the causes of the involvement of association services in the process of implementing the construction auction services in the construction of Public Works Brebes District. The causes are as described in Table 1.

Table 1: Factors in Contractor Associates Involvement Trigger.

Administration Criteria
Requests that a specific work package carried out individual government officials, the complexity of the procedures of certification bodies construction services business, the inconsistency level of competence and ability of business services with the construction certificate, the complexity of the procedures of certification experts and skilled labor, the inconsistency level of competence and ability of experts and skilled workers with a construction certificate services, the complexity of licensing procedures in the field of construction services.
Technical Criteria
Few projects in a year, strict competition because the number of partner services construction, low quality of work due to the price quote that is not competitive, low level of understanding of the scope of partnership work being offered, the size of the project likely to be sold due to limited resources, limited supplies and equipment owned partner, low education level of experts and skilled workers of the partner, low level of attention to the importance of partnership in the K3 system construction project.
Financial Criteria
Low level of ability to make partner in the price quote, the condition of instability in the financial partner auction service construction.

While in the Item Total Correlation Corrected, apparently there are some variables that have a value of r is smaller than the value of r is thus the table, so that to increases the

reliability level up to 85.1% only six grains research variables used, namely the existence of a specific work package request made individual government officials, the complexity of the procedures of certification bodies construction services business, due to low quality of work that is not price competitive bidding, the project likely to be sold due to limited resources, low education level of experts and skilled workers of the partner, and the condition of instability in the financial partner the auction service construction.

Results based on comparative analysis of the membership association, found only one variable that has significant differences, namely the variable complexity of the procedures of certification bodies construction services business with a value Asymp.Sig = 0.046. Then, comparative analysis based on employee status, was found two variables that have significant differences, the variables of a particular work request package made with the individual government officials with a Asymp.Sig value = 0.001 and the variable quality of the work due to the low price bid is not competitive with the value Asymp. sig = 0.022.

5. DISCUSSION

Various phases of research and research data analysis process that includes the validity and reliability testing, comparative analysis, and descriptive statistical analysis, obtained some of findings which is the cause of the involvement of the Association of Construction Services in the process of construction on the auction service Department of Public Works Brebes District is the request packet work that is done a certain individual government officials, the complexity of the procedures of certification bodies construction services business, due to low quality of work that is not price competitive bidding, the project likely to be sold due to limited resources, low education level of experts and skilled workers of the partner, and the instability partner in the financial condition of the auction service construction.

It could not be denied that the auction service in the construction of very large possibility of the occurrence of conspiracy. This often cannot be avoided but cannot be sustained. Conspiracy arising in auction service since construction should be completed early in satisfactory for all parties. If neglected, it will be a bad habit that is considered can decrease the performance of the construction as a whole, in this case will cause a restriction for the construction services business in general.

The request packet of a certain job done individual government officials variable. With demand packages that work done by individual government officials resulted in at least the number of jobs offered. It is not because of the number of projects with a number of service providers that have constructed, the services of the Association of Construction discuss to establish a forum of construction services, called 'faction'. This is done with the intent and purpose to make the way to the fair distribution of projects for each member based on the number of associations that are owned or the nature and type of projects offered. This variable has differences based on respondents' perception of the status of employees, this can only happen due to the directorship of respondents would better understand the problems that occurred in the scope of business in a system of government.

The complexity of the procedures of certification bodies construction services business variable. As is known, that the National Certificate Business Services Construction (SBUJK) is one of the main requirements that must be owned provider of construction services for the construction of the auction services. However, this is often a problem for service providers to get a certificate in construction, both business entities and individuals, so that service providers make the construction activities to do business. In line with the understanding, the variable is also strengthened by previous research on the authority of the Association of Construction Services to develop, in this case carry the certification agency business services construction is still a difficulty for the construction of service [12]. This variable has differences based on respondents' perceptions of the membership association, it is possible for each association has a certification procedure and a different standard.

The low quality of work due to the price quote that is not competitive variable. Based on the experience available, from some of the auction that was conducted with the competitive bidding (free fight), it is possible that the quality of work produced is not good, the price bid submitted by the participants are often very low. So that the Association of Construction Services as the vessel's construction company service providers need to find a way to create a business climate conducive deems. Conditions had a positive impact on the quality of work produced, as with the settings such that the price bid submitted by the participants tends to be higher near plafond budget. On the other hand, it is preferred to prevent entry of the potential and limits competition in general. This is contrary to Law No. 5/1999 Article 22 of the auction process or activity to the goods or services with a competitive price quote and open competition as the broadest. This variable has differences based on respondents' perception of the status of employees, this can only happen due to the directorship of respondents would better understand the business impact and risk of the company owned.

The variable size of the project likely to be sold due to limited resources variable. Not a bit of service construction company that is not competent in conducting business, this can be seen from the many providers of construction only as a role player or a broker in the construction auction services. This means that, easily sell them to buy the work of the project is established, while there is no competence to perform the job. Typically, they lend only other company to partner with a certain amount of compensation in accordance with the agreement. For that is the Association of Construction Services to do a role in the interest of the members and the creation of a conducive business climate. This is starting back with the settings included in Law No. 18/1999 Article 8 of

the business requirements, expertise, skills and business entities and individuals in the field of construction services.

The low level of education experts and skilled workers of the partner variable. Most of the education level of experts and skilled workers of the agency business services construction is very low and does not support the competence in the field of construction services. As is known, that the certificate and Expertise Skills Certificate (SKA-SKT) is one of the main requirements that must be owned provider of construction services for the construction of the auction services. Therefore, the Association of Construction Services to perform the obligation of the workforce that belongs to members. This is certainly in line with what is mandated in Law No. 18/1999 which requires the creation of business professionalism in the field of construction services. This setting is found in Article 9 of the terms of employment, both experts and skilled labor for the construction of business services.

The instability condition of financial partners in the construction auction services variable. Because of the low level of competence construction service providers, especially those related to the ability of financial companies, the goal is to be formed the Association of Construction Services to provide counseling, guidance, help and protect and defend the interests of members. In this case, the association helps members to the financial difficulties of conducting business, so that the expected welfare of the members still guaranteed.

Validation results of research carried out by request and approval of some of the specialist construction services, to ensure that research results are relevant to the facts that occurred in the field. Based on the experts, the demand variables specific work package that the government made an official person can only occur due to weak supervision system and law enforcement officers by the authorities. This problem is actually usual and old case. Almost most of the work required and making fitful construction service providers. System of cooperation in the negative among individual government officials, in this case the many parties concerned to show the impact each other, so that the work request is associated with efforts to defend the budget.

The complexity of the procedures of certification bodies construction services business as a specialist, does not actually relatively complex, even too simple, so it is said less comprehensive. It should forward the process of certification with the facts capability construction service providers in the management of construction, such as production management or field that is expected measurable indication of the capacity in the construction of the project construction.

However, one expert argued that the procedure would still be a certification difficulties experienced construction service providers, because of the complexity of the complex bureaucracy. The fact the process of certification to the private parties in this case the association, does not guarantee the improvement of competence and professionalism of the spirit.

6. CONCLUSION

After several phases of research, such as collect data, process data, interpret data, analyze data, and validate the results of research, the conclusions obtained are as follows: The factors which is the cause of the involvement of the Association of Construction Services in the process of construction on the auction service Brebes District are certain work packages requested by government employee, the quality of work is low in terms of low competitiveness in price, the probability to sell the projects is high as a result of few resources, companies have low education background expertise and low skill resources, and the company financial ability is unsteady during tender.

ABSTRACT

Green infrastructure discussed in this paper relates to the connective matrices of green paces found in and around urban and urban-fringe landscapes. The prepositions of this research are fragmented in urbanized landscape area is critical to ecological condition and urban sustainability, green infrastructure hubs and corridors are hostile to a majority of the inhabitants, and natural conditions in urban and peri urban areas are important to be linked.
This paper rapidly assessed and analyzed the schematic views of green infrastructure elements and distribution in peri urban area using a quantitative descriptive as a methodological research. Research conducted in Manado City, North Sulawesi Province and selected peri urban area as a case study. This paper examined a number of diverse research areas that have attributed value to the ideas underpinning green infrastructure planning. A review also is made for assessing the concept of green infrastructure for conservation purpose. Finally, this paper concluded with further development of green infrastructure planning. Through this, I have developed an evidence base and a set of criteria to provide planning solutions for conservation using green infrastructure approach application.

Keywords
Green infrastructure, assessment, adaptive planning, peri urban

1. INTRODUCTION

The rise in green infrastructure research has coincided with a reassessment of what landscapes should be in terms of form and function. Green infrastructure as a term relates to the connective matrices of green spaces that can be found in and around urban and urban-fringe landscapes. They provide a number of complimentary benefits for ecological, economic and social spheres and have been increasingly viewed as concept that both planners and practitioners can draw on.. Policy and planning integration, landscape multi-functionality and organizational cooperation are all ideas that underpin the growth of green infrastructure, but are also important developments in planning policy as a whole. What needs to be solved now is how green infrastructure as a concept and as landscape management process can be implemented in planning practice.

1.1 Green Infrastructure and Conservation

Green Infrastructure is a system, which strategically planned and managed as network of wilderness, parks, greenways, conservation easements, and working lands with conservation value that supports native species, maintains natural ecological processes, sustains air and water resources, and contributes to the health and quality of life for communities and people [Mark *et al* 2008].

The Green Infrastructure network encompasses a wide range of landscape elements, including natural areas - such as wetlands, woodlands, waterways, and wildlife habitat; public and private conservation lands - such as nature preserves, wildlife corridors, greenways, and parks; and public and private working lands of conservation value - such as forests, farms, and ranches. It also incorporates outdoor recreation and trail networks [

Infrastructure is defined as - "the substructure or underlying foundation, especially the basic installations and facilities on which the continuance and growth of a community or state depends" [Webster's New World Dictionary]. Infrastructure is definitely about building roads, electric power lines and water systems as well as social infrastructure such as schools, hospitals and libraries. However, the concept of Green Infrastructure covering elevates air, land, and water to an equal footing with built infrastructure and transforms open space [Bryant 2002].

Green infrastructure is a consideration to ecosystem benefits, storm water management, drinking water protection, ground water recharge, support working-land, increase property values and enhance quality of life. The term green infrastructure have its ability to invoke images of planned networks of green spaces that benefit wildlife and people, link urban settings to rural ones.

2. METODOLOGY

2.1 General Description of Study Area

Research was conducted in Manado City. The city is situated in the Northern part of Sulawesi Island, Indonesia (as shown in figure 1)

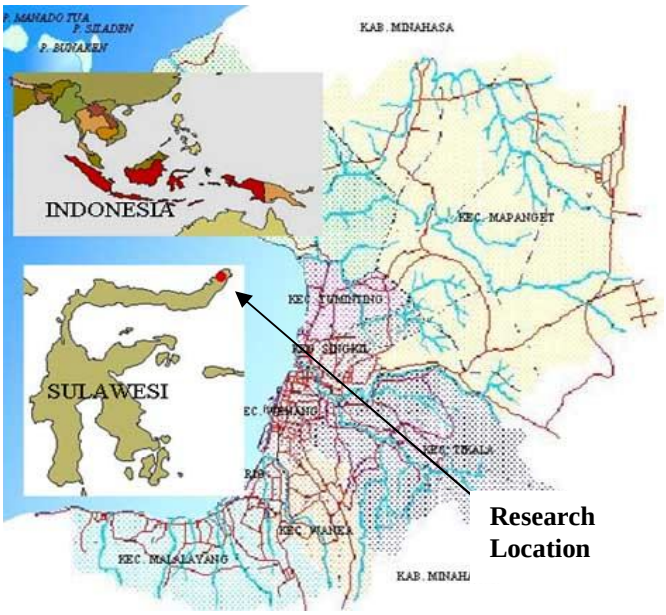

Figure 1. Research location (source: Manado in Figure 2008)

Manado is a capital city of North Sulawesi Province, encompassing 157.126 square kilometres, with the population of 410.033 people reside in 9 districts and 87 sub districts (Manado in Figure 2008). Manado is well known with the spectacular Bunaken Marine National Park, the hospitality of its gentle and friendly people, and diversity in harmony. The city is described as the biggest urban area in the north of east Indonesia region. Hills and plains that meet the coast at Manado Bay frame the plains along western boundary and define the environment of the city. Specifically, Manado has its open water territories that include administratively several small islands i.e, Bunaken Island, Siladen Island and Manado Tua Island. It is a rapidly developing city experiencing urban development in North Sulawesi since 1995. Intense population growth has resulted in extensive and rapid land use changes and the replacement of lands and open spaces with residential, commercial, industrial and infrastructure development.

2.2 Study Site Selection

This study selected peri urban green infrastructure (GI) systems. The GI systems include a range of different GI types including roadsides, pathways, riparian, ponds and patches of green spaces based upon the characteristics of the systems, types and sizes in which they were located. The research began with conducting an evaluation of the existing green infrastructure conditions and sought to provide planning and management frameworks for future consideration. To initiate the research process, secondary data was obtained include air photos and some report data relevant to the study area. The location and extent of all green spaces and GI were the verified in the field.

2.3 Green Infrastructure Survey

This research was conducted by visiting study site over March to May 2009 to observe the patches or hubs and greenway corridors and to assess the biological conditions. To quantify the land use, aerial photography data was applied using ArcView 3.2 software.

3. RESEARCH ANALYSIS

3.1 Rapid Green Infrastructure Assessment

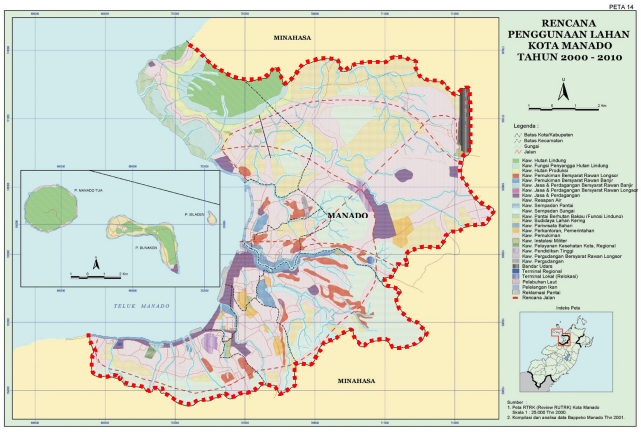

Figure 2. Land Use Planning of Manado City 2000-2010

The purpose of the land use assessment was the identification and mapping of existing green infrastructure in peri urban of Manado City. Land use data were used as the basis for assessment. Map of Manado at scale 1:25.000 and GIS analysis data was used to assess existing GI. This information provided an overview of existing land uses and vegetation within the urban boundary. Existing land use and land cover were categorized using a classification system developed by the National Land Division of Indonesia. Land use and land cover were identified based on what could be "seen" by the satellite. Figure 3 indicates the existing land cover and land use in Minahasa Regency include Manado City and surrounding region. Majority of land are conversed into plantation fields across urban, peri urban and boundary areas.

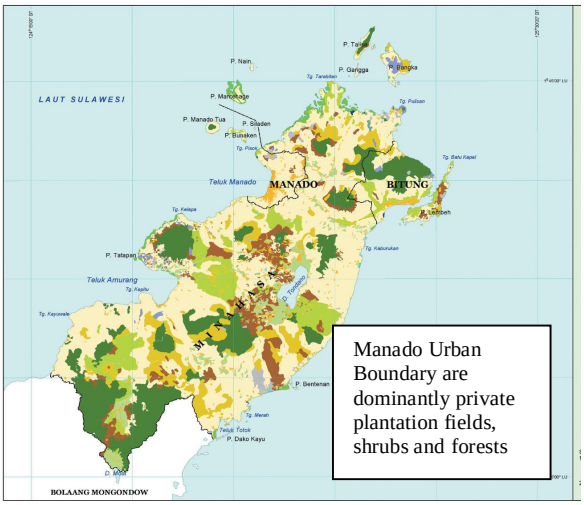

Figure 3. Map of Existing Land Use in Minahasa Regency

3.2 Evaluation of Green infrastructure Systems

A green infrastructure system is best viewed as network or web of open spaces and pathways that provide many benefits and the opportunity for people and animals to travel through the urban environment. Although most greenway corridors are at least partially conserved, the transportation aspects of the suburban greenway and agricultural matrices and hubs fall short of providing a complete or continuous system (as shown in figure 4 below). Many hectares within potential greenway corridors have already been developed for commercial and residential uses. Building blocks or components make up a green infrastructure system. These include greenways, the links in the system, as well as parks, preserves and cultural/ historic sites, which can serve as system hubs, as shown in table 1.

Figure 4. Infrastructure and housing development in Manado

Type of Green Infrastructure	Functions
Landscape Linkages	Linear protected areas that provide sufficient area of space for native plants and animals to flourish while serving as corridors connecting ecosystems and landscapes.
Conservation corridors	Less extensive linear protected areas, serve as biological connecting corridors and also provide outdoor, resource-based recreational opportunities.
Greenbelts	Protected natural lands or working landscape surrounding cities that preserve agricultural productivity as well as to balance and direct urban and suburban growth.
Recreational corridors	Linear open spaces to intense recreational use for residents and visitors.
Scenic corridors	A linear protected corridors and lands for scenic quality and other aesthetic considerations.
Utilitarian corridors	Linear features, such as powerline and pipeline rights-of-way and canals that help connect recreational, cultural or natural system features.
Trails	Designated trails provide access to and appreciation of the values of natural areas, green spaces and historic sites.
Hubs and sites (Reserves, regional parks and preserves, and ecological sites)	The system serves different purposes i.e conserving biological diversity and natural resources, protect important historical and cultural sites and provide some nature-based recreation opportunities, provide ecological benefits, and conserve important or unique natural or geologic features.
Cultural/Historical/ Recreational Sites	Community parks or cultural/historical sites provide recreational opportunities, help protect and interpret cultural heritage and can often serve as a system origin or destination
Urban area	Serve as human hubs for GI systems

The habitat conditions in the green infrastructure system have been assessed in terms of biodiversity conservation purposes without disregard the social and cultural aspects. Based upon indicators of habitat size, vegetation cover, structural diversity and vegetation composition (Jansen and Healey 2003; Parkes *et al* 2003), the actual condition of peri urban area visually assessed and score qualitatively as very small, small, medium and large. Forest patches and riparian corridor are likely to be useful for increasing ecological connectivity and creating green infrastructure network. In the study area, a scale of 0 to 4 was applied for sub-indicator using applicable method of scoring and weighting, as shown in table 2. The result shows significant and potential green infrastructure to be developed and connected between hubs and corridors in peri urban area and create urban greenbelt. Although the majority of land had been conversed into residential, plantation field, there are still opportunities for urban biodiversity conservation.

Table 2. Method of Scoring used to evaluate the green patch condition in study area

Category	Indicator	Sub-Indicator	Score	Method
Patchs/hubs Condition	Patche / hubs Size	Relative patch size	0 - 4	0=non; 1=very small; 2=small; 3=medium; 4=large
	Vegetation Cover	Canopy cover	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61% cover
		Middlestorey	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61% cover
		Understorey	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61% cover
		Ground Cover	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61% cover
	Structural Diversity	Number of Layers	0 - 4	0=No layers; 1=1 layer; 2=2 layers; 3=3 layers; 4=groundcover, understorey, middlestorey and canopy layers present
		Leaf Litter	0 - 4	0=none; 1=1-29%; 2= 30-50%; 3= 52-65%; 4= >66% groundcover
		Logs and Rocks	0 - 4	0=none; 1= small quantities; 2= abundant but some removed; 3= abundant relatively average intake, 4= abundant relatively large intake
	Composition	Natives in Canopy	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61%
		Natives in middle storey	0 – 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61%
		Natives in under storey	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61%
		Natives in Ground Cover	0 - 4	0=absent; 1=1-20%; 2=21-40%; 3=41-60; 4≥61%

Riparian corridors, as part of green space system are primary component in building green infrastructure system. The pattern of Manado City's major streams are eight catchments and riparian systems, which are relevant for developing green infrastructure zones. The open spaces along these streams and their tributaries create opportunities for linking the city's open spaces systems.

Figure 5. Riverine system in Manado City. Tondano river as main stream and small creeks are flow through the urban area and the rivers are include in the Tondano Regional Catchment Development (PWS Tondano).

4. RESULTS

Green infrastructure in the study area was categorized into three classes based upon overall patch conditions evaluation. Class A with high diversity of vegetation and layers are likely to attract wildlife, i.e. birds and small mammals, while class B have moderate and Class C have poor in vegetation-layer density. However, potential patch for conservation purpose can be established by re-vegetation and being connected to a green networks.

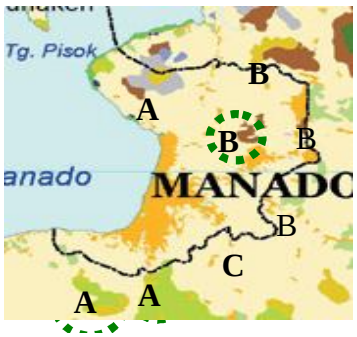

Figure 6. Identification of Potential GI systems

Figure 7. Greenbelt desired

Potential hubs and green corridor in peri urban Manado are described in table 3.

Table 3.Hubs identification and Classification

Patch and potential GI	Classification
Gunung Tumpa Protected Area	A
Pineleng Hills	A
Outer Ring Road Corridor	C
Plantation Fields	C
Swamp and Ponds	B
Shrubs forest	A
Riparian Greenways	A

Limited research time constrained this inquiry and the rigor of the fieldwork, and continuing research on biological condition as well as animal presence and occupant in urban area, particularly pattern and distribution of native species is recommended.

A green infrastructure with ecosystem network can be understood as a set of ecosystem patches, which functionally are connected by flow of organism and interactions within the landscape matrix. Structural components in the matrix include roads, fields and edges. In connection with biodiversity conservation, the ecosystem network is a multi concept include greenways (Ahern 2002), conservation networks (Grove 2003), and ecological networks (Grimm *et al* 2000). Scientists have identified some general design guidelines which can increase biological values of green networks and help minimize the potential negative impacts. Nearly all scientists agree that functional corridors and connectivity and the goal of any green infrastructure planning must be explicitly stated and analyzed (Noss and Coorperrider 1994 in Groves 2003).

5. CONCLUSION AND DISCUSSION

5.1 Planning Strategy

Traditionally, green infrastructures are planned for public utilities, roads, pipes and grey infrastructure, the green space located in leftover or unbuildable land and green space planning limited to development site i.e. lots, internal trails and pocket parks. However, better planning strategies can be developed, by first conduct inventory and assess natural and historic features and functions, secondly, develop a protection and management strategy, third, plan green spaces, such as parks, trails and habitat connections before locating built elements and lastly, connect hubs and green patches across regions and across ownerships. Green infrastructure planning as well as grey infrastructure ideally is plan simultaneously and given equal priority in the planning process. It is also planned as complementary systems and equally considered in the funding process.

A framework of Green infrastructure as a tool for informing decision-making is needed. A set of basic stage is designed as follows:

- Inventory of natural and historic resources
- Identify opportunity and constraints
- Determine risks to identify resources
- Integrate findings and goals into local and regional comprehensive plan
- Amend local ordinances to reflect identified goals

5.2 DISCUSSION

Significant biodiversity conservation is concerned distributed throughout the city, and is particularly concentrated along the outer margin of the city. Urban areas, particularly river ways and mouth adjacent near shore zones are integral to the conservation of urban biodiversity. It is needed to re-thinking and addresses the methods for constructing the conservation blueprint, the distribution of biodiversity features relative to urban areas, and highlight current work of the local government in Manado and nationally Indonesia to address urban threats to biodiversity conservation and knowing that greenways provide a chain of different habitats permeating the urban environment. We suggest that planners can have a positive impact on urban biodiversity by slowing the pace of redevelopment and by not hurrying to tidy up and redevelop brownfield sites, converse land and clear the spaces contain green elements.

5.2.1 Green Infrastructure and Conservation Challenges

Nowadays the accelerated consumption or conversion of open lands in relation with land conservation in Indonesia has been in challenge. The conversion of natural areas and working lands has resulted in increased habitat fragmentation, loss of biodiversity and wildlife populations, disruption of natural landscape processes, impairment of carbon storage and the degradation of air and water resources [Davies et al 2004]. It has also had numerous social consequences including the loss of vital services provided by natural systems, increased public and private costs of providing services to dispersed development, a decreased sense of community and the loss of the connection people feel with nature and with each other [Laurian 2008].

To address these concerns, governments across Indonesia, have developed regulatory approaches to resource conservation, species protection, facilities sitting, air and water quality and land management [www.kehati.or.id]. Local jurisdictions have implemented comprehensive plans; however, many of the communities have not approved the invested heavily in roads, sewers and other public works or "gray infrastructure". Increasingly, communities are investing in parks, open space, farmland and forest protection and in other elements of green space.

Although current approaches can count many accomplishments toward protecting natural systems and processes, improving environmental quality and delivering transportation and other community services, important objectives still go unmet. This patchwork of well-intentioned plans and regulatory approaches by themselves are not sufficient to arrest the decline of species, natural resources and systems or dispel the feeling that we are still losing our quality of life and important measures of the "good life." However, haphazard development as well as haphazard conservation - conservation activities that are reactive, site-specific, narrowly focused or not well integrated with other efforts should be addressed. It is a need of smart growth to strategically direct and influence the patterns of land development and "smart conservation" to direct our nation's

conservation practices [Mark et al 2008]. Green Infrastructure - strategically planned and locally managed networks of protected green space with multiple purposes - is of critical importance to ensuring clean air, abundant clean water, and healthy landscapes for all people today and for future generations. Green Infrastructure provides a solution that ensures environmental protection and a higher quality of life for communities as well as regulatory predictability for landowners and investors.

ACKNOWLEDGMENT

I wish to thank Centre of Minahasa Regency for GIS data and Map Base. I also give thank to Prof. Dr. Sangkertadi, DEA for assistance and suggestion in this research project.

ABSTRACT

Preloading is a method of soil improvement by applying temporary loads on soil layer in the field to increase the shear strength and decrease the settlement at post-construction stage. Laboratory tests was conducted by using triaxial apparatus to simulate the real condition in the field. The soil samples were saturated in the triaxial test until the coefficient B is above 0.97. At the first step of the consolidation stage in the triaxial test, loading is given for 24 hours in amount of 1,5 Pc' and then the cell pressure is released to site pressure condition for another 24 hours, which Pc' value was obtained from consolidation test. And at the second step, loading is given in amount of 2 Pc' for 24 hours and then the cell pressure is released to site pressure condition. Shearing the samples in drained test is carried out slowly under condition of no excess pore pressure until achieving maximum stress and then the test is conducted to strain of 18 %.The test results indicated that the soils parameters under consolidated drained test with preloading are higher than the unconsolidated undrained test and gives a increase the shear strength to support permanent load.

Keywords: *preloading, soft soil, shear strength, consolidated drained, pore pressure, strain*

1. INTRODUCTION

The safety of buildings construction located on soft soil should be ensured against failure and tolerable settlement. One of the applied method in the field is preloading. This method is to increase the shear strength capacity and decrease the settlement during post construction phase by applying load on soil layer.

To simulate the real condition in the field, laboratory study of preloading effect on shear strength in drained condition was conducted on Bekasi soft soils by using triaxial apparatus.

Chin et al. [7] giving detailed information concerning design and construction control of embankment over soft cohesive soils by using preloading or surcharging in the field accompanied with installation of vertical drains to increase the consolidation time. While Damoerin et al. [9] have studied the effect of preloading to shear strength on soft soils with limited consolidation time during 4 hours under consolidated undrained triaxial test. Bouferra et al. [4] have studied on sand under undrained cyclic loading and give information that a large preloading induces a reduction of the resistance of sands to liquefaction.

Consolidated drained triaxial test with preloading on soft soils was conducted to simulate the real condition in the field accompanied with installation of vertical drains to increase the consolidation time. The test results indicated that the soils parameters under consolidated drained test with preloading are higher than the unconsolidated undrained test and gives an increasing shear strength parameters.

2. TEST PROCEDURE

Test on soil samples consist of physical and engineering properties. The engineering properties test consist of consolidation and consolidated drained triaxial test. Pc' value was

obtained from consolidation test and parameter of shear strength was obtained from drained triaxial test.
The soil samples were saturated in the triaxial test until the coefficient B is above 0.97. At the first step of the consolidation stage in the triaxial test, loading is given for 24 hours in amount of 1,5 Pc' and then the cell pressure is released to site pressure condition for another 24 hours. And at the second step, loading is given in amount of 2 Pc' for 24 hours and then the cell pressure is released to site pressure condition. Shearing the samples in drained test is carried out slowly under condition of no excess pore pressure until achieving maximum stress and then the test is conducted to strain of 18 %.

3. TEST RESULTS AND ANALYSIS

3.1 Physical Properties

The physical properties test results are shown in Table 1.

Table 1: Physical properties of Bekasi soft soils.

No.	Physical parameters	value
1	Natural water content	64 %
2	Spesific Gravity	2.639
3	Unit Weight (gr/cm^3)	1.6-1.7
4	Atterberg Limits - Liquid Limit, LL (%) - Plastic Limit, PL (%) - Plasticity Index , PI (%)	 84.137 41.14 40.11
5	Sieve Analysis - Sand (%) - Silt (%) - Clay (%)	 10 71.69 18.31

3.2. Engineering Properties

Generally, the engineering properties are necessary for design of foundation, earth structures and slope.

3.2.1 Consolidation Test

Based on the results of consolidation test, it can be found that the maximum vertical burden pressure has sustained on the sample in the past and it is known as the *preconsolidation pressure* (Pc'). The value of Pc' and overconsolidation ratio (OCR) value which are 137 kPa and 13.564 respectively. The value of Pc' can be used at preloading are 1.5 Pc' and 2.0 Pc' for consolidated drained triaxial test.

3.2.2 Consolidated Drained Triaxial Test

Shearing the samples in drained test is carried out slowly under condition of no excess pore pressure with speed of 0.004 %/minute until achieving maximum deviator stress and then the test is conducted to strain of 18 %. In this test, the effective stress can't be influenced by excess pore water pressure.
Based on the curve about the relation between deviator stress and strain as shown in Figure 1, it can be observed that deviator stress will decrease to strain of 18 % after reaching maximum deviator stress value. The samples reach the maximum deviator stress on strain of < 4 % and it indicates that the soil in over consolidation condition, more stiffer and compact The maximum deviator stress and strain can be seen at Table 2.

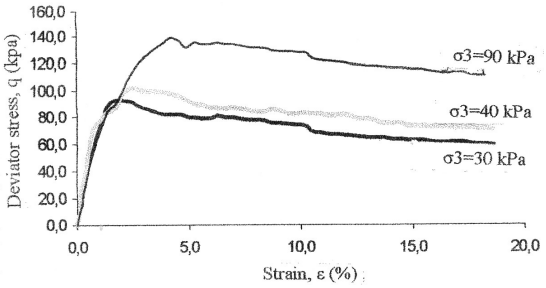

Figure 1: Relation between deviator stress, q and strain, ε.

Table 2: Maximum deviator stress and strain value

σ'$_3$ (kPa)	qmax. (kPa)	ε (%)
30	93,4056	1,76
40	102,4848	2,46
90	139,0411	4,22

3.2.3. Critical State Path

Based on the critical state path method with effective stress of $p' = [1/3(\sigma'_1 + 2\sigma'_3)] = [1/3(\sigma_1 + 2\sigma_3)]$ and deviator stress of $q = (\sigma_1 - \sigma_3)$, illustrated the relationship between deviator and effective stress as shown in Figure 2.

M parameter dan q_o value can be found in Figure 2 and λ_{NCL}, N, λ_{CSL}, Γ parameter can obtained on the curve about the relation between specific volume (v) and ln (effective stress, p') in Figure 3 and 4.

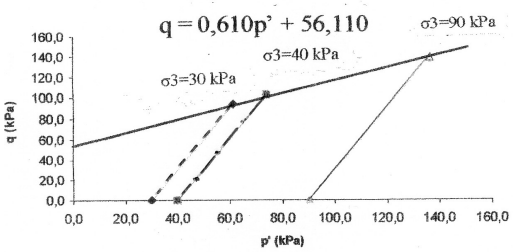

Figure 2: The stress path in q : p' for a drained test on over consolidated sample with a preloading

3.2.4 M Parameter & qo value and C' & Ǿ Parameter

Based on the curve figuring the relation between deviator, q and effective stress, p' as shown in Figure 2, M parameter and q_o value can be obtained. And M parameter can be determined as gradient between q and p' value at failure condition. q_o value is an intersection between gradient line and original point. It indicates that soil in over consolidation condition and have been received the preloading in the past.
M parameter dan q_o value can be used to obtain shear strength parameter of C' and Ǿ by using equation of (1) and (2) as follows:

$$\phi' = \sin^{-1}\left(\frac{3xM}{6+M}\right) \quad \text{..... (1)}$$

$$c' = \left(\frac{3-\sin\phi'}{6-\sin\phi'}\right)q_o \quad \text{..... (2)}$$

Based on the formula 1 and 2 [5], the value C' and Ǿ are given in Table 3.

Table 3: M parameter & q_o value

Parameter	Value
M	0,610
q_o (kPa)	56,110
ϕ' (o)	16,072
c' (kPa)	26,695

3.2.5 Parameter of λ_{NCL}, N, λ_{CSL}, & Γ

These parameter are found from: (i). Graph equations of specific volume (v = 1 + e) versus ln (effective stress, p') on Figure 3 and 4; (ii). Normal Consolidation Line (NCL) with equation of $v = N - \lambda \ln p'$ and (iii). Critical State Line (CSL) with equation of $v = \Gamma - \lambda \ln p'$. By using p = 1 kPa, the value of N , λ *and* Γ can be obtained as shown in Table 4. Normal Consolidation Line (NCL) located on the left of Critical State Line (CSL).
It can be seen from Table 4 that this parameter value by preloading of 2 cycles are smaller than by preloading of 1 cycle. This indicates that volume of soil will be decreasing under preloading.

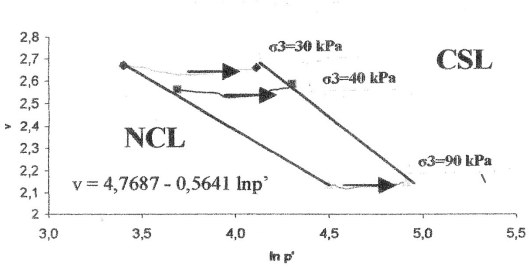

Figure 3: Relation between specific volume, v and ln (effective stress,p') by preloading of 1 cycle (2 Pc').

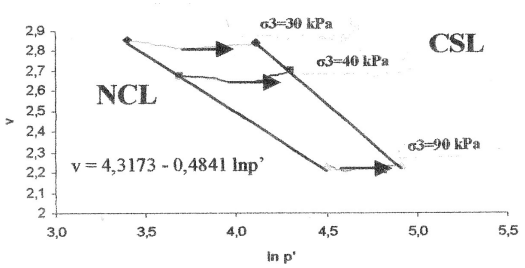

Figure 4: Relation between specific volume, v and ln (effective stress,p') by preloading of 2 cycles (1.5 Pc' and 2 Pc')

Table 4: Parameter of λ_{NCL}, N, λ_{CSL}, & Γ and c' dan ϕ' parameter

Preloading	λ_{NCL}	N	λ_{CSL}	Γ
1.5 Pc and 2 Pc	0.484	4.317	0.633	5.264
2 Pc	0.564	4.768	0.739	5.879

4. Parameter of shear strength under preloading and without preloading.

The particles of soil sample are smaller and more compact than the initial condition. Parameter of shear strength on soil samples under preloading are greater than without preloading as presented in Table 5 as follows:

Table 5: Shear strength parameter

Test type	c′ (kPa)	ϕ′ (o)
UU -Saturation* (without preloading)	17.47	4.28
CU- Saturation **) 4hours preloading (1.5 Pc & 2 Pc)	20.06	12.22
CD - 24hours preloading (1.5 Pc & 2 Pc)	26.695	16.072

(Inti, 2003) *)
(Damoerin et al., 2009) **)

4. CONCLUSION

Influence of preloading with 24 hours consolidation time on shear strength under consolidated drained triaxial test, yielding conclusion as follows:

- Effect of preloading at 1 cycle and 2 cycle on shear strength parameter (C' & Ǿ) is relatively small.
- The increasing of Ǿ value is quite significant and C' value is significant compare to the unconsolidated undrained test.
- M parameter is obtained also quite significant ranging from 0.075 to 0.610.
- qo parameter is obtained quite significant ranging from 17.426 to 56.11.
- Preloading effect on soil samples under consolidated drained test indicated that there is an improvement shear strength parameter value.

ACKNOWLEDGMENT

The authors would like to express the gratitute to the Civil Engineering Departement, Faculty of Engineering – University of Indonesia for the financial support for this study.

ABSTRACT

Jakarta lies in low-lying deltas served by Ciliwung River and many other small rivers. Jakarta also represents over populated area thus open and green areas more and more decreased. Since infiltration capacities of land in Jakarta, decreased, surface runoff has become bigger. As a result, Jakarta often faces flood disaster stricken. Flood disaster affects in human life and properties that includes urban infrastructures. The objectives of this study is to identify and develop a model or mitigation strategy to provide mitigation on urban infrastructures such as water and drinking water supply and also sanitation facilities after floods and to enhance the ability of the community to cope with the flood disaster. Primary data supported with questioner and secondary data obtained by studying the literature. The results of this study show that the height of water flood average a meter and the highest was 4 meter. The flood areas have drained within 5 days. However, the degree of damage on buildings and property is relatively minor during flood. The victims averagely have been living in their house more than 25 years and had experienced hit by floods at least two times. Thus, community learnt from their experience to overcome and prepare themselves in facing next flood in order to reduce the damage, suffering, and losses.

Key word

Floods, water supply, drinking water, sanitation, cope with flooding.

*) This research is Funded by Competitive Based Institution Program (Program Hibah Institusi), University of Indonesia and Directorate General of Higher Education, Department of National Education, 2008.

I. INTRODUCTION

Indonesia generaly has high rainfall, lies in seismic zone and surrounding with many active volcanous. Therefore, Indonesia has more risks to face disasters anytime. That chareacteristic is sensitive for flooded, drought, fire, tsunami and other disasters. The experiences that happen continually and similarly can be reduced the effect as well as the risk.

Jakarta as a capital city of Indonesia with huge population has variety of city infrastructures and facilities such as housing, social facilities, electricity, health services and education as well as transportation. Jakarta lies in low-lying land and as a part of Ciliwung river basin. Therefore, Jakarta will receive water that overflows from surrounding hills or mountain thus discharge into Java Sea. Based on this condition, Jakarta has more risk to face flood disaster and has proved over the last 10 years. Meteorologists forecast five yearly floods at 2002 would repeat at 2007, 2012 and so on. However, the floods occurred at 2008 faster than forecasting before. The forecasting indicates that floods' duration will be more often in the future.

2. OBJECTIVES

The objectives of this study is to identify and develop a model or mitigation strategy to provide mitigation on urban infrastructures such as water and drinking water supply and also sanitation facilities after floods and to enhance the ability of the community to cope with the flood disaster.

The target would be achieved by this study is to encourage the community to compose a guideline in order facing flood disasters.

3. THE STUDY LOCATION

There were five regions of Jakarta would be identified thoroughly by this study, namely West Jakarta, South Jakarta, Center of Jakarta, East Jakarta and North Jakarta. The five region of Jakarta can be seen on Figure 1.

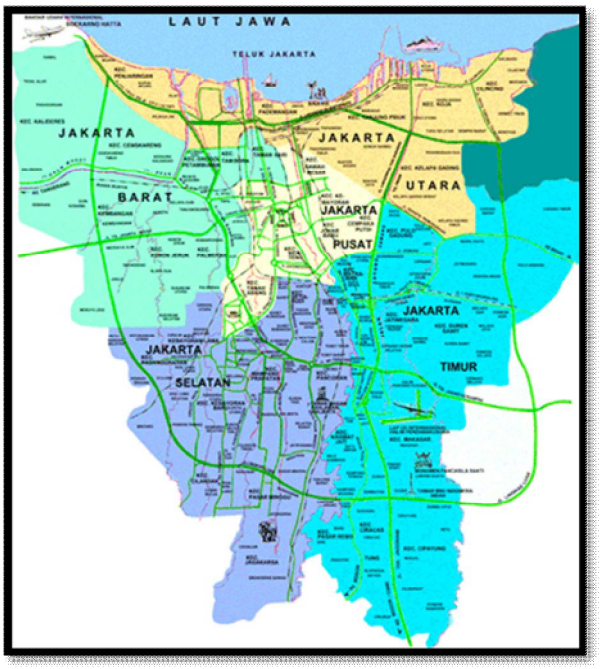

Figure 1. Map of Jakarta [2]

4. LITERATURE STUDY

There are 13 river flow in Jakarta. Ciliwung River is the longest river with length 117 km and divided into five regions [2]. The quality of upstream has shown better than downstream and particularly region that flows through Jakarta is the worse. The water quality of other rivers nor differ from Ciliwung River.
Jakarta Environmental Institution Agency (Badan Lingkungan Hidup Daerah/BLHD) represents a local government to monitor water quality from surface water, such as river and lakes, and groundwater. The quality of river shows as Pollution Index (PI). Based on BLHD monitoring data [1] , the entire region at Ciliwung River indicated moderate to heavy pollution. Not far, 50% of monitored well found contaminated with E. coli.

Clean water supplied by Water Treatment Plant which operated by Local Government Company (PAM JAYA). Therefore, only 60.21% of community served by this company [2]. Meanwhile, 38% community utilizes groundwater as water resource.

Coping mechanism or process is the ability of people to control any inconvenience, danger or emergency condition [5]. This mechanism divided into three strategis namely appraisal focussed strategy, problem focused strategy and emotional focused coping. People can choose one or combining of those strategies which best for themselves. In facing the crisis, people comes through grieving process that divided into five phases as mention on Figure 2 below [5]. People do not have to follow the entire phases but it depends on their endurance.

Figure 2. Phase in Crisis

5. METHODOLOGY

This study use ex-post facto approach and causal comparative method to observe several variables. The purposive sampling method appointed as sampling method in this study. Number of sample calculated by Newbold equation [4] as follow:

$$n = \left[\frac{z_{\alpha/2}\sigma}{B} \right]^2 \qquad (1)$$

Based on that equation, minimum number of sample is 267 whereas in this study, number of sample taken about 500 which divided into 100 samples at each region.

Primary data supported with questioner and field observation. The survey conducted during rainy season on September to November 2008. Meanwhile, secondary data obtained by studying relevance literature.

5. RESULT AND DISCUSSION

5.1. Condition before Floods

There were eleven areas at Jakarta that critical on floods disaster based on aerial view Citra Landsat. Critical area in West Jakarta is Cengkareng, Grogol, Petamburan, and Kalideres. Critical area in South Jakarta is Kebayoran Baru, Mampang Prapatan, and Pasarminggu. Critical area in East of Jakarta is Cipayung, Ciracas, Kramatjati, and Makasar. Critical area in Centre of Jakarta is Tanah Abang, Bendungan Hilir, Karet Tengsin, Kampung Bali, Kebon Melati, Blora and Kebon Kacang.

Observation on respondent in South of Jakarta show that the community in flooded area averagely has been living for 25 years. However, several respondents have been living almost 60 year. Based on that condition, they already had an experience facing floods.

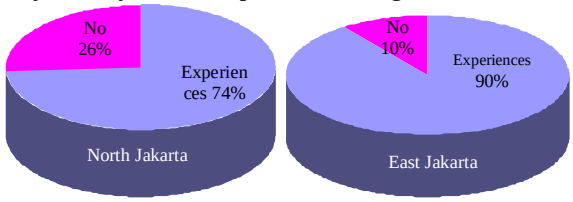

Figure 3. Percentage of respondent who have flood experienced at North and East Region of Jakarta

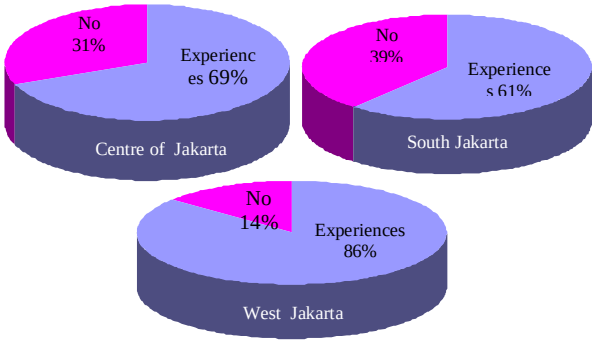

Figure 4. Percentage of respondent who have flood experienced at Centre, South and West Region of Jakarta

Figure 3 and 4 show the percentage of respondents who have flood experienced from East Region of Jakarta higher than other region. Whereas, respondent from South Jakarta is at the least experienced compare with other regions.

Number of people live in a house is about 4 to 5 person in South of Jakarta. Almost every house in the entire regions consists of more than four persons in the house. Table 1 shows length of stay and number of people live in a house among 500 respondent.

People have known how to prepare their house to face floods. Their use some strategies in order to reduce damage, suffering, and losses during floods. One of their strategies is upgrading the house become two levels (storey). Therefore, they can evacuate themselves and rescues their valuable goods to the second floor.

Tabel 1: Length of stay and number of people in a house

Region	Length of stay > 25 years	Number of family > 4 people
West of Jakarta	100	100
South of Jakarta	50	100
Center of Jakarta	50	100
East of Jakarta	100	100
North of Jakarta	100	100

Table 2 below shows the height and wide of respondent house. The entire respondent in Centre and East of Jakarta owning a house with height more than three meters. That height is suitable to anticipate floods which water level could reach more than three meters. However, water level of floods tends to increase that the last occurrence reached up to four meters. In a state of floods, the more of family member will make evacuation process easier and faster. Unfortunately, several respondents have limited space so it is not enough or too crowded for big family.

Table 2: Height and wide of responden house

Region	Height of the house > 3m	Area of house > 40m^2
West of Jakarta	24	50
South of Jakarta	48	100
Center of Jakarta	100	100
East of Jakarta	100	100
North of Jakarta	48	100

Almost the entire respondents already have supplied with water from PAM JAYA. They aware and consider about important of health. Besides, their knowledge about quality and benefit of clean and drinking water is good enough to maintain healthy life. However, in contrary, sanitation facilities such as toilet and septic tank paid less attention to respondent. Most

respondents utilize sharing toilet as well as communal toilet for daily activities. This condition shows on Table 3.

Table 3: The coverage of water supply and sanitation facilities before floods

Region	Water Supplied from PAM JAYA	Sanitation Facilities
West of Jakarta	94	32
South of Jakarta	70	14
Center of Jakarta	93	18
East of Jakarta	74	23
North of Jakarta	94	27

Respondent, which do not get water supplied by PAM JAYA, will try to find another source such as groundwater or buying to other seller.

5.2. Condition during Floods

Beside food and cloth, water supply and sanitation become a big problem during floods. Electricity always shuts down for safety reason. Therefore, people that use electricity equipment such as water pump cannot access clean water from their house or their neighborhoods.

Government and several non-government organizations (NGO) try to help with distributing mineral water to evacuation centre. However, they could reach not the entire flooded area due the difficulties of transportation. Some area is under water so it is not possible to go through that area. Table 4 shows precentage of community that received water supply and sanitation aids.

Table 4: The coverage of water supply and sanitation facilities during floods

Region	Water Supply Facilities	Sanitation Facilities
West of Jakarta	89	75
South of Jakarta	17	14
Center of Jakarta	80	18
East of Jakarta	47	61
North of Jakarta	69	81

There are several water resources that utilize by respondent during floods such as water piping from PAM JAYA, groundwater, package water, and buying to water hawker. They utilize one resource or combining resources to fulfill their needs. The variety of water resources that utilized by respondent can be seen at Figure 5 and 6 below.

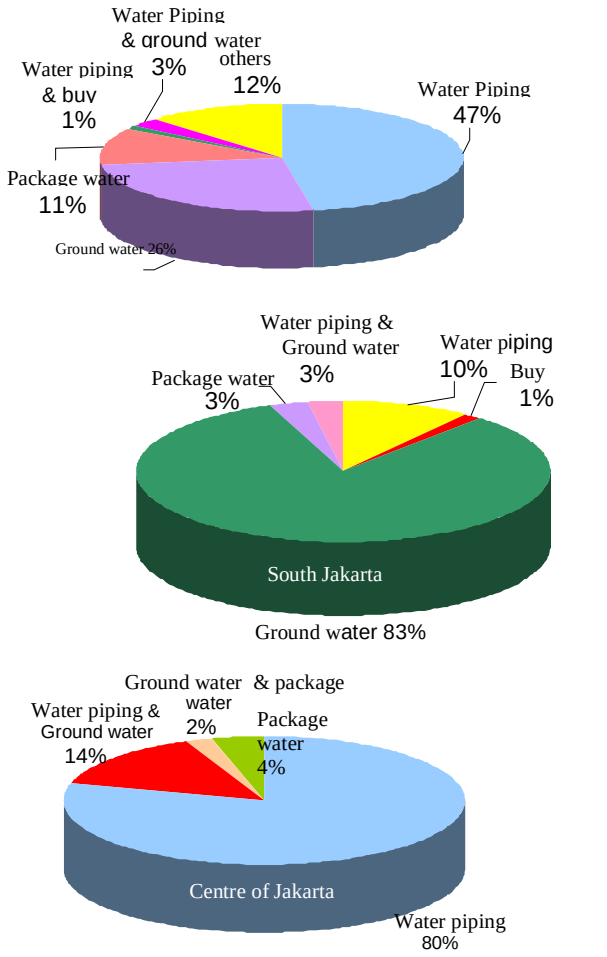

Figure 5. The variety of water resources that utilized by respondent at East, South and Centre of Jakarta

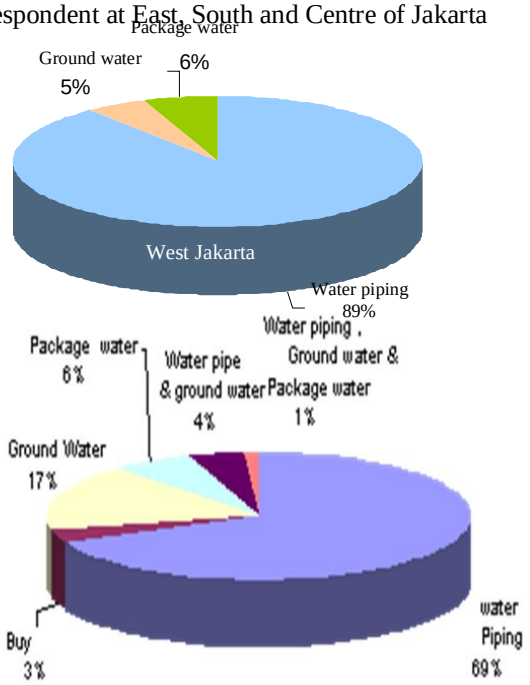

Figure 6. The variety of water resources that utilized by respondent at west and north of Jakarta

Table 4 also indicates the coverage of water supply decreased during floods compare with normal condition before floods. On the other hand, coverage of sanitations facilities increase during floods. This matter caused by government and NGOs aids that provide mobile sanitation equipment. In addition, people, who do not hit by floods, lent their facilities to flood refugee. Consequently, the coverage of sanitation facilities increased.

Flood disaster resulted damage, suffering, and losses to victims. They have to move a while as long as their house is under water. They become a refugee and live in a tent, school, or other public facilities that do not hit by flood until indefinites time. They can go to work or other place because of limited transportation and dried areas during floods. There is no electricity and no income for non-formal worker or non-employee. Consequently, they become dependent on aids.

The condition that mention before gave a sadness to floods victims. Figure 7 depicted what respondents felt during floods. Dominantly, victims become more fatefully in facing floods disasters. Nevertheless, there are several victims felt angry and sad.

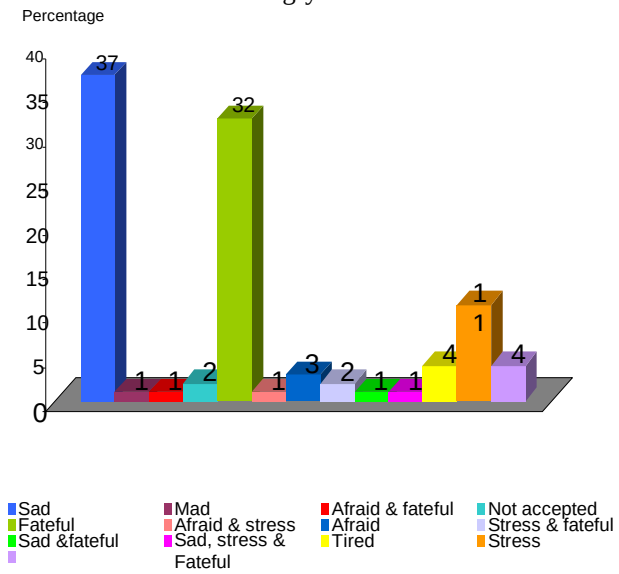

Figure 7. Respondent Feeling Facing Flood Disaster

In order to move back to normal life, the flood victims should get through the entire problem with coping mechanism. Besides, the entire aids from government, NGOs, and other communities will help the victims to cope their sadness, angry, and fateful feeling. With helping, they can overcome their sorrow faster.

CONCLUSION

The community who lived more than 25 years in floods area has experienced to face flood disaster. The government, comunity as well as other parties can not ignore flood risk sincef floods take lives and damage property. They developed strategy to reduce damage, suffering, and losses. One of their strategies is upgrading their height of house. People need water and sanitation facilitates during floods. Government, NGOs, and other community can help victims with providing and distributing water and sanitation facilities. Clean water usually served by PAM JAYA as long as in the state of flood.

Although in Jakarta at there are 12 ponds to catch flood water, however almost all reduced their volume because of sedimentation process and need more rehabilitation and maintaining. However flood control and rehabilitation are very expensive, the local government of DKI Jakarta will continue to finish channel surounding Jakarta, known as East Flooded Channel (Banjir Kanal Timur).

Victims felt angry and sad during floods. Therefore, fateful is dominant feeling for victims. They have to get through the entire problem caused by flood with coping mechanism.

Centre Government as well as local government, community should work together to make a good plan to overcome flooded hazard. Flooding affect people and their property and caused health problem, both physical and emotional, damage building and content of building and landscaping.

ABSTRACT

On the dawn of March 27, 2009 all of a sudden Situ Gintung Dam in South Tangerang, Banten, Indonesia was being headline on the media allover the world. A 10-meter high earthen dam breached with almost 100-dead toll brings us to a controversy, whether it will be rebuilt or removed. As compare to the situation in the US where around 60 small dams were scheduled for removal in 2008 alone, mostly due to no-longer-served its intended purpose and/or in order to restore its ecological integrity by restoring the free movement of fish and other aquatic organisms. This paper discusses thoroughly the complexity of issues to be considered and the decision-making process to be taken for both possibilities.

Keywords
Situ Gintung Dam controversy; rebuilt or removed; considerations.

1. BACKGROUND INFORMATION

The exact figure of dams allover the world is uncertain, NRC estimated around 2.5 million dams in 1990. According to the latest update by the USACE National Inventory of Dams (NID, 2009), there are 82,642 dams in the US, and approximately one third of these dams pose a "high" or "significant" hazard to life and property if failure occurs. Over one third of these dams are already fifty years old, and in another ten years, more than 60% of these dams will have reached the half-century mark. The deterioration of aging dams creates a financial burden for dam authorities and safety hazards to those living downstream. According to the National Performance of Dams Program at Stanford University, 1,595 significant hazard dams are within one mile of a downstream city.

In the world's record of disasters due to human technical failures, the 1975 collapse of China's Banqiao reservoir dam in Henan province ranked first, which was in a matter of days, 26 dams collapsed one after another, which resulted in massive flooding in nine counties and one town. The total number of deaths recorded was around 240,000. Note that in China there are 85,160 reservoirs, which a total of 3,486 dams collapsed from 1954 to 2005.

As indicated by International River Network, the cause of failure of various types of dams (earthfill, rockfill, gravity, multi-arch, buttress, arch, tailings dam) were either due to overtopping (35%), piping (38%), structural failure or geological/foundation weaknesses (21%), and others 6%. Referring ICOLD (International Committee on Large Dams) Bulletin 109, the statistics of dam failures worldwide (excl. China & USSR) were dominated by overtopping during operation of fill dams, which were less than 30m high.

After the event on the dawn of March 27, 2009, the aging Situ Gintung Dam in South Tangerang, Banten, Indonesia contributed to the statistics of devastating dam failures with almost 100-dead toll, hundreds of victims and missing people. On March 31, 2009, the Directorate General of Water Resources, Ministry of Public Work, has come up with a recommendation to build new check-dam more upstream in order to preserve reservoir function.

According to World Commission on Dams, the consensus among river ecologists is that dams are the single greatest cause of the decline of river ecosystems, since by design dams alter the natural flow regime. Dams also require ongoing maintenance, and can have significant economic impacts on dam authorities, the surrounding community and society in general.

Therefore, despite the long history and importance of dams, there is a growing awareness to remove them. Decommissioning or removal of dams has primarily taken place in the US and Europe, and the trend is likely to go worldwide. Dam “decommissioning” means the deactivation of a dam project’s principle functions and may include: dismantling power generating equipment, permanently opening dam gates, partial breaching of earthen structures, or complete and permanent removal.

The American Rivers organization has documented approximately 750 dam decommissioning since 1912, with the pace picking up to between 20 and 50 each year for the last 10 years. Currently in the United States, more dams are being removed than built. In the year 2008 alone, there were 64 dams removed or scheduled to be removed.

The situation in the US Dam Removal Cited reasons for removal (American Rivers et al., 1999):

- Environmental — 43%
- Safety — 30%
- Economics — 18%
- Failure — 6%
- Unauthorized structure — 4%
- Recreation — 2%

Influencing public opinion can be a lengthy and difficult process, since many groups are involved in dam removal decisions. Scientific information about the benefits and drawbacks of dam removal should be used as the basis of decision making. Dam removal is becoming a new socio-politic-scientific endeavor.

Several tools exist to assist communities and decision makers in evaluating the option of removing a dam. This paper discussing two decision-making guides for dam retain or removal; and exploring the possibility to employ the guidelines for Situ Gintung case.

2. THE DECISION-MAKING MODELS FOR DAM RETAIN OR REMOVAL

Influencing public opinion can be a lengthy and difficult process. Many groups are involved in dam removal decisions; local residents, citizens groups, local government, state government agencies, federal government agencies, businesses and environmental groups. Opponents to dam removal raise concerns such as the effect on property values, recreation, and town identity, while proponents of dam removal raise concerns such as public safety, the cost of maintaining an aging dam, and water quality problems created by dams.

Based on previous work by Stephanie Lindloff, River Alliance of Wisconsin, ten common concerns about dam repair and removal are the following: (1) "If the dam is removed, the river will turn into a mere trickle or even dry up"; (2) "We'll have more flooding problems"; (3) "All that will be left are stinking mud flats"; (4) "If the dam is removed, who will own the 'new' land?"; (5) "If the dam is removed, wildlife habitat will be lost and wildlife will suffer"; (6) "Will property values be affected?"; (7) "Who will pay for the dam's repair or removal?"; (8) "The dam has historical value"; (9) "Dam removal will introduce exotic and/or disease species"; (10) "I've heard you can get sick because of dam repair or removal".

There are several tools exist to assist communities and decision makers in evaluating the option of removing a dam. The following are two tools from two reliable sources, which already approved to be powerful, namely:

- "Exploring Dam Removal: A Decision-Making Guide". A joint project report written by American Rivers and Trout Unlimited for dam removal and river restoration work in 2002.
- "Dam Repair or Removal: A Decision-Making Guide". Document prepared based on a project funded by the Wisconsin Department of Natural Resources and in part by University of Wisconsin-Madison Institute for Environmental Studies.

2.1. Exploring Dam Removal: A Decision-Making Guide Developed by American Rivers and Trout Unlimited (AR & TU)

In exploring whether a dam should be removed or retained, the considerations are structured as follow:

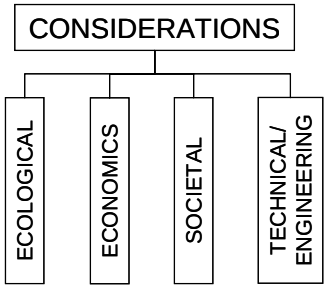

Figure 1: Consideration Structure of AR & TU Decision-Making Guide

Considerations that should be addressed and the bottom line of each issue are summarized in the following table:

Table 1: Considerations, Issues and Bottom Line of AR & TU Decision-Making Guide

	Issues	Bottom Line
ECOLOGICAL CONSIDERATIONS	A. Upstream Flow and Habitat	Will the restored river and riparian habitat upstream outweigh the loss of impounded habitat?
	B. Downstream Flow and Habitat	Is dam removal necessary to restore natural flows to the river? Do the benefits of restored flows outweigh the impacts on species that prefer unnatural flows?
	C. Fish and Wildlife	Is the net impact of dam removal on fish and wildlife populations positive or negative?
	D. Passage and Movement of Fish and Other Species	Will dam removal improve safe passage of migrating fish and movement of resident fish and wildlife? Is dam removal necessary to accomplish this? Can dam removal be done without enabling the spread of undesirable species?
	E. Sediment Movement	What is the current net impact of the accumulated sediment on the impoundment and downstream habitats? How will sediments released during dam removal

	Issues	Bottom Line
		impact the riparian and riverine habitats in the short and long term?
	F. Water Quality	Will dam removal have a net benefit on water quality, taking into account both short-term and long-term impacts and benefits?
	G. Riparian Areas	Will there be a net gain in the amount and quality of riparian habitat as a result of dam removal?
	H. Wetland Areas	How will the wetlands gained by dam removal compare in amount, type, and habitat value to the wetlands lost by dam removal?
	I. Location of the Dam within the Watershed	Will dam removal significantly enhance the river's ecological values, given the location of the dam relative to other dams in the watershed?
ECONOMIC CONSIDERATIONS	A. Dam Owner's Costs and Benefits	Are the long-term costs of operating and maintaining the dam less or more than the costs of removing the dam? Do any benefits of the dam need to be replaced, and if so, by whom?
	B. Societal Costs and Benefits	Are others in the community responsible for any additional costs and benefits of maintaining or removing the dam?
	C. Recreational Costs and Benefits	Will dam removal positively or negatively influence community revenues from recreation?
	D. Environmental Costs and Benefits	Do the net environmental costs (or benefits) of keeping the dam outweigh the net environmental costs (or benefits) of removing the dam?
	E. Property Values	Will dam removal positively or negatively affect property values adjacent to the stream? Will these effects, if any, be short or long term?
	F. Distribution of Costs and Benefits	Who benefits the most from retaining/removing the dam? Who bears the costs for retaining/removing the dam?
	G. Availability of Funding for Dam Repair or Removal	What funds are available to pay for dam maintenance/repair or removal?
SOCIETAL CONSIDERA	A. Community Understanding of the Dam, the River, and Dam Removal	Do the decision-makers and other concerned parties have sufficient information to make an informed decision about dam removal or dam retention?

	Issues	Bottom Line
	B. Service(s) Provided by the Dam	Does the dam provide any services? Are these services as valuable as the services provided by a free-flowing river? If yes, can these services be provided through alternative means?
	C. Who Benefits From and Who Bears the Costs of the Dam	Who benefits from and who bears the costs of the dam? Who will benefit from and who will bear the cost of a restored river?
	D. Community Sentiments Toward the Dam and the River	How do community members feel about the dam? About the river? About dam removal?
	E. Historical Role of the Dam	Does the dam have true historical value, and are there ways to commemorate the historical value without keeping the dam?
TECHNICAL/ENGINEERING CONSIDERATIONS	A. Feasibility of Repairing and Maintaining the Dam	
	A1. Safety Repairs or Upgrades	If the dam is unsafe, will dam removal cost less than repairs and ongoing maintenance? Are repairs to the dam prohibitively expensive?
	A2. Repairs or Upgrades to Continue Efficiently Providing the Dam's Intended Uses	If expensive upgrades are needed to maintain the dam's services, is it more cost effective to remove the dam and find alternatives to replace those services?
	A3. Mitigation of the Dam's Environmental Impacts	If environmental mitigation measures are needed, is it more cost effective to keep the dam and mitigate for its environmental impacts or remove the dam?
	B. Feasibility and Design of Dam Removal	
	B1. Obtaining Dam Removal Permits	Will permitting requirements affect the design, cost or feasibility of the removal? Are there permitting requirements for dam repair, reconstruction, or related to any of the services provided by the dam that will affect the feasibility or cost of keeping the dam?
	B2. Protecting Against Environmental Impacts	What steps must be taken to eliminate or minimize the environmental impacts of the dam removal?
	B3. Managing Sediment	Is there a feasible method of managing the sediment behind the dam?
	B4. Removing Structures	What is the most cost effective and environmentally sound dam removal method?

	Issues	Bottom Line
	B5. Protecting Infrastructure	Are there structures that will have to be stabilized, retrofitted, or relocated if the dam is removed?
	B6. Restoring the Channel	Does the new river channel need to be actively designed or can the river naturally find its own channel?
	B7. Restoring Recovered Land	Will the recovered land need to be actively re-vegetated?

To see the complete checklist questions and toolboxes, one should consult "Exploring Dam Removal: A Decision-Making Guide" in <http://www.americanrivers.org/>.

2.2. Dam Repair or Removal: A Decision-Making Guide Developed by Wisconsin Department of Natural Resources (WDNR) and University of Wisconsin-Madison (UWM)

The document "Dam Repair or Removal: A Decision-Making Guide" is a main reference for The Water Resources Management workshop (WRM) 2000, which is a regular part of the curriculum of the Water Resources Management graduate program at the University of Wisconsin-Madison. The workshop is conducted based on five modules in the document, and involves an interdisciplinary team of faculty and graduate students in the analysis of a contemporary water resources problem.

Considerations of dam retain or removal is structured as follow:

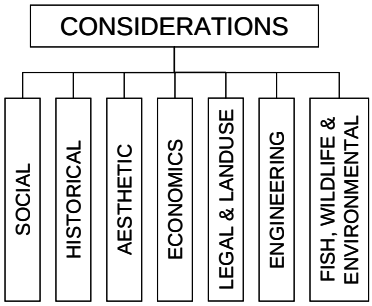

Figure 2: Considerations Structure of WDNR & UWM Decision-Making Guide

The outline of considerations, issues and checklist questions of WDNR & UWM Decision-Making Guide is summarized in the following table:

Table 2: Considerations, Issues and Checklist Questions WDNR & UWM Decision-Making Guide

	Issues	Checklist Questions
SOCIAL	• Community attitudes • Process of decision-making	• What is the social value of the dam and the impoundment? • What are community attitudes toward the dam? • What type of decision-making process will be used for deciding whether to remove or repair the dam?
HISTORICAL	• Historical facts • Historic preservation options	• What is the history of the dam? • Are historical community events hosted at the site? • Is the dam's historical value primarily through association with an adjoining building or structure (for example, a millhouse) versus the impoundment?
AESTHETICS	• Aesthetic concerns • Possible changes in the scenery • Options for enhancing visual appeal	• What are the community's primary aesthetic concerns? • How will the environment of the area change with our decision to repair or remove the dam? • What opportunities exist for enhancing the look of our community as a result of our decision to repair or remove the dam?
ECONOMICS	• Costs Construction costs Safety and liability cost Operation and maintenance costs • Property values Benefits Recreational benefits Environmental benefits • Funding	• What is the cost of repairing or rebuilding the dam? • What is the cost of removing the dam? • If sediment is an issue, what is the cost of addressing the sediment that has accumulated behind the dam? What if the sediments are contaminated? What is the cost of properly disposing the sediment? • Are property values expected to increase or decrease in the surrounding area if the dam and pond are around for another several decades or if the dam is removed? • What funding sources are available to cover construction costs and costs of operation and maintenance with repair or removal?

	Issues	Checklist Questions
LEGAL & LAND USE	• Historical overview of legal regulation on dams • Legal definitions • Repair/removal issues • Role of the Regulatory Commission • Land ownership identification: Dams and flooded lands	• What are the important regulatory considerations? • Who owns the dam? • What are the important land use considerations if the dam is repaired or removed? • What happens to the land submerged by the impoundment if the dam is removed? Who will own the land?
ENGINEERING	• Dam safety and hazard classification • Flood studies • Structure assessment and analysis • Emergency Action Plan • Sediment management	• What is a dam safety inspection? How often does the dam owner need to perform it? • What is the size, type, age and safety condition of the dam? • What is the hazard ranking of the dam (that is, how much potential damage could be caused if the dam were to fail)? • Does the dam provide flood protection? Does the dam meet necessary flood standards? What is the flood passage capacity of the dam? • Would the dam survive maximum headwater conditions (impoundment filled to the top)? Is it possible to see sliding, overturning or foundation failure (such as cracks, holes, crumbled sections, and so forth)?
FISH, WILDLIFE & ENVIRONMENTAL	• Fish/wildlife communities • Effects on fish and other aquatic wildlife habitat • Effect on wetlands • Species of concern • Watershed, water quality, and groundwater	• What is the quality of habitat in the impoundment? Upstream? Downstream? • What is the amount and type of lake or pond habitat that would be lost through dam removal (for example, how many acres of warm-water fishery? How many acres of waterfowl habitat)? • What are the amount and type of reconnected river habitat that would be gained through dam removal? • How would dam removal/repair affect wetlands? • Are the species affected by dam related activities species of concern? Are there endangered species present?

To see the complete checklist questions and toolboxes, one should consult Water Resources Management Practicum 2000: "Dam Repair or Removal: A Decision-Making Guide", in <http://www.ies.wisc.edu/research/wrm00/>.

2.3. Decision-Making Process

A well designed decision-making process can address safety, economic, and environmental concerns and also satisfy the desire of community members and other stakeholders to participate actively in shaping the future of the dam and related natural resources in their community.

The experiences of numerous Wisconsin, USA, communities that have faced the decision-making whether to remove or retain suggest that designing and adhering to a well considered collaborative decision-making process can significantly reduce the conflicts.

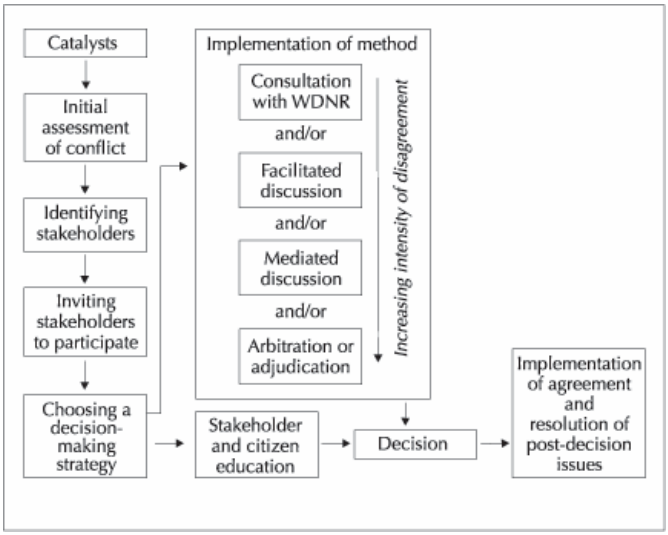

Figure 3: Principal components involved in designing and implementing an appropriate decision-making process.

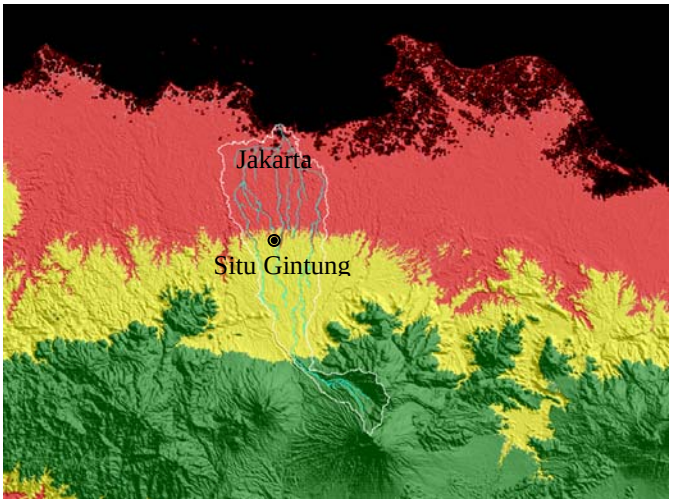
3. THE SITU GINTUNG CASE

3.1. Situ Gintung Disaster Feature

Situ Gintung Dam was built during the Dutch occupancy in the year 1932-1934. The condition before the dam break was already degraded. The originally 31 Ha reservoir with 10m depth, currently (before its burst) only around 21 Ha left with the depth ranging from 3 to 4 meter.

Located in the vicinity of Jakarta, the storage capacity of the Situ Gintung reservoir diminished gradually within 76 years, mainly due to the pressure of urbanization.

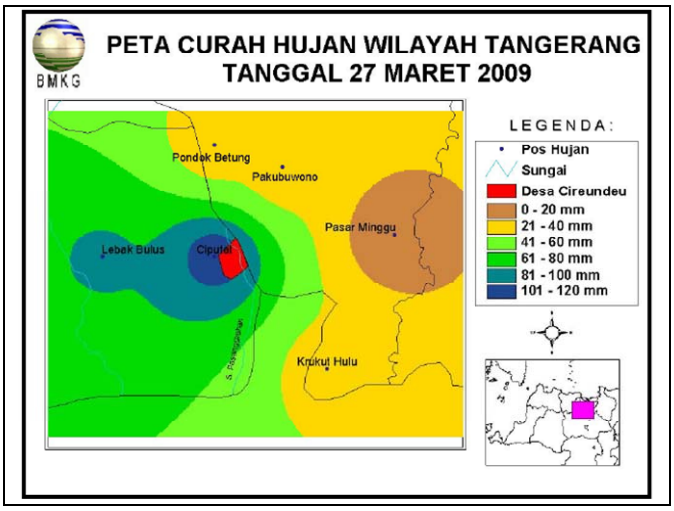


Source: The BPPT, 2009
Figure 4: Location of Situ Gintung Dam.

Based on 1:25,000 Earth Imagery Map, the 2008 land use distribution of the catchment area of Situ Gintung reservoir is dominated by housing (39.70%) and farmland (22.80%). The total catchment area is just around 112.50 Ha.

Source: The BPPT, 2009.
Figure 5: Catchment Area of Situ Gintung Resevoir.

The BPPT (The Agency for the Assessment and Application Technology) has conducted analysis concerning the trigger of Situ Gintung dam failure. Most likely the reason of dam burst was manifold, but the weakest point of the dam was its aging spillway structure. Piping through the spillway crack, and high intensity rainfall brought the dam to collapse.



Source: The BMKG, 2009.
Figure 6: Rainfall Distribution on March 27, 2009.

According to the BMKG (Meteorology, Climatology and Geophysics Agency), the total area-rainfall on the preceding day was 113.20 mm.

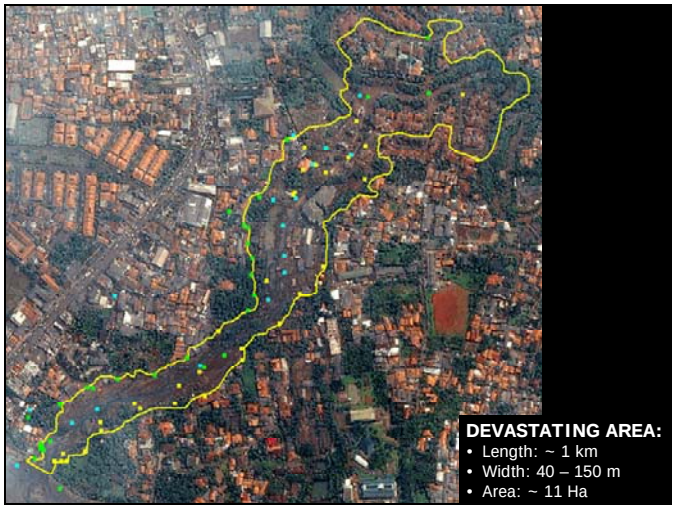
Although the Situ Gintung dam failure was not the one and only catastrophic event due to human technical failures, the number of dead-toll, hundreds of victims and missing

people was indeed very massive in comparison to i.e. the collapse of Teton Dam in Idaho, USA, where a 90m high dam burst with 'only' 11 dead-toll.

Source: KOMPAS/WISNU WIDIANTORO, 2009
Figure 7: Situ Gintung, Situation Aftermath, March 27, 2009.

The dense housing complexes which occupied floodplains immediately downstream of the dam actually should have never been allowed to be there. People who have chosen to build houses and decided to live there should have known about the regulation and also the most important, about the potential hazard.

The scale of devastating hazard area covered around 11 Ha with 1km in length and 40-150m in width. Within minutes 316 permanent and semi-permanent houses were torn down and billion of rupiahs losses were obvious.



Source: The BPPT, 2009
Figure 8: Devastating Area Downstream of Situ Gintung Dam

3.2. Proposal of Post-Disaster Management

Technical Properties of Situ Gintung Dam/Reservoir can be summarized as follow:

- Dam: ca. 200m-length and ca. 7m-height.
- Appurtenances: one 5mx1.5m spillway and two intakes
- Function: originally for irrigation, then converted into conservation facility utilized for recreation and fisheries.
- Downstream channel: ca. 2m-width channel, tributary of Pasanggrahan river, floodplains occupied by dense housing complexes.

The Directorate General of Water Resource (DGWR), Ministry of Public Works has come up with three options of long-term post-disaster management as summarized on the following table:

Table 3: Proposal of Long-Term Post-Disaster Management

First-Option	Second-Option	Third-Option
Reconstruction alternatives/scenarios: a. Dam location alternatives: rebuild at the same spot (alternative 1); relocate more upstream (alternative 2). b. Select the best fit dam-type. c. Reorganize land usage upstream and downstream area of the dam, in line with the existing regulation; and consider the risk factors of dam safety. d. Enhance the post-construction management approach (dam/reservoir authority, operation and maintenance of dam and reservoir)	Dam decommissioning through: reorganization of previous reservoir area usage and also the downstream part of the dam; river revival; usage of previous reservoir area as public and/or recreational facilities; and cultivation of greenbelt area as aquatic buffer.	Combination of First- & Second-Option by constructing new lower check-dam and its appurtenances more upstream (alternative 2) in order to preserve reservoir function in the form of river-channel (hence smaller) storage. The reservoir serves as conservation facility, which should followed by: reorganizing the land usage upstream and downstream area of the dam, in line with the existing regulation; and consider the risk factors of dam safety. enhancing the post-construction management approach (authority, operation and maintenance of dam and reservoir) utilizing the

First-Option	Second-Option	Third-Option
		previous reservoir area as public and/or recreational facilities; and cultivating greenbelt area as aquatic buffer.

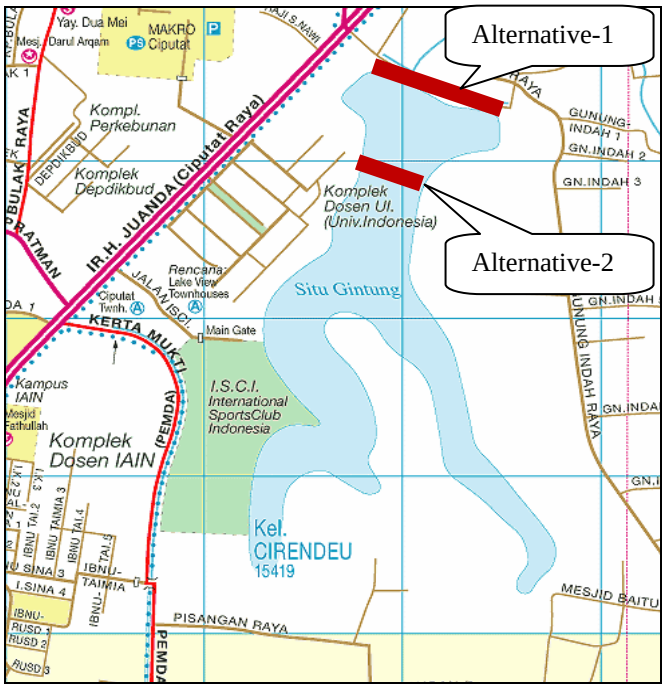
Source: The DGWR, Ministry of Public Work, 2009.

Table 4: Dam Location Alternatives

	Alternative 1	Alternative 2
Dam height	15m	5m
Dam lenght	270m	170m
Inundation area	214,000m^2	161,500m^2
Storage	3,210,000m^3	807,500m^3
Spillway	5x1.5m	5x1m

Source: The DGWR, Ministry of Public Work, 2009.

The dam location alternatives are presented on the following figure.

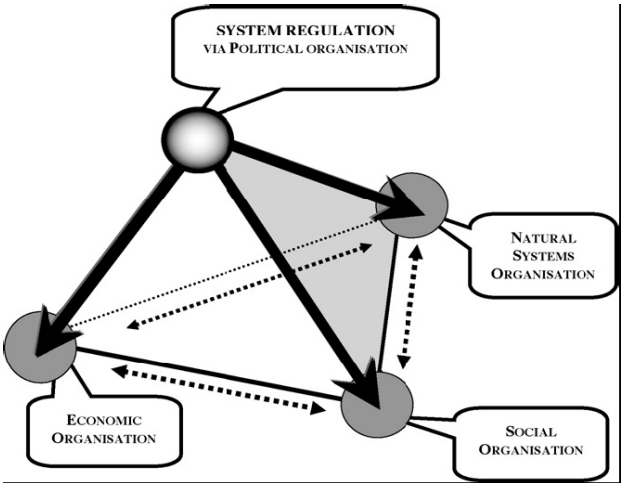


Source: The DGWR, Ministry of Public Work, 2009.
Figure 9: Dam Location Alternatives.

Just within four days after the disaster, on March 31, 2009, to be precise, the DGWR has decided the Third-Option as the most viable one.

4. DISCUSSION

To bear in mind the "Four Spheres" Prism of Sustainability (O'Connor, 2006), there were perfect match to both decision-making guides discussed earlier.



Source: Michelle Graymore, et.al., 2008.
Figure 9: "Four Spheres" Prism of Sustainability.

The "Four Spheres" Prism of Sustainability can accommodate the complexity of interaction and intertwining nature among the issues. I.e. without doing thorough design procedures is impossible to do the estimation of construction costs, safety and other liability risks, as well as operation and maintenance costs; and without conducting surveillances to stakeholders, is impossible to estimate the benefit of recreation, aesthetic, and ecological, as well as property value. Therefore, the economic consideration is a result of manifold preceding thorough assessment of various considerations.

Further discussion is needed as consequence of choosing the third option of DGWR proposal, among others:

Reorganizing the land usage upstream and downstream area of the dam:

- Do the decision-makers and other concerned parties have sufficient information to make decision?
- What is the land-use classification of the land downstream of the dam? What is the level of development at and below the dam site?
- If the properties will be required to carry flood insurance, are property values expected to increase or decrease in the surrounding area? In the flood zone?
- Are property values expected to increase or decrease with the change from lake to river aesthetics?
- How do community members feel about the dam? What is the current level of support for keeping the dam? Do any local/regional/national officials or anybody else support dam retention? How powerful are they?
- Does the dam have true historical value?

Considering the risk factors of dam safety:

- What is the hazard ranking of the dam? Does the National Dam Safety Program Act affect the dam?
- What will be the impacts of dam failure? What are the costs of dam failure flood insurance? For other liability insurance policies?
- How many properties must carry flood insurance because they are in the flood zone if the dam were to fail? Are there buildings below the dam that cannot be occupied because of the dam break analysis?
- What insurance costs will be avoided in relation to the decision? How many homes, buildings, and other properties will be removed from the catastrophic flood zone and no longer be required to carry flood insurance?
- Is there any Emergency Action Plan (EAP) applies? How does it work?
- Does the dam provide flood protection? Does the dam meet necessary flood standards? What is the flood passage capacity of the dam? Would the dam survive maximum headwater conditions?
- Have floodplain studies been administered previously?
- Would there be a need for design or construction of new appurtenances?
- How will the sediment built up behind the dam be handled? How much sediment would potentially be released downstream? How would it impact the stream?

Enhancing the post-construction management approach (authority, operation and maintenance of dam and reservoir):

- What will periodic inspections of the dam cost to prevent future problems?
- Will the dam have appurtenances that require someone to operate them? How much will dam appurtenances operation cost?
- How often will dredging the reservoir need to be done? How much will it cost?
- Will sediment controls need to be maintained? What does the sediment controls maintenance cost?
- Does the reservoir require vegetation control? What does the vegetation control cost?
- If part of the former reservoir is converted into a park or other natural area, how much would be the maintenance cost?

Utilizing the previous reservoir area as public and/or recreational facilities and cultivating greenbelt area as aquatic buffer:

- What type, location, and extent of existing wetlands created by the dam will be lost? What type, location, and extent of lands could be gained? How will the land gained be managed?
- How many people enjoy the activities on the reservoir? On the river? How much do the people value each activity on the reservoir? On the river?
- Do any businesses rely directly or indirectly on recreation at the reservoir? At the river? What is the economic value of the recreational business at the reservoir? At the river?
- What is the economic value of recreating at a new park or natural area?
- Are recreation businesses currently dependent on the reservoir flexible enough to focus on river recreation?
- What are the recreational opportunities associated with the decision? Are new businesses catering to river recreation likely to be established?
- What impact will the decision have on the watershed? Will surface water quality improve/worsen? Does the dam and impoundment affect groundwater levels in the area?
- Will the recovered land need to be actively re-vegetated?

5. CONCLUDING REMARKS

Making a final decision, whether Situ Gintung Dam/Reservoir should be rebuilt or removed, is not a simple task. There are considerable issues need to be taken into considerations. The “Four Spheres” Prism of Sustainability can accommodate the nature of interrelations and intertwining among the issues.

Once all of the data/information is gathered, many factors should be examined thoroughly and comprehensively, in order to understand the influences on the decision, including:

- The societal, economics and ecological circumstances surrounding the case;
- The complexity of the issues;
- The legal and political context in which a decision must be made;
- The amount of controversy surrounding the decision;
- The impetus for considering all possible alternatives;
- The number, identities, and strength of various stakeholders.
- Etc. etc.

ACKNOWLEDGMENT

In preparing this paper, we gratefully acknowledge the assistance from our students Andi, Evi, Yanur and Zainal.

Special thank goes to American Rivers and Trout Unlimited, as well as to Wisconsin Department of Natural Resources and University of Wisconsin-Madison with their generosity in encouraging people to make use their joint project reports.

ABSTRACT

NaCl as the most active element of seawater which is cause chemical react with Portland cement can decelerate the setting time and reducing strength both of concrete and mortar,. The salty water research using NaCl 2,5% to 7%, influences the compressive and flexural strength of mortar. Mortars composition are 1:4 and 1:5 Portland cement : fine aggregate. Test based on flowtable value 110%. The salty water using NaCl 3,5 % to 7 % is used to mix concrete with w/c ratio 0.5 to observe its compressive and indirect tensile strength. Both of them observed in28 and 56 days

- *The strength of nature mortar's 1:5 is lower than 1:4*
- *Compressive and flexure with 2,5% to 3,5% NaCl increase, but decreases inline with adding NaCl. Increases till 28 days old, but decreases at 56 days.*
- *Slump value and wet density of concrete increase with 3,5% NaCl* but *decreases inline with adding NaCl*
- *Initial setting time of concrete increases with adding 3,5 % and 7 % but the 5% NaCl takes longer than the concrete without NaCl.*
- *Compressive and indirect tensile strength of salty concrete increase with 3,5% NaCl but decreases inline by adding NaCl percentages.*

Keywords: *Mortar, concrete, NaCL, compressive strength, flexural strength, indirect tensile strength.*

1. INTRODUCTION

Houses-building project for the 30 million lower and middle class inhabitants, which consists of 5,9 million head of family approximately 800,000 to 1,000,000 houses.

In accordance to the house-building project, it is not impossible that the contaminated-by-sea water that will be used in the paired-wall and mortar making process may reduce both of the strength and durability of the building which later may caused a violation of minimum building safety terms.

Literature Review

The salt crystal will react with Portland cement until weathering not so long. The same case with ceramic or cement brick because consist of same raw materials, like Al_2O_3, SiO_2 and Fe_2O_3.

NaCl is the easy soluble salt, so the Na^+ and Cl^- ion stay in solution permanently. When the solution evaporated, it can get natrium chlorida (NaCl) crystal.

The following formula says what happen until neutralization or salty react.

$NaCl\ (aq) + H2O\ (l) \longrightarrow HCl\ (aq) +$
(Garam) (Air) (Asam kuat) $NaOH\ (aq)$
Basa lemah)

Water forming: $H^+\ (aq) + OH^-\ (aq) \longrightarrow H2O\ (l)$

Salt forming: $Na^+\ (aq) + Cl^-\ (aq) \longrightarrow NaCl\ (aq)$

The salt behavior is electrolyte, did not change lacmus paper color, and disengage metal and acid leftover ion. The salt reaction happen when acid + alkali = salt + water. Alkali behavior is produce OH^- ion, bitter, and smoothly, electrolyte, corrosive, and reacts with indicator and change it color.

Beside chemical reaction, salt crystallization in void of both mortar and concrete can shattered because of crystallization pressure. Hence salt crystallization occur in water evaporated, salt attack occur in both mortar and concrete on water's surface. Salt turn up with capillary act, so salty attack occurs in permeable of both mortar and concrete. That is although explain the early strength high, but decreases after 28 days.

Methodology

The research method is doing some experiment about material testing base on SNI and ASTM standards to know physical and mechanical behavior both mortar and concrete in laboratories.

Material using for mix both of mortar and concrete involve fine and coarse aggregate with 40mm diameter, Portland Cement, and water polluted NaCl, from 2,5% to 7% with details as follows :

1. For mortar 2,5%; 3,5%; 5%; and 7%
2. For concrete 3,5%; 5%; and 7%

3. TABLES AND FIGURES

Summary data from mortar and concrete testing performance in table and diagram as follows:

Table 1. Summary of mortar testing with and without NaCl

AGE, days	MOR WITHOUT COMPRESSIVE STRENGTH, N/mm²		T A R NaCl FLEXURE STRENGTH, N/mm²		MORTAR WITH NaCl

28	2.55	2.48	1.98	1.61
56	3.16	2.83	2.77	2.01

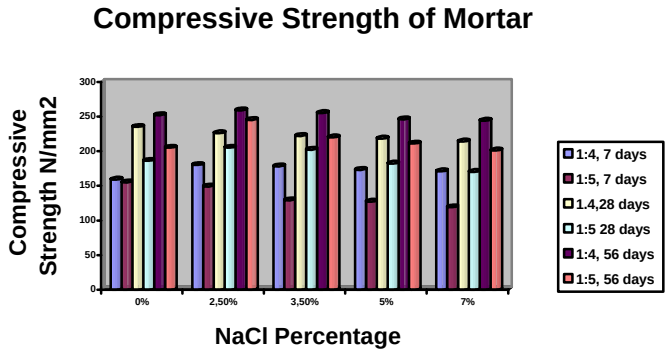

Figure 1. Summary of compressive strength of mortar with and without NaCl

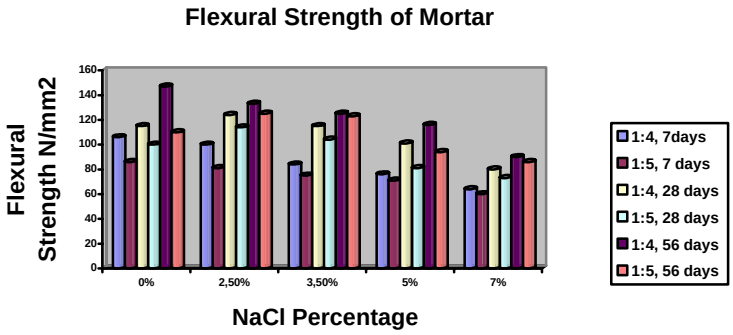

Figure 2. Summary of flexural strength of mortar with and without NaCl

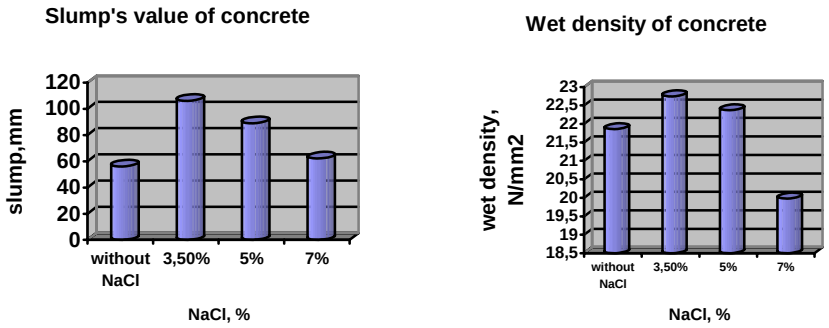

Figure 3. Summary of physical value of concrete with and without NaCl

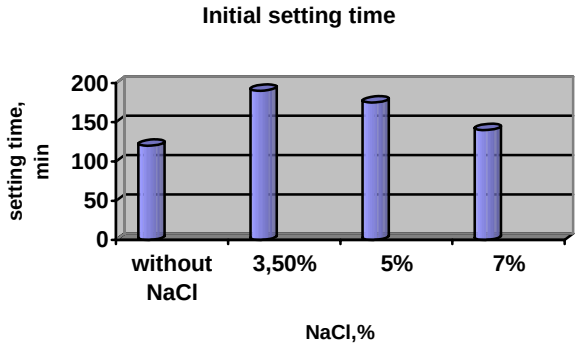

Figure 4. Summary of compressive strength of concrete with and without NaCl

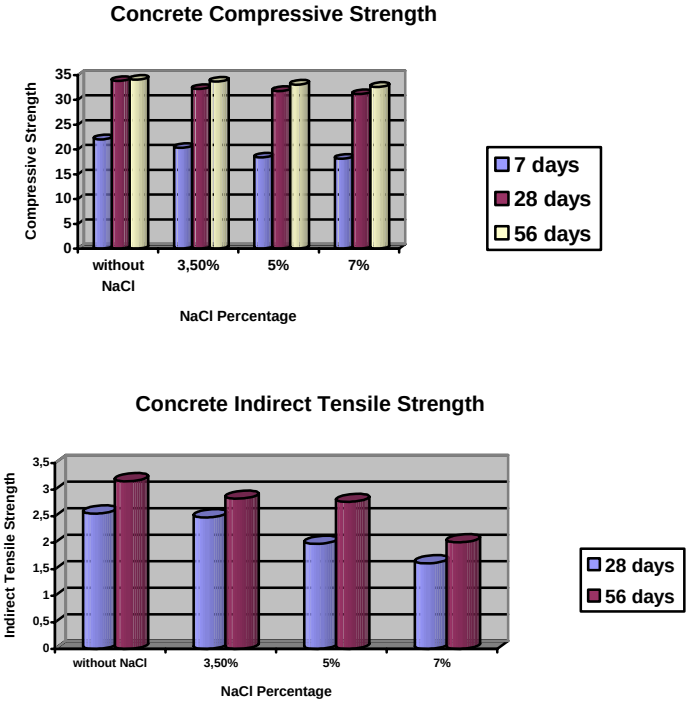

Figure 5. Summary of indirect tensile strength of concrete with and without NaCl

4. DISCUSSION

Workability is an important aspect in mortar. The determination is set by using aggregate with environment condition-suited water level, so the based-on mortar workability strength level determination is subject to ASTM standard. The stirred with contained NaCl water-concrete and mortar, as the matter of fact, have stronger power at the early time, and decrease, although not significant after that, compared to the stirred without NaCl mortars and concrete.

5. CONCLUSION

The conclusions are:

- ❖ Compressive and flexure nature mortar's strength decreases inline with adding fine aggregate. However the strength of 1:5 is lower than 1:4
- ❖ Compressive and flexure salty mortar with 2,5% to 3,5% NaCl increase, but decreases inline with adding NaCl percentages, and increases until 28 and 56 days old.
- ❖ Slump value of concrete increase with 3,5% NaCl but decreases inline with adding NaCl percentages
- ❖ Wet density of concrete increase with 3,5% NaCl but decreases inline with adding NaCl percentages
- ❖ Initial setting time of concrete increases with adding 3,5 %, and 7 % compared to 5% NaCl percentages, but the 5% NaCl takes longer than the concrete without NaCl.
- ❖ Compressive and indirect tensile strength of salty concrete decreases inline by adding NaCl percentages.
- ❖ Ultimately, salty water influences the strength decrease of both concrete and mortar.

ABSTRACT

Poor air quality in indoor environments has been recognized as an important factor that can lead humans to be exposed to different types of pollutants. During the last decade, Jakarta experiences high rainfall intensity causing severe and regular flooding in significant portion of the city due to limited open space and poor drainage. Flood damage varies throughout the city, with some areas flooded to the rooflines while the others might have been spared. Previous studies found that different types of pollutants have been identified in indoor environment such as VOCs, NOx, CO, and bioaerosol pollutants like fungi and bacteria. These fungi and bacteria are not only contaminated indoor environment but also emitted toxin and allergens that can give impact to human health. The objective of this study is to review public health consequences of indoor air pollution to Jakarta population after flood.

Keywords:

indoor air pollution, health, flood, Jakarta

1. INTRODUCTION

Poor air quality in indoor environments has been recognized as an important factor that can lead humans to be exposed to different types of pollutants. There are three factors associated with indoor air quality. Firstly, many studies on human activity pattern showed that people spend more time indoors than outdoors hence there is higher possibility that they expose more to indoor pollutants. A second factor is the negative impact of indoor air quality on human health. The third factor is higher pollutant concentration in indoor rather than outdoor environments. Due to economic development in the last several decades Jakarta faces serious environmental issues like shortage of clean water during dry season, regular flood during rainy season and increased concentrations of air pollutant. With population of more than 8 million and total area of 662 sq km, the city is well known with high population density and urban planning mismanagement. Located in tropical country, Jakarta experiences high rainfall intensity causing severe and regular flooding in significant portion of the city due to limited open space and poor drainage. Almost 40% (265 km2) Jakarta's areas are under sea level and only 17% of those total are has polder system to flood. Flood damage varies throughout the city, with some areas flooded to the rooflines while the others might have been spared.

There are many studies on Jakarta's flood and most of them focused on the condition during the disaster such as the quality of flood water, community coping mechanism, providing clean water and sanitation facilities, etc. On the other hand none of the previous studies mentioned indoor air pollution concern during cleanup and rehabilitation.

Many studies found that different types of pollutants have been identified in indoor environment such as VOCs, NOx, CO, and bioaerosol pollutants like *Penicillium sp* and *Aspergillus*. These fungi and bacteria are not only contaminated indoor environment but also emitted toxin and allergens that can give impact to human health.

The objective of this study is to review public health consequences of indoor air pollution to Jakarta population after flood. Literature reviews and secondary data have been extensively used to identify many factors that contribute to different kinds of diseases that emerge due to Jakarta's flood, choice of housing material, and weather condition. Comparisons among Jakarta conditions with other similar cities around the world were also conducted.

2. INDOOR AIR POLLUTION DUE TO FLOOD

Flooding in Jakarta was not only struck poor but also rich area. During rainy season, regularly the black, smelling water altogether with a lot of garbage poured onto many parts of the city. One of important impact of flood is the length and height of standing water. In 2008 Hartono and Novita investigated that the length of standing water due to Jakarta's flood is varied

ISSN 114-1284

among different areas. From table 1 it is showed that the longest is 30 days and the shortest is 5 days.

Tabel 1. Height and Length of Jakarta's Flood

	West Jakarta	South Jakarta	Central Jakarta	East Jakarta
Length of standing water (days)	8 - 30	6 - 30	5 – 14	14 - 60
Height of standing water (meter)	0.5 - 2	0.5 - 4	0.5 - 2	4 - 10

Source: Hartono and Novita, 2008

It is known that standing water remaining from the flood can be a breeding ground for microorganism. Fungal colonies may develop to visible state in as little as one week. Many fungi occupy surfaces in direct contact with water. These complex communities of fungi, bacteria, protozoa, and algae embedded in mucopolysaccharide matrix called *biofilms* [1] Even after the water recede, bacteria, virus, fungi, mold, and many other contaminants pose a risk to the vulnerable people like the elderly, children, and anyone with chronic disease. Previous investigatiom on flooding in the greater New Orleans found that visible mold growth was significantly associated with flood height 3 ft (0.9 m)[8]. Furthermore study by Solomon *et al.* (2006) estimated 24-hr mold concentrations ranged from 21,000 to 102,000 spores/m3 in outdoor air and from 11,000 to 645,000 spores/m3 in indoor air. They mentioned that the mean outdoor spore concentration in flooded areas was roughly double the concentration in non-flooded areas (66,167 vs. 33,179 spores/m3; $p < 0.05$) with the highest concentrations were inside homes. It was also found that high concentration of indoor fungi and bacteria in flood damaged building contributed to poor indoor air quality more than 3 months after the structures have been reclaimed from flood damaged [3].

Mold and mildew are common terminology used for fungal indoor air pollutant. The predominant fungi indoors were *cladosporium*, *aspergillus* and *penicilium* species although *stachybotrys* was also detected in some studies [9,10]. Previous study found that *Trichoderma* grows optimally in environment with water activity while *Penicillium* sp grows in wide range water activity [2].

Study on Jakarta flood water quality by Oguma (2009) also found viruses and bacteria. These viruses and bacteria are listed in the following table:

Table 2. Viruses and bacteria found in Jakarta's flood water

Viruses	Bacteria
Adenovirus	*Escherichia coli*
Enterovirus	Total coliforms (TC)
Hepatitis A virus	
Norovirus G1	
Norovirus G2	

Source: Oguma, 2009

Those virus listed in Table 2 can cause diarrhea in human and although the bacteria are non pathogenic, but indicate high possibility of fecal contamination.

Furthermore concern of health consequences is not only caused of flood water but also sediment quality. Unfortunately no specific report or scientific studies on Jakarta's flood sediment. However other similar study had been conducted at New Orleans's area after Katrina and Rita[6]. It is found that these sediments came from multiple sources and contain of physical organic, inorganic chemicals, and microbial contamination.

3. FACTORS CONTRIBUTING TO MICROBIAL GROWTH

Different factors contribute to the growth of microbes in indoor environment. Among others are humidity, temperatures, types of building materials, and the availability of carbon as food source. Moisture is probably the most important factor supporting overall indoor fungal growth. With temperature range from 24-30^{o}C during Jakarta's rainy season and humidity can reach more than 100%, fungi can growth very rapidly. In addition most of Jakarta's houses build from bricks and woods that are porous hence reducing moisture can be a big challenge. The distribution of moisture in the material, the type of fungi present, and the material on which the fungi are growing will impact the appearance of surface fungal growth. It has been mentioned that rapid growth of mesophilic or zerotolerant fungi may occur even in the dust when water activity became very high, leading to moldy odors and to drastic changes in the dust populations [1].

4. HEALTH CONSEQUENCES

Different kind of infectious diseases commonly emerge during and after the flood such as dysenteries, asthma, skin rash, etc. Many of these diseases usually traced to the decrease of sanitation condition and lack of clean water. There is lack of studies on fungi or bacteria exposures following flood-damaged housing in Jakarta. Even Crisis Center at Indonesian Health Department only generalized disease such as skin rash and asthma without identifying the source of the diseases.

On the other hand, concerns have been expressed about the potential human health impacts that might have resulted not only from exposure to the growth of fungi and bacteria, but also to the flood sediment during cleanup and rehabilitation of flooded areas. The primary routes of fungal exposures in indoor environment are most likely dermal and inhalation. It was found that exposure to fungal contamination can lead to several infectious and noninfectious health effects impacting the respiratory system, skin, and eyes [4]. Significant exposures probably occur when fungal spores, fungal mycelia, and contaminated growth substrate are aerosolized, especially as a result of handling of moldy material [9]. Furthermore latter

finding mentioned that the allergens of fungi are probably digestive enzymes that are released as the spore germinates [1]. In addition, recent findings also mentioned MVOC (Microbial Volatile Organic Compounds) as chemicals that present in the indoor environment as the result of the metabolic actions of bacteria and fungi. Although they were produced in low concentrations and exposure to MVOCs has not been conclusively linked to health effects but it was suggested that the potential of these chemicals to act ac broad indicators of the ecological state of a building may be realized.

Although adverse health effects of fungal exposure usually categorized as infections, allergic or hypersensitivity reactions, or toxic-irritant reactions but carcinogenicity, induction of tremors, or damage to the immune system or major organs were also reported as the most encountered mycotoxin effects [9]. High respiratory morbidity and allergic complaints had been also reported in occupants mold building structures [2]. Some of hypersensitivity diseases caused by fungi include hayfever and asthma, allergic fungal sinusitis, and hypersensitifity pneumonitis.

5. PREVENTION STRATEGIES

In the aftermath of floods, it is recommended that community and public health department work together to reduce risks of indoor air pollution. Preventing fungi to growth after the flood should be chose as the first option and this can be achieved by removing flood water, controlling humidity, and preventing condensation. Using oxidation agents (such as bleaching) will not only reduce the probability of fungal and bacteria amplification, but also kill them. Note that concentrations of fungal or bacteria aerosols increase during removal activities hence respiratory protection is strongly advised during removal.

Developing cleanup procedures to minimize dust generated from the sediment during rehabilitation of flooded area hence exposure to contaminants such as heavy metals can be reduced.

The development of a public health surveillance strategy among persons repopulating areas after extensive flooding is recommended to assess potential health effects and the effectiveness of prevention efforts.

6. CONCLUSSIONS

Jakarta's populations have been exposed to different kind of diseases due to the regular flooding. Standing water remaining from the flood, flood damaged building materials; flood sediment can be a breeding ground for microorganism such as fungi and bacteria.

Limited study of indoor air pollution and lack of knowledge among Jakarta populations, health workers and government officials on high possibilities of the growth of fungi and bacteria and quality of the sediment in flooded house causes Jakarta populations continually expose to indoor air pollutants even long after the flood receded. It is recommended that many prevention strategies should be conducted to minimize the risks associated with flood.

ABSTRACT

Pedestrian is vulnerable against traffic accident, due to its speed, maneuver ability to avoid collision and less coverable, which encountered of problems require various forms of guidance, safe separated facilities, and convenience to walk. Pedestrian facilities aimed at segregation, integration and separation, its services and function need primary input comprises of walking speed, density and the area used by individual or platoon, and volume. All of those characteristics are influence by habit, climate and body measure and gender issues. Typical facilities for pedestrian are footpath, crossing, pedestrian bridge, and pedestrian mall. This paper discusses research results related with characteristics of pedestrian in different situations, and facilities in relatively similar area conditions. Some selected areas in the Jakarta Province – Indonesia was observed.

The study is focused on characteristic of pedestrian comprises of speed, flow and density. Observation is done in foot path along the main road and junction in the area of Sarinah - Central Jakarta. It is found that speed range between 47,5 to 71 meter per second, space occupied was relatively bigger than as mention in other references, and density was found 198 people per square meter. Further analysis is on the relationship between parameters, considering gender and age. Density is measured by person per area since pedestrian moving more flexible instead of following straight path lane. The relationship between parameters is similar with the flow phenomena of vehicles flow. Further research is tried to define better characteristic relationship between parameter along a segment of foot path, since in the first stage of research relationship of each two parameter was assumed as linear. It is found that the behavior of pedestrian characteristics is varying among them shelves as well as over time and space, which leads to develop a model suitable to the real condition. Previous model was made under the assumption continuous condition of flow and its facilities regarded the same in terms of time and space. Relationship between parameter is found not always occurred in one same regime, but depend on flow condition. Multi regime model could be more suitable to explain free flow and congested flow condition. With the increase of flow, different type of regime will occurred characterized by discontinuity of curve in one or more points. That means relationship was represented by more than one equation. This observation is undertaken in a special foot path located at University of Indonesia campus.

On the safety aspect, research is undertaken to analyzed interaction between vehicle and pedestrian crossers. The result leads to indentify decision process to across the road safely with a certain time gap of vehicle traffic. It is found 3.75 second as critical gap, neglected the proportion of pedestrian population. Significant variable influencing to decide crossing road are age, physical condition, freedom of maneuver, walking speed and gap situations. If join distribution is ignored, 61%- 73% prefer to across in safe condition identify with age, number of person and walking speed. Considering join distribution, 68%-78% across the road above 3.75 second gap.

1. INTRODUCTION

Pedestrian oriented in urban planning should be used in the planning process to implement environmentally friendly urban space. Physically pedestrian is vulnerable against traffic accident, due to its speed, maneuver ability to avoid collision and less coverable, which encountered of problems require various

forms of guidance, safe separated facilities, and convenience to walk. To provide safety and comfort, pedestrian facilities aimed at segregation, integration and separation. Its services and function need primary input comprises of walking speed, density and the area used by individual or platoon, and flow of pedestrian or flow rate (volume).

Pedestrian's basic characteristic is assumed similar with vehicle traffic flow. It means that when pedestrian travel in linear path and faster speed that is indication of efficient flow, while in congested flow condition provides some disutility to pedestrian [1]. That assumption is reflected the pedestrian real condition but it is not an accurate since pedestrian exhibit complex movement pattern. Pedestrian do not follow a fix lane compare to vehicle movement and tend to have free choice along the route on utility, swerving if encountered any obstructions and previous experience or out of habit. Compare to vehicle movement, pedestrian flows tend to move in a significant degree of randomness. Even flow in pedestrian design analysis makes use of term commonly used in traffic engineering, density or number of pedestrian per unit area is more complicated to be visualized. Flow of pedestrian (u) is estimated from the speed and space occupied (average space per person), relationship between speed and density [2] [3] [4] is linear.

In the basic planning process prediction of spatial movement are often inadequate and to some extent insufficient. This situation is because most of the traffic modeling focused on the vehicles traffic component as transport system and people movement has been to a certain extent dependent of motorized vehicles. To provide pedestrian facilities need knowledge and tools to understand the characteristic of pedestrian by measuring flows, analyzing patterns and identifying function of the movement. Accurate estimation on the impact of plan and pedestrian behavior is required [5].

Sidewalk design [6] provides standard for facility design based of pedestrian level of service (PLOS), in which primary measure of effectiveness is pedestrian space occupancy (density) and flow rates (speed). It indicates free flow movement from the highest to the lowest level of service, while PLOS is noted as "A" indicates the highest level or free flow movement in the other extreme level of "F" means a standstill condition.

Level of service for walkways for pedestrian has been studied by some researchers particularly in the situation ignoring bi-directional flows such as works by Fruin (1987), HCM, (2000), Tanaboriboon and Guyano (1989) in Bangkok, Gerilla GP, Hokao, K, Takayama Y (1955). Most of the results show some similarity between parameter if converted to level of service concepts.

This paper describes characteristics of pedestrian and type of facilities to serve pedestrian movement based on a series of observations in some streets and area in Jakarta - Indonesia. Basic characteristics such as flow, density and space, selection of type of facilities is discussed and identifies the relationship between parameters to estimate average speed and space occupied, and selection type of facilities.

2. METHOD OF SURVEY

Two different places with different type of pedestrian footpath are chosen in the Sarinah area of Central Jakarta and special footpath located at the campus compound the University of Indonesia – Depok. Pedestrian footpath in University Campus is built in the area relatively free from vehicle interferences, with bi-directional flows. Discussion on this topic is divided into two different locations with different condition. In total there are 13 streets in Central Jakarta and one location at Campus of University of Indonesia in Depok.

Criteria to choose observed location are: (i) number of pedestrian; (ii) physical characteristic of facility, separation with vehicle flow; (iii) accommodate peak and off peak flow. Video camera, stop-watch is used to record pedestrian movement, surface pavement is marked, dotted marking horizontally every 70 cm and 500cm longitudinal along the footpath. The length of observed lane is 15.00meter, and period of observation between 09.00 to 10.00 am and 13.00 to 14.00 am.

3. CHARACTERISTIC OF PEDESTRIAN

Observation is undertaken in some pedestrian footpath along some streets. Two different places with different type of pedestrian footpath are chosen, such as road sidewalk in located in some street in the Central City of Jakarta and footpath located at the campus the University of Indonesia – Depok.

3.1 Single Regime

The result of observation at side walk at some stretch of streets in Jakarta [7] (is shown in

Table 1. Parameter is classified by gender, the result shows that average speed for male is higher than female, 51 meter/minute and 50 meter/minute for male and female respectively. However, if we combine both male and female in one group of sample the average speed is higher than speed classified by gender (57 meter/minute). The speed in Jakarta relatively lower compare to the number from some research results observed in Europe [1] (79 meter/minute), United States [2] (81 meter/minute), and in Singapore [8] (76 meter/minutes), which is similar with jaywalking person speed.

Table 1. Parameter of Pedestrian on road sidewalk.

Parameter	Male	Female	Combine
Average speed m/minute	51	50	57
Highest speed m/minute	77	64	77
Lowest speed m/minute	48	41	41
Sample Person	38	25	63

The equation to model pedestrian characteristic assumed that relationship between parameter is linear and apply to all condition which range from free flow to congested flow condition. This phenomenon is called as single regime.

The relationship between pedestrian parameter based on data collected is mathematically written in **Table 2**. Equation is established based on the free flow speed from combination of male and female. Symbol uses for the equation is speed (u), density (k) and flow (u). Since pedestrian movement is not fixed in one lane, it needs to define one additional parameter which is space in unit area per person symbolized as (M).

Table 2. Relationship between parameters

Relationships	Equations
v = f (u)	$v = 4.83(57\text{-}u)\text{-}0.085(57\text{-}u)^2$
v = f (k)	$v = 57k - 11.8k^2$
v = f (M)	$v = 1/(M)^2\ (57M - 11.8)$
u = f (k)	$u = 57 - 11.8k$
u = f (M)	$u = 57 - 11.8/(M)$

The result from observation along the footpath at University campus is shown in **Table 3. Table 3** describe the equation representing relationships between two parameters develop with different model, such as Greenshields, Underwood, and Greenberg. One model is develop to represent the most suit and appropriate with local condition, which represented by row number (4) in **Table 3.**

Table 3. Relationship between parameter for single regime

Speed - Density	Flow – Speed	Flow – Density
Greenshields		
$u = 79.84 - 21.41*k$	$q = 3.729*u - 0.0467u^2$	$q = 79.84*k - 21.41*k^2$
Underwood		
$u = 80.964*e^{(-0.326k)}$	$q = 3.067*u* \ln(80.964/u)$	$q = 80.964*k*e^{(0.326K)}$
Greenberg		
$u = 60.514 - 9.716*\ln(k)$	$q = 507 * u*e^{*(U/9.716)}$	$q = 60.514*9.716*k* \ln(k)$
Alternative Model		
$u = 1/(0.0121 + (0.005*k)$	$q = \{(1/0.005)\text{-}2.42*u\}$	$q=k/\{0.0121+(0.005*k)\}$

Table 4 shows value of pedestrian parameter, compare to result shown in **Table 3** the number are relatively lower. This difference may cause by different characteristic of pedestrian and different environment condition.

Table 4 Parameter of Pedestrian on foot path.

Parameter	Model			
	(1)	(2)	(3)	(4)
Density - congested (ped/m2)	3.73	26.93	506.88 *	16.528
Optimum speed (M/mnt)	39.93	29.79	9.72*	0.005*
Optimum density (ped/m2)	1.86*	3.07	186.42	200*
Maximum flow (ped/m/mnt)	74	91	1812*	200*

Note: (1)Greenshields; (2) Underwood; (3) Greenberg (4) alternative model.

3.2 Multi Regime

Linearization of relationship between parameter is not always occurring for all conditions or variations of flow. To characterize variation of flow in particular when flow becomes higher and almost reach optimum density, it is found the line curve should draw with discontinuity at one particular point reflecting different condition. It means that to represent all variations of flow, equations need to accommodate point of discontinuity. It needs to develop more than one equation for each pair of parameter relationship. The problem is how to determine point of deflect and number of fractions which represented by different equations with different model. This condition is called as multi regime approach.

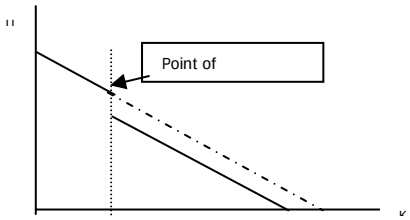

Figure 1 Curve discontinuity

To observe the possibility that condition, one segment of foot-path in Campus of University of Indonesia with bi-directional flow is chosen. **Table 4** shows the value of free flow speed calculated by different analytical model, range between 79.84 to 82,64 meter/minute. This number is relatively similar with speed of pedestrian walking in the city center by means of side road footpath. (9).

Table 4 Free flow speed for model evaluated

Model Analysis	Free flow speed (Meter/menit)	R^2
Greenshields	79.84	0.80
Underwood	80.96	0.812
Greenberg	∞	0.749
Proposed model	82.64	0.811

Multi regime approach is expected to develop relationship between two parameters which closer to the real condition in the field. The key component (parameter K) to develop curve is rely on point of discontinuity. For this particular case based on data collected and trend of curve, it is found that the discontinuity at the value of K equal to 70..

Table 5 Relationship between parameter for model evaluated

Speed - Density	**Flow – Speed**	**Flow – Density**
***Greenberg*- Greenshields; K ≤ 0.70**		
u = 79.72 – 21.37*k	q = 3.73*u – 0.047*u^2	q = 79.72*k – 21.37*k^2
Greenberg – Greenberg; K > 0.70		
u = 58.53 – 25.41*lnk	q = 9.97*u*$e^{(-U/25.41)}$	q = (58.53*k– 25.41*k*lnk)
***Eddi* – Underwood K ≤ 0.70**		
u= 79.84*$e^{(-0.29K)}$	q = 3.45*u*ln(79.84/u)	q = 79.84*k*$e^{(-0.29K)}$
Eddie - Greenberg >0.70		
u = 58.53 – 25.41*lnk	q = 9.97*u*$e^{(-U/25.41)}$	q = (58.53*k– 25.41*k*lnk)
***Proposed* - UI K ≤ 0.70**		
u = 1/(0.0.125+(0.04 *k))	q = 1/(0.04) - 3.125*u	q = k/(0.0125 + 0.004*k)
Proposed Model - Greenberg >0.70		
u = 58.53 – 25.41*lnk	q = 9.97*u*$e^{(-U/25.41)}$	q = (58.53*K– 25.41*k*lnk)

Relationship occur is develop with two models, it verify by level of statistical significant. The set of equation with is shown in **Table 5**, for speed-density, flow-speed and flow-density. **Table 6 is** describes statistical test result from the developed equation as shown in Table 5. From the combination significance level are relatively low, with the two are the highest.

Table 6 Statistical test value of models

Model Analysis	Value		
	R^2	F test	t-test
Greenberg	0.525 0.682	73.62 88.43	66.08 51.45
Eddie	0.545 0.682	301.83 88.43	69.37 51.45
Proposed Model	0.561 0.682	63.68 88.43	74.22 51.45

4. PEDESTRIAN FACILITIES

4.1 Safety Approaches

Pedestrian face high risk when across network segments cause by interaction between vehicles flows and pedestrian flows. **[10]** Accident analysis and modeling is needed to develop in order to characterize the effect for pedestrian crossing road. Attempt to develop the model is not intensively investigate since pedestrian behavior is strongly related to complex human factors. On the other aspect, pedestrians risk exposure is significant when moving across network segment. Difficulties to cross the street reflect aspect of accessibility which is also equal to other transportation mode. [11] It is need to estimate probability for overall approach to model characteristics pedestrian decision to across or to wait until condition allows to safely crossing. Probability to cross is influenced by vehicles flows, gap acceptance between vehicles movement and number of pedestrians which means that pedestrian has a critical gap to cross the street. Dept of Transport UK (**Note TA/10/80**) formulates the possible conflict use the relationship between **V** (flow of vehicles, vehicle per hour) and P (number of pedestrian, person per hour), multiplying **P** with $\mathbf{V^2}$.

Table 8. Type of pedestrian crossing PV^2

Parameter PV^2	**P**	**V**	**Type of Facility**
$>10^8$	80 – 1100	200 - 800	Zebra
$>2 \times 10^8$	80 – 1100	400 -	Divided zebra
$>10^8$	80 – 1100	Over 800	Pelican
$>10^8$	Over 1100	Over 300	Pelican
$>2 \times 10^8$	80 – 1100	Over 760	Divided pelican
$>2 \times 10^8$	Over 1100	400	Divided pelican

Source: Department of Transport, UK – TA/10/80

This value indicates the rate of conflict between vehicles and pedestrian crossers, and use as a mean to select a safe pedestrian crossing type. (**Table 8**).

4.2 Pedestrian Crossing

Facility Type Crossing behavior is determined by the gap acceptance theory which means that pedestrian has a critical gap to safely cross the street. Model based on pedestrian level of conflict however still limited to local behavior. Implementation of approaches and model PV^2 in some observed street in Jakarta proven that range of PV^2 value is higher than value given by DoT. UK. Data for observed street is shown in **Table 9**.

Table 9 P and V values at observation sites

Street name	P	V	PV^2
Senopati	121	1717	3.60E+08
Panglima Polim	197	2832	1.6E+09
Cokroaminoto	248	3195	2.5E+09
Kebon Sirih	352	3671	4.7E+09
Dr. Sutomo	291	4903	7.0E+09
Dr. Sahardjo	366	5061	9.4E+09
Menteng Raya	368	6788	1.7E+10
Rasuna Said	1047	8639	7.8E+10
Gajah Mada	1435	5097	3.7E+10
Hayam Wuruk	1280	5037	3.2E+10
Kramat Raya	250	10918	3.0E+10
Tomang Raya	569	6384	2.3E+10
Pramuka	397	7267	2.1E+10

For the same type of facility, pedestrian and vehicles flows on observed street are higher compare for to value stated by DoT UK. Parameter of PV2 is significantly differ and hence resulting a different type of facilities for safe crossing. High volume of traffic with low speed vehicles allow pedestrian to cross the street resulted in relatively safe.

Table 10 Proposed Type of Pedestrian Facility

PV^2	P	V	Type of Facility
$>5x10^9$	100 - 1250	2000 – 5000	Zebra
$>10^{10}$	100 - 1250	3500 – 7000	Zebra with traffic light
$>5x10^9$	100 – 1250	>5000	Traffic light or bridge
$>5x10^9$	>1250	>2000	Traffic light or bridge
$>10^{10}$	100 - 1250	>7000	Bridge
$>10^{10}$	>1250	>3500	Bridge

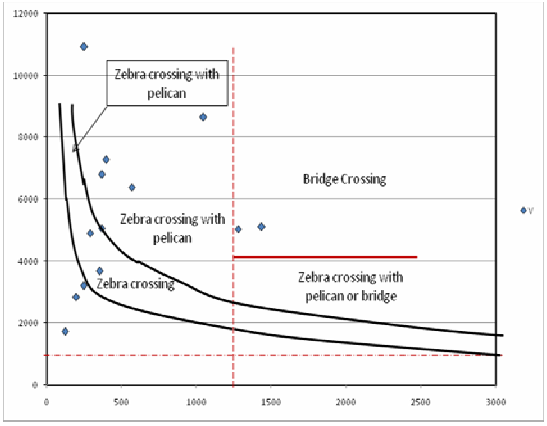

Figure 2 Selection of Pedestrian Facilities based on PV^2 value.

The result of observation and type of pedestrian crossing facility for Jakarta is shown in **Table 10**. [4] [7]

Decision to Cross There are two major factors influencing decision for pedestrian to cross the street: (i) internal factor: age, gender, platoon dimension, physical and mental condition, and freedom to maneuver; (ii) external factors: traffic flow. To characterized decision process, logit model is applied with individual behavior to choose one of best alternatives from at least three possible choices, such as: (i) not to cross; (ii) to cross at critical gap; and (iii) safe crossing. Model develop to accommodate is equitation with utility function: $u = a_0 + a_i x_i + a_n x_n$; ; where n= attribute index, a_0= constanta for utility function; and a_n = utility coefficient function.

From the total sample of 924 people, three utility functions for each possibility is developed and written as follow: (11) (**Sutanto, Agah, Andi, 1999**)

$u_i = -0.324 + 0.263x_i + 0.314x_2 + 0.264x_3 + 0.885x_4 + 0.249x_5 + 0.499x_6 + 0.198x_7$

$u_2 = -0.368 + 0.253x_i + 0.824x_2 + 0.226x_3 + 0.426x_4 + 0.513x_6 + 1.062x_7 + 0.252x_8$

$u_3 = -0.376 + 0.801x_i + 2.941x_2 + 0.292x_3 + 1.628x_4 + 0.559x_5 + 1.760x_5 + 0.533x_7$

The eight variables are: (1)age; (2)speed; (3)gender; (4)freedom to maneuver; (5)gap; (6) delay of pedestrian; (7)platoon; (8)vehicle gaps for safe crossing.

Results shows that about 55.85% pedestrian decide to cross in a critical condition, which means that flow of vehicles, are high and gap is critical. Avoidance of pedestrian for their safety is considered less, since there are some 72,99% of pedestrian crossing the road. The

number of percentage is almost three times comparing to the possibility to cross be a safe condition that is 25,19%.

5. CONCLUSIONS

To provide safe and comfort pedestrian facilities, basic characteristic of pedestrian is important input which influence by behavior of person, environmental conditions and traffic flow. On gender basis is found difference between male and female, in which speed of female is relatively lower compare to male. Relationship between parameter is relatively similar with vehicle flows, however since pedestrian does not follow in fix lane determination of flow must consider space per pedestrian. The relationship of two analytical parameters is found not always linear and can be represented by one model. Combination of two or more model is found to be realistic to represent better condition of pedestrian flow.

Safety factor for pedestrian in observed area (Jakarta) is found not treated as mayor parameter to cross the street. However, compare to the standard develop by DoT, -UK, the facility need to be provided is more moderate. This may cause by high volume with low speed providing small space for pedestrian to cross. Need enforcement both for pedestrian and driver to follow the rule in order to increase road safety.

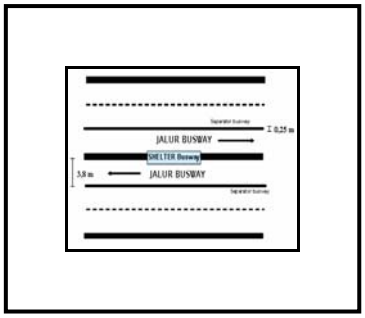
ABSTRACT

Effective and efficient maintenance program and rehabilitation would affect the life cycle and level of service highway pavement. Strategic steps for



maintenance program understanding and knowledge of the type and severity level of pavement damage is important to be taken into account. This paper discusses deteriorations of the pavement occurred along the corridor of special bus lane as called "busway – lane". This stretch of corridor is experiencing a high frequency of repetitive wheel loads and moving on the relatively same paths. Combination of high frequency, loading characteristic and same wheel paths has resulted in severe distress along the corridor and greater potential acceleration of pavement deterioration on corridor due to buses use. Bus lane use the existing flexible pavement lane, one inner lane occupied from the total of three fast lanes. After open to traffic damage gradually appeared in the pavement surface particularly at the bus stop and wheel path. Total weight of bus including about 80 passengers on board is approximately 15.000 kg. The object of research is Busway lane on corridor Blok M – Stasiun Kota in Jakarta – Indonesia. Total corridor length observed is 12.90 km and 3.80 meter width with total of 20 bus shelters and distance between shelters is 650 meter. There are 91 buses operated in total with the gap of 1.2 to 3.0 minutes during working hours from 05.00 to 22.00.

In order to indentify the type, quantity, and quality of pavement damage, survey is conducted by visual observation. Observation is conducted every 30.00 meters to maximum 150.00 meters length, digital camera used to take picture, map sheet and survey form use to record the surface pavement condition, and straight ruler to measure dimension (length or area) of distress as well as the depth of rut. The recorded data and information would be use as a mean to predict the type of distress, furthermore to find possible solution for the problems encountered refer to measured cracks and other mode of surface pavement damages or distresses. Air and surface pavement temperatures are also measured to analyze the impact and contribution of temperature. Result of visual observation combined with the characteristic of layers beneath pavement surface is analyzed and investigated to estimate contribution of sub-base and base which are mostly granular base materials. From the observed results it is found that the most frequent distress was potholes (33,33%), rutting 19,87% and other types range between 15%-4%. The results show typical damage characteristic, both of single type or combination of several types of distresses while the severity ranged from low to high. However, minimum influence of temperature is found.

Keywords
pavement maintenance, visual observation, distresses, special bus lane.

1. INTRODUCTION

One of the strategic components in pavement management is an ability to estimate and to predict pavement performance distresses and potential failure due to loading and environmental aspects such as temperature and water. This needs objective system and ranking performance criteria to provide comprehensive information to cover type pavement distresses and specific indicative failure condition in particular for the road network system. Pavement condition prediction[1] [2] done through investigation in the field with either using destructive or non destructive testing method. Non-destructive method is relatively faster to undertake and provide initial pavement condition prediction.

This method uses visual observation directly in the field visually by the team of at least three persons and in combination with desk evaluation to interpret any indication and performances from picture taken at the site, or measures pavement surface deflection with one selected equipment types such as Benkelman Beam or Dynaflect, measures skid resistance and surface pavement roughness using roughness meter. [3] [4] [5] Knowledge of the various types and its frequency are important, since it can help in identifying the cause of distresses and also as a means to select most probable repair. It is important to identify the design method and provide pavement management system to find a most effective strategy for maintenance and rehabilitation. [6]

Level of distress is classified with major type such as cracking, patching and potholes, surface deformation, surface defect and other defects [7] [8]. However with a systematic maintenance supported by a consistent, uniform basis data and information collected from the road network of all distresses found in the field will help longer live and more convenient pavement for the rider. Distress is one of the important consideration and primary parameter in pavement design. In particular if mechanistic-empirical method is applied, each failure criterion should be developed separately to overcome or to find proper solution of each specific distress. Typical distress could occur in one specific road condition which experiencing by load with unique types and characteristics. Premature failure will occur due to overloaded vehicles traffic or very high repetition of load (axle load) passing same path or the road pavement surface represented by rutting along wheel path.

As found in some references and previous research [8] [9] [10] typical pattern of deterioration in asphalt pavement is rutting, which develop in relatively rapidly during the first opening to traffic flow and later after reaching a certain period of time or number of vehicles repetition level of deterioration is slower. Other type of distress such as fatigue or cracks normally does not occur in the early stage of services, until sometime after carrying a high number of vehicle wheel repetitions. However, it will develop in relatively rapidly when pavement is weakens. In Indonesia with relatively constant high temperature which creates higher surface temperature compare to air temperature, bleeding will occur if asphalt content is too high, or crack will developed cause by consistency of asphalt.

This paper discusses deteriorations of the pavement occurred along the corridor of special bus lane as called “bus way – lane” located in Jakarta - Indonesia. This stretch of corridor was experiencing a high frequency of repetitive wheel loads and moving on the relatively same paths

2. METHOD OF OBSERVATION

2.1 Distress Survey

Observation is undertaken in combination of direct observation in the site and photograph at selected point coincide with the entire defect found from visual observation. All parts of pavement surface along the corridor are observed and the result is drawing in the map identifying the type, area and distance from a coordinate system. To have a representative distress type and close to real condition [7] [8]**,** team of observer must at least comprises of three persons, observation must have mapping format and distress symbols.

Each segment of observation must not exceed 150 meter, however it is suggested to measure every 30 meter segment of road. The result of this must cover type, number of each distress types and level of severity also the exact location. All of the findings are written in a survey format and drawn in distress map. FHWA method of visual observation to identify type of distress is used as survey format in this research. The result is grouped by the type of distresses to produce a map showing type and frequency as well as location. [4] [9] Referring to the manual from FHWA, deterioration is grouped into 4 (four) of specific groups plus one distress which has different characteristics and geometric as defined

in the first four group. Group classification is: cracking, patching and potholes, surface deformation and surface defects, and to simplify so that easier to note in the field observation code number of distress type is normally used rather than write full name of distress type. (**Table 1**). Severity or level of deterioration is broken down into three levels such as low (L), medium (M) and H (high), e.i: **1-L**, means fatigue cracking (**1**) with low severity (**L**).

Table 1. List of group classification and type of distresses

Code	Group classification	Type of Distress
1	Cracking	Fatigue Cracking

14	Miscellaneous Distresses	Lane To Shoulder Drop-off
15		Water Bleeding and Pumping

2.2 Site Characteristics

Lane Function and the User Since the year of 2003 a new system of public transport has been introduced and offered to the traveler in Jakarta called "Bus Way", which means passenger bus rapid transit, a bus system ride on a special lane of road network system. Bus way in term of infrastructure is designed as a special lane taking one inner lane from the three or more of the existing road lanes and separated by concrete divider to avoid friction and conflict with other traffic vehicles. With this kind of lane, operating speed could be maintained in a constant rate. The first corridor is along the route of Blok M in South Jakarta stretches to Kota located at the business center at North Jakarta with the total length of 12,90 kilometer facilitated with 20 shelters, average lane width is 3.80 meters, and distance between shelters is 650 meters (**Figure 1**). Some widening of road is constructed due to the limit of existing width varies between 0.60 meters to 1.00 meters. The existing pavement is flexible pavement and has been overlaid by hot-mix asphalt concrete several times since the first time of construction to have minimum of 3.80 meter width. However due to the difficulties to find the real condition of existing pavement layer and its overlay surface to maintain good road, detail of layer thickness is not possible to draw in detail. (**Figure 2**)

Bus is operated daily with operating hours started at 05.00 until 22.00, headway time during peak hours is between 1.20 to 3.00 minutes. Maximum gross vehicle weight of bus is 15.000 kilograms and resulted from combination of it is owned weight of 9.340 kilograms and total passenger weight of 4.860 kilograms. Maximum carrying capacity of bus of 85 passengers comprises of 35 sittings and 50 standees with the average body weight of 60 kilograms and approximately another 800 kilogram of goods. Number of buses operating in the observed corridor is shown in **Table 2.**

2.3 Field observation

Since the early period of opening and bus operation, this special lane experiencing pavement deterioration which may be caused by higher number of traffics from the bus operation compared to the other existing conventional lane in the same flow direction. This situation leads to finding the most possible cause of the distress which in turn will be used as tool to select a proper method to prevent pavement damages. Field observation collects detailed information of each part of the pavement damage and measures it

by the length or area of particular distress type. Type and symbol refer to the FHWA method is used as reference.

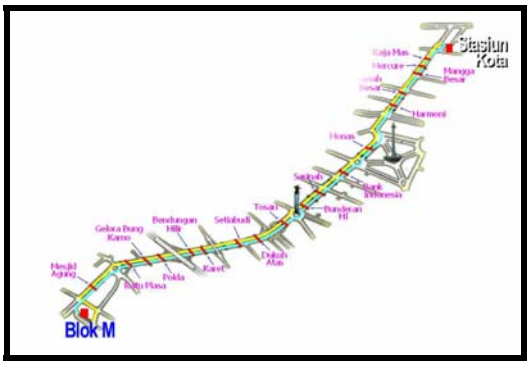

Figure 1 *Map of bus-way lane and shelters on corridor Blok M- Stasiun Kota – Jakarta*

Both air temperature and pavement surface temperature are measure at each part of visual observed segment. However, the measurement is not taken in the same period of time since it follows the measurement of distress. Special observation is done for distress type of rutting. The depth of rut is measured using ruler and taken at every 30 meter, both on the left and right side of bus wheels. From the observation data are collected geometrically, type and location of each distress includes width of bus lane, the width of developed rutting, as well as air and surface temperature. Number of bus traffic flow was taken from the bus authority. Equipment and tool used are: digital camera, thermometer to measure surface pavement temperature, ruler, marking tools and form of data sheet. Distress map sheet is referred to FHWA format and 30 meter segment of observation is applied. From the total of 12.90 km. 2.79 km. was selected as research subject location at corridor I busway (Blok M – Kota).

3. ANALYSIS

3.1 Findings

From the entire stretch of road of 93 sections (30 meters per section) all types of distresses include number of each type is shown in **Table 3**. The number is cumulative of total sections ignoring severity level of deterioration; it is meant that there are 72 locations with fatigue cracking for all type of severity in this classification.

Of the total 15 types of distress observed, the five major types are ranked as the most frequent and detail is shown in **Table 4**. The table also shows two important indicators which are (i) average of each type, and (ii) severity level divided into three levels. Average is calculated from all numbers of type found during observation and depend on the characteristics of each type are measured by area (meter square) or by length (meter length). In the last three columns, level of severity is shown in three different levels (**H=high; M=medium; L=low**), each number in column (in %) is average and calculated from the total length observed road.

Performance of each type is shown in **Figure 2**

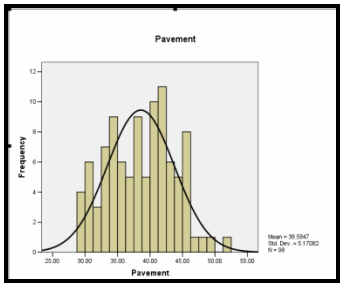
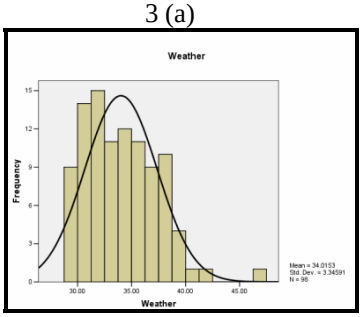
15.00	-	-	-	1	1.1	100
16.00	1	1.1	100			
Total	93	100		85	100	

The most frequent and dominant distress along the observed bus-way route is potholes with 33.33%, rutting for about 29.87%, failure cracking of 15.38%, patching of 13,89%, longitudinal cracking of 4,91%. However, bleeding is not found during observation period noted that surface temperature measured is below 53^0C. Surface pavement temperature is between $29,1^0$C – $51,4^0$C. Wide range of measured temperature is influence by the timing of measurement since it is following the visual observation time, some are taken in the morning and the rest are in the mid day. Frequency distribution of surface and air temperature is shown in **Figure 3**.



3 (a)



3.(b)

Figure 3 Distribution of measured (a) pavement temperature and (b) air temperature temperature

3.2 Types and Level of Distresses

Rutting This type of distress is a dominant distress found along the observed road after potholes. Rutting is surface depression in the wheel path it will be seen as evident after rain when it is filled by water. This problem normally occurred when pavement in subjected to load from vehicles wheels either overload or riding on the same track, it will create more serious effect when combination of heavy load and riding in relatively the same wheel track. This case is very similar with the lane servicing bus-way system causing phenomena like channeling effect. Detail performance of rutting along the wheel path is shown in **Table 5.** The depth of rut is significant in number ranging between 11.0 mm to maximum 20.0 mm and its frequency which ranges from 11 to 22 from the total number of rut observed. This shows that the effect of traffic is considerable giving strong influence to this type of pavement and vehicle movement characteristics. The depth of rut is approximately 40% -50% of the initial pavement thickness which indicates pavement have been heavily damage.

Further evaluation based on collected data shows there are 375 point or locations of defect, of which some 366 point (97,6% of total defect) are located at wheel path, compare to 9 points defects outside of wheel path. This has proven that load repetitions applied on the same path will influence significant effect to the pavement performance.

Combination of Distresses Failure of pavement does not always show one type, but in many cases, as it is found in this research combination of two or more types failures frequently occurred. In one segment per 30 meter length of observation there also occur in combination of more than one type of distress. As shown in **Figure 4** the most frequent distress is combinations of two types per 30 meter segment, and the highest combination per 30 meter is 19 types. The average combination per 30 meter is found as 4 combination of distresses type, those numbers indicate that distresses always occurred of more than one type and this likely occurs when the maintenance program is delayed. There is time lag between the indication and early stage of distress development and repair action must be done.

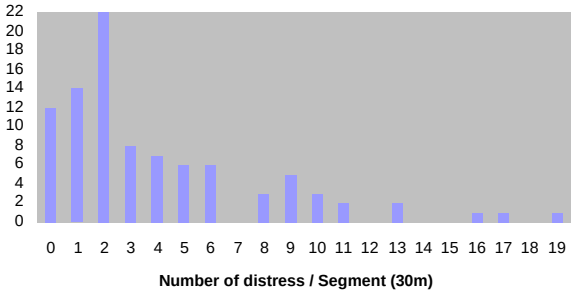


Figure 4 Frequency distribution of distress along the corridor (*horizontal axis representing length of corridor per 30 meter, and vertical shows frequency of distresses*)

Temperature and Distress Hot-mix asphalt concrete is susceptible to temperature which

influence by characteristic of asphalt as binding agent. Temperature affects the resilient modulus of asphalt layers and elastic and viscoelastic properties of hotmix asphalt concrete.

One of the indications of distress caused by high surface temperature is bleeding, however in this research as seen in **Table 6** this type is no found.

Table 6 Correlation between distress classification and temperatures

Location (shelter)	Distress classification		Temperature	
	Type(s)	Number	Pavement	Air
Sawah Besar – Harmoni	Potholes; fatigue cracking patching longitudinal cracking	10	33	33.76
Glodok – Olimo	Potholes, fatigue cracking, longitudinal cracking	9	33	31
Sarinah – Bank Indonesia	Potholes, patching	2	41.8	36.03
Mangga Besar – Sawah Besar	Potholes, fatigue cracking, longitudinal cracking, patching	4	37.6	32.6
Bank Indonesia – Sarinah	Potholes, patching	4	42.4	37

Bus Shelter and Distress Results from field observation shows that distress appear in the area and its surrounding area of shelter are significantly differ from others found along segment. Stop and go bus operation results friction and highly concentrated shear stress in pavement surface. Typically shoving, ruts, raveling and potholes are found, in which shoving are the dominant distress type. (**Figure 5**)

Figure 5 Typical failures in the area of bus shelter

4. CONCLUSIONS

1. Distress type dominating the bus way corridor are potholes (33,33%), rutting (19,87%), fatigue cracking (15,38%), patching (13,89%), transverse cracking (41,9%).
2. Distresses in the area of bus shelter is unique caused by combination of repeated loading and stop and go bus operation causing heavily damage pavement, combination between rutting, shoving and potholes. Higher strength of pavement need to overcome the problem and better drainage to avoid surface filled with still water.
3. Temperature does not contribute to the common problem of higher temperature such as bleeding which may be caused by proper asphalt content in design of asphalt concrete mix.
4. High frequency of load repetition and combined with moving in the same path creates combination of distress in the same segment, with the average of four types of distresses in the same location. Potholes is found as a dominant type of distress is indicates excess of surface water and impact of wheel load.
5. Surface deformation in the form of rutting along the corridor is the effect of wheel load impact, this is caused by less strength of layer both surface and layer beneath.
6. The total of all distresses along the observed corridor as much as 375 point of failures shows that special attention need to taken

into account in term of pavement strength, refer to the number of failure 366 out of 375 occur along the wheel path.

7. Combination of more than two types of distress caused by late action to overcome the problem which lead to foster the deterioration rate and potential to a worst pavement condition

ABSTRACK

In general, Indonesian construction industry is still struggling with inefficiency and ineffectiveness which is caused by delayed sechedule and cost overrun. There is a need to improvement the performance of Indonesian construction industry by integrated value engineering and risk management to succeed in the delivery their desired outcomes by maximize value and minimize uncertainty. Value engineering and risk management can assist in creating a culture which enhances project performance by reducing risks. Value Engineering provides an effective process to maximize value in line with the owners and end users requirements; meanwhile risk management provides a process for managing risk. Both processes should be integrated on every significant design, development and construction project. Focusing on the integration of value engineering and risk management applica-tion on the other countries, this paper intends to give clear direction of the subject to be studied, by discussing the scope and approach of both value and risk management. The paper has a conclusion that there is the potential for construction industry in Indonesia to improve the effectiveness and efficiency by implementation the integration of value engineering and risk management. The result of this research is intended to contributing to national construction industry.

1. INTRODUCTION

Construction sector in Indonesia has grown since the beginning 1970's and held an important role in national development. This sector has significantly contributed to other social and economy sector growth. BPS Data 2006 showed that market share on national construction sector has grown to 8,6 % of GDP or equivalent to Rp. 52,3 Trillion in second quarter of 2006 [1]. The importance of this sector is obviously supported a conducive business environment and developed capability.

In general, Indonesian construction industry is still struggling with inefficiency and ineffectiveness during the implementation process of its constructions. Many waste in form of activities which utilizes resources cannot produce expected value, whereas construction project performance should be assessed on how those project management system could contribute added value to the related parties either cost side or time. Abduh (2007) argued that the waste of construction industry in Indonesia has reached 57% whereas the activity which gives additional value is only 10% [2]. This issue is obviously shown inefficiency and ineffectiveness. Alwi et al. (2002) identified the problem of inefficiency and ineffectiveness of Indonesia's construction industry and summed up that the main cause factor is delayed sechedule and impacted to the cost overrun [3]. This condition surely needs contractor's ability to be able to increase effectivity and efectiveness within the management of its construction's project [4],[5]. Contractor shall seek a method, concept, and program to manage project in order to be able reach his goal on vitable period, cost and quality [6].

There are 2 substantial conditions for the success of a project, first; contractor's capability to require expected value by project owner with initial agreed cost of the contract and, second; the effort of minimizing the impact of unavoidable risk and possible project loss [7]. First condition can be fulfilled by *value engineering (VE)* which provides effective ways to maximization value in certain project according to owner expectation. Whereas the second condition is overcome by implementing risk

management contributed to effective process in order to control the risk of a project. Value engineering and risk management within construction industry has been widely applied and accepted as the best tool for effectively management project [8]. The combination of value engineering and risk management within integration process is an excellent strategy which is able to maximize the project value and reduce uncertainty the agreed cost frame. This paper reports a investigated the arguments and the potential for their integration to promote effective and efficient construction industry in Indonesia.

2. METHODOLOGY

A study literature was undertaken to investigate current thinking on the applications of VE and RM in the construction industry in other countries as two discrete disciplines, and to establish the extent to which the literature address for the potential for their integration. This paper explores the procedures and process of VE and RM that has done by others researchers.

3. VALUE ENGINEERING IN CONSTRUCTION INDUSTRY

There is no single definition of VE or VM or of the other terms such as Value Analysis. The pioneer Miles (1961) defined VE as " an organized creative approach which has for its purpose the efficient identification of unnecessary cost" [9]. A definition which encapsulates the principles of VE is as value at systematic, multidisciplinary effort directed towards analyzing the functions of projects for the purpose of achieving the best value at the lowest overall life cycle cost [10]. The same definition was develop by Robinson & John (1997) that VE is a systemic process uses analytical, creative and evaluation techniques on a multi-disciplined basis to achieve the desired functions in a design or process while maximizing value and maintaining or improving required function.

The concept of function is based on the principle that the value of an object is determined by what use is fulfilled and is not related to its cost. VE use to eliminate unnecessary life-cycle costs without sacrificing safety, quality, environmental compliances or other functional requirements and it will increases innovation opportunities, improves cost effectiveness, enhances performance and fosters partnering among the owner, engineering and builder [12].

As a systematic process, VE focused on identifiable steps collectivity known as Job Plan Procedure, which was firstly founded by Miles in 1961 using 40 hour workshop. Developed from Mile's original Job Plan, 6 steps are included from information gathering and criteria setting to decision-making-related to selected options. In current practice, Hannan (1994) developed into three distinct stages of Pre-Study, Main Study (Workshop) and Post-Study activities, all focused on structured problem identification and problem solving [13]. The Society of American Value Engineers or SAVE International published its own job plan in 1997 while Male et al (1998) have their own as well. The different of job plan phases and procedures are as shown in Table 1.

VE is a multi-disciplinary approach based on an interaction of different disciplines providing a collective analysis of all aspects of a project and the cost implications of ideas so as to achieve the best value. Generally VE is applied when there is a well defined scheme in order to optimize costs and benefits. Palmer (1992) support that the earlier in the design process VE studies are carried out, the greater the potential for cost reduction and the lower the extra design cost of implementing proposals, as the majority of cost is committed during the early design stages [17].

Table 1.Job Plan Procedure [8],[15],[16]

LaMiles (1961)	Hannan (1994)	SAVE International (1997)	Male et al (1998)
Orientation Information	Pre Study Phase	Pre-study Phase	Pre-Study Phase
Speculation Analysis	Main Study Phase	Value Study Phase	Information Phase Creativity Phase Evaluation Phase Development Phase
Summary Conclusion	Post-Study Phase	Post-Study Phase	Consensus Phase

Since its introduction into the construction industry, VE has faced resistance. The same problem is happened in Indonesian construction industry. Green (1999) have founded many argue that the confused and inconsistent use the terminology and the lack of a standard definition are barriers to its widespread use [18]. VE is also associated with many misconceptions, such as VE for cost reduction exercise, somehow the aim of VE study is to lower cost whilst retaining or enhancing quality and performance requirements.

We frequently apply value management much earlier in the project lifecycle, in order to embark on the optimal project to provide an exceptionally powerful way of exploring client's needs in depth, addressing inconsistencies and expressing these in a language that all parties, whether technically informed or new to the construction industry [19]. This results in the following benefits:

1. It defines what the owners and end users mean by value and provides the basis for making decisions, throughout the project, on the basis of value. It provides a means for optimizing the balance between differing stakeholders' needs.
2. It establishes the value profile as the basis for clear briefs which reflect the client's priorities and expectations, expressed in a language that all can understand. This improves communications between all stakeholders so that each can understand and respect other's constraints and requirements.
3. It ensures that the project is the most cost-effective way of delivering the business benefits and provides a basis for retaining the business case. It addresses both the monetary and non-monetary benefits.
4. It supports good design through improved communications, mutual learning and enhanced team working, leading to better technical solutions with enhanced performance and quality where it matters. The methods encourage challenging the status quo and developing innovative design solutions.
5. It provides a way of measuring value, taking into account non-monetary benefits, and demonstrating that value for money has been achieved.

Nowadays value engineering is a contraption to render a better utilization of the financial sources, project timing and eventually the betterment of the project value. Value Engineering can be utilized as an appropriate strategy to enhance project implementation and to access the supreme purposes of the project.

4. RISK MANAGEMENT IN CONSTRUCTION INDUSTRY

Risk Management is defined as "the systematic process of identifying, analyzing and responding to project risk, including maximizing the probability and consequences of positive events and minimizing the probability and consequences of negative events to the project objectives" , and also as "an uncertain event or set of circumstances that, should it occur, will have an effect on the achievement on the project's objectives" [20],[21]. The concept of risk management is started with gambling, which is a game of chance, and makes profits based on prediction [19]. Champan & Ward (2002) implies that a source of risk is any factor that can affect project performance, and risk arises when this effect uncertain and significant in its impact on project performance [22]. Risk exists as a consequence of uncertainty while risk management describes the deliberate management of uncertainty or its effects [23],[24].

The aims and objectives of Risk management is to ensure that risks are identified at project inception, their potential impacts allowed for and where possible the risks or their impacts minimized and to improve project performance via systematic identification, appraisal and management of project related risk [22],[24],[25]. In the other word, the aim of risk management is not to eliminate risk but to control it. Successful risk management reduces the uncertainty in achieving a successful outcome to acceptable and manageable levels [19]. Risk Management ensures that risks are identified, reviewed and mitigated accordingly and key stakeholders are made aware of the risks prior to any decision making.

As a systematic process, there are many models used to manage the risks. The standard model is divided into 4 parts namely risk identification, risk analysis, risk response and risk monitoring and review. Meanwhile Baker et al (1999) developed that the methodology encompasses 5 staged: identification, analysis, evaluation, response and monitoring.

Source of risk central to construction industry activities can be grouped under the heading of physical and environmental, design, logistic, cost, legislation and constructability. Also the multiplicity of parties with different roles and aims, the project complexity and the fragmentation of the construction industry are further sources of risk. Project risks are considered to be dynamic and therefore risk assessment should be a continuous process spanning all phases [26].

A formal risk management process delivers the following benefits for the project team [19]:

1. It enables management to embark on innovative, high reward projects in the knowledge that they can control the risks.
2. It requires that the management infrastructure is in place to deliver successful outcomes. This includes setting clear, realistic and achievable project objectives from the outset.
3. It established the risk profile of the project, enabling the appropriate allocation of risk, so that the party best placed to manage it has the responsibility for doing so. Risk allocation is a key component of contract documentation.
4. It allows the team to manage risk effectively, concentrate resources on the things that really matter, resulting in risk reduction as the project proceeds. It also enables them to capitalize on opportunities revealed through use of the process.

On construction industry, risk can have a positive impact upon project performance. Although the current literature has the tendency to present risk as a negative element, but it can be argued that the main benefit of risk management is to help project managers ensure that project objectives are not

affected by adverse effects [7],[15]. Risk management is not a means of removing all the risks, but facilitates explicit decision making which will mitigate the effects of certain risks. This other benefits include: enabling decisions to be more systematic and objective, allowing comparison of the robustness of projects in relation to specific uncertainties, comparing the relative importance of each risk, providing an improved understanding of the project, promoting feedback and information transfer, and heightening awareness of the range of possible outcomes [28].

5. THE POTENTIAL OF INTEGRATED VALUE ENGINEERING AND RISK MANAGEMENT

The idea of integrating Value Management and Risk has started more than ten years ago as many professionals realized that it is impossible to separate between value and risk. Dell'Isola (1997) cited that the opportunity of integrating value management (VM) in conjunction with the formal risk assessment and analysis started in 1993 when a city port authority required a value engineering (VE) effort that would be augmented with an application of a risk assessment [29].

The main idea for integrating VM and RM is to optimize value on a project, minimize the time taken act and to produce results with optimum performance and quality. VE is about articulating what represents value in terms of projects benefits while risk management is about identifying causes of uncertainty and what can go wrong. Thus to optimize value, that is essential that the construction industry actively manage both value and risk. It is necessary to take risks to maximize value. Both activities complement each other to maximize the chances of project success, which is VE can reduce risk and risk Management provides opportunities to increase value.

Value engineering and risk management are two well-established disciplines recognized as a part of best practice [15]. The links between them are strong. Risk is managed it is possible to achieve a cost saving and an enhancement in value, while value is considered there may be risks associated with each phases. Norton & McElligott (1995) suggest that risk management may be enhanced by VE, using the VE team to either audit or produce a project's risk management plan [10]. In a combined approach there is potential to benefit from the assembled multidisciplinary team and also to promote the introduction of risk management into an organization [30]. Since the risk management is mainly perceived as a negative process a combined approach could mean that advantage could be taken of the creative, positive atmosphere of value engineering study to generate ideas to mitigate risks or identify opportunities.

In the construction industry, both VE and RM are well and widely accepted as best practice tools for effective management of projects [31],[25]. Griffin (2006) said that the issue is no longer about whether they should be used but whether the processes should be integrated [32]. The application of VE will help client to identify the best way of meeting business need while RM is used to manage the risks associated with the solution that offers the best whole-life value to the business and should not be seen as barrier to innovation [25].

It is arguable that the integration of RM and VM can be used to reduce the negative impact on projects and to assist value improvement [8]. While this is so, the risk of available alternatives will influence the decision about project objectives and preferred outline designs which strengthen the idea of combining RM and VM [30]. Furthermore, Othman (2004) supported the idea of integration of VM and RM as two complimentary disciplines, saying that best value could not be achieved unless associated risks have been managed. The reasons why there is a need to integrate between VM and RM is as follows [26], [30],[34],[35]:

1. Utilisation of the same resources/multi-disciplinary team hence avoiding duplication of effort.
2. Involvement of stakeholders in the workshops.
3. Good way of introducing VM and RM into an organization.
4. Maintain and improve future appraisals and assessment of projects.
5. Influences the VM proceeds in this case-option appraisal, by allowing the users to consider specific options used in the past similar projects.
6. Makes them aware of their weakness and strengths.
7. Shortening he time taken to develop viable solutions based on the risks facing a project.
8. Identifies specific risk allocation structures in association to contrast strategies.
9. Provides in-depth assessment process.

5.1. Advantages of Integrating Value and Risk

There are four advantages in integrating value and risk management practices [31]:

1. Integration enables value and risk issues to be considered together. From the very beginning of the project a full picture is available to help decision-makers develop an understanding of opportunities and uncertainties.
2. Integration is more efficient, not only from the depth and quality of the discussion process, but

also because fewer workshops and meetings are required.

3. The use of this integrated discourages the use of ambigious and inconsistent language and so promote a common team understanding and coordinated effort to realize the client's objectives. This should reduce the levels of confusion in the industry and make it easier for facilitators and others to work within project team.
4. Any value management, value analysis, value engineering or risk management tool or other relevant business management tool can be incorporated where, and whenever desired.

5.2. How to Integrated Value Engineer-ing and Risk Management; Learn from Other

Workshops are useful way of identifying project risk and therefore it possible to combine risk and value engineering in the some workshop [30]. There are some papers published which strongly suggest integrating the risk management with value engineering. Kirk (1995) introduces the probabilistic estimating concept by combining range estimating and Monte Carlo Simulation instead of traditional Determining estimating [36]. This practice also gives the decision-maker a better confidence when determining the contingency for the project. Mootanah (1998) also made a very intensive study on the interactive strategy for value and risk management framework, and he proposed the possible interface as shown in Figure 1 [37].

In the UK, a general guide in integrating value and risk management is provided by OGC, identified as The Gateway Process. This process helps to reduce overall project risk by examining the project at critical stages in its life cycle to provide assurance that it can progress successfully to the next stage [25]. Kirk (1995) and Thompson (2004) suggested that value and risk management could be integrated in a workshop through the job plan process with risk considerations in each phases as shown in table 2 [35],[36].

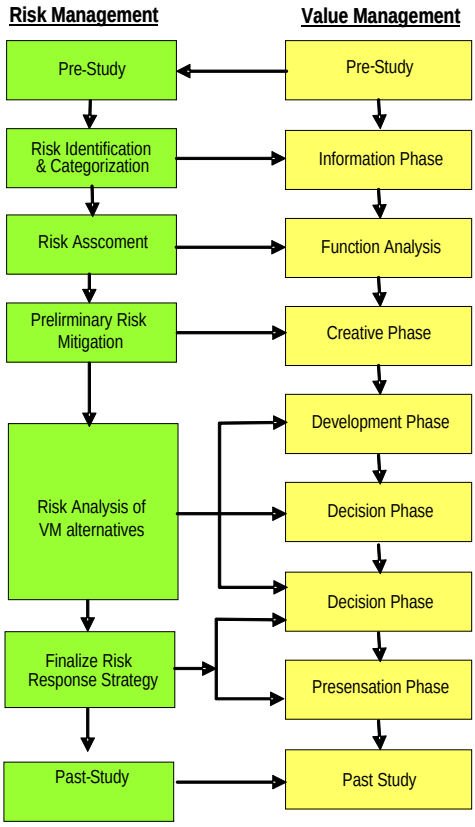

Figure 1 : Possible Interface of Value and Risk Management (Mootanah, etc)

Dallas (2006) developed the milestones for integrated value and risk management and found that to reflect project progress the objective of value and risk studies change as the project moves from stage to stage [19]. The evolution of most Development and Construction Project is, by their nature, an interactive process as shown on Figure 2 [8]

Although there are different approaches towards the use of integrated value and risk management, this literature study found out many similarities on integration (Berawi et al, 2007). The first similarity is about aims and objectives whereby all projects have clear sets of aims and objectives to be achieved after the workshop. Secondly, the workshops were conducted according to the basic principles which consist of techniques like job plan and brainstorming.

Table -2
Risk considerations and activities in Job Plan phases

Job Plan Phase	Risk Considerations	RM Activities
Information Phase	Listing of known risks, issues, problems associated with the project Project may have been initiated as a result of a problem or a risk	Identify risk issues Determine risk impact Perform risk analysis of designer cost estimate
Function Analysis Phase	Some functions may address or be influenced by know risks	Brainstorming Risk mitigation
Creative Phase	Ideas may address how to get around known or possible risks	
Evaluation Phase	Evaluation criteria should include risk items to eliminate ideas which have a very high risk associated with them	Consider risk as a weighted criterion
Development Phase	Risk allowances associated with each proposal at all stages of a project, especially during the construction and operation and maintenance will give a better comparison of proposals during any cost/ benefit analysis using whole life costing Time implications	Conduct RA of VA alternative design
Presentation Phase	The risk that not everyone will sign up to the preferred proposal and how to deal with it	Present RA with suggested mitigations Recommend project cost & contingency
Implementation Phase		Perform second risk analysis of final reconciled proposal

Job plan and brainstorming played vital part in conducting VE studies to generate ideas, evaluate and develop them during the workshops. The third similarity concerns on the risk aspect and risk management workshops.

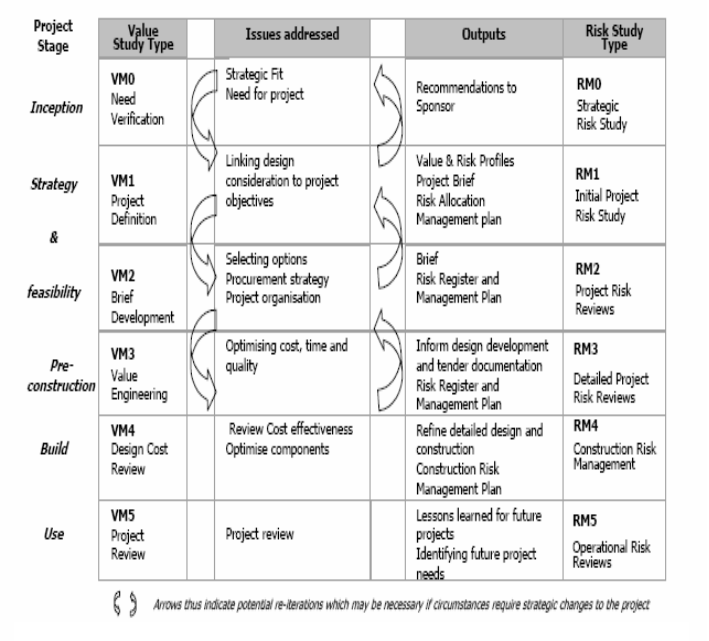

Figure 2. Milestones for Integrated Value and Risk Management Reviews

6. INTEGRATED VALUE AND RISK MANAGEMENT ON INDONESIA CONSTRUCTION INDUSTRY

VE has an important role on industry to continually improve the innovative construction management which is implemented on many construction projects and infrastructure in developed countries such as UK and Iran, especially for the high cost projects (Palmer et al, 1996, Bytheway & Charles, 1971, Berawi & Woodhead,2005). In the Indonesia construction industry, the implementation of value engineering, risk management and also infrastructure projects are still not popular (Marzuki, 2007, Soemardi, 2006). Eventually if we pointed on normative aspect, the implementation of value engineering was defined at Article 23 Law No. 18/1999 about Construction Services which declares that if it is found any inefficiency indication occurred because of unusual construction price, design construction or construction method, therefore it will be recommended to use the value engineering.

This statement is being strengthened by Peraturan Pemerintah RI Nomor 29/2000 which declares that for high risk construction project is shall be conducted a pre-feasibility study, feasibility study, general and technical planning. Meanwhile Peraturan Menteri Pekerjaan Umum no. 45/PRT/M/2007 about the Technical Guidelines of the Government Building Construcion stated that Indonesia's government wish to increase efficiency and effectiveness of construction industries by implemented value engineering. Regarding to Article 2, The technical guidance aims to render a government building accords to its function,

requirement the safety, health, convenience, easily and efficient on resource purpose with effective and efficient.

Based on the fact that the delay and cost overrun happened on many Indonesia's construction industries, this paper is aimed as a preliminary study on how the integration of VE and risk can improve the value and minimize the risk. Therefore, it will improve the eficiency and efectiveness of Indonesia construction industry as it was applied on other countries. Hereafter it will be conducted a sequel study to find how it is implemented on Indonesia construction industry as its condition and the readiness of the construction industries stakeholder.

7. CONCLUSION

This paper concerns on the integrated value and risk management that have been conducted on other countries to be studied and implemented on Indonesia construction industry. As the literature study which has been done, it is concluded that the integration of value engineering and risk management in a project at various countries was applied and widely accepted as a best tool for improvement better effective project management (Weatherhead and Griffin, 2006). Combination of both within one integration process is a good strategy to maximize value of a project meanwhile reducing risk in a cost frame that was already conducted. Thus it can be concluded that the implementation of value and risk management on a construction industry project in Indonesia should be improved the efficiency and effectiveness throughout the value maximization and the risk minimization. The next research will be focused on how to integrate the value and risk management on Indonesia construction industry as its own consideration.

ABSTRACT

Building facades and their design strategies play a significant role in achieving optimal thermal performance. The aim of the design is to provide an adequate quality of thermally and visually comfortable environments to the occupants by utilising minimal energy consumptions. Opaque walls and glazed windows should have should have the ability to attenuate and modulate the solar heat received at their surfaces. They should also allow sufficient day lighting for the building. The usage of glass facade has become a standard design in most office buildings due to its high aesthetics, high visible and modular systems. This paper investigates the facade designs of low energy office buildings in Malaysia. A comparison study on how these passive designs contribute to energy efficiency in the tropical country is conducted in LEO Building and ZEO building in Malaysia. It will also highlight the occupants' perception on the building interior comfort and aesthetic value relative to the surrounding glass facade. This paper is presenting a detailed comparison study of LEO Building and ZEO Building, based on the facade design considerations, performances and environmental comforts. It is expected to give further insight on effective facade design for such low energy office buildings.

Keywords:
Aesthetic value, environmental comfort, energy efficiency, facade design, low energy office.

1.0 INTRODUCTION

Malaysia has consumed approximately 50% of the total energy consumption for air-conditioning in non-residential buildings. The electricity demand in Malaysia is expected to grow 6% to 8% per annum [1]. As a result, the development of energy efficient building is urgently needed! Besides M&E system, responsive building facade is one of the important components to achieve energy efficiency by reducing the need for cooling, lighting and ventilation [5]. Facade design and construction has great potential in controlling its interior environment, through the high levels used of insulation, energy efficient windows and passive solar design techniques. Furthermore, the usage of glass facade has become a standard design for office buildings due to its high visible, high aesthetic and modular system.

The design strategies of Low Energy Office Buildings in Malaysia have integrated high performance building facades which provide high quality and comfortable environment for the occupants. This paper investigates the facade design in Low Energy Office (LEO) Building and Zero Energy Office (ZEO) Building in Malaysia by means of comparative analysis in reducing the energy consumption.

2.0 LOW ENERGY OFFICE (LEO) BUILDING

The Low Energy Office (LEO) Building is the building of Ministry of Energy, Water and Communication (MEWC). It is the first example of a government building in Malaysia which demonstrates the integration of the best energy efficiency measures, and low environmental impact without compromising on user comfort. The ultimate goal of LEO Building is to achieve energy savings of more than 50% compared to conventional office buildings in Malaysia.

This building has become the Winner of 2006 ASEAN Energy Award for the New and Existing Energy Efficient Buildings. The design aspects that brought LEO building to the Award are:

i. Passive building design (building orientation, shape, natural ventilation, etc.),
ii. Active design of M&E systems (air-conditioning and lighting), and
iii. Low Energy office equipments

The main focus of this paper falls on LEO Building's passive building design connecting to its facade significance.

3.0 ZERO ENERGY OFFICE (ZEO) BUILDING

The Zero Energy Office (ZEO) Building is the new headquarter for Malaysia Energy Centre. The building consumes very low amount of energy and it is experimental proven that ZEO is 80% more energy efficient than a typical office building. The building energy consumption will become net zero only when the Building Integrated Photovoltaic (BIPV) is attached.

To achieve this, the integrated whole building design approach and systems are being implemented with the following main strategies:-

i. Passive building design (building orientation, shape, natural ventilation, etc.)
ii. Renewable energy supply system (photovoltaic systems)
iii. Active design of M&E systems (air-conditioning and lighting)
iv. Low energy office equipments

Nevertheless, the main focus of this paper falls on ZEO Building's passive building design with its advance facade design such as thermo wall and double low-e glazing in order to maintain the occupants' comfort.

4.0 THE SOLAR STUDY OF FACADE DESIGN

There are various components of space heat gains from internal and external sources. The external heat gains into the building are mainly from the external sources (solar radiation). The external heat gets in the building through the processes of conduction and convection from the building envelopes i.e. wall and windows. Internal sources such as occupants, electric lights and equipments also provide heat inside the building as they are actively operated [2].

A sun path diagram is a plot of the path of the sun across the sky using the sun's elevation in the sky for one axis and the azimuthal position of the sun for the other axis [3]. Figure 1 shows the sun path in Kuala Lumpur which is beneficial to the facade design to maximize daylight used but decrease solar heating load in a building.

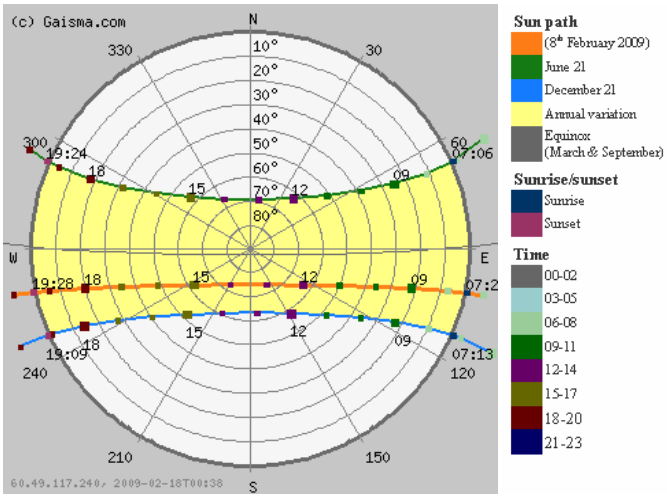

Figure 1: Sun Chart plotted for determining the sun path in Kuala Lumpur for the whole year and also the daily sun path from 7am to 7pm [4].

As solar radiation impinges on the non-shaded window glass, approximately 10% of the radiant heat of clear glass is reflected back outdoors, part of it (5-50%, depending on composition & thickness of glass) is absorbed by the glass and the remainder is transmitted directly indoors [2].

Figure 2 shows the absorption, reflection and transmission of solar radiation in glass.

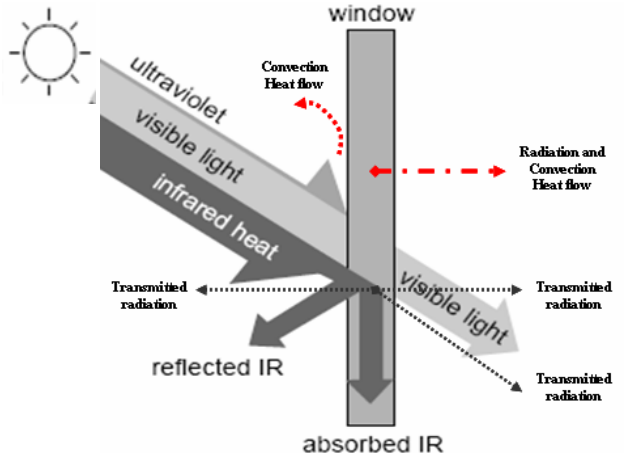

Figure 2: The absorption, reflection and transmission of solar radiation in glass [8].

The Sun provides the daylight in two ways. Part of the sun's energy reaches the earth's surface as direct sunlight. Some of the other part is scattered by the atmosphere and produces the blue sky. This is called as diffused sunlight. The direct sunlight may cause excessive brightness which may contribute to visual discomfort or what we called as glare.

5.0 PASSIVE DESIGN STRATEGIES FOR FACADE

i. A building design should firstly understand how climate response can influence its facade performance. Tropical climate buildings would require a facade that able to keep the building cool however the cold countries would prefer to keep the building warm.
ii. Besides the climate, the site condition and landscape are also important design factors. The facade may be warmed up by the hot air through convection. Green roof, green wall and water features may lower down the surrounding air temperature and provide higher moisture in the air. Trees are also good shading devices to protect glazing from direct sunlight, and lower the indoor air temperature [9].
iii. A building shape, form and orientation may determine the receipt of solar radiation. It was found that a spherical building consumes lesser energy. In Malaysia, east and west facing windows are getting direct absorption of heat into the building. Thus, most building windows are facing north or south.
iv. Office buildings are major glazed facade building. In Malaysia, the work stations shall be located along the building perimeter to encourage the full use of daylight and good views. The secondary function rooms shall be located at the core of the building.
v. Insulated material is essential to act as a barrier from heat transferring in and out from the building. There are few commonly available insulating materials in Malaysia:
    - Aerated Concrete
    - Mineral Wool
    - Low-e double glazing
vi. The recommended maximum window to wall ratios for Malaysian buildings are always high for south & north facades but lower for east & west facade [9].
vii. The shading devices are preventing direct sunlight for good visual and thermal comfort. Punch hole window with light shelves is best in shading direct radiation, and also bounces natural light deeper into building interiors. The adjustable louvers with shading fins are widely used at most of the office building windows [9].
viii. Designing the facade with more openings between two building blocks, big opening at facade, ample size and number of windows and sufficient ventilation louvers may assist in cross-ventilation.
ix. Windows may influence occupant thermal comfort by heat gain or heat loss through the glass, which either raises or lowers the room air temperature, and by radiation exchange between occupant and the glass and other surroundings.
x. The application of glass facade can influence the charm of a building through the exterior outlook, high visible for indoor and outdoor views and good visual comfort

6.0 A COMPARISON CASE STUDY ON FAÇADE DESIGN AND ENERGY PERORMANCE

6.1 Facade passive design strategies

Table 1 compares the passive design features for LEO Building and ZEO Building. It was found that LEO Building is greater in the passive design aspects with its green roof design, internal cooling items and the atrium design for thermal stack effect. All these features are not found in ZEO Building.

However, ZEO Building has a unique design feature which is not found in LEO building i.e. the self-shading facade, which shades against the direct solar radiation into the building.

Figure 3 and figure 4 show both buildings are L-shape on plan with the main facades are facing north and south. Most office areas are designed along the facades to maximise the use of daylight.

Figure 3: The interior space layout of LEO Building shows the office areas are designed along the facades to maximise the use of daylight. It is L-shape on plan with and the main facades are facing north and south.

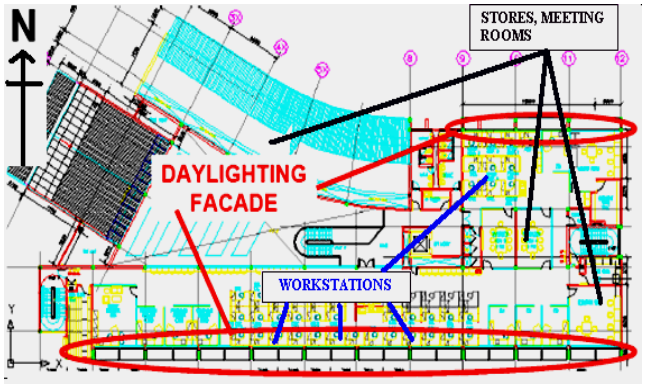

Figure 4: The interior space layout of ZEO building shows the workstations are designed along the facades. The building is also L-shape on plan and the daylighting facades are also facing north and south.

Table 1: The comparison of facade design strategies in LEO Building & ZEO Building.

Design Factors	Ministry of Energy, Water and Communications - LEO	Malaysia Energy Centre - ZEO
Climate Conditions	• Putrajaya: Hot & high humidity • Daily temperature: 27°C - 35°C	• Bangi: Hot & high humidity • Daily temperature: 27°C - 35°C
Site condition	Well planned office complex	Low density area with manufacturing companies & shop lots
Landscape design	Low-rise plants & young trees	Low-rise plants, young trees, negligible water feature
Roof garden	Roof garden exists	No roof garden
Building orientation	Main facades are facing north and south	Main facades are facing north and south
Internal cooling effects	Artificial water wall, interior landscape	Limited low-rise pots plants
Window to wall ratios	Minimum number of windows at east and west facades	Minimum number of windows at east and west facades
Building size	GFA: 38,700m^2 (height: 7-storeys)	GFA: 4,000m^2 (height: 3-storeys)
Building form and shape	• L-shape on plan • Affected by punch hole windows, light shelves & overhangs	• L-shape on plan • Affected by split windows, light shelves & self shading facade
Interior space layout	Perimeter – Workstations Core – secondary function rooms	Perimeter – Workstations Core – secondary function rooms
Natural ventilation	Atrium – thermal stack effect	Atrium – open air concept

6.2 Opaque wall design, material & thermal performances

Table 2 compares the wall energy performances in LEO Building and ZEO Building. The designs of the wall in both of the buildings lead to high reduction in the use of electricity for cooling.

However, .the solar absorption, U-Value, conductivity, internal and external surface temperatures of Thermowall in ZEO building were generally showing more energy efficient results compared to the Aerated Lightweight Concrete Wall in LEO Building.

Table 3 compares the glass energy performances in LEO Building and ZEO Building. The spectrally selective low-e double glazing used in ZEO Building windows is greater compared to the light green tinted tempered glass in LEO building, as its low-e coating is able to reflect majority of the infrared (IR) and ultraviolet (UV) light back to the ambient. The Argon gas layer between the panes decreases the heat transfer activity through conduction and convection.

Table 2: The comparison of thermal performance of wall in LEO Building & ZEO Building.

OPAQUE WALL	MEWC LEO Building 200mm Aerated Lightweight Concrete Wall	PTM ZEO Building 100mm Thermowall
Wall surface area	Large (7-storey high)	Small (3-storey high)
Solar absorption	Low (light brown/ grey & white painted surfaces)	Lower (white and nearly white painted surfaces)
U-Value	0.6 W/m^{2}K	0.56 W/m^{2}K
Conductivity	0.12 W/mK	0.056 W/mK
Internal Surface Temperature	Average: 27.79 °C	Average: 27.02 °C
External Surface Temperature	Average: 34.13 °C	Average: 34.86 °C

Table 3: The comparison of glazing performances in LEO Building & ZEO Building.

BUILDING	MEWC LEO BUILDING	PTM ZEO BUILDING
Type of Glass	12mm Light green tinted tempered glass (Single)	6mm Tempered Coated Low-E Glass + A16 with Argon gas + 4mm Clear Tempered Float Glass
Window to wall ratios	• North & south – High (30-40%) • East – Low (≈ 25%) • West – Lowest (negligible)	• North & south – High (30-40%) • East – Low (≈ 20%) • West – Lowest (negligible)
Window shading systems	• Punch hole windows with light shelves (lower floors) • Exterior louvres (higher floors)	• Split windows with mirror light shelves
Daylight penetration	Punched hole windows and light shelves reflecting some of the light further into the room.	Diffused daylight →mirror light shelves → highly reflected fixed blind (top of split window) → reflective mirror at the ceiling → inside the building for a deeper distance.
Illuminance (Lux)	• Full Daylit area – average 959 lux (without internal shading devices) • Semi Daylit area – average 686 lux (with the aid of artificial lights)	• Full Daylit area 1– average 695 lux (without internal shading devices) • Full Daylit area 2– average 488 lux (with the aid of skylights)
VT (%)	63.1	50.0
SHGC	0.50	0.29
U-Value	5.70 W/m^2/K	1.10 W/m^2/K
Conductivity	0.068 W/mK	0.029 W/mK
Int. surface temperature	Average: 29.7^{o}C	Average: 27.6^{o}C
Ext. surface temperature	Average: 35.8^{o}C	Average: 33.7^{o}C

6.3 Glass facade design, material, lighting effect & thermal performances

The comparison study results on their SHGC, U-Value, conductivity, internal and external surface temperatures also demonstrate greater thermal performance of the spectrally selective low-e double glazing. Besides, the spectrally selective low-e double glazing VT is only 50%. Hence the illuminance readings obtained from ZEO are lower compared to LEO Building, but has achieved the visual comfort for all clerical and office works. However, the illuminance taken for LEO building is higher and not within the visual comfort range for all clerical and office works. Therefore, internal shading devices are always applied in LEO Building.

Figure 5 shows the window shading systems provided in LEO building and ZEO building. The punch hole window with light shelf in LEO Building blocks the direct sunlight and reflects part of the sunlight further into the room. The split window system with mirror light shelf at north and south facades of ZEO Building allow deeper daylight penetration and without glare. The diffused daylight collected at the mirror light shelves will be reflected through the highly reflected fixed blind (top of split window), and blinds reflecting light upwards to the reflective mirror at the ceiling, and subsequently reflects it back into the building for a deeper distance.

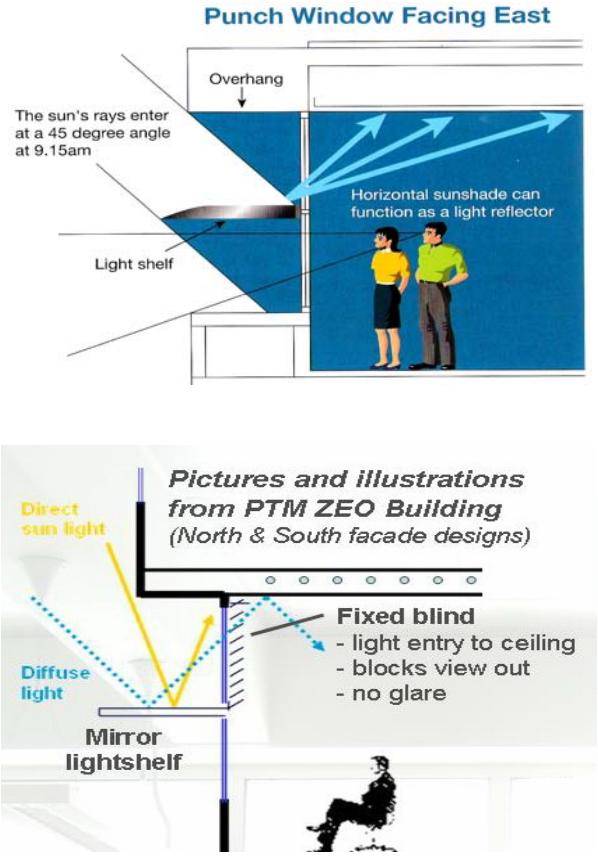

Figure 5: Punch hole windows with light shelf in LEO Building (top) and split window system with mirror light shelf in ZEO Building (bottom).

7.0 COMPARISON SURVEY ON BUILDING INTERIOR COMFORTS & AESTHETIC VALUE

Table 4: The comparison of occupants' viewpoints on the building interior comforts and aesthetic value of the application of glass facade in LEO Building & ZEO Building.

SURVEY QUESTIONS	MEWC LEO BUILDING	PTM ZEO BUILDING
Respondents' sitting position	Majority 49% - east	Majority 60% - south
Importance of glass facade	Majority 76% agree	Majority 80% agree
Reason of glass facade is highly preferred	Maximisation of daylight use - 76% agree	Maximisation of daylight use - 100% agree
Most comfortable factor of sitting nearby the glass facade	Sufficiency of visible daylight - 73% agree	Sufficiency of visible daylight - 100% agree
Improvement of health & productivity	58% agree	52% agree
Lighting condition	▪ 39% preferred combination of both natural daylight & artificial light ▪ 46% are using natural daylight only	• 56% preferred natural daylight only • 64% are using combination of both natural daylight & artificial light
Frequency of internal shading devices are opened	Majority (55%) - seldom	Majority (52%) - always

Daylight quality & visual comfort nearby the glass facade	• 58% – daylight provided is ideal for PC work • 55% – never feel glare from daylight source • 48% – experienced the shadow for all clerical and office works • 39% – experienced insufficient daylight for both paper work and PC work.	• 60% – daylight provided is ideal for PC work • 68% – never feel glare from daylight source • 48% – never experience the shadow for all clerical and office works • 48% – experienced insufficient daylight for paper work
Reason of glass facade is aesthetic	67% – elegant of its transparency & modular system & can observe outdoor view and scenery	68% – elegant of its transparency & modular system
Thermal comfort of sitting nearby glass facade	48% – unbiased (not warm and not cool)	44% – unbiased (not warm and not cool)
Factors affecting thermal comfort	67% – indoor air temperature (air-conditioning temperature)	92% – indoor air temperature (air-conditioning temperature)

Table 4 compares the occupants' perception on the building interior comforts and aesthetic value on the application of glass facade in LEO Building and ZEO Building.

Generally, ZEO Building respondents were more satisfied on the daylight quality in their working place compared to LEO Building respondents, where they preferred to use daylight more than other lighting sources for all clerical and office works. This indicates positive remark for the spectrally selective low-e double glazing, which provides ample daylight without discomfort glares into the building, based on the occupant perceptions.

Most of the LEO Building and ZEO Building respondents did not comment on the thermal condition around the glass facade. However, more respondents from ZEO Building did not feel warm when sitting nearby the glass facade compared to LEO Building respondents.

In addition, more respondents from ZEO Building felt that the indoor air temperature is the main factors that affecting the thermal comfort in their working place. This reveals the spectrally selective low-e double glazing in ZEO Building is better in thermal resistance compared to the light green tinted tempered glass in LEO Building, based on the occupant perceptions.

Most of both buildings' occupant opined that glass facade is aesthetic due to its elegant, high transparency and modular system. However, ZEO Building respondents were slightly more in favour to this factor compared to LEO Building respondents. This reveals the occupants were more satisfied with the building exterior outlook compared to the view from the internal office.

8.0 CONCLUSIONS

Although ZEO Building is more energy efficient on the overall performance compared to LEO Building, however the facade design considerations with natural environment are greater in LEO building. The design features of green roof, internal landscape and the atrium design for thermal stack effect in LEO Building are not found in ZEO building.

Both buildings facade designs have contributed to very little energy consumption by reducing the use of electricity mainly for lighting and cooling. However, the thermowall with rockwool insulation, split window system with spectrally low-e double glazing and mirror light shelves in ZEO building are found to be more advanced compared to the aerated lightweight concrete wall and punch hole window with light shelves in LEO Building.

More respondents in ZEO Building opined that glass facade at their working place is providing high quality daylight, better thermal performance, better thermal comfort and well exterior outlook compared to the respondents in LEO Building.

9.0 ACKNOWLEDGMENT

The authors wish to acknowledge the financial support from the University of Malaya for this research.

ABSTRACT

Green infrastructure in cities is essential for the citizens to improve their health and to develop social, cultural, and commercial interaction. Disabled people, however, are excluded from these opportunities because of their difficulties in surmounting any physical barriers. By providing barrier-free infrastructure for disabled people, the green infrastructure is sustained, as inhabitants may opt for walking, bicycling, and using public transport, while leaving their own motor vehicles at home. To analyze this topic, the author employs the qualitative method with a heuristic orientation that allows the use of personal experience of being impeded by barriers. Casual talks with few disabled people about their personal experience in dealing with barriers, and a thorough review of relevant texts support the analysis. The result reveals that the realization of barrier-free infrastructure will take time to happen, which is attributable to the constraint of economic struggle for survival. But, barrier-free infrastructure will have a significant effect on the sustainability of green infrastructure. In conclusion, the inclusion and exclusion of disabled people regarding the green infrastructure is a question of how well they are accepted by the general public. The degree of mutual public acceptance of different social groups is a yardstick of social sustainability.

Keywords: *disabled people, ambulant disability, barrier-free infrastructure, green infrastructure, universal design*

1. INTRODUCTION

Public urban green spaces hold a vital role in people's lives. Parks, for example, offer green environments that are open to the public, usually without charge. Parks are places where people come for sport, recreation, and social interaction with all kinds of people. Not only does the green scenery engender people's appreciation of nature, but natural green also improves their health. While green infrastructure is so beneficial for all lives on planet earth, it does not completely serve disabled people who have special needs in regard to their limited mobility. A careful observation about the parks in Bandung, the city where the author lives and works, shows that it is unlikely for disabled people to enjoy the green and fresher air of the parks. The hilly parcel of land, the narrow footpath, the uneven surfaces, the dirty benches, and the step(s), are impediments for disabled people. They can hardly walk or wheel their chair in a park. The physical barriers are not only difficult to surmount for personal independent mobility, but also for the carers.

It has been claimed that parks are the lungs of the city. Certainly, this is undeniable, particularly with the high level of pollution in the air that stems from emissions of carbon dioxide from motor vehicles. This is one of the reasons that in Jakarta once a month, environment authorities enforce a "Motor-vehicle-free Day"[1]. The implementation of such a day is quite effective in keeping the level of pollution down. The benefit for the community is the opportunity to walk, jog, bike, play, and just have fun, without disturbances from motor vehicles that produce much commotion. This all aim at leading a healthier life for the citizens, which ultimately reduce the cost of health problems and slow down the energy consumption. In this lifestyle of health and recreation, disabled people are disregarded. They do not have the physical capability to take part in outdoor pleasure. The core of green infrastructure is to recognize the value of nature for the human environment [1], which disabled people are also entitled to delight in.

1.1 The purpose

Against this background and problem, the purpose of the paper seeks how the barrier-free infrastructure sustains green infrastructure. One approach is the "low impact development", which in this paper is defined as barrier-free infrastructure that does not prompt people to damage and pollute the environment. Instead, the barrier-free infrastructure sustains the green and natural environment by motivating citizens to opt for walking, cycling, and using public transportation, while leaving their motor vehicles at home. This is in line with the program of

[1] Translated from *Hari Bebas Kendaraan Bermotor* (*HBKB*)

HBKB which target is to convert private car owners to using public transportation. To achieve this, the built environment ought to be cleared from unnecessary impediments. If builders create such physical environment, disabled people will have the same opportunity as the non-disabled people to lead a more meaningful and healthier life.

2. METHODOLOGY

Data collection for this paper is carried out by employing four forms: text reading, informal talks, careful observation, and personal experience. These four forms are intertwined and each form should not be analyzed of its own. The text is obtained from books, internet, journals, and an unpublished article. Adding to the text are personal talks with some ambulant disabled people who live in Bandung. The talks were done in the past, but they are still valid to be included in this paper, because problems with physical barriers do not change through the passage of time. Personal opinions of being ambulant disabled and the challenges of confronting physical and attitudinal barriers have enriched the analysis and interpretation of this study. Observations about the built environment encompasses the residences of those disabled people; public buildings (banks, hospitals, religious worship places, universities, government offices); public open spaces (streets, sidewalks, parks); and the public transport (mini vans, tricycled pedicabs, motorcycle cabs). Other observations are about the manner disabled people overcome physical barriers. With their physical limitation, they maneuver their way among the obstacles to reach the place they intend to go. These detailed observations are done, because the author of this paper is physically disabled and thus, might claim to have an intimate knowledge of disability issues. Furthermore, she has been studying these issues for over a decade. Social research that uses personal experience is called heuristic, an orientation of the qualitative inquiry.

3. DEFINING DISABILITY

Indonesia holds the premise that a disability is a physical or/ and mental impairment endured by the individual. The impairment is perceived as a 'personal tragedy' with all the oppressions that follow [3]. In Ototake's words "poor darling," which lead parents to become overprotective towards their disabled children. With this negative outlook, these children might develop the thought that a community needs to feel sorry for them [4]. Focusing on the disabled persons, professionals are obliged to facilitate them, so they are able to function better in society.

The provision of accessible environments is thus essential in the lives of disabled people. To be independently mobile is, in fact, a basic human need. Referring to the design of the built environment and independent mobility, there are four categories of disabled people [5]:

a) mobility-impaired: ambulant and non-ambulant (wheelchair user);
b) sensory: visual and hearing impairment;
c) cognitive: mental illness, and developmental or learning disability;
d) multiple: a combination of any or all of the above.

Ambulant disabled people are those who are able to walk, either with or without crutches, walking sticks, braces, or walking frames. The non-ambulant disabled people are the wheelchair users, who are unable to walk and depend solely on a wheelchair for mobility. While all four categories are in need for special designs to participate fully in society, this paper highlights the people with mobility impairment. This category has often been the target of various technological strategies and adaptations [6] to alleviate the difficulties caused by their limited mobility and to give them equal opportunities in integrating into mainstream society.

3.1 The ordinances

Efforts to improve the quality of life of disabled people have been done in Indonesia. In relation to the built environment, the Department of Public Works", through the Directorate of Building and Environment Planning, Directorate General of Housing, has formulated and published Ordinance Number 30/PRT/M/2006 of the Republic of Indonesia about "Technical Guidelines for Facilities and Accessibilities of Buildings and Environments." For the welfare of disabled people, the Department of Social Affairs, through the Bureau of Law, has made the publication of Ordinance Number 43 Year 1998 of the Republic of Indonesia about "Improving the Social Welfare of Disabled People." The application of the ordinances is far from its accomplishment. Most disabled people do not receive government aid and do not get assistive devices or the necessary medical treatment for their mobility. "There are few legal and social pressures to promote a non-discriminatory stance on disability," according to Byrne [7]. An example of this is the Department of Public Works that publicized Decree Number 469/KPTS/1998 of the Republic of Indonesia about "Technical Requirements of Accessibilities for Public Buildings and Environments" in 1998. Eight years on, the 2006 ordinance was made public. After a lapse of eight years, there are no significant changes of the built environment. Another example is the pilot project of Gambir train station in Jakarta. In 2000, authorities equipped the station with standard facilities for disabled people, such as ramps, talking elevators, a special bell for asking help, train schedules in Braille, lowered phone booths for people in wheelchair, special toilets, and a parking space reserved for disabled people [8]. Now, 2009, these standard facilities do not function at all. Inevitably, there must be stricter enforcement of existing rules to provide barrier-free environments.

3.2 The social challenge

Disabled people in general make little or no progress in their lives. The causes are many; it may be problems of economy, social situation, education and employment opportunities, or/ and the lack of volition of the disabled persons. The last point is central in their lives. Everything they do and everything they think is a product of their volition. If they have no strong desire to make progress, not much can be done, for outsiders are only in the capability to provide facilities and to give them support.

The causal link between the country's economic crisis and the minimal services and facilities for disabled people, means that they have to make the best out of their 'personal tragedy' by themselves and their family. Their dependence on others is obvious. As they do not earn a reliable income, family members are responsible for their livelihood. Furthermore, society at large often perceives disabled people as an embarrassment and there is little empathy to encourage them to develop personally. This kind of judgment and stigma affect the lives of disabled people who are not considered valuable members of the community. They remain housebound, uneducated, and unskilled [7]. As no one assists and guides them, they become passive and may think that their impairment is a personal tragedy or is valued as "poor me" [4]. How can this social challenge be overcome? By removing the mental barriers of the people, that is mostly provoked by "sheer unfamiliarity" [4] with disabled people. This may engender the premise that disabled people are different, helpless, and weird. Educating a society, particularly targeting at children, is important. Disability is simply a physical trait of the person, like wearing glasses, being fat/ thin, short/ tall, dark/ light [4]. Instead of thinking that disabled people are different and weird, society ought to accept them as unique individuals.

4. ENVIRONMENTS THAT "DISABLE" PEOPLE

Mobility and accessibility are two inseparable factors that are of great concern for disabled people. The current physical condition of Bandung is nothing but barriers, not only for disabled people, but for all citizens as well. The difference between the two groups, the disabled and the non-disabled people, is that the latter is often not aware of the barriers as they have no difficulties surmounting them. These barriers and hindrances are physical and human-made, and inhibit the easy passage of people. Real examples encompass the:
- sidewalk: narrow and high sidewalks with loosened tiles; busy thoroughfares that are not equipped with standard sidewalks;
- vehicular road: open holes on vehicular roads due to torrential rains and the passing of heavy trucks;
- public transport: public vans that stop suddenly to wait for passengers;
- environment: the dusty air in dry seasons and the muddy streets during monsoons;
- road users: motor-cyclists who drive at excessive speed;
- negligence: absence of fences or barricades at the edge of descent continuous water flow; haphazard construction.

The above examples are not exhaustive, but they give an idea about the disorders that occur on the streets. This is one of the reasons that many citizens choose to use their own private motor vehicles, cars and motorcycles, for their destinations, which of course will add the level of pollution in the air. People on main streets that lack shady trees will find it uncomfortable to walk. Even for short distances, younger people opt for public transport rather than walking through dust or under the scorching weather. In such environments people with mobility problems are less capable to take part in the hustle and bustle of the city. But, on the other hand, the non-disabled people can still enjoy the city's life despite the tumult and barriers.

4.1 Movement on the streets

Streets in Asian cities are "places where people spend most of their lives" [9], an indication that citizens value more outdoors activities than indoor life. On the streets, people endure difficulties to move in a straight line. Pedestrians face impediments in front and underfoot [10] and they have to stay alert to possible harms caused by the different speed of vehicles that maneuver for space. The slow pace of a tricycled pedicab that uses human energy results in the congestion of other vehicles, while the faster speed of motor vehicles scares off pedestrians. The continuous flow of traffic and the quick timing of the red traffic light engender pedestrians to be careless and violate the rules of crossing the street properly. They cross at any time and from any spot they wish, as waiting for the traffic flow to subside is futile. Pedestrians assume drivers to be responsible for their safety. As vehicles literally cover the road, pedestrians have to thread their way between cars and motorcycles [11].

Sidewalks along main roads and thoroughfares are strategic sites for economic activities of low-income and informal traders who hardly leave space for pedestrians. Added to this are the cars and motorbikes parked along the edge of the vehicular street. At dawn, we can find wet markets that occupy half the width of the vehicular road which may continue until late morning. Only when most of the items are sold out do hawkers and vendors vacate the space, leaving behind a huge mound of litter. Walking down the street is often a sequence of interruptions and encounters that disrupt smooth passage [9].

In a disabled-unfriendly city like Bandung, there is hardly space for the limited mobility of disabled and elderly people. The middle- and higher-income people have their domestic helpers and private chauffeurs to run

errands for them. While some disabled people strive for independent living, they also appreciate helpers who save them from troubles on the streets. On the streets, people with limited mobility have to nerve themselves to walk along the edge of vehicular roads, of getting on and off the public van, of crossing the street, and of walking on uneven sidewalks. These difficulties are not so much caused physical disability, since everyone on the street is likewise struggling for any form of survival.

5. THE LACK OF STATISTICAL INFORMATION

There are no reliable and updated statistics for the number of disabled people in Indonesia. The World Health Organization (WHO) estimates that ten percent of the population is disabled [8]. Without accurate data, this paper has limitations to analyze completely and convincingly regarding the importance of providing accessible urban infrastructure. Nonetheless, the sound logic of the current design requires such infrastructure indeed. Statistics would support the agreement on the necessity of barrier-free infrastructure, if figures on the following aspects were available, that is the number of: ambulant disabled people, those who live in the city, the level of education, the type of employment, those who work in the formal sector, those who use their private motor vehicle or public transport, and those who live with a family. Such elaborated information may not be available for a long time. This pessimistic view derives from the indication that the entity and need of disabled people are not a preference for the government compared with other social groups. Disabled people have to make their own concerted effort to make progressive changes in their lives without the government's support. Disability is indeed not a crucial topic to be included in the government's priority list, compared with the alleviation of the inhabitants' poverty. As Indonesia is still struggling with the country's economic crisis, services and facilities for disabled people are minimal [7]. However, we cannot disregard the fact that disabled people have their share in making up the plurality of a society. To neglect disabled people means to ignore human potentials. We should bear in mind that to become disabled is not a person's choice and individuals may not want to live with a disability.

6. ANALYZING GREEN INFRASTRUCTURE AND UNIVERSAL DESIGN

Indonesia is well-known for its tropical lush green nature which can be sustained, if only people resist the temptation to transform a large part of the natural environment into "a new shape" [5], called the built environment. The green infrastructure has to be planned in advance, before the transformation of land begins. By doing so, land can be designated appropriately for recreation and doing physical exercise, improving the community's health, and energy savings. For the benefit, of people, green infrastructure in cities "forms a tapestry of open space that serves and guides smart growth" [1]. In cities, parks, trails, green ways and other open spaces serve the human need for social contact. As social beings, we reach maturity through harmony and friction with people surrounding us; the quality of our personality will not fully develop in isolation. In Bandung some parks are filled with citizens who do mainly exercise, like walking, while inhaling the fresh morning air. Communication among them is vital for the development of social, commercial, and cultural interaction; personal contact provides the fundamental part of such links [13]. As they regularly meet and communicate, an active community of morning walkers could be formed. If such is the case, the green infrastructure has achieved its purpose. People with disabilities, however, hardly receive the benefits of this infrastructure, because [12]:
- the design of the green infrastructure are full of physical barriers: footpaths with staircases, width of footpaths does not cater for the need of persons on wheelchair and people with walking sticks;
- the public transport is inaccessible for most ambulant disabled people.

These barriers cause many disabled people prefer staying indoors [12]. An effective solution to the problem of excluding disabled people is to implement the universal design which principle does not discriminate against any potential user of the green infrastructure. The former approach, barrier-free environment, aims at easing the difficulties that disabled people face. It is often referred to as "designing for special needs" [13]. Because green infrastructure is used by various groups of inhabitants, the provision of separate routes for disabled people is unnecessary and socially not acceptable. Universal design, on the other hand, does not attempt to make separate provision for these people, but emphasizes that the design of the built environment provides accessibility and usability for all sectors of the society simultaneously [13].

6.1 Universal design

Universal design means designing buildings and exterior spaces that can be used by all people, regardless of their level of ability or disability. The term "universal design" was coined in 1980 by the late Ronald L. Mace, who founded the Center for Universal Design in North Carolina, USA.

Universal design or inclusive design is not a design style, but an orientation to design that is based on the premises that:
- Disability is not a special condition of a few people;
- If the design works well for disabled people, it works better for everyone;
- Usability and aesthetics are mutually compatible.

The ability to move around comfortably, conveniently, and safely, must be the standard of a well-designed

infrastructure. The provision of such infrastructure will generate low impact development. It will be most likely that people prefer walking to driving a car or riding a motorcycle and this purpose reduces environmental damage and air pollution. As the universal design gives value to all individuals, they enjoy the opportunities and amenities with minimum constraints. It is therefore imperative to create infrastructures for all kinds of people and should not just be provided for the sake of the city planning requirement.

7. CONCLUSION

As a member of the United Nations, Indonesia has heeded the mandate of ESCAP (Economic and Social Commission for Asia and the Pacific) to remove physical barriers [5]. As a response, the government has publicized ordinances, has built ramps on campus of the Department of Public Works, and has conducted national conferences. These actions, however, do not lead to the realization of constructing barrier-free infrastructure in public spaces. One of the causes of this failure is attributable to the constraint of economic struggle for survival. All sorts of economic trade occur on public spaces, such as sidewalks and parks, which are tolerated at the expense of more chaotic traffic and increasing jaywalkers. On the streets, ambulant disabled people are ignored and street users are so immersed in their own struggle, that there is hardly room for unselfish concern. Furthermore, the government has to prioritize the improvement of per capita income, education, employment, health, sanitation and clean water, low cost housing, and land acquisition. Its preoccupation with coping and surviving leaves hardly any resource for the development of equity, social justice, basic human needs, environmental awareness, and welfare. It is not surprising that the needs of disabled people are not a priority in the list of survival concerns [11].

When basic human needs are met, and social justice and equity assured, disabled people can demand barrier-free infrastructure. For now, disabled people should make use of human assistance by asking passers-by for help when they are not able to surmount physical barriers.

7.1 A note on green infrastructure

The inclusion and exclusion of disabled people regarding the green infrastructure is a question of how well they are accepted by the general public. Today, the inhabitants of a city are made up of diverse people, who are often very different from each other. With a low degree of mutual acceptance of using public infrastructure may lead to conflict and in the long run will create an unsustainable society. This does not only apply to disabled people, but also other marginalized social groups, such as ethnic minorities. The degree of mutual public acceptance of different social groups is a yardstick of social sustainability [12].

ABSTRACT

Land use changes reduced the pervious fraction of watershed area. An alternative to solve this problem is introducing concept of Low Impact Development (LID). LID is technology in managing surface runoff starting from its sources (rainfall). This approach is known as off-stream approach. The implementation of LID concept will only be effective if all people who live especially on the upper part of the watershed take part. However, this situation most likely can generate sentiment of unfairness, since the upstream people have to bear the cost of the program, while the beneficiaries are the people who live in the downstream part of the watershed. Implementing new paradigm with 3R principles (reduce, reuse, recycle) will decrease the quantity of solid waste disposed to final disposal site (TPA.) Simultaneously, implementing traffic calming and managing urban transporter is aimed to improve quality of life to resettlement region as urban transport un-regularity. These three activities will ask people to contribute to achieve the program aim to improve the environment in Depok.. A research with respondent survey method is intended to know people participation in these programs. The research result is a recommendation to decision makers in developing implementation policies regarding solid waste management, rainwater management, and also urban transportation management in the City of Depok. In water resource management research, people agree that they are also responsible to contribute to flood disaster mitigation, even though they realize that they gain no direct benefit from such program. In case of solid waste management, the result of a research shows that people are willing to participate within solid waste management with 3R principles. The results of transportation management research show that respondents are agree that "the road hump" as speed limit marker.

Keywords

water resources, solid waste, urban transportation, Low Impact Development, 3R, road hump

**) Funded by Competitive Based Program (Program Hibah Kompetisi B) Directorate General of Higher Education, Department of National Education, 2008*

1. INTRODUCTION

Kecamatan Sukmajaya, in the year 2006 has population density around 6,600 per square kilometer, and it is starting to face environmental problems for example in managing its water resources, solid waste and also urban transportation.

In the year 2006 Department of Civil Engineering FTUI was successful in competing for B-Program grant launched by the Directorate General of Higher Education. The B-Program Competitive Grant (*PHK-B: Program Hibah Kompetisi B*) last from 2007 up to 2009. The program proposed to perform "*green infrastructure by design*" research and community outreach focusing in the field of: integrated solid waste management, water resources management and also urban transportation management. The aim of the program is promoting improvement of Kecamatan Sukmajaya environment with "*green design*" concept.

Parallel with increasing population growth of Sukmajaya, number of solid waste is also increasing, and now become major problem for city of Sukmajaya. For example, solid wastes are in many places such as in a river bank makes the river contaminated. Others are limited of solid waste infrastructure; human resources and budget are making it worse for solid waste management. Lastly, solid waste collecting services has limited coverage, accumulated solid

waste increased and no more land available for final disposal (TPA) are crucial points to develop solid waste management for city of Depok

Implementing new paradigm such as 3R (reduce, reuse, recycle) principles and optimization solid waste treatment in every *kelurahan* with building solid waste plant unit (*Unit Pengolahan Sampah = UPS*), will decrease the quantity of solid waste disposed to TPA and also reduced solid waste infrastructure. Join activities has been made between University of Indonesia (UI) and Division of Clean and Environment, Local Government of Depok to implement program of 3R and empowered people in this program. Program faced difficulties such as people lacked of knowledge how to live healthy and how to activate 3R, and also people refuse local government program to build UPS in several locations.

Land use changes reduced the pervious fraction of watershed area. An alternative to solve this problem is introducing concept of Low Impact Development (LID). LID is technology in managing surface runoff starting from its sources (rainfall). This approach is known as off-stream approach. The implementation of LID concept will only be effective if all people who live especially on the upper part of the watershed take part. However, this situation most likely can generate sentiment of unfairness, since the upstream people have to bear the cost of the program, while the beneficiaries are the people who live in the downstream part of the watershed.

To encourage the upstream people to implement the LID program, a compensation scheme should be developed. The compensation is based on the implemented LID facilities. The implementation scale is grouped into three categories namely: individual (household), communal and region. The compensation rate is based on the budget needed for construction, and operation & maintenance of the facilities for each scale. The form of compensation at individual (household) scale is numerous, namely: design and technical specification for operation & maintenance of facilities, construction material (or in-cash), construction workers (or in-cash), turn-key project, land compensation (in-cash or tax deduction).

Relates to transportation aspect, the unsustainable infrastructure development is reflected in the high level of traffic jam, air pollution, and of road accident. In Indonesia, the condition of urban environment is getting worse because of the public transportation operational pattern.

Two research programs have been conducted:

1. Developing of traffic calming is for making a liveable street and socialization improvement in neighborhoods.
2. Rationalization of public transport to improve urban public transport quality.

Key success of those three programs depends on the level of people participation in running those programs. Therefore a research of people participation in form of people willingness to support those programs should be conducted.

Study on water resources management is aimed: (1) to know the willingness of people to participate in flood disaster mitigation and their responsibility; (2) to know the preference of upstream people relating to the compensation form in order to optimize the result; (3) to decide people, characteristic of compensation preferred by upstream based on its implementation scale.

The water resources management research was conducted in *Kecamatan* Sukmajaya covering *Kelurahan* Sukmajaya, Abadijaya, and Mekarjaya. Target respondents were community member as benefeceries.

The aims of study of integrated domestic waste management are (1) to know people willingness to participate in domestic waste management with 3R concept; (2) to be familiar with participation form of people within domestic waste management with 3R concept.

The study of integrated domestic waste management is implemented at in *Kecamatan* Sukmajaya covering *Kelurahan* Kalibaru, Abadijaya and Mekarjaya. Target respondents were community member as benefeceries

The research result is a recommendation to decision makers in developing implementation policies regarding rainwater management, solid waste management, and also urban transportation management in the City of Depok.

2. METHODS

2.1 Integrated Domestic Waste Management Based On 3R Principle.

Respondent's questioners for domestic waste management survey are arranged in orderly fashion from recommendation of integrated domestic waste management model. The questioners are divide into 3 parts consist of (1) questions which intend to see community participation level in domestic waste management; (2) questions which intend to see form of community participation in domestic waste management; (3) questions which intend to see community recompense for services of domestic waste management. All questions cover:

- Willingness to separate domestic waste which materials can be recycled.
- Willingness to accomplish organic domestic waste treatment turn into compost.
- Form of community contribution on domestic waste management implementation with 3R basis.
- Form of domestic waste management organization with 3R basis.
- Willingness to separate domestic waste and sell it to collector
- Willingness to pay domestic waste management retribution.

The result were analyzed with descriptive approach with discussing quantitative and qualitative data to figure out research synthesis

2.2 Water Resources Management

Respondent survey method was conducted using a set of questionnaire as instrument. The control variables employed were economics and education. The inquiry covering:

- *Willingness to participate in flood disaster mitigation*

- *Willingness to implement LID concept based on land and financial availability*
- *Acceptance to implement LID concept in relation to the responsibility in flood mitigation and its benefits resulted from LID implementation*
- *Preference form of compensation for implementing LID concept*
- *Respondent identities in relation to their motivation to implement LID concept at individual (household), communal, and region scales.*

Individual respondents were categorized based on their land ownership. 100 of respondents were divided into 3 categories:

- *Category I is respondents with land ownership < 90 m2.*
- *Category II is respondents with land ownership > 90 m2 up to < 150 m2.*
- *Category III is respondents with land ownership > 90 m2.*

The survey result was processed using Frequency Distribution and Cross Tabulation methods. Frequency Distribution was aimed to figure out the number of responses for each question, and Cross Tabulation was aimed to know interrelation among responses. The analysis and synthesis of research result were conducted using descriptive approach based on quantitative and qualitative data.

2.3 Urban Transportation Management

Transportation strategies require changes in public attitudes and behavior. The more a particular scheme is supported by the groups affected, the more likely will the implementation of the scheme be successful. There is also of strong evidence that local support will also possible to provide additional tangible and intangible benefits e.g. additional financial support in particular for maintaining the scheme and improving quality of the neighborhood and therefore will increase housing values and quality of life. For these reasons a series of meeting were carried out to the resident in *Kecamatan* Sukmajaya.

3. RESULT AND DISCUSSION

3.1. Integrated Domestic Waste Management Based On 3R Principle

Division of Clean and Environment, Local Government of Depok has their strategies with new paradigm year 2008 recently. Their strategies consist of:

1. Implementing new paradigm with 3R principles (reduce, reuse, and recycle) and people empowerment in this program
2. Performing most favorable of domestic waste at TPA at each sub-district with construct domestic waste treatment unit (UPS)
3. Executing to lessen domestic waste at TPA with undertakes domestic waste management at first in UPS will be built.
4. Improving people empowerment to undertake domestic compost
5. Preparing and implementing Local Government Decree regarding clean management in accordance to Decree No. 18 Year 2008 on Domestic Waste Management.

Division of Clean and Environment is facing problems where people have no ability to understand clean life style and implementation of 3R. Limited of infrastructure, human resources and financing are other problems faced by government and these situation must have more pay attention. Other, people refuse government program to build UPS. All repudiate can cause building UPS are behind schedule, therefore target of building UPS can not be accomplished

The survey results were analyzed covers:

a. People participation level within domestic waste management.

- People willingness to accomplish domestic waste separation develops into several parts that can be recycled.
- People willingness to treat organic domestic waste to develop into compost

b. Form of people participation within domestic waste management

- Contribution Form can be achieved within domestic waste management implementation based on 3R principles.
- People keen to split domestic waste and sell it to collector.

c. Willingness to pay in Domestic Waste Management

- Organization for Domestic waste manager based on 3R principles
- Willingness to pay domestic waste retribution

a. People participation level within domestic waste management

- *Willingness to separate domestic waste turn into small parts and it can be recycled.*

The survey result shows that people willingness to participate within domestic waste separation consist of 42% respondent throw domestic waste including several parts can be recycled, and other, 57% respondent has already separated material can be recycled which this material can be sold (14%), reuse almost 7% and give material to people who needed (36%). Basically, 91% respondents have knowledge that domestic waste must be separated before they pitch it, but only 24% respondents carry out material separation for recycle purpose. Based on question of respondent willingness to participate in integrated domestic waste management with 3R basis, almost 85% respondent willing and able to participate in this program, only 9% respondents said no to participate and 6% respondent no answers.

Other question such as how people willing to separate material turn into recycle process, number of respondent answer this question was 71% said yes, and the rest said no. The result of survey showed that people can be empowered in domestic waste management with 3R principles. Recently, people had already split domestic waste to become organic and an-organic domestic waste, even though they don't really understand the purpose of domestic waste separation. For that reason, government officer have

to clarify and disseminate domestic waste management with 3R principles means and also to introduce the economic value of domestic waste has been separated.

- *Willingness to treat organic domestic waste turn into compost*

In this moment, some people had already treated their own domestic waste to develop into compost. Conducting organic domestic waste to become compost is only 11% respondent performed it, converted into livestock food is 3% respondent give this answer, and filing it is almost 86% respondents answered this question. In addition, number of respondents which is agree to treat their domestic waste turn into compost in their house is 59% respondents, and respondent who is disagreed is only 2%.

Based on the study area, most people deny making compost because of they have not land. The other reason is that they have little information and knowledge to make compost right, no odor, benefit for them and compost has big value.

b. People Participation Form Within Domestic Waste Management

- *People Participation Form*

People have a choice to contribute during domestic waste management program with 3R basis such as make a payment (31%), clean up domestic waste in their environment (29%), carry their own domestic waste to generation point (15%), or split their own domestic waste into 2 parts i.e. organic material and an-organic material (13%), and split organic material which is a form of their contribution (9%). In brief, pay and clean domestic waste in their environment is the greater choices among them. For that reason, it should be figure out another their contribution form to carry on domestic waste management program, and people obtain to recognize it.

- *Willingness to split domestic waste and sell it to collector*

Respondent response to question of what should they do after splitting their domestic waste, the answer are they will give the product after splitting to collector (39%), sell it to scavenger-collector (28%), sell it to collector (28%) and no answer (2%).. From respondents who is agree to sell recycled material to collector and get money, 39% respondents are in agreement that the money should be save in RT/RW for gathering needs, the other said that the money should be a payment for domestic waste manager. From the result of survey shows that people concur to that recycled material is sold it to scavenger or collector and the money is utilized to pay domestic waste management services and/or for gathering needs.

c. Willingness to Pay for Domestic Waste Management

- *Form of organization for domestic waste management with 3R basis.*

Respondents propose domestic waste management organization in RT/RW region are a new form of free organization (85%), other disagree (14%) and no answer (1%). Therefore, a proposed form of organization is to have board of RT/RW or board of Head of Sub-district to become a member of that organization (32%), voluntary (23%), and *Pemuda Karang Taruna* as a member of organization board (13%).

The result of survey showed that people agreed that domestic waste management organization in their neighborhood should be formed and work independently with head of *RT/RW* or *kelurahan* as prime mover and also a member o organization board

- *Willingness to pay for domestic waste management retribution.*

People generally recognize that to manage domestic waste needs money, which is showed from answer of respondents (91%), other they are not familiar with (3%) and no answer (6%). People who pay for their retribution, almost 87% respondents disburse routinely for domestic waste management services, and the rest are not. The number of 50% respondents pay the bill of domestic waste management services less than Rp. 10.000,- and 24% respondents pay approximately Rp. 10.000,- up to Rp. 20.000,-.

For people who do not disburse for domestic waste management services, they do not get a billing payment or notice to pay (35%), other respondents (24%) felt unsatisfied with its services, and 12% respondents have no money to pay, and also about 12% respondents had different reasons.

People really understand and realize that domestic waste management needs money that means they will get a good services and the consequences they have to pay. The bill for domestic waste management services is varied depend on type of services, for that reason this payment should be made standard. This means people willing to pay based on its services they get and the management of domestic waste can work their jobs with sufficient budget available. Furthermore, the local government officers have assignment to socialize a number of payments for domestic waste management services per month to their people.

3.2 Water Resources Management

The analysis and synthesis of survey result covers:

a. Community responsibility concerning flood disaster mitigation

b. Community willingness to participate individually

- *Willingness to participate in form of devoted land and financial contribution*
- *Individual preference of compensation form*

c. Community willingness to participate communally

- *Willingness to participate in form of financial contribution*
- *Communal preference of compensation form*

a. **Community Responsibility Concerning Flood Disaster Mitigation**

87% of respondents are aware that flood disaster mitigation is everybody responsibility. They are also aware that not only the downstream people are responsible for the flooding in the downstream area. The upstream people committed to contribute to conservation effort through their contribution in form of land and financial commitment, although they realized that direct benefit will go to the downstream people.

The form of preferred compensation for their active participation in flood mitigation were: 67% of respondents wanted a reward system such as improvement of public services, 16% wanted tax deduction, and 14% wanted increasing their land valuation.
For respondents who do not want to participate in the program, an intensive socialization program should be conducted in order to develop their awareness, that the flood disaster mitigation needs a holistic approach, which needs participation (also) from upstream people, who occupy the recharge area.

b. **Community Willingness to Participate Individually**

• *Willingness to participate in form of devoted land and financial contribution*

The willingness to participate in form of devoted land depends on the availability of excess on their land parcels. That is why the category III respondents (76%) are dominantly ready to devote their land for implementing LID program. In general more than 50% of all categories respondents are committed to participate. They are aware that they should not convert the whole parcel area into impervious cover, since rainwater can only infiltrate into the ground through pervious area. In most cases the reason for objection is unavailability of excess land (89.7%), and the rest criticize, that individual initiatives will not be effective.
The willingness to participate in form of financial contribution depends on their income per month. It is understandable that only 29% of category I respondents willing to participate, since 67.6% of them have income less than Rp. 4,000,000.-. Even the category III respondents only 55% are ready to contribute. The objection mostly due to no extra budget (63%); it should be bear by the government (35%); extra money will be used for other purposes (20%).

• *Individual preference of compensation form*

Preference of respondents is dominated by turn-key-project, since most of them are government officials or private employees, who do not have enough time to supervise the construction.

People Participation	Category I	Category II	Category III
Land and Financial	• Const. Material • Design & Technical Specification • Const. Workers • Turn Key Project	• Turn Key Project	• Design & Technical Specification • Const. Material • Const. Workers • Turn Key Project
Land	• Turn Key Project	• Turn Key Project	• Design & Technical Specification • Const. Material • Const. Workers • Turn Key Project
Financial	• Turn Key Project	• Turn Key Project	• Design & Technical Specification • Const. Material • Const. Workers • Turn Key Project

c**. Community willingness to Participate Communally**

• *Willingness to participate in form of financial contribution*

Willingness to participate communally in form of financial contribution for construction conservation facilities is high. Only 3% are refusing to participate. This high level of participatory is a good starting point to emerge a social capital or strength social bounding in the community system. In fact, it means those community has capability to support development and improvement of social capital.
Collective financial contribution is preferred, since this is more affordable.

• *Communal preference of compensation form*

The form of preferred compensation is reward system. It means, government should improve their services capacity and pay more attention to the community needs.

3. 3 Urban Transportation Management

Speed is a significant factor in accidents. A safer speed for built up areas is not more than 20 km/h and no aggressive acceleration or stop and go movements occurs by the traffic. The quality of life can be affected by growing volumes of traffic and traffic traveling at inappropriate speeds. One way to solve the problem is by introduce traffic calming. Various instruments for traffic calming and the most important are road humps for reducing travel speed of vehicles.
A series of meeting were carried out to the resident in *Kecamatan* Sukmajaya. Basically support depends on their personal conditions. For example, residents in the more affluent area are prefer totally ban of through traffic or “rat run” and not interest whatever of traffic calming benefits. They do not bother the fact that street network in Depok is limited. On the other hand people living in less affluent area are enthusiastic with the concept of traffic calming.
Issues of who are the publics are important understood. Basically there are three groups can be represented (IHT, 1997):
1. Those who are users of transport services and networks, by any mode of transport ;
2. Those who are affected by the scheme in the area concerned; and
3. Those who provide transport infrastructure or operate the transport services.

In the case the second sub group is the target of public involving because traffic calming is more area concerned rather than transport services users. Consultation leaflets and questionnaires were carried out by the team and the results are follows:
1. Residents in the concerned areas agreed that the existing road humps are not properly design. Instead of to protect the neighborhood, the actual conditions, the road becomes dangerous to the traffic in particular to motorcycles and deteriorates the road structure because the road humps are blocking the drainage channels.
2. Residents also agreed that motorcycle riders are the most concern of why residents installed road humps. Because there no local government guidelines and involvement, the road humps are not properly designed.

3. Residents are hoping that local government will adopts UI's design and through the regulation becomes the formal guidelines for installing road humps as a part of traffic calming programs
4. As a result, traffic calming program must be formally binding as a local act (*Peraturan Daerah*) and the guidelines must be adopted as a part of the regulation.

4. CONCLUSION

4.1 Integrated Domestic Waste Management Based On 3R Principle

(1) People recognize that domestic waste that parts can be recycled should be separated before going to final generation point. People also willing to participate implementing 3R principle at sources point when integrated domestic waste management based on 3R put into practice. To enforce people understanding on 3R principle and its advantage, hence government should do an elucidation on integrated domestic waste management based on 3R and also introducing economic value comes from domestic waste separation. From socialization program of 3R principle and other programs that implemented by government of Depok city therefore those programs will support reducing domestic waste in final generation point and promote to do domestic waste preparation at treatment plant unit (UPS).
(2) Recently, several people in community had already recycled organic domestic waste turn into compost. On the other hand, many people do not agree making compost at their place, because there is not land available and also they do not know the advantages and economic value of compost. For that reason, government should made identification which region is appropriate to produce compost and provide more information on using compost for their interests. In addition, there is no possibility to make compost at domestic waste sources, then build UPS will be imposed at that region.
(3) Community is agreed that they have to form a self standing unit of domestic waste management organization and the member and board come from RT/RW organization.
(4) People recognized that they have to pay domestic waste collecting services. The billing payment for its service is varied depends on type of services. Therefore, it should be made a standard of billing payment equal to its service, and the management of domestic waste work properly because the finance is always available. To enforce community willing to pay domestic waste services, government should decide the number of payment correctly.

4.2. Water Resources Management

(1) People realize that flood disaster mitigation is responsibility of all stakeholders. This can be seen when upstream people build conservation facilities as part of flood disaster mitigation in down-stream region.
(2) Community willingness to participate individually is shown in form of devoted land and financial contribution. Based on land ownership category (category I < 90 m2; category II > 90 up to < 150 ; and category III > 150 m2) it can be concluded that: In general more than 50% of all categories respondents are committed to participate. They are aware that they should not convert the whole parcel area into impervious cover. In most cases the reason for objection is unavailability of excess land (89.7%). Only 29% of category I respondents willing to participate, since 67.6% of them have income less than Rp. 4,000,000.-.
(3) Preference of respondents is dominated by turn-key-project.
(4) Willingness to participate communally in form of financial contribution for construction conservation facilities is higher than individual participation. Only 3% are refusing to participate. This high level participatory is a good starting point to emerge a social capital or strength social bounding in the community system. Collective financial contribution is preferred, since this is more affordable.
(5) Communal preference of compensation form is reward system.

4.3 Urban Transportation Management

(1) Residents in the concerned areas agreed that the existing road humps are not properly design and that motorcycle riders are the most concern of why residents installed road humps. The road humps are not built properly designed, since there is no local government guidelines and involvement
(2) Traffic calming program must be formally binding as a local act (*Peraturan Daerah*) and the guidelines must be adopted as a part of the regulation.

ABSTRACT

The length of toll road in China so fantastic, there are currently 53,600 km of toll road traversing the country – the second longest in the world behind the United States, which has 89,000 km. And China plans to have 85,000 km of toll road by 2020.
Meanwhile, in East Asia including Indonesia, Malaysia, Philippines, and Thailand, in 2006 there were respectively 608 km, 2,332 km, 181 km, and 176 km.
In this paper wants to see the relationship of length of toll road to population as independent variable and foreign direct investment (FDI), Toll road investment, land area, gross domestic product (GDP) as dependent variable.
The method of this study use econometric analysis on pooled data.
The result of this study will see how China and Malaysia maintain their toll road investment to sustain their GDP, and how the length of toll road growth in Indonesia, Philippines, and Thailand lower than China or Malaysia.

Keywords
Example:
toll road, econometric analysis, pooled data.

1. INTRODUCTION

Analysis at this paper will use panel data or pooled data as estimation method to compare the relationship of inter-residue and to identify and measure effects that are simply not detectable in pure cross-section or pure time-series data [1]. The case of this paper is toll road infrastructure as an equation of residue structure. Basically, this estimation is General Least Square (GLS) as an equation of system. Pooled data or panel data analysis at this paper considered to be equation system with certain residual covariant matrix structure.

1.1. Population and Sample

Population in this research is: firstly, equation model of toll road length ratio as population of country and toll road length. Second, FDI ratio as toll road investment and land area. Third, GDP in a country. And sample of countries are China, Indonesia, Malaysia, Filipina, and Thailand. Totally sample are 50,starts the year 1996 until 2006.

1.2. Sources of Data

The countries that applied in this research are China, Indonesia, Malaysia, Filipina, and Thailand for toll road length, population, Foreign Direct Investment (FDI), toll road investment, and GDP, start began 1996 until 2006.
Data collected by using pooled data, where time-series and cross-section data was merged so that number of observations to become number of years is multiplied with number of states. Data type applied is secondary data where: a) length of toll road in China (CCB International , China Toll Road, China and Hong Kong Equity Research, and Chinadaily [3], Indonesia [4], Malaysia [5], Philippines [6], [7], [8], Thailand [9]; b) Population [10], [11], [12], and [13]; (c) FDI [14]; d) Toll Road Investment [15]; e) Land Area [16]; f) GDP [17]. Data can be seen on Table 1.

1.3. Econometric Model

1.3.1. General Structure Model

Model Structure in general is given as follows:
$lnrtoll_{it} = \alpha_1 + \beta_{i1} lnrfdi_{it} + \beta_{i2} lngdp_{it} + \varepsilon_{it}$

where:
$lnrtoll_t$ *:* ratio between turnpike lengths with population
$lnrfdi_t$ *:* ratio between multiplications between FDI (million dollars) with invesment of turnpike (million dollars) divided soil; land;ground wide (square km)
$lngdp_t$*:* GDP (million dollar)
α_1 = intercept, β_1 *until* β_k = slope, ε_{it} = stochastic disturbance term and i = number of individuals. Pays attention to that α and β varies for all individual. This model indicates that parameter α and β varies. Successively in part of this will be studied:
1). Model Structure I (called as also common model / common) what indicates that all effect from variable in each same individual (uniform) so that we are not akam sees effect from individual, hence model becomes:
$lnrtoll_{it} = \alpha_1 + \beta_1 lnrfdi_{it} + \beta_2 lngdp_t + \varepsilon_{it}$
2) Model Structure III / V that is economical indicates that effect from variable in each individual differs in. Model structure who applied is for following:
$lnrtoll_{it} = \alpha_1 + \beta_{i1} lnrfdi_{it} + \beta_{i2} lngdp_t + \varepsilon_{it}$
Pays attention to that α and β varies for all individual.
Where structure Model III applies solution is using heterokedastic condition without existence of correlation between units (GLS) while Structure Model V applies solution is using heterokedastic condition with existence of correlation between units (SUR).
3). Model Structure IV where effect from every unique variable is specified according to assumption of its(the economics. If we assume that effect from same lnrfdi to all states while effect from lngdp differs in to all states.

Workmanship procedure at Eviews applies pooled data:

2. ESTIMATION WITH STRUCTURE COVARIAN

2.1. Structure Common (Model I)

To finalize econometric model like this there are some methods as according to assumption condition of this V structure that is condition A) homokedastic, B) heterokedastic structure, C) autocorrelation structure, D) structural existence of correlation between error term. This condition will be explained one by one at part following.

2.1.1.Homocedastic Structure

Solution of this model can apply GLS or OLS. Estimation with OLS has been studied at Estimation random coefficient. Estimates for this Model structure can be done either at object pool or object system.

Way of pooled data called as procedure at pool data where:

- Dependent of Variable : lnrtoll?
- Sample : 1996 2006
- Common Coefficient : lnrfdi? lngdp? Shows coefficient? same for every individual
- Specific Coefficient :
- Intercept : common, shows intercept ? 1 differs in every individual.
- Weighting: No Weights shows applied [by] method OLS with assumption Homokedastik.

2.1.2. *Object System* (OLS)

Specification of at object system is written:

LNRTOLL_CH = C(1) + C(2)*LNRFDI_CH + C(3)*LNGDP_CH

LNRTOLL_IND = C(1) + C(2)*LNRFDI_IND + C(3)*LNGDP_IND

LNRTOLL_MSIA = C(1) + C(2)*LNRFDI_MSIA + C(3)*LNGDP_MSIA

LNRTOLL_PH = C(1) + C(2)*LNRFDI_PH + C(3)*LNGDP_PH

LNRTOLL_TH = C(1) + C(2)*LNRFDI_TH + C(3)*LNGDP_TH

- Estimation methods : ordinary Least Square
- Iteration Control : Iterate Coefficient to convergence
- Sample : 1996 2006

2.1.3. Heterokedastic Structure and There Is No Cross Sectional Correlation

For solving of GLS/WLS, eviews memeberikan facility with weighting: bawah weights with iterate to

convergence, where ? 21 anticipated by doing iteration so that is gotten value ? which most efficient.

2.1.3.1. *Object Pool* (GLS/WLS : *Cross Sectional Weight*)

Estimator WLS/GLS with procedure pool applies Weighting : cross sectional weight shows applied [by] method GLS with assumption Heterokedastik.
If it is applied White Heteroskedasticity-Consistent Standard Errors & Covariance, happened at errors standard.
Result Of Estimation:
Estimator WLS/GLS and iterate to convergence gives result of estimation as follows:
Measurement of errors standard based on e'e/(nT). We will differentiate result of this with result of regression with other method hereunder.

2.1.3.2. *Object System* (GLS/WLS)

For estimator GLS/WLS, procedure at object system done as:

- **Estimation methods** : *Weighted Least Square*
- **Iteration Control**: *Iterate Coefficient to convergence*

For estimator GLS/WLS with iteration, procedure at object system done as:

- **Estimation methods** : *Weighted Least Square*
- **Iteration Control**: *Simultaneous Updating*

Both giving the same estimation with above pool object. Difference happened at Standard Error.

2.1.4. Heterokedastic Structure and There Are Cross Sectional Correlation (SUR)

Much the same to with heterokedastic model which has been studied, main difference with model before all is that there is correlation at errors between equations . Means diagonal OFF filled by bilinear covariant is not null.

Solution of estimation can apply good of feasible generalized least square (FGLS) and also maximum likelihood estimator (MLE)
Eviews provides this structure choice Pooled Estimator with procedure SUR, while at System Estimation with procedure estimation methods SUR.
Other solution by using FGLS is obtained by doing estimation beforehand at ? 2i, where Maximum likelihood estimator is generalized least square. Estimation with method FGLS, eviews applies procedure SUR and estimation with method maximum likelihood estimator (MLE), eviws applies procedure SUR with iteration. Procedure workmanship at Eviews can apply two procedures that is pooled data or apply system equation.
2.1.4.1. Object Pool (SUR /FGLS) dan MLE
Estimator SUR with procedure pool applies weighting : SUR shows method GLS with assumption Heterokedastik with existence of correlation between units.
Way of pooled data conceived of procedure at pool data where:

- Dependent Variable *: lnrtoll?*
- Sample : *1996 2006*
- Common Coefficient : *lnrfdi? lngdp? Menunjukkan coefficient β* sama untuk setiap individu
- Cross Section Specific Coefficient :
- Intercept : *common*, menunjukkan intercept α1 berbeda untuk setiap individu.
- Weighting : *SUR*
- Iteration Control:

Estimator SUR with iteration (MLE) with procedure pool applies Weighting: SUR and Iterate Coefficient to convergence.

- Dependent Variable : *lnrtoll?*
- Sample : *1996 2006*
- Common Coefficient : *lnrfdi? lngdp? Menunjukkan coefficient β* sama untuk setiap individu
- Cross Section Specific Coefficient :
- Intercept : *common*, menunjukkan intercept α1 berbeda untuk setiap individu.
- Weighting : *SUR*
- Iteration Control: *Iterate to convergence*

Result Of Estimation without White Heteroskedasticity-Consisntent Standard Errors & Convergence as follows:

Measurement of errors standard based on e'e/(nT). We will differentiate result of this with result of regression with other method hereunder.
2.1.4.2. Object System (SUR(FGLS) dan MLE)
For estimator FGLS (SUR), procedure at object system done as:

- Estimation methods : *SUR*
- Iteration Control : *Iteration Coefficient to convergence*

Persamaan:
LNRTOLL_CH = C(1) + C(2)*LNRFDI_CH + C(3)*LNGDP_CH

LNRTOLL_IND = C(1) + C(2)*LNRFDI_IND + C(3)*LNGDP_IND
LNRTOLL_MSIA = C(1) + C(2)*LNRFDI_MSIA + C(3)*LNGDP_MSIA

LNRTOLL_PH = C(1) + C(2)*LNRFDI_PH + C(3)*LNGDP_PH

LNRTOLL_TH = C(1) + C(2)*LNRFDI_TH + C(3)*LNGDP_TH
Result Of Estimation:
For estimator MLE, procedure at object system done as:

- Estimation methods : *SUR*
- Iteration Control : *Simultaneous Updating*

2.1. Random Structure (Model III/V)

As explained to be above, Structure III/V that is economical indicates that effect from variable in each individual differs in. Model structure who applied is as follows:

$lnrtoll_{it} = \alpha_1 + \beta_{i1}\, lnrfdi_{it} + \beta_{i2}\, lngdp_{it} + \varepsilon_{it}$
Pays attention to that ? and ? varies for all individual. Estimates for this Struktur Model can be done at object pool and object system. In procedure at object pool is:
Way of pooled data conceived of procedure at pool data where:

- Dependent Variable : *lnrtoll?*
- Sample : *1996 2006*
- Common Coefficient :
- Cross Section Specific Coefficient : *lnrfdi? lngdp? Menunjukkan coefficient β* sama untuk setiap individu
- Intercept : *Fixed*, menunjukkan intercept α1 berbeda untuk setiap individu.
- Weighting : *(choose)*
  - No Weighting if using method GLS with homokedastic assumption.
  - Bawah weight if using method GLS (heterokedastic without existence of correlation between units). In classification of model as Model III
  - SUR if using method GLS (heterokedastic with existence of correlation between units). In classification of Model as Model V.
- Iteration Control: (select;chooses)
  - Without iteration control if using not to apply method MLE
  - Iterate Coefficient to convergence if using not to apply method MLE

Way of system conceived of procedure System where specification at object system is written:
LNRTOLL_CH = C(11) + C(12)*LNRFDI_CH + C(13)*LNGDP_CH

LNRTOLL_IND = C(21) + C(22)*LNRFDI_IND + C(23)*LNGDP_IND

LNRTOLL_MSIA = C(31) + C(32)*LNRFDI_MSIA + C(33)*LNGDP_MSIA

LNRTOLL_PH = C(41) + C(42)*LNRFDI_PH + C(43)*LNGDP_PH

LNRTOLL_TH = C(51) + C(52)*LNRFDI_TH + C(53)*LNGDP_TH

- Estimation methods: (select;chooses)
  - OLS juka menggunkan method OLS with homokedastic assumption
  - WLS bawah weights if using method GLS (heterokedastic without existence of correlation between units). In classification of model as Model III
  - SUR if using method GLS (heterokedastic with existence of correlation between units). In classification of model as Model V
- Iteration Control : (select;chooses)
  - Iterate Coefficient to convergence: if using not to apply method MLE
  - Simulation Updating: if using applies method MLE

2.1.2.1. Estimation MLE

Here made as Model V, where it is assumed that economic model has relationship (correlation) residue between banks (individual), so that at procedure pool we apply way following:

- Specific Coefficient: lnrfdi? lngdp? Shows coefficient ? differs in every individual

- Intercept: Fixed, shows intercept ? 1 differs in every individual

- Weighting :
  - SUR if using method GLS (heterokedastic with existence of correlation between units)
- **Iteration Control:**
  - Simultaneous Updating if using applies method MLE

Result Of Estimation is as follows:
While at procedure system we apply procedure:

- Estimation methods:
  - SUR if using method GLS (heterokedastic with correlation between units)

- Iteration Control:
  - Simultaneous Updating: If using applies method MLE

Result Of Estimation is as follows:

2.1.5. Random Structure (Model IV)

2.1.5.1. Estimation SUR/FGLS

At Model Structure IV-A, we assume that effect from lnrfdi differs in to turnpike length ratio while effect from same lngdp to turnpike length ratio.

Model is assumed [by] there is relationship (correlation) between individuals (SUR). Model structure who applied is as follows:

$$lnrtoll_{it} = \alpha_1 + \beta_1 lnrfdi_{it} + \beta_{i2} lngdp_{it} + \varepsilon_{it}$$

Note: ? permanent 1 for all individual and ? 3 varies for semuaindividu. Estimated for this Model structure can only be done at object system.

Way of system conceived of procedure System where at object system is written:

LNRTOLL_CH = C(11) + C(12)*LNRFDI_CH + C(13)*LNGDP_CH

LNRTOLL_IND = C(21) + C(22)*LNRFDI_IND + C(13)*LNGDP_IND

LNRTOLL_MSIA = C(31) + C(32)*LNRFDI_MSIA + C(13)*LNGDP_MSIA

LNRTOLL_PH = C(41) + C(42)*LNRFDI_PH + C(13)*LNGDP_PH

LNRTOLL_TH = C(51) + C(52)*LNRFDI_TH + C(13)*LNGDP_TH

Note: Pays attention to that permanent lngdp parameter for all individual

- **Estimation methods:**
  - SUR if using metodeGLS (heterokedastic with existence of correlation between units) In classification of model as Model V
- **Iteration Cotrol:**
  - Iterate Coefficient to convergence: if using not to apply method MLE

Test Statistic	Value	df	Probability
Chi-square	41536.70	4	0.0000

Null Hypothesis Summary:

Normalized Restriction (= 0)	Value	Std. Err.
C(13) - C(53)	-5.530420	0.216005
C(23) - C(53)	-8.901487	0.253040
C(33) - C(53)	-7.039943	0.302901
C(43) - C(53)	-8.235944	0.214723

Restrictions are linear in coefficients.

Result of Estimation is as follows:

3. Determination of Model

3.1. Choosing A Model IV-A and V

In determining model who is better is done [by] examination with testing in the large Wald at equation of system (system equation) Formulation of hypothesizing is as follows:

$H_0 : \beta_{2CH} = \beta_{2IND} = \ldots = \beta_{2TH}$: is model IV-a with MLE
H_1 : not H_0 : is model V with MLE
Note: we can only differentiate to model with the same bilinear covariant structure. Here we take example that there are correlation of residue between individuals (

SUR) with estimator MLE. By paying attention to above hypothesizing formula, model restriksi is model IV-A and model restriksi do not be model V.

Way of system conceived of procedure System where specification at object system is written:

LNRTOLL_CH = C(11) + C(12)*LNRFDI_CH + C(13)*LNGDP_CH

LNRTOLL_IND = C(21) + C(22)*LNRFDI_IND + C(23)*LNGDP_IND

LNRTOLL_MSIA = C(31) + C(32)*LNRFDI_MSIA + C(33)*LNGDP_MSIA

LNRTOLL_PH = C(41) + C(42)*LNRFDI_PH + C(43)*LNGDP_PH

LNRTOLL_TH = C(51) + C(52)*LNRFDI_TH + C(53)*LNGDP_TH

Initial step, we are estimation beforehand model structure which more unrestriksi (Model V), then we are restriksi at test wald:

C(13)=C(23)=C(33)=C(43)=C(53)
Got result:

Wald Test:
System: SYST_MDL3_SUR1

Showing above examination is rejection H_0 : $\beta_{2CH} = \beta_{2IND} = \ldots = \beta_{2TH}$: that is model IV-A dg MLE. So model who is better is model where effect GDP is not uniform to lnrtoll from every state (individual).

3.1.2. **Choosing A Model II and V**

At this examination , we test better which model to explain variable dependen that is model by assuming existence of idividu V (individual effect α differs in and variable effect β is same) with model without existence of individual effect (individual effect ? differs in and variable effect ? differs in), Model V. Examination here is done with testing in the large Wald at equation of system (system equation).

Hypothesizing formula is as follows:

$H_0 : \beta_{1CH} = \beta_{1IND} = \ldots = \beta_{1TH}$

$\beta_{2CH} = \beta_{2IND} = \ldots = \beta_{2TH}$
: that is model IV-A dg MLE

H1 : non H0 : that is model V with MLE

Wald Test:
System: SYST_MDL3_SUR1

Test Statistic	Value	df	Probability
Chi-square	633074.8	8	0.0000

Null Hypothesis Summary:

Normalized Restriction (= 0)	Value	Std. Err.
C(12) - C(52)	-0.406834	0.013409
C(22) - C(52)	-0.084310	0.025852
C(32) - C(52)	-0.201638	0.066396
C(42) - C(52)	-0.128286	0.022314
C(13) - C(53)	-5.530420	0.216005
C(23) - C(53)	-8.901487	0.253040
C(33) - C(53)	-7.039943	0.302901
C(43) - C(53)	-8.235944	0.214723

Restrictions are linear in coefficients.

Note: we can only differentiate to model with the same bilinear covariant structure. Here we take example that there are correlation of residue between individuals (SUR) with estimator MLE. By paying attention to above hypothesizing formula, model restriksi is model II and model restriksi do not be model V.

Way of system conceived of procedure System where specification at object system is written:

LNRTOLL_CH = C(11) + C(12)*LNRFDI_CH + C(13)*LNGDP_CH

LNRTOLL_IND = C(21) + C(22)*LNRFDI_IND + C(23)*LNGDP_IND

LNRTOLL_MSIA = C(31) + C(32)*LNRFDI_MSIA + C(33)*LNGDP_MSIA

LNRTOLL_PH = C(41) + C(42)*LNRFDI_PH + C(43)*LNGDP_PH

LNRTOLL_TH = C(51) + C(52)*LNRFDI_TH + C(53)*LNGDP_TH

Initial step, we are estimation beforehand model structure which more unrestriksi (Model V) then we are restriksi at test wald:

c(12)=c(22)=c(32)=c(42)=c(52),
c(13)=c(23)=c(33)=c(43)=c(53)
Got result:

Showing above examination is rejection H_0 : $\beta_{1CH} = \beta_{1IND} = \ldots = \beta_{1TH}$: that is model II dg MLE. So model who is better is model where effect of all variables is not uniform to lnrtoll from every state (individual).

3.1.3. **Choosing A Model II and I**

Kitapun can do examination of model between common, that is model where effect from all same variables to dependent variable of all individuals and there is no fixed effect (Model I) with model existence of individual effect (Model II). Examination here is done with testing in the large Wald at equation of system (system equation). Hypothesizing formula is as follows:

H_0 : $\alpha_{CH} = \alpha_{IND} = \ldots = \alpha_{TH,}$: yaitu model I (common) dengan GLS
H1 : $\alpha_{CH} \neq \alpha_{IND} \neq \ldots \neq \alpha_{TH,}$: yaitu model II (fixed efect) dengan GLS
Note: we can only differentiate to model with the same bilinear covariant structure. Here we take example that there are correlation of residue between individuals (SUR) without estimator MLE. By paying attention to above hypothesizing formula, model restriksi is model I and model restriksi do not be Model II. In examination of this Wald, usage of procedure pool cannot be done. For the purpose is applied procedure system.

Initial step, we are estimation beforehand model structure which more unrestriksi (Model II).

Specification of model is:

LNRTOLL_CH = C(11) + C(2)*LNRFDI_CH + C(3)*LNGDP_CH

LNRTOLL_IND = C(21) + C(2)*LNRFDI_IND + C(3)*LNGDP_IND

LNRTOLL_MSIA = C(31) + C(2)*LNRFDI_MSIA + C(3)*LNGDP_MSIA

LNRTOLL_PH = C(41) + C(2)*LNRFDI_PH + C(3)*LNGDP_PH

LNRTOLL_TH = C(51) + C(2)*LNRFDI_TH + C(3)*LNGDP_TH

And the graph of that model can be seen on Figure 1.

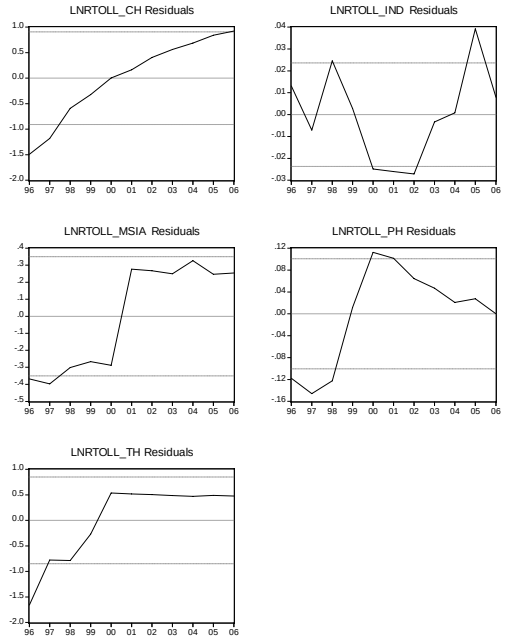

Figure 1. Model II and V

Test Wald as follows:
C(11)=C(21)=C(31)=C(41)=C(51)

Showing above examination is rejection H_0 : $\alpha_{CH} = \alpha_{IND} = \ldots = \alpha_{TH}$: that is model I (common). So model who is better is model where effect of all variables is not uniform to lnrtoll from every state (individual).

4. CONCLUSION

Model who is better is Model V with MLE
Specification Of Model:

LNRTOLL_CH = C(11) + C(12)*LNRFDI_CH + C(13)*LNGDP_CH
LNRTOLL_IND = C(21) + C(22)*LNRFDI_IND + C(23)*LNGDP_IND
LNRTOLL_MSIA = C(31) + C(32)*LNRFDI_MSIA + C(33)*LNGDP_MSIA
LNRTOLL_PH = C(41) + C(42)*LNRFDI_PH + C(43)*LNGDP_PH
LNRTOLL_TH = C(51) + C(52)*LNRFDI_TH + C(53)*LNGDP_TH

And the graph of that model can be seen on Figure 2.

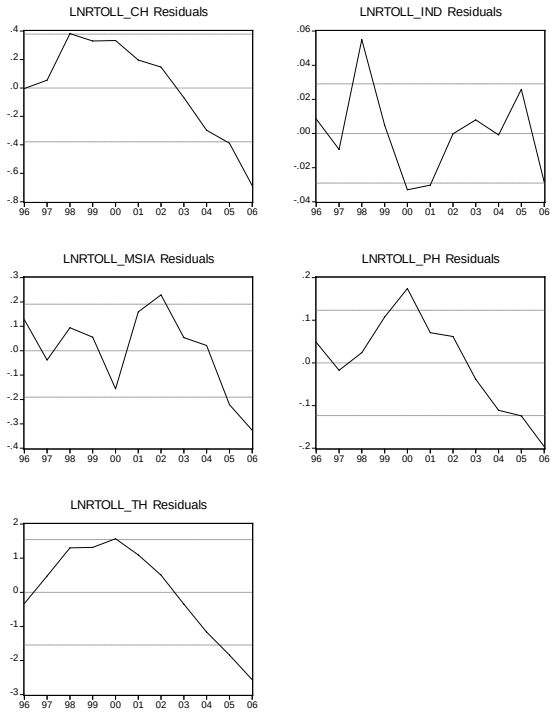

Figure 2. Model V with MLE

ABSTRACT

Supiori was appearing as new regency on west side of Biak Island in Papua Province, Eastern of Indonesia. As a new autonomic administrative area Supiori Regency has some vision, mission, objectives, and goals, to improve the community live in all sectors by development programs. This is a unique point to be discussed, because before legitimated as one autonomic regency separated from Biak Numfor regency, the area of Supiori is dominated by conservation forest area. The first activity to reach this regency vision is arrange the area land use planning which still keep the boundary of conservation forest area. So this is interesting problem to arrange the development planning to increase the quality of community live in all sectors and at the same time the green area which covered by the law as the conservation forest must be kept at it boundary lines. After area land use planning arranged and reviewed, the second step must be arranged as a derivation of it, is transportation system planning. In the fact Supiori regency has only limited transportation infrastructure, with low quantity of dimension and low quality of structure. This study will explore the quantitative and qualitative aspects of transport planning analysis of Supiori regency in Biak Island. Data collecting is done in January, 2009 including land use planning review, traffic and existing transport infrastructure investigation, and social economics data. The data is got from the site as primary data and also from local government office in the form of statistical printed data and also maps as secondary data. For quantitative analysis of planning this study use the most known model of Four Step Transport Planning Model, especially the three steps including Trip Generation, Trip Distribution and Modal Split. The models were derived in form of mathematical model which can be processed in numerical data and output with use computer. Trip generation was estimated from population and number of household data, and trip distribution calibrated with use primary traffic data which transform to be prior origin-destination matrix and distance matrix which transform to be cost matrix with negative exponential function, processed with gravity model and multi regression calibration to determine cost function parameter. The result using the model is quantity estimating of person and freight movement demand in Supiori Regency area in the form of future origin destination matrix which describes the movement from zone to zone inside this regency. From estimating results the transport planning and future program policy in transportation for this regency was stated. The resume of this are: port infrastructure, road and bridges and terminals planning for connecting each districts and separated little islands. All of these infrastructures prepared and controlled to be kept out of forest conservation area.

Keywords: *conservation forest boundary, new regency development, person and movement estimation model, transport planning, future policy program*

1. INTRODUCTION

The development planning of Supiori Regency transportation network is derived from land use planning and policy, which arranged with basic principle of development as follows:

- **Hierarchies**
  Transportation network is develop with consider the hierarchies of a nodes as acitivity centers which is already stated in land use planning. This can be told that transportation network must be planned in order to make work or estabish the nodes hierarchies stated in land use planning.
  In this case system base of analisys must be held as the principle of qualitative and quantitative analysis process. Systemic relationship must be viewed both between transportation network and land use, also between nodes inside transportation network it self.

ISSN 114-1284

- **Geography**

  The geographical basic principle mean that transportation network system development determination factor of shape, configuration, quantity and quality of network systems to be develope. Several aspects of these principles are: morphology, hydrology, natural disaster, and conservation forest.

- **Economy**

  The economy basic principle issues a declaration that transportation system arrangement for one region must consider the economic system behaviour of it. This economic system behaviour will be key factor of the role and function of transportation network inside region system that being developed.

  For the region with progressive economic system the role and function of transportation network is to supply the demand of peoples and freights movements derived from progressive economic activity, this agree with the philosopy as well known as " ships follow the trade". But for developing region the role and function of taransportation network accidentally is to generate the economy progress of the region. And for most new regency region, this role of transportation network is, of course, more appropriate, especially according with the acceleration of East Indonesia development.

  But in this case the carefully attention must be held in the transportation planning, because of many regions are play the role as the conservation area, and have the important tropical forest as the part of pneumonia of the earth. This role is very important for the sustainability of it region development and for whole people in the world whose live now even next generation that will be born. [1]

- **To Support The Region Development**

  The basic principle of region development issue the declaration that the arrangement of transportation network must take attention and support to the development of the region according with the concept and development planning of region space and it land use. With refer to Regency's RTRW (Indonesian: Recana Tata Ruang Wilayah, that mean is Regional Land Use Planning), the transportation network development will more clear, optimal and harmonic with the direction of future it regency land use and activity. The purpose of transportation network development planning is not allowed to make opposite with space and land use planning, and also it regency's economic characteristic. It must be in one must be consider geographical capacity limit. Geographical capacity limit act the role as

  coordinating view, legality, and also integrated with future ecological sustainability thinking. [2][3][4][5]

2. TRANSPORTATION SYSTEM PLANNING OF SUPIORI REGENCY

According to bacis principles above, the first and important step of transportation planning for Supiori Regency is to identify and state center points of regional planning. The analysis done for determine hierarchy pattern of activity system of those center points and derive it to identify support patern in the shape of transportation system configuration. In determination of activity centers, the main reference is strartegic policy of local government which is already state and legalited.

Due to basic thinking above, there is conclusion as follows:

1. Because of Supiori Regency's administrative area boundary is new transport boundary system which just begin to growth, the estimation of transport demand used the method of scenario.
2. The calculation of travel pattern base on origin-destination zone (according activity center as a center point of zone) inside the region.
3. Transport demand estimation calculated with use four step method. [6]
4. The meanning of transport demand estimation, in this case, is included the direction of above scenarios.

With refer to The RTRW of Supiori Regency that has established in It local government policy, the activity center point which in modelling act as the center point of zone an in model calculation mean as nodes, identify according to following Criterias :

A. Hierarchy of cities system which satated in RTRW
B. Transportation system policy stated in RTRW
C. Distribution of center of district
D. Distribution of recidence centers at recidenced islands outside main island of Supiori (Biak).
E. Already act as existing transportation nodes.

The result of analysis is as shown in Table 1. And the transport system component established in each nodes is identified as shown in Table 2.
Map of Supiori Regency is shown in figure 1.

2.1 Estimated Person Transport Demand of Supiori Regency

Calculation and analysis result from secondary data, which use atraction and production index, is derived numerical estimation of production and atraction of transport demand as described in Table 3. Accelerated with the recent policy that establised Supiori as a new regency, the amount of population increased and growth fast enought, as shown in Table 4. Population growth than adopted as the growth factor for production and atraction of person transport movement, this can be draw the estimating amount of transport demand in next the year of 2014, and 2024, as shown in Table 5 and Table 6, respectively.

This simple estimation give the description that transportation demand in Supiori Regency will be continuous increase in next 20 years until the year of 2024.

2.2 Estimated Freight Transport of Supiori Regency

In this case the estimation of freight movement inside and outside of Supiori Regency is base on daily basic freight demand of population. The standar for this have issued by Ministry of Communication of Republic of Indonesia, as describe in Table 7. From Table 7 can be determine basic consumption demand of population for each district. Freight transport demand estimation calculating result in the form of freight production-atraction for future until the year of 2014, 2019, and 2024, is shown in Table 8, Table 9, Table 10, respectively. Also in these table stated the demand of freight vehicles in according with 12 ton capacity of trucks. The growth of freight transport demand in future will attend to the demand of higher capacity of trucks.

2.3 Transportation Development Program of Supiori Regency

The development program stated for Supiori Regency in order to anticipate it transport demand above is included surface transport and water (sea) transport. For surface transport the main program is develope the new road on west area of Biak Island, in order to make out island link road.
Freight transport growth in another side need to be anticipate, if the estimating amount of freight calculated above is happend in future, of course the exsisting bridges that recent planted in Supiori Regency all must be replaced by steel or concrete bridges, which will stronger enought to use by heavy trucks.
Another program besides surface transport development is port development at Marsram Village, East Supiori Distric. For Air transport the important program is take place in surface transport that is the demand in improving the road to be use from all districts inside Supiori Regency to be arrived in Biak Airport in time, according with flying schedule.
The piers or traditional little port need to be developed at each separated island (Mapia, Aruri, Rani, Befondi, and Sowek) in order to establish an easy communication with main land of Supiori Regency area, or the western side of Biak Island.

3. DISCUSSION

The important think to discuss in this paper is according to the special characteristic of Supiori Regency in case of that this regency is growth from conservation forest. Until the research of this topic held in the field, there is still the strictly rule that must be keep, about the boundary line of conservation forest in Supiori Regency. The discussion is have done too with RTRW planner team, and the commitment is make the development planning of this regency with still keep the boundary of conservation forest. So the future development area of regency capital city of Soriwendari is made in the shape of long line to southest direction, out side and following the shape of conservation forest boundary land.

Some key developments in reaching target audiences are now pinpointed because of their potential importance for the field and for transportation. Then a diverse set of threads, “catalyzing a future,” are identified which show promise for energizing the field of road ecology, as well as noticeably improving both surface transportation and nature on the land around us [7]. The quality targets are the starting point when the desirable long-term state of the existing road network is formulated for important natural and cultural heritage assets [8]. The relation between new road development even can be integrated with more details conservation program [9] [10]. New road projects are not only aimed at alleviating congestion created by the growing population pressures, but are concurrently viewed in relation to the natural landscape. As future roadway alignments are considered, planners and designers are using the environmental landscape as a tool to design sustainable roadway projects in an effort to preserve a healthy interconnected landscape for future generations. [11]

4. CONCLUSSIONS

There are 3 conclusion come from this study, as follows:

1) Transport demand of Supiori Regency is still low.
2) The development of transportation network in Supiori Regency, Biak Island is necessary to anticipate the population and economic growth till meet the optimum equilibrium between population-economic activity-ecology.
3) Out line island ring road development at western of Biak Island, still need to make the back up transportation facilities beside water (sea) transportation that can be used 24 hours per days along the year, and not depend on the seasons. Is this case boat transportation not always available if the sea wave is too high.
4) New link road that across in direction of south-north in the middle of Supiori Regency is not allowable, because this can be destroy the conservation forest. Also in the same time, as have studied from topography data, it is not technically feasible too.

ABSTRACT

Urbanization process, especially population growth and construction development do not proportionally balance with public space provision for accomodate the community activities. This situation will subsequently lead to unsatisfactory condition of urban society. The objectives of this research are to describe various perception of people about the existence of public space available in town and to observe their behavioral pattern in using public area, which is later on able to contribute basic concept for developping the appropriate urban space design and management system. Three samples of public open spaces taken for the study are in Manado, Indonesia. This study focusses firstly on, how the existence of public space can function with the demand and expectation of people in town ; Secondly is, how far, the urban space design available has been able to accommodate all the public expectations. Method used in this research are interview, questionnaire, and behavioral mapping. The research findings, in general, show that there are negatives perceptions and complain concerning the design of public space and amenities. Meanwhile behavioral mapping conclude that some activities are taken in wrong places and some elements of public open spaces are properly unused and inattentive while some other are over capacity.

***Key words** : public openspace, urban space design, human perception, spatial behavior.*

1. INTRODUCTION

Urban regeneration and construction development tend to sacrify urban land areas which are formerly reserved for public facility including urban public openspace. Meanwhile public openspaces play important role for urban life, because it has social and psychological values to support daily activities for inhabitant.

Provision and management of public openspace recently do not reach the main problems yet, especially to give properly response against actual needs of the people who live in urban area.

Carr, 1992, finds that planning and designing public openspace must convey 3 values, those are :
1). Responsive , means it should respond the basic needs of users ; comfort, relaxation, engagement active/passive, and discovery.
2). Democratic , means freely accessible for all the people
3). Meaningful, means having strong relationship between users and its millieu .

Carr also define that good design of public openspace is when there is harmony between physical environment and social dimension, which can stimulate users activities, comfort, and encourage social relation among users.

Rishbeth, 2001, observed and remarked that certain etnisgroups living in the urban area, prefer to make their own public space in the neighbourhood openspace. It conclude that the existence of public openspace in the urban area raised on different perception of the respective users .

Some groups assume that the existence of public open space give positive contributions for their daily living, on the other hand, it often brings anxious, fears and other negative impact. Unpleasant things might happened in it. Furthermore, the relationship between users activities and setting system of an openspace will build specific behavior which are definitely different from one place to another.

2. OBJECTIVES

In general, this research try to expand theory and models of urban design setting in term of urban development and

management based on perceptions and behavior study of urban society as users. Whereas specifically the objectives of the research focused on two issues.
First issue is, to gather some information about human perception concerning openspace available in town and secondly is to develop behavior mapping method by doing Post Occupancy Evaluation (POE) on public openspace in Manado.

Furthermore, the research findings will be useful to develop theory and models of urban development and planning which may contribute to urban development evaluation and policy for Manado and other medium size cities.

Within the most of discussions about architecture, environment and behavior studies, terms of behavior setting was defined in 2 categories, that is system of setting and system of activity. Both are strongly related to compose behavior setting. (Haryadi and Setiawan, 1995). System of setting , also called system of place and space, represents a series of physical elements linked eachother and formed certain relation and can be functioned for certain activities. Meanwhile system of activity figure out a series of human behavior deliberately performed by people individually or in groups.

3. METODOLOGY

Methods used in this reseach are physical observation on the spot by recording the whole elements exist into worksheets, distribution the questionnaires, and interview some visitors. The application of behavioral mapping used place-centered mapping method. Physical observation method try to figure out performance of a place which will define the environmental quality of public space. Meanwhile questionnaires dan interviews with the visitors try to explore public opinion about the existence of the place.
Bevahior mapping is relatively new in urban planning and design approach. Yet, it still limited on several models explored by reseachers, and place-centered mapping is one of favourable model to figure on human behavior using its millieu.

3.1. Reseach Location

Research conducted in Manado, the capital city of North Sulawesi. It is a medium size city with population about 450 inhabitants. Manado is located in the coastal area, at the edge of Manado bay. For the last 10 years, construction development grew rapidly and changes happens in parts of the city.

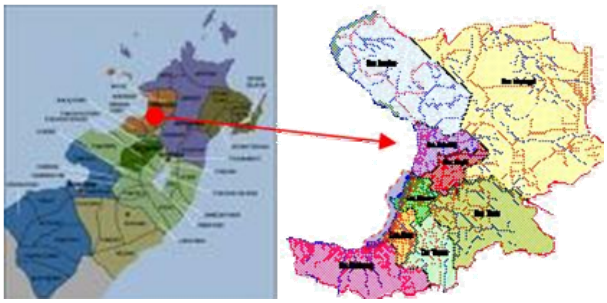

Figure 1 : Map of North Sulawesi & Manado City

3.2. Questionnaires

Substances of the questionnaires classified by :

- Participants personal background
- Various kind of activities and its frequency
- Impression and response about the situation.
- Public opinion concerning the performance.

Questionnaires were distributed proportionally depend on the capacity of 3 different object in Manado. Execution considered the intensity of people who participate and benefit the objects. Number of respondent was assumed 20% capacity of the millieu, so that composition of respondents are different in each objects. Operation took place on office hours and holiday.

3.3 Behavior Mapping

Behavior mapping is built based on the result of observation human activities, during a certain period which produce spatial activities pattern, restricted by some elements in the object.
This study proposed place-centered method from behavior mapping, for exploring which elements in the setting are dominantly give influence and support main activities.
Four steps of mappings are :

1. Prepare a worksheet as basic map by recording all physical elements presumed to stimulate some action in the setting.
2. Making a list of actions and decide the symbols for each activities .
3. In a certain time period, register the whole activities occurs using symbols on the worsheet prepared.
4. Transform whole information in the informative map.

4. FINDINGS AND DISCUSSION

4.1. Description of Research Objects

Research conducted at 3 main objects of public openspace in Manado, the capital city of North Sulawesi. There are Taman Kesatuan Bangsa (TKB), Sparta Tikala, and Bahu Mall. Those 3 public openspaces are the favourite place that people prefer to visit during their free time, mostly on the weekend.

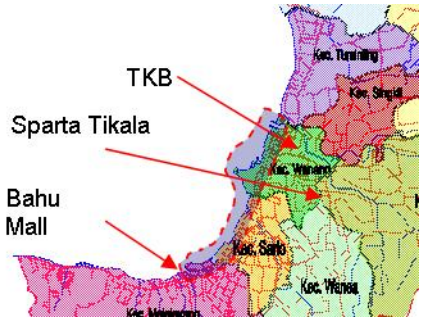

Figure 2 : Locations of Research Objects

a. Taman Kesatuan Bangsa (TKB)

TKB is an old square plaza on the Central Bisiness District area in Manado. Surrounded by commercial building, this square has historical background and become an important place because it has been designed since early period of urban growth. It has been renoved from times to times according to urban redevelopment process.

On the peak hours, this square is intensively occupied. Most of the visitors use the square as a pedestrian way to move from one side to another. Some others used as a resting area. There are some coffee shops on the site available for spending breaktimes. For the last few years , local authority has built an open theatre in the square for making this square more attractive. On the evening hours, the place become so quiet because all the stores adjecent were closed, and no activities around.

Extension of central commercial modern towards the seaside area had slowly removed economic activities and reduced density of this area.

Figure 3 : TKB and it's surroundings

b. Lapangan Spata Tikala

Sparta Tikala is a formal openspace, a small park with grass and trees, created in front of local government official buildings. It has jogging track and benches insides. There are different elements and functions on the site. People use the park for playing or doing some exercises, rendez-vous, ceremony, or other social affairs. Sometimes they use for exhibition and promotion affairs.

During the day, this place is relatively quiet. On the north and south sides, outside the park, there are pedestrian ways with benches and big trees that formed comfortable space for shading.

Although the park has lower density of usage, the existence of place give particular impression for the citizens.

Figure 4 : Lapangan Sparta Tikala

c.Bahu Mall Seaside Area

Another kind of openspace in the city is coastal zones that exist along 20 kms of Manado coastal lines. One of the most successful design for public openspace is Bahu Mall recreation center. People of Manado enjoy much having meal in many circumstances, particularly during recreation time. This social phenomenon lead the authority provides many cafetaria in the recreation center like Bahu Mall seaside area.

Conception of the reclamation area in coastal zones is multifunction area consist of recreation, commercial and sporting facilities. Morning hours, people do some exercises regularly, and during the day, commercial and cafetaria predominant the whole area. In the afternoon, teenagers occupied some interesting spot area just to chat or relaxation. They enjoy the beatiful scenery of the sun goes down to the earth, and it is the best moment in this .

On Sunday morning or holidays, the place is more crowded because some people from the region come to visit the area.

Figure 5 : Bahu Mall seaside area

Table 1
Existing Condition at 3 objects

Situation	TKB (1)	TIKALA (2)	BAHU MAL (3)
Spatial Shapes	Square 74 x 33 m	Trapesium 105 x 93 m	Square 62 x187m
Access	2 entrance gates on east and west sides	Main entrance at the east and west sides.	Main entraces from south dan east sides
Border lines	Fences and trotoir arround and shopping arena in north and westsides	Streets arround with high traffic density	Coastal line in northwest , street and parking area and commercial buildings surrounding.
Dimension of space	2442 m2	9765 m2	11594 m2
Materials used	beton floor with decorative garden	Grass court in the middle, surrounding by pedestrian /beton and decorative garden	Asphalt and ground covered
Height	30 cm from street level	10 - 20 cm from street level	100 - 120 cm from sea level

4. 2 Spatial Behavior of Urban Community

Behavior setting as design approach simply define as interaction between human action and its millieu or surrounding matters. Thus, behavior setting consists a group of people doing some actions or activities, taking place in a particular spaces, spending duration and in the restricted conditions .
Behavior mapping in public openspace could be applied by observing every movement produced periodically and drawing it into a sketch of maps.
The research observed 3 different locations in Manado and conducted at 3 different occasions; early in morning hours (06.00 – 10.00) , at noon (12.00-14.00) , and in the afternoon (16.00-18.00) Those were conducted on working days and holidays.

Table 2
Examples of Behaviour Mapping Process at Taman Kesatuan Bangsa (TKB)

System of Activity	Location : TKB Time :	Behavior Mapping
1.Standing in group and talking		2. Walking/ Passing Through		
3. Sitting, talking, eating		

The result indicates that people used public openspace only for passive activities, and follows setting available. Eventually some elements are ignored and unused like some benches at Tikala, and open theatre at TKB.

Figure 6 : community behavior in openspace of Manado

Urban Community in Manado generally use the openspace available for leisure or doing some exercises in the morning. For particular groups, especially teenagers, the needs of public space is important for social activities or special ocassion like playing and friendship gathering. For new couple, the existence of public openspace is necessary for doing some sport or playing with children and other family.

Obviously, the importance of openspace is to refresh urban air quality, however it has to be taking into account its social aspect for accomodate the needs of expression and education for urban community.

Constructions of behavior mapping on 3 locations as case studies, there are some different pattern in using the place.

Tabel 3
Users activities in Public Openspace

DIFFERENT AGE GROUPS	Spatial Function		
	TKB	SPARTA TIKALA	BAHU MAL
Teenagers (15 – 21)	Walking/ Passing through Sitting/eating	Sitting , talking Excescise/ sport	Walking Sitting. talking Sport /games
Adult (21 – 45)	Walking/Passing through Sitting/take rest Standing/Talking	Sitting, talking Sport activity	Walking Sport Sitting/talking
Elders (>45)	Sitting	Sitting	Sitting Walking

4.3 Openspace Performance

Space performance in architecture, either indoor or outdoor, determined by seveval things. In case of outdoors, it could be designed by provision supporting elements likes trees, sculpture, pond, or benches. All these elements should be well interpreted by individual senses. Exploration about human perception against space performance examines how far the combination elements enable to stimulate the positive feelings of human being.

Community perception about existence of pulic openspace in Manado generate some understanding about the needs and types of openspace suitable for their habitual life. 180 participants have been involved with the interviews and questionnaires. They were grouped on 3 catagories :
teenagers (15 – 19 years old) – 63 participants
adult (20 – 45 years old) – 101 participants
and elders (> 45 years old) - 16 participants
Percerption of openspace is represented by components : Personal interest, spatial impression and importance of spatial equipments.

Table 4 shows that some element of openspace have been perceived differently by each groups.

Table 4
Users Perceptions of 3 locations based on different age groups

Perception Variable	Components	% of each groups		
		(15-19)	(20-45)	(> 45)
Personal Interest	Atmosphere	49	22	44
	Accessibility	21	29	44
	Supporting Facility	27	29	13
Spatial Impression	Temperature	38	43	31
	Cleanliness	33	39	63
	Safety	13	10	0
Importance of equipments	Lights	10	14	13
	Benches	24	12	0
	Public telephone	25	29	13
	Waste disposal	43	27	38
	Shelter	29	42	19

Personal Interest

First group is interested in atmosphere of the object. They think nuance is important things in the object (49 %), and so the third group. They marked that ambience can influence the attractiveness of a place. It shows that teenagers and elders need more atmosphere in the openspace to support their activities outdoors. Furthermore, teenagers need more dynamics, colorful and pleasant space, while the elders prefer peaceful and comfortable place. Second group (20 – 45 years old), in fact, do not even care about the atmosphere as long as they could easily do their activities like sports and playing.
Table 4 also shows that only third groups pay more attention about accesibility (44%). It it obvious that elders have handycap in mobility compared to others.

All respondents perceived that supporting facility of public openspace has no relationship with attractiveness of a public openspace. Therefore, supporting facilities are not the reason why they visit a public openspace.

In such a case, human interest, especially teenagers group against space performance is when the openspace offers ambience which can support their outdoor activity. Whereas the elders prefer openspace completed with atmosphere and good accesibility.

Spatial Impression

. Most of the respondent felt inconvenient being in the objects because it is hot and dirty. Although there are some trees for shading, they do not fucnctioned well to reduce temperature. Local authority has provided some waste disposal box in each corner, but trash and wastepapers are scattered around.

63% of the elders complain that objects are very unclean. It indicates that elders is more concern about cleanliness compare to other groups. In the future, local government should pay more attention concerning shading and cleanliness of parks and squares in town.

4.3.3 Urban Amenities & Equipments

Benches, Shelters, garbage trays, telephone box, light fixtures are some equipment needed for outdoor activities. Their existences will support various activities outdoors .
Most of the teenagers and the elders proposed improvement of waste disposal system of public openspace. While the young couples concern about shading and shelter. (42%)

5. CONCLUSION AND RECOMMENDATION

Spatial behavior of urban community in Manado depends on system of setting available. Limitation of its usage caused by its design of elements. Lacks of shading area caused people could not enjoy the scenery of sunset. Limitation of number and various activities are caused by spatial condition which could not represent the real need of users. Some activities are taken in wrong places like playing on the parking area. Some elements of public open spaces are properly unused and inattentive while some other are over capacity, like pedestrian and paving for doing exercises.

In case of 3 objects observed, spatial design and supporting facilities could influence human behavior in two ways, it means , if design product could be perceived well, there will be positive behavior of users. On the contrary, if it was perceived negatively, there will be negative reaction of users. Spatial quality of public openspace depends on elements offered in respective area. In such cases, 3 object observed have many aspects ignored that generate negative impression from users. Negative impression concerning architectural design is, complain about microclimate and maintainance/ cleanliness.

Application of behavior mapping combined with interview about spatial impression supposed to be representation of real needs of existences of public space in Manado. It should be concidered by designers and policy makers to make a decision for urban change.

Behavior mapping method has been used for building design evaluation, and it is important to expand the application for outdoor facilities, especially for public facilities. Public space design should consider interaction between users and its millieu, so that it will help to stimulate positive behavior of the users.

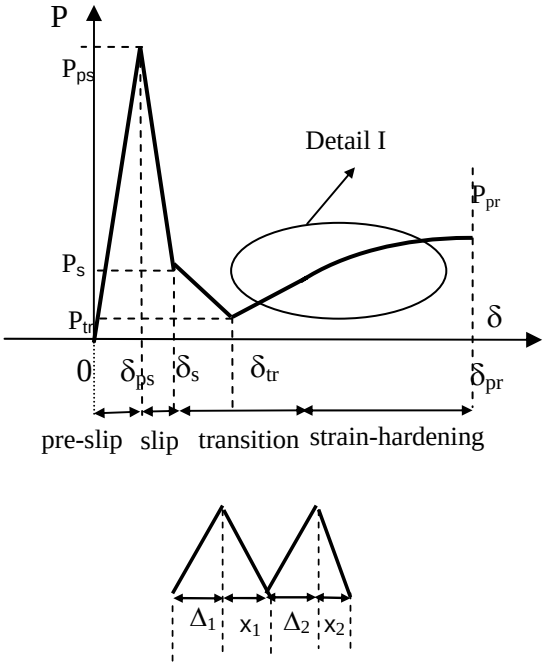
ABSTRACT

Nylon mesh has been proven to give higher ductility for beam compared to unconfined one. This research takes a fracture based approach as failure analysis because fracture mechanics has become a solution to prohibit a catastrophic failure of structure. This research refers to previous experiment data. The data is analyzed further in this paper by analytical method. The experiment method was run by third point flexural test of specimens. The specimens consisted of four concrete beams with dimension of 15x20x600 mm, two beams were confined with nylon mesh and two other beams were unconfined. The concrete beams were designed with compressive strength f'_c about 30 MPa. The analytical method calculates longitudinal and transversal strain and also determines a fracture parameter, it is stable crack length. The research meets conclusions that: (a) transversal strain of confined beams is higher compared to unconfined ones; (b) the deformation of nylon mesh is going to achieve stable crack until it is failure; (c) failure analysis shows that those values of transversal strain of specimens (0.12-0.13) mentioned in Table 1 are laid on stage of transition; and (d) the previous model fit to the experiment results, that the stable crack length achieved for specimens is about 36-40 mm.

Keywords
Failure, nylon, confinement, beam, fracture

1. INTRODUCTION

The confinement takes an important role in improving beam's ductility. Nylon mesh has been proven to give higher ductility for beam compared to unconfined one. Previous research reported by ([1],[2]) noticed that nylon has great value of tension strength and elongation. Nylon also has unique characteristic of 'yield point elongation' which provides optimal stable crack length when it is embedded in cementitious matrix.



Detail I

Figure 1 : Relation of load-displacement of fractured pullout
([1],[2])

Recall [1],[2]. The model of fractured pullout ([1],[2]) is formulated by equation (1) and result a P-δ (load-displacement) curve (Figure 1). The curve consists of 4 (three) stages: (a) Stage of pre-

ISSN 114-1284

slip, (2) Stage of slip, (3) Stage of transition, and (4) Stage of strain-hardening.

$$P_n = \left(r_{\Delta I}\frac{a_1}{a_2}E_{ps}A\right)+\left(r_{\Delta II}\frac{a_1}{a_2}E_sA\right)+\left(r_{\Delta III}\frac{a_1}{a_2}E_{tr}A\right)+\left(r_{\Delta III}\frac{a_1}{a_2}E_{pr}A\right) \quad (1)$$

Where:

P_n = load (N)
A = fiber section area (mm^2)
E_{pr} = modulus of elasticity at stage of strain-hardening (MPa)
E_{ps} = modulus of elasticity at stage of pre-slip (MPa)
E_s = modulus of elasticity at stage of slip (MPa)
E_{tr} = modulus of elasticity at stage of transition (MPa)
a_1 = total displacement of a stage (mm)
a_2 = initial length of specimen or fiber that is specific for every stage (mm)
$r_{\Delta I}$ = ratio of total free-end fiber displacement of free-end at stage of pre-slip
$r_{\Delta II}$ = ratio of total free-end fiber displacement of free-end at stage of slip
$r_{\Delta III}$ = ratio of total free-end fiber displacement of free-end at stage of strain-hardening

The fracture phenomenon happened during pullout process can be explained as follow ([1],[2]). During the stage of pre-slip, the fiber is fully embedded in cementitious matrix, thus the fracture process phenomenon has not already happened yet. After critical matrix stress $\overline{\sigma}_m$ exceeded, a crack is created and the stage of slip and unstable fracture process begin. The normal fracture generated instantaneously and then followed by lateral fracture after the separation of specimen. Hence, the unstable fracture process change into stable fracture process when the stable crack length reached at the end of slip stage or transition stage. The stable fracture process will initiate the stage of strain-hardening with 'jagged' phenomenon. During the stage of strain-hardening, the increase of strain ε will increase the stress σ along the fiber until the fiber gets broken.

The theoretical modeling of fractured pull-out is covering all the phenomenon exists during the experimental test. The phenomenon is captured as fracture phenomenon, hence, the unstable crack will always exist ([1],[2]). This unstable crack will change to be stable crack only if the crack arrester is emerged.

Stable crack length of fractured pullout ([1],[2]) defined as follow.

$$l_2 = \frac{0.5c}{\overline{\varepsilon}} \quad (2)$$

Where:

l_2 = stable crack length (mm)
c = crack width (mm)
$\overline{\varepsilon}$ = critical fiber strain

Transversal strain can be expressed by

$$\varepsilon_{tr} = \frac{(h+\delta)-h}{h} \quad (3)$$

Where:

ε_{tr} = transversal strain
h = height of beam (mm)
δ = deflection of beam (mm)

Longitudinal strain can be expressed by

$$\varepsilon_l = -\kappa\delta \quad (4)$$

Where:

ε_l = longitudinal strain
κ = curvature of beam (mm^{-1})
δ = deflection of beam (mm)

While the curvature of ductility [4] is expressed by equation (5) as follow.

$$\kappa = \frac{1}{\rho} = \frac{M}{EI} \quad (5)$$

Where:

κ = curvature of beam (mm^{-1})
ρ = the radius of curvature at a specific point on elastic curve (mm)
M = internal moment (Nmm)
E = material's modulus of elasticity (MPa)
I = beam's moment of inertia computed about the neutral axis (mm^4)

The mechanism of confining effect [7] can be explained as follow. Transversal reinforcement is lightly stressed at lower compressive stress, hence, the concrete is not influenced by the

reinforcement. When ultimate stress is almost reached, the transversal strain of concrete is rapidly increasing, that is caused by crack propagation. Therefore, concrete will expand and compress the transversal reinforcement. If compressive area is confined by closed transversal reinforcement such as hoops, ties, or spiral reinforcement, then the ductility of beam will be increased very fast. Later, the beam performance is more ductile in ultimate stage.

Several previous researches noticed about the importance of confinement for raising higher performance of beam with various media such as meshes, sheets, jackets, etc, but no research try to use nylon mesh to confine the beams but This research referred to previous experiment data ([3]-[6]). The data is analyzed further in this paper by analytical method. The previous research shows good performance of confined beams with nylon mesh This research referred to previous experiment data ([3]-[6]). The data is analyzed further in this paper by analytical method. Hence, it is interesting to investigate further the failure of nylon mesh as beam confinement by fracture mechanics approach.

The fracture mechanics approach has been implemented in many concrete structure failure analyses ([8]-[22]). According to [21], the problem of strain-softening and strain-hardening is engaged to crack distribution. This crack distribution takes a role as a trigger of structure failure because of the improvement of localized crack to be fracture. The suppression of concrete fracture can be implemented by increasing the toughness and tension ductility [22].

The fracture mechanics analysis is also applied to pull-out problem that is closely tight to bond mechanism and interface characteristic of fiber-cementitious matrix. [23] explains that interface bond becomes a significant factor in improving the performance of fiber cementitious composites. Hence, the behaviour of bond between fiber and cementitious matrix can be characterized by pull-out test. The result of pull-out test is giving descriptions of whole composites, selecting the main ingredient of composites, and predicting the structure failure of composites [24].

This research takes a fracture based approach as failure analysis of unconfined and confined beams of previous research ([3]-[6]). It is necessary to conduct fractured based failure analysis because fracture mechanics has become a solution to prohibit a catastrophic failure of structure. By using fracture mechanics, the design is going to achieve more safety margin for structure and higher economic value as well as structural benefit.

2. METHODS

This research refers to previous experiment data ([3]-[6]). The data is analyzed further in this paper by analytical method. The experiment method of previous research ([3]-[6]) was run by third point flexural test of specimens. The specimens consisted of four concrete beams with dimension of 15x20x600 mm, two beams were confined with nylon mesh and two other beams were unconfined ([3]-[6]). The concrete beams were designed with compressive strength f'_c about 30 MPa. The analytical method calculates longitudinal and transversal strain and also determines a fracture parameter, it is stable crack length.

Nylon mesh dimension ([3]-[6]) described by Figure 2. The confined specimen is described by Figure 3 ([3]-[6]), while the setting of third point flexural test is described by Figure 4 ([6]).

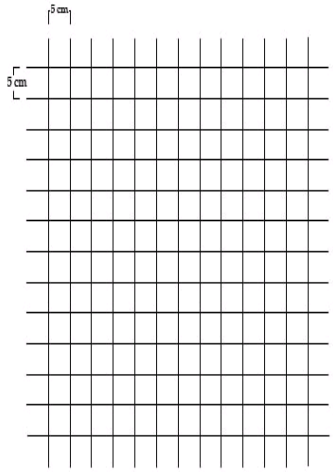


Figure 2 : Dimension of nylon mesh ([3]-[6])

Figure 3 : Specimen with nylon mesh confinement
([3]-[6])

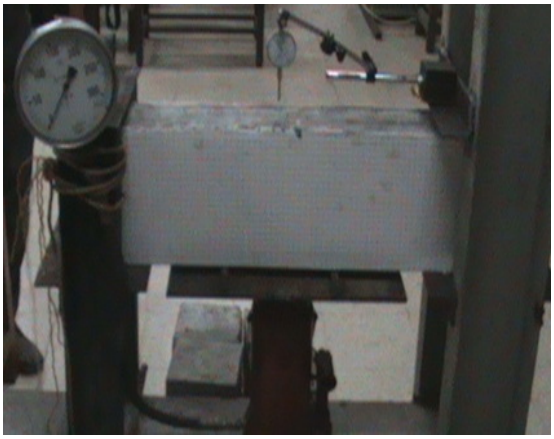

Figure 4 : Third point flexural test setting
([3]-[6])

3. RESULTS AND DISCUSSION

Previous research ([3]-[6]) show (Figure 5) that the ultimate load of confined beams increase about 30-40% (1489,6 N, 1421 N) compared to the unconfined ones while its displacement also increase about 40-70% (24 mm, 26,7 mm). It is proved that the increase of displacement emphasizes that the ductility of beams also increases at ultimate load until beams collapse.

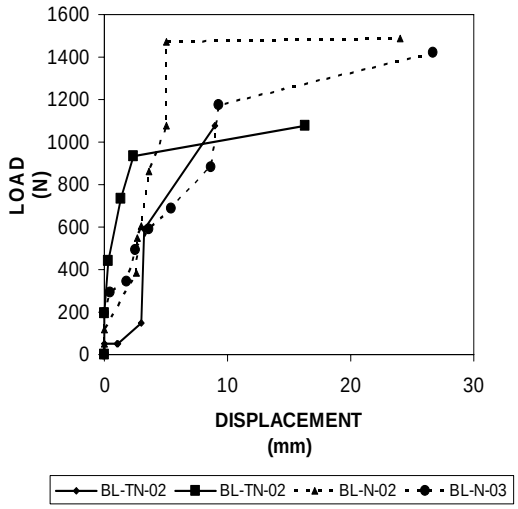

Figure 5 : Load-Displacement Relationship during the Loading History
([3]-[6])

The strain of confined and unconfined beams is shown by Table 1. Table 1 shows that transversal strain of confined beams is higher compared to unconfined ones. Transversal strain for unconfined beams (BL-TN-02 and 03) is about 0.04-0.08, while for confined beams (BL-N-02 and 03) is about 0.12-0.13. Longitudinal strain unconfined beams is about 0.00000042-0.00000077, while for confined beams is about 0.0000015-0.0000016.

Table 1 : Strain of confined and unconfined beams

SPECIMEN CODE	LONGITUDINAL STRAIN	TRANSVERSAL STRAIN
BL-TN-02	-0,0000004275	0,045
BL-TN-03	-0,0000007743	0,0815
BL-N-02	-0,0000015744	0,12
BL-N-03	-0,0000016714	0,1335

Table 2 : Stable crack length of confined beams

SPECIMEN CODE	STABLE CRACK LENGTH (mm)
BL-N-02	41,67
BL-N-03	37,45

According to ([1],[2]), the nylon itself has maximum strain of about 1.1. Stable crack length of confined beams based on Equation 2 is about 37-41 mm and described more clearly in Table 2.

Previous model of ([1],[2]) that is fractured pullout with full embedded nylon fiber l_f = 100 mm (that means it the specimen has 50 mm each part) conveys strain of 0.04966-0.342 for its stage of transition. Hence, failure analysis shows that those values of transversal strain of specimens (0.12-0.13) mentioned in Table 1 are laid on stage of transition. It could be said that whenever transversal strain achieved, stable crack length occured. Stable crack length of previous model is 36.44 mm while the confined beams are about 37-41 mm. Hence, the previous model fit to the experiment results, that the stable crack length achieved is about 36-40 mm.

4. CONCLUSIONS

The research meets conclusions that:

a) transversal strain of confined beams is higher compared to unconfined ones;
b) the deformation of nylon mesh is going to achieve stable crack until it is failure;
c) failure analysis shows that those values of transversal strain of specimens (0.12-0.13) mentioned in Table 1 are laid on stage of transition;
d) the previous model fit to the experiment results, that the stable crack length achieved for specimens is about 36-40 mm.

ABSTRACT

The research purposes to implement fracture based approach in failure analysis of nylon 600 fiber and also partly embedded nylon 600 fiber in cementitious matrix. The methods are experiment and analytical by modeling. The experiment activities consist of tension test of nylon 600 fiber and pullout test of partly embedded nylon 600 fiber in cementitious matrix with length 150 mm and 180 mm. The research meets conclusions: (1) Whenever fracture takes place, it is always an unstable crack; (2) Stable cracks are established by the presence of crack arrester; (3) After the establishment of stable cracks, increasing strain beyond strain ε_1 will not increase stress σ_1, hence do not induce additional fracture; (4) Increasing of strain ε after the establishment of stable cracks in point g will increase stress, the second slip will not take place; (5) Broken nylon fibers have a longer embedded length because of the possibility of crack arrester presence is bigger than the shorter ones; and (6) Since the middle right side of matrix is at the intersection point with fiber acts as crack arrester in the beginning of pull-out process, then the load-displacement (P-δ) and stress-strain (σ–ε) curves of pull-out test will be the same as the load-displacement (P-δ) and stress-strain (σ–ε) curves of fiber tension test.

Fracture, failure, nylon 600, pullout

1. INTRODUCTION

Nylon 600 fiber has great value of tension strength, elongation, tension strength, and also elastic modulus ([1], [2], [11]). The embedded nylon 600 fiber provides optimal stable crack length, and improves strain-hardening property ([1]-[11]). Because of its advantages, nylon 600 is believed to be applied into cementitious matrix to achieve best performace of cementitious matrix or concrete.

A popular approach to fracture problems is fracture mechanics. Fracture mechanics is very important in case of fiber cementitious composites. The improvement of fiber cementitious composites such as FRC, HPRFCC, and ECC seldom implements the fiber application such as nylon, which is categorized as synthetic fiber. It should be noted that fiber takes an important role in determining whole fiber-reinforced cementitious composite (FRC) performance. Previous researches have proved a better performance of ECC using various synthetic fiber surfaces [12], high performance as alike steel performance [13], and even higher compressive stress for irradiated nylon fiber by gamma [14]. The nylon fiber has a special characteristic of multiple constrictions at stretching condition [15] called 'yield point elongation' that has magnitude of 200%-300% of initial fiber length.

According to Bazant [16], the failure of concrete structures should consider the strain-softening related to distributed cracking, localized crack that grows to larger fracture prior to failure, and also bridging stresses at the fracture front. Therefore, the suppression of fracture of concrete can be implemented by improving higher toughness and higher tensile ductility [17]. Hence, the application of nylon 600 fiber into cementitious matrix is proper effort to achieve ductility performance.

It is important to recognize the properties of interfaces between fiber and cementitious matrices by a pull-out test and then takes failure analysis by fracture based approach. The research purposes to implement fracture based approach in

ISSN 114-1284

failure analysis of nylon 600 fiber and also partly embedded nylon 600 fiber in cementitious matrix.

2. METHODS

This research conducts experiment and analytical methods. The experiment activities consist of tension test of nylon 600 fiber and also pull-out test of partly embedded nylon 600 fiber in cementitious matrix. The analytical method conveys pull-out modeling.

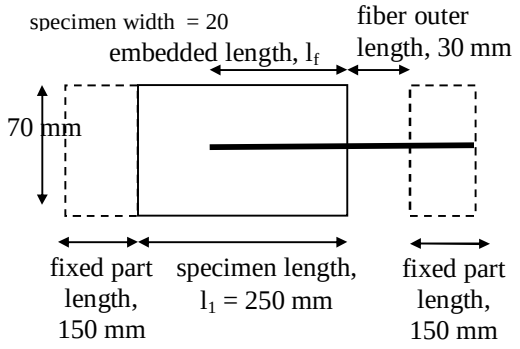

Figure 1: Dimension of specimen

The dimension of specimens is shown by Figure 1 while the setting of pullout test by Figure 3. The pull-out test is provided by computerized Universal Testing Machine "Hung Ta". The nylon 600 fiber is made in Indonesia with 1.1. mm in diameter and embedded length 150 mm and 180 mm for partly fiber embedded specimens. Mix design for cementitious matrix is cement : sand : water ratio of 1:1:0.6. Analytical method applied by modeling and formulation of theoretical model ([1], [2], [11]). The analytical models are built based on experiment result.

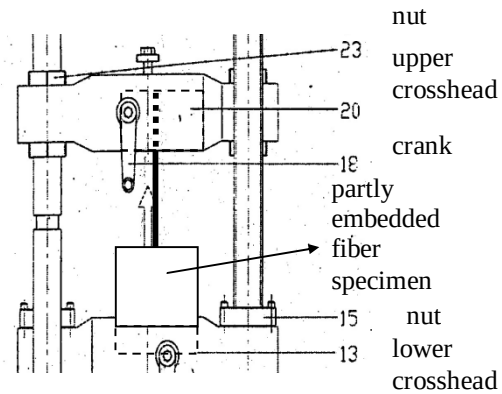

Figure 2 : Setting for pullout test

3. RESULTS AND DISCUSSION

3.1. Results

The results show that nylon 600 fiber has average maximum tension stress of 1471.21 MPa. Figure 3 shows relation of stress-strain of nylon 600 tension test with average maximum strain of 0.89, average maximum elongation of 84.11%, and average maximum tension load of 1398.13 N. A unique property of nylon fiber is shown by 'jagged' phenomenon on stress-strain ($\sigma-\varepsilon$) curves as also shown by Figure 3. This phenomenon is caused by the yield point elongation and the viscosity of nylon itself.

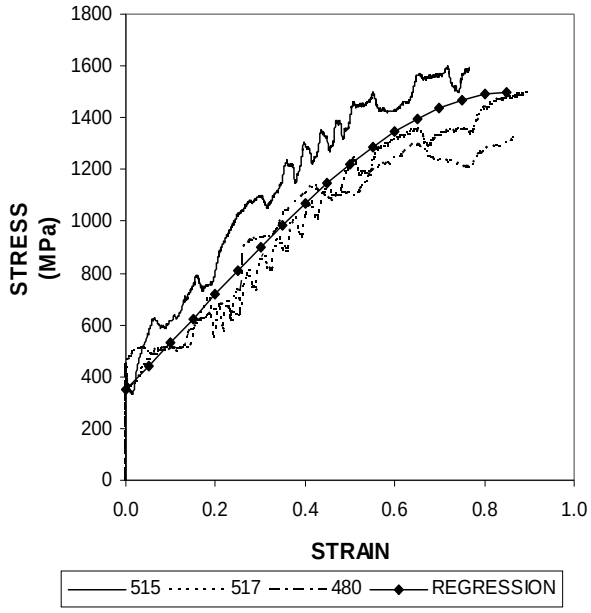

Figure 3 : Relation of stress-strain of nylon 600 tension test

The results of pullout test are shown below. Firstly, the experiment results show that the pullout test represent fracture phenomenon in some stages during pull-out process. Figure 4 describes the stages: (a) Pre-slip stage, (b) Slip stage, and (c) Strain-hardening stage. The pre-slip loads are about 400-430 N and pre-slip displacements are no more than 0.1 mm. The slip loads are in the same range of pre-slip loads with displacements of 3-4 mm. The strain-hardening loads are observed as 1300-1500 N and its displacement about 150-190 mm.

ISSN 114-1284

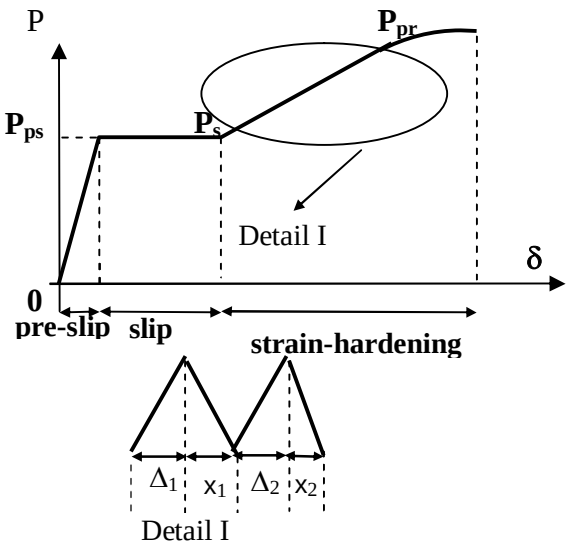

Figure 4 : The stages during pullout process

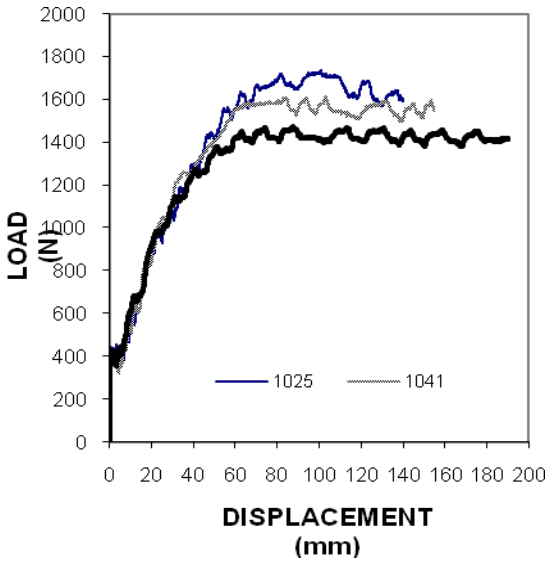

Figure 5 : Relation of load-displacement of specimen with embedded length (l_f) of 150 mm and 180 mm

Figure 5 describes relation of load-displacement of specimen with embedded length (l_f) of 150 mm and 180 mm. Specimen 1025 and 1041 have embedded length l_f = 150 mm while specimen 2438 has l_f = 180 mm. Specimen with l_f = 180 mm has bigger displacement (190.2 mm) than l_f = 150 mm (140.08 and 154.76 mm). On the contrary, specimen with l_f = 180 mm has lower ultimit load (1400 N) than l_f = 150 mm (1500-1600 N).

Relation of stress-strain of specimen with embedded length (l_f) of 150 mm and 180 mm is described by Figure 6. Specimen with l_f = 180 mm has bigger strain (2.8) compared to l_f = 150 mm (2.06 and 2.28). On the contrary, specimen with l_f = 180 mm has lower ultimit stress (1500 N) than l_f = 150 mm (1600-1800 N).

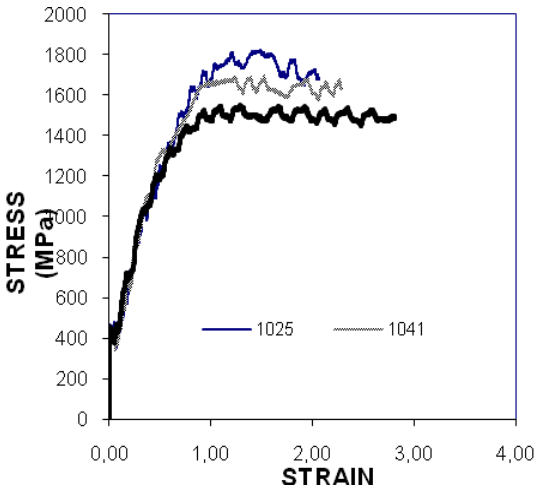

Figure 6 : Relation of stress-strain of specimen with embedded length (l_f) of 150 mm and 180 mm

The results were analyzed to become basis of pullout modeling. Several aspects have been considered in the modeling: (1) Fracture capacity of embedded fiber is a function of Poisson's ratio of fiber, (2) Some stages exist during the pull-out and fracture pull-out process, (4) A 'jagged' phenomenon exists on strain-hardening part of load-displacement (P-δ) and stress-strain (σ–ε) curves of pull-out, and (4) Unstable and stable

ISSN 114-1284

fracture process phenomenon exist during the pull-out process.

Pullout modeling conceives a formulation of load which is a function of displacement that is expressed by Equation 1.

$$P_n = \left(r_{\Delta I}\frac{a_1}{a_2}E_{ps}A\right) + \left(r_{\Delta II}\frac{a_1}{a_2}E_sA\right) + \left(r_{\Delta III}\frac{a_1}{a_2}E_{pr}A\right) \quad (1)$$

Where:

P_n = load (N)
A = fiber section area (mm^2)
E_{pr} = modulus of elasticity at stage of strain-hardening (MPa)
E_{ps} = modulus of elasticity at stage of pre-slip (MPa)
E_s = modulus of elasticity at stage of slip (MPa)
a_1 = total displacement of a stage (mm)
a_2 = initial length of specimen or fiber that is specific for every stage (mm)
$r_{\Delta I}$ = ratio of total free-end fiber displacement of free-end at stage of pre-slip
$r_{\Delta II}$ = ratio of total free-end fiber displacement of free-end at stage of slip
$r_{\Delta III}$ = ratio of total free-end fiber displacement of free-end at stage of strain-hardening

The range value of E_s, E_{ps}, dan E_{pr} for pull-out model is described by Table 1.

Tabel 1 : Range value of E_s, E_{ps}, and E_{pr}

	STAGE OF PRE-SELIP	STAGE OF SLIP		STAGE OF STRAIN-HARDENING
		INITIAL SLIP	POST SLIP	
l_f (mm)	E_{ps} (x 10^3 MPa)	E_s (x 10^3 MPa)	E_s (MPa)	$E_{pr} = E_n$ (MPa)
150	500 - 650	3000 - 4000	500 -1500	400 - 2500
180	500 - 650	4000 - 5000	500 -1500	400 - 2500

Pullout modeling also conveys a formulation for stable crack length as expressed by Equation 2.

$$l_2 = \frac{\bar{\delta} - \bar{\varepsilon} l_0}{\bar{\varepsilon}} \quad (2)$$

Where:

l_2 = stable crack length (mm)
l_0 = initial outer fiber length (mm)
$\bar{\delta}$ = fiber displacement at time of stable fracture achieved (mm)
$\bar{\varepsilon}$ = critical fiber strain

Stable crack length for each embedded length can be calculated based on experiment results as explained by Table 2.

Tabel 2 : Stable Crack Length of Specimens

l_f (mm)	l_2 (mm)
150	37,7375
180	37,7375

The pullout model then built based on experiment results and described by Figure 7-10 as follow.

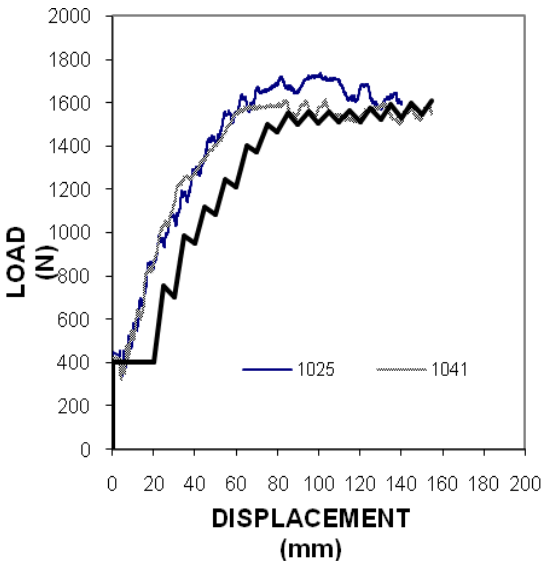

Figure 6 : Relation of load-displacement of experiment results and model with embedded length l_f = 150 mm

ISSN 114-1284

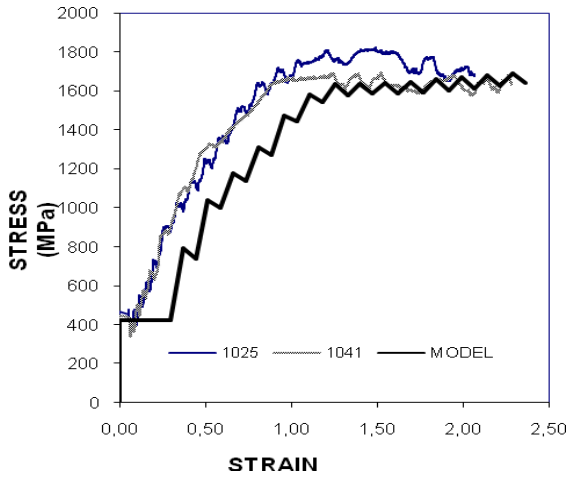

Figure 7 : Relation of stress-strain of experiment results and model with embedded length l_f = 150 mm

Figure 6 and 7 show that the model fit to the experiment results. For relation of load-displacement of experiment results and model with embedded length l_f = 150 mm (Figure 6), the model achieves stage of with load of about 400 N and stage of strain hardening with load of about 1500 N. Figure 7 shows that for stress-strain relation the model achieved stress at stage of slip with load about 400 MPa and stage of strain-hardening with load about 1600 MPa.

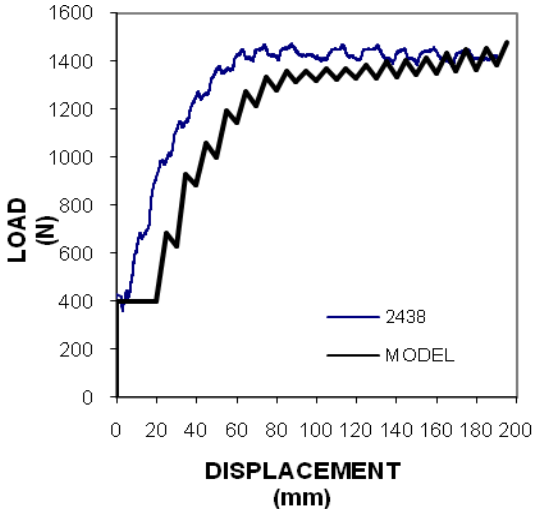

Figure 8 : Relation of load-displacement of experiment results and model with embedded length l_f = 180 mm

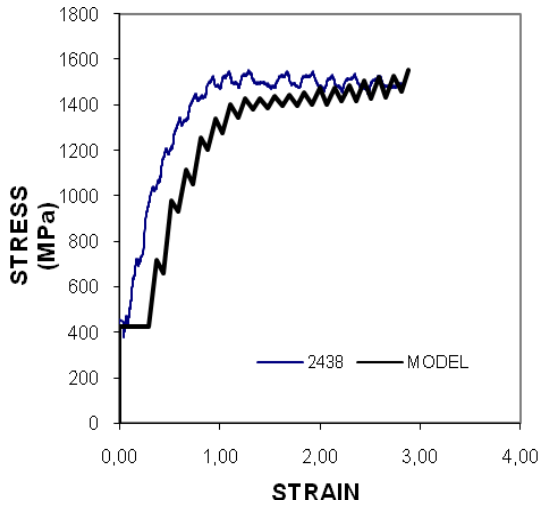

Figure 9 : Relation of stress-strain of experiment results and model with embedded length l_f = 180 mm

Figure 8 and 9 also describe that the model fit to experiment results. Figure 8 shows that the model also achieve stage of slip with load of about 400 N and stage of strain-hardening with load of about 1350 N. It is lower than the loads achieved by the specimens with embedded length of l_f = 150 mm.

The same phenomenon happened for stress-strain relation of Figure 9. The model achieve stage of slip with load of about 400 MPa and stage of strain-hardening with load of about 1400 MPa. It is lower than the loads achieved by the specimens with embedded length of l_f = 150 mm.

3.2. Discussion

Whenever fracture takes place, it is always an unstable crack. Unstable crack will change into stable crack with certain condition. Stable crack length will be occured when the crack arrester presents. It means, the phenomenon of unstable fracture that happened at the stage of pre-slip will change into stable fracture at the stage of slip.

It is interesting that the load and stress of embeded length l_f = 180 mm are lower compared to l_f = 150 mm. However, the displacement for embeded length l_f = 180 mm is bigger compared to l_f = 150 mm. It can be explained as follow. The long embedded length (150 mm and 180 mm)

produces broken fiber when specimen gets failure. It should be noted that long embedded length of specimen is related to the possibility of crack arrester presence. Because of that bigger possibility makes the strain-hardening part in load-displacement curve is longer for long embedded fiber length. The stable crack length will be achieved in stable fracture.

For both embedded length l_f = 150 mm and l_f = 180 mm, the stable crack length are the same, l_2 = 37,7375 mm (Table 2). It can be seen (Figure 7-10) that they achieve same critical load and stress at the stage of slip that the stable fracture occured. Hence, the modeling represents the fracture phenomenon in appropriate way.

4. CONCLUSIONS

The research meets conclusions:

a) Whenever fracture takes place, it is always an unstable crack;
b) Stable cracks are established by the presence of crack arrester;
c) After the establishment of stable cracks, increasing strain beyond strain ε_1 will not increase stress σ_1 (the slip stage exists), hence do not induce additional fracture;
d) Increasing of strain ε after the establishment of stable cracks in point g will increase stress σ (the strain-hardening stage exist), the second slip will not take place;
e) Broken nylon fibers have a longer embedded length because of the possibility of crack arrester presence is bigger than the shorter ones;
f) Since the middle right side of matrix is at the intersection point with fiber acts as crack arrester in the beginning of pull-out process, then the load-displacement (P-δ) and stress-strain (σ–ε) curves of pull-out test will be the same as the load-displacement (P-δ) and stress-strain (σ–ε) curves of fiber tension test

ACKNOWLEDGMENT

The author gratefully acknowledges UBCHEA (United Board of Higher Christian Education) for supporting research grant (2005-2007); and to Prof. Ir. Moh. Sahari Besari, MSc., PhD as Promotor; and also to Prof. Bambang Suryoatmono, PhD. as Co-Promotor; for their great contributions of ideas, discussions, and intensive assistance to the dissertation.

ABSTRACT

This paper contains the intention of thermal discomfort of pedestrian area in tropical humid environment, especially for the people in walking activity. This study applied field measurements, questionnaires and calculations. Day time thermal measurements of outdoor spaces and pedestrian ways were realized. At the same time we distributed questionnaire on thermal feeling to the people who walked on pedestrian way. Thermal measurement includes air temperature, radiant temperature, wind and humidity. Scale of thermal feeling refer to the AHSRAE definition. We had 24 subjects who filled the questionnaire on comfort feeling. They walked on pedestrian way for 5 minutes or of about 300 m long distance. Three types of pedestrian way were examined. Type-1 is pedestrian well protected under trees canopy, type-2 is pedestrian partially protected by trees canopy, and type-3 is pedestrian totally exposed to solar radiation. The study was done at noon under clear sky, when temperature is assumed to be maximum in a day. The results, in general show that there is different up to 3 scales between thermal comfort under trees and without trees shading. Beside, the dynamic discomfort was found for the people in walking activity.

Outdoor comfort, Tropical humid, Open-space

1. INTRODUCTION

Architect or urban designer's major task is to create the best possible outdoor environment to the people's activities. Soft and hard materials implemented for outdoor spaces, play important role determining convective and radiant temperature of its environment. Outdoor thermal comfort is therefore depends on utilization of landscape material. A good thermal performance that gives comfortable microclimate of urban space will be one of primary point of interest for the visitors or even for the migrants to do their outdoor activities: parking, relaxing, walking, retailing, etc. The landscape materials such as grass, trees, asphalts, concrete-block,. etc, which are implemented at and surround of pedestrian ways, may influence the microclimate and thermal comfort at urban space. In hot and humid areas, a state of discomfort is often caused by ambient atmosphere which are too hot and very humid, with a higher solar radiation. Under these conditions, sweat rate and skin evaporation are considered to be primary factors for feelings of thermal comfort. Such active control is not possible exteriorly, but some degree of control is needed for human comfort. Wind, solar radiation and precipitation are factors to be considered. Since the solar radiation can be controlled using vegetation or man-made shelter constructions, wind velocities play an important role to increase comfort feelings by evaporative cooling.

Each site has its own microclimate, determined by its local surrounding, by the weather, and by the character of urban area. Many of scientific studies have shown that the city is warmer than the surrounding countryside. This effect is known as the urban heat island. Urban activity without good control may cause of increasing of air temperature insides city and its hinterland. Vast enhanced hard material covering the ground and utilizes metal for roofing that has reflectance towards sun radiation push acceleration the happening of urban heat island. In urban areas, natural vegetation is often removed and replaced by non-evaporating, non-transpiring impervious surfaces. Under such alteration, the partitioning of incoming solar radiation into fluxes of sensible and latent heat is skewed in favor of increased sensible heat flux as evapotranspirative surfaces are reduced.

Open space or exterior facilities are an essential element of urban design, and they are not just part of a beautification program. Rather, they are a comfort system as well as a support element for retailing, pedestrian ways and others vitalities of urban spaces. Soft and hard materials covering park space, roofing and wall, play important role determining convective and radiant temperature of its environment. Outdoor thermal comfort is therefore also depends on utilization of surface material.

It is always of interested to study the exterior thermal performance of the cities in tropical humid countries. Many of developing countries are located in the tropical zones. The global era in 21st centuries and the warning of climate

ISSN 114-1284

changes may influence the direction of agglomeration strategy of the cities. Development policy to make grow up the cities is therefore oriented to the friendly environment principles. Nowadays green technology or friendly environment is common strategy to develop many sectors. By the 21st century 70-80 per cent of the world's population will live in cities and towns, demanding higher standards of comfort, goods and wealth. At present, the only means mankind knows of meeting these demands is by increasing output and pillaging the earth's resources. Although both the tools and technologies exist to build new cities with minimum impact on the environment, not many examples exist [1]

In hot and humid areas, a state of discomfort is often caused by ambient atmosphere which are too hot and very humid, with a higher solar radiation. Under these conditions, sweat rate and skin evaporation are considered to be primary factors for feelings of thermal comfort. Such active control is not possible exteriorly, but some degree of control is needed for human comfort. Wind, solar radiation and precipitation are factors to be considered. Since the solar radiation can be controlled using vegetation or man-made shelter constructions, wind velocities play an important role to increase comfort feelings by evaporative cooling.

From the view point of coordinated city and energy planning efforts, it must be considered that the potential for natural thermal conditioning of spaces in buildings is not only a function of building technology, but also of the city's volumetric pattern, including non-built elements such as trees and grass. From the view point of urban climatology and energy efficient building, trees have multiple effects on potential utilization of conservation and passive design strategies, that can be summed up as follows:

- Reduction of the urban heat island effect, as consequence of lower heat flows absorbed and released by concrete-block, paving-stone, wall and roofs due to the shading provided by tree crowns and the reduction of the air temperature due to evapotranspiration.
- Reduction of cooling loads caused by reduced incident radiation on glazed surfaces, reduction of sol-air temperature on roofs and walls shaded by trees and lower ambient temperature as previously described.

This paper contains the intention of thermal performance of outdoor environment in the center town of Manado city, Indonesia, located in humid tropical climate zone. Manado is the capital of North Sulawesi Province in Indonesia, and actually is being prepared to be an important international city supported by its favorable geographical position and its industry and tourism attractions. Manado is one of some Indonesia's cities which will face a remarkable urbanization in 21st centuries.

The objective of the study is to know outdoor thermal impact of materials and vegetation covering pedestrian area in the tropical environment

2. BRIEF THEORY AND REFERENCES

In agreement with ASHRAE (American Society of Heating, Referigerating and Air Conditioning Engineers) thermal comfort for a person is here defined as "*that condition of mind which expresses satisfaction with the thermal environment*". Thermal neutrality for a person is defined as the condition in which the subject would prefer neither warmer nor cooler surroundings. The reason for creating thermal comfort is first and foremost to satisfy man's desire to feel thermally comfortable, in line with his desire for comfort in other directions. Man's intellectual, manual and perceptual performance is in general highest when he is in thermal comfort. The most important variables which influence the condition of thermal comfort are: activity level (heat production in the body), thermal resistance of the clothing (clo-value), air temperature, mean radiant temperature, relative air velocity and water vapor pressure in ambient air.

The discomfort associated with exposure to warm and humid environments is attributed to the conscious awareness of perspiration and an elevated body temperature. The secretion of sweat onto the skin surface permits the dissipation of metabolic heat from the body by evaporation when the loss of heat by radiation and convection is insufficient to maintain thermal balance. In warm conditions in the resting, individual and with increased metabolic levels associated with work and exercise; it was recognize that unpleasantness and thermal discomfort are associated with sweating, rather than skin or body temperature.

The DISC scale that represent a correlation introducing sweat rate and percentage of skin wetness is more adapted to be used for prediction of thermal feeling in hot and humid environment [3],[5]

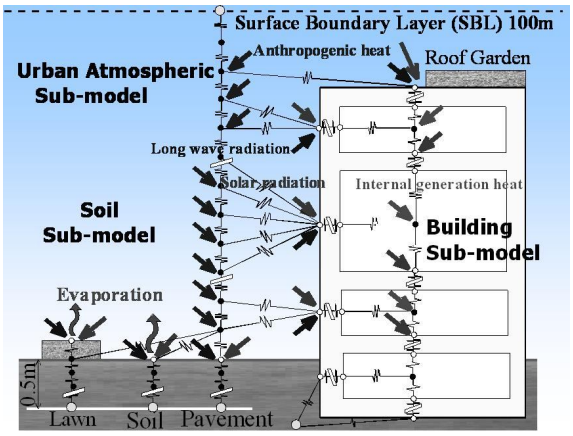

Figure.1. Analogical thermal modeling of city environment [2].

ISSN 114-1284

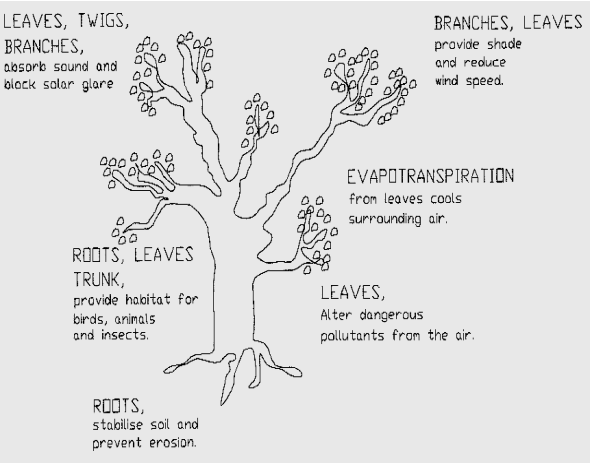

Figure.2. Role of trees component in reducing thermal effect and save living environment [4]

The environmental parameters affecting thermal comfort conditions outdoors, even-though similar to indoors, are encountered within a much wider range and are more variable. Therefore due to this complexity, in terms of variability, temporal and spatial, as well as the great range of activities people are engaged in, there have been very few attempts to understand comfort conditions outside
Trees are recommended as considerable shade component, because its organic material is both non-reflection and non-transmission to heat penetration. A very large area of non-shading open space using hard covering may cause increasing of urban heat island effect. Since the city is too hot, it is therefore needed more of energy to make cool-down the environment. There is a close relation between design strategy of open space and impact of energy demand of city. Covering ground with grass vegetation may give a reduction of one scale of thermal comfort at noon [6]

+1	1	Slightly Uncomfortable
+2	2	Uncomfortable
+3	3	Very Uncomfortable
+4	4	Untolerable

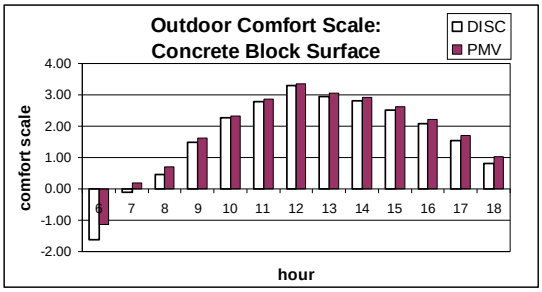

Figure.3. Calculation of comfort scale of open-space environment using Concrete-block for surface [6]

The measurements realized by Jörg Spangenberg [7] in Brazil, indicated that a public park with good vegetation has a cooling effect with around 2°C lower than its surroundings. The surface temperature measurements also showed that natural surfaces are considerably cooler than commonly used construction materials such as concrete and asphalt. The results from the simulations presented in the study clearly show that vegetation in the form of trees has a great potential of improving the microclimate and mitigate heat stress in a hot humid climate. The leaf area index (LAI) and leaf area density (LAD) of the canopy proved to be important metrics, which have a significant influence on the microclimate. The denser the tree canopy (higher LAI and LAD), the lower the air and surface temperatures and the better the thermal comfort for hot-humid climate. In general, trees provide, under their canopies (locally restricted), significant improvements on thermal comfort principally during midday and in the early afternoon as they provide overhead shading by attenuating the solar radiation. The crucial benefit of shade, resulting in considerably lower mean radiant temperatures, has more influence on the thermal comfort.

3. METHODS

This research focuses the relations between urban design variables and thermal comfort. The research objects are the empirical and rational predictive models of outdoor thermal comfort for walking activity. The urban environment of Manado city, Indonesia was chosen as locations of the study. Three areas of open space located in the centre of the city were taken place as sample geographic. This study applied field measurements, questionnaires and simple calculations. Day time thermal measurements of outdoor spaces and pedestrian ways were realized. The field research consists of 3 different pedestrian way variables and 24 applied questionnaires. Three types of pedestrian way were examined. Type-1 is pedestrian well protected under trees canopy, type-2 is pedestrian partially (± 50%) protected by trees canopy, and type-3 is pedestrian totally exposed to solar radiation. All of the pedestrian way ground surface is covered by paving concrete. This field study was done at noon under clear sky, when temperature is assumed to be maximum in a day. Calculation of thermal comfort applying DISC was also realized applying parameters obtained by field measurement. A form (questionnaire) was designed to record human thermal impact on a comfort scale along with other information of interest such as location; date; time; age; sex; height, weight and dressing of subject; and climatic measurements: wind, air temperature, mean radiant temperature and air humidity. Subjects (pedestrians) were asked their state of thermal comfort each 1 minute for along of 5 minutes in walking activity (1.8 met). They started answer the question after about 2 minutes walked on a shadowed open-space. Each respondent need 7 minutes in this field experiment. They clothed of tropical style dress.

The frequency distribution of experienced thermal stress on a comfort scale is shown in Table.2

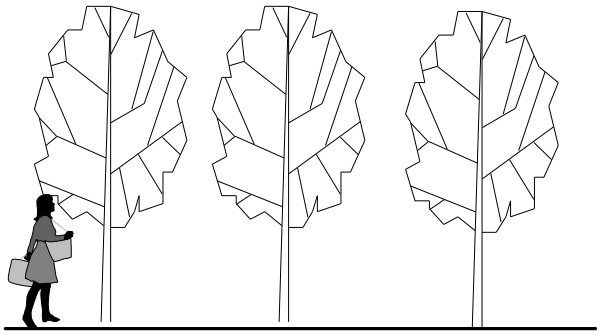
Table.2. Distribution of the respondents

	Pedestrian Type-1	Pedestrian Type-2	Pedestrian Type-3
Men	3	4	5
Women	5	4	3
Total	8	8	8

Climatic measurement equipments were used are : infrared thermometer, thermo-hygrometer, and anemometer.

A proposed regression model called dynamic discomfort scale (DISC $_{dyn}$) was developed by exploration of the results from questionnaires, time-exposure, climatic measurements and combined with DISC formulation. The term of dynamic is to be correlated to the function of time along activity, or:

$$DISC_{dyn} = f\{DISC, t\} \; ; \; t \text{ in minute}$$



Pedestrian way type-1

Pedestrian way type-2

Pedestrian way type-3

4. RESULTS AND DISCUSSION

Thermal feel responds recorded from questionnaires indicate influence of time-exposure of the body to the climatic environment, especially for the case of sun exposed pedestrian. With the same climatic condition, after 5 minutes exposed to the sun in walking activity, human feel very uncomfortable. It was also noted that there is a linear increasing respond of thermal feeling from first minute to the fifth (from comfortable scale to very uncomfortable). For the case where pedestrian way is not totally exposed to the sun (about 50% protected from the sun), it was found that there is a small change of the respond from first minute to the fifth. Table 3 to 5 show the result from measurement and questionnaires for all types of pedestrian way. Respondents filled the questionnaire of thermal comfort in terms of syntax: *slightly cool, comfort, slightly uncomfortable, uncomfortable, very uncomfortable, or feel head pain (untolerable).*

For the case of pedestrian way type-1 (Table 3) that was fully protected to direct solar radiation, most of people feel enough comfortable after 5 minutes in walking activity. There were only 4 responds (10%) that fill slightly uncomfortable after 5 minutes walking. This is may be caused by effect of low wind velocity that influence feel of comfort or decrease comfort level by evaporative process. In that case the wind velocity was of 0.1 to 0.2 m/s with air temperature of 31 to 32^{0}C.

For the case of pedestrian way type-2 (Table 4) it were found significant different values compared to the case of type-1. Situation slightly uncomfortable and uncomfortable were found several times after 4 to 5 minutes of walking activity. This is certainly impact of radiant temperature from direct solar gain on the pedestrian area. People feel uncomfortable when radiant and air temperatures are relatively high with low air velocity.

People feel more uncomfortable and very uncomfortable when they walk on the pedestrian way that is totally exposed

to direct sun shine. Even they may feel intolerable condition and feel of pain head due of solar radiation penetration after 5 minutes of walking (Table 5)

Table 5. Results of pedestrian way type-3

	5	33.7	58.1	0.5	69.8	3.0	

From the results of questionnaires and climatic measurements, we developed three regression correlations of dynamic discomfort scale ($DISC_{dyn}$) using statistic method. The equations are as follow:

For pedestrian totally exposed to the sun:

$DISC_{dyn} = ABS\ [DISC - 6.45 + 0.0402\ t + 6.541\ log\ (t) - 2.5096\ (log(t))^2\ ]$

For pedestrian partially ($\pm$ 50%) exposed to the sun:

$DISC_{dyn} = ABS\ [DISC - 4.42 - 0.0525\ t + 0.8193\ log\ (t) + 1.8047\ (log(t))^2\ ]$

For pedestrian totally protected from the sun:

$DISC_{dyn} = ABS\ [DISC - 3.75 - 0.0372\ t - 0.3109\ log\ (t) + 2.0962\ (log(t))^2\ ]$

Where :

$DISC$ = $3.9338\ Sw + 0.0158\ Ds - 0.3348$ [5]

t = time of exposure to outdoor environment (minute), $t > 0$

Sw = Percentage of skin wettedness

Ds = Sweat rate (g/h)

Note: equations to calculate Sw and Ds may be obtained from some references related to physiological comfort.

Figure.6 is a x-y graphic that shows a comparison of thermal feel scale obtained by equation of $DISC_{dyn}$ and thermal feel from questionnaires for the case of pedestrian way type-3 (totally exposed to sun shine).

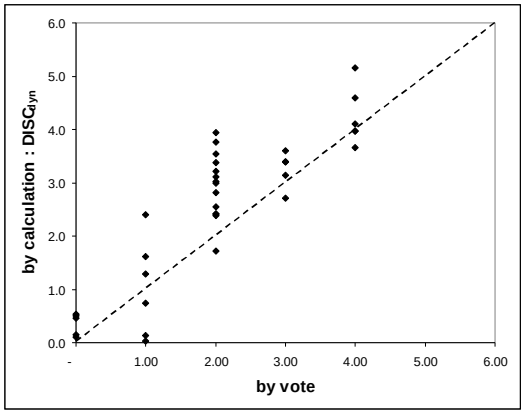

Figure.6. Comparison of Comfort feeling by DISCdyn and from questionnaires

Figures 7,8, and 9 show three types of non-linear line of dynamic discomfort ($DISC_{dyn}$) as the function of time exposure for subject adult (ADU = $\pm$ 1.6 m^2) wearing tropical cloth (0.6 clo), in walking activity (1.8 met), wind 0.4 m/s, and RH=70%.

Looking at the figure 8, we get a state of very uncomfortable (scale=3) after 4 minutes walking at noon for the case of pedestrian totally exposed to direct solar gain. While for the case of pedestrian under trees protection, we may get situation slightly uncomfortable after 5 minutes walking (Figure 7).

Using these graphics we may decide where we must implant the trees and to know the distance each others. If a state of uncomfortable (scale=2) is assumed as the limited value of comfort, then we can decide to implant vegetations or trees after 2 minutes walking, or of about each 100 meters maximum (man speed walking is about 3 km/h). If a state of slightly uncomfortable (scale=2) is to be assumed as the

ISSN 114-1284

limited situation of minimum comfort, then we get a distance of about 50 to 75 meters between trees.

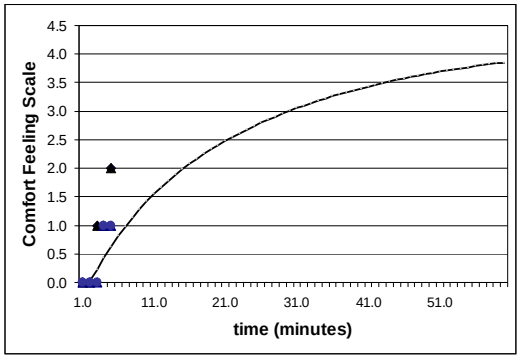

Figure 7. Application of $DISC_{dyn}$ in humid and tropical environment on pedestrian way type-1.

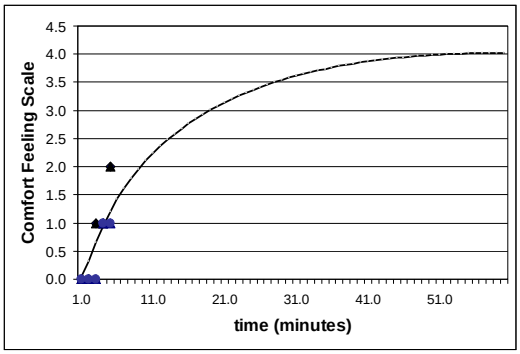

Figure 8. Application of $DISC_{dyn}$ in humid and tropical environment on pedestrian way type-2.

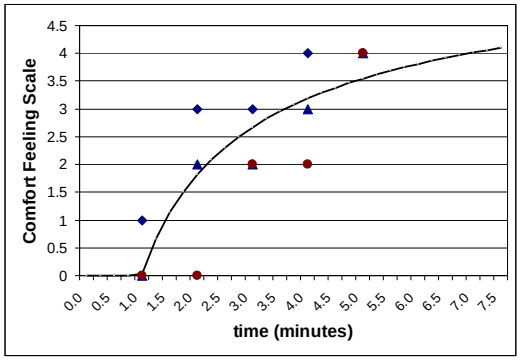

Figure 9. Application of $DISC_{dyn}$ in humid and tropical environment on pedestrian way type-3. Comparison with values from questionnaires (scatter points)

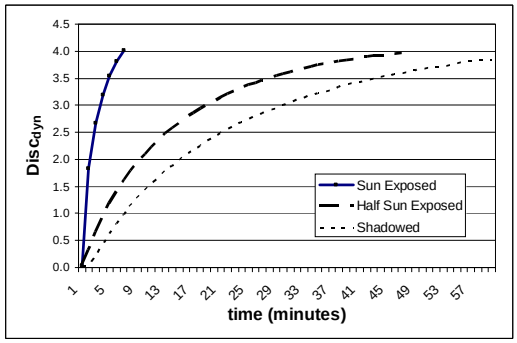

Figure.10. Comparison of increasing line of discomfort for 3 types of pedestrian environment.

5. BRIEF CONCLUSION

This study explores situation of outdoor discomfort that is dynamically changed as function of time in minutes. We may know the respond feel of the body that is exposed to certain climatic environment along certain times. Pedestrian materials such as trees, vegetations and paving concrete may influence significantly the situation of discomfort. We may stated that the positive impact of trees is more significant to increase thermal comfort feel, comparing to the influence of materials of pedestrian way. Influence of radiant temperature is enough strong to make the body feel uncomfortable.

Other results of this study are three non-linear regression equations of the dynamic discomfort scale ($DISC_{dyn}$) for the people in walking activity, representing the three types of pedestrian way which were examined. We may use the equation to decide the position of trees for pedestrian ways.

Finally we may make statement that this study give a valuable contribution for the research on outdoor thermal comfort especially to make green the pedestrian way in the tropics and humid cities.

ABSTRACT

Jakarta has experienced every complex problems related to its transportation system. Problems of transportation in Jakarta Metropolitan is felt more days are are more problems. Now, problem related to existing public vehicles in Jakarta is bad public transportation system management, especially the balance of total public transportation fleet with total passengers. This research is to rationalize amount of public transportation in certain routes in Jakarta, so ideal ratio can be gotten between fleets and passengers. Data processing is carried out by using AHP method to choose research location and determine priorities of project as research object. System Modeling of Problems is carried out by using dynamic Program, in this matter, by using Powersim Software. Based on result of model developed, total public transportation rationally in Tanjung Priok – Cilincing (M-14) Route is 30 vehicles. Those amounts will give high load factor value if they are integrated with innovation as public transportation scheduling system, so they can increase drivers' income as amount of Rp. 940.650,-, and can decrease traffic jam.

Keywords
public transportation, route, priority, system, dynamic simulation

1. INTRODUCTION

1.1 Background

Transportation problems in Jakarta Metropolitan City have been felt that more days are more problems. Any efforts are tried by DKI Government, but those are not carried out comprehensively, so the result cannot give real effect. The grow of total vehicles in DKI Jakarta for last 10 years is 6% per year and millions of vehicles from outside of Jakarta come into Jakarta and cause traffic jam in many roads in Jakarta. Repair of public transportation system constitutes main solution which should be immediately carried out by Local Government of DKI. Safe, comfortable and proper and timely public transportation constitutes target that should be implemented.

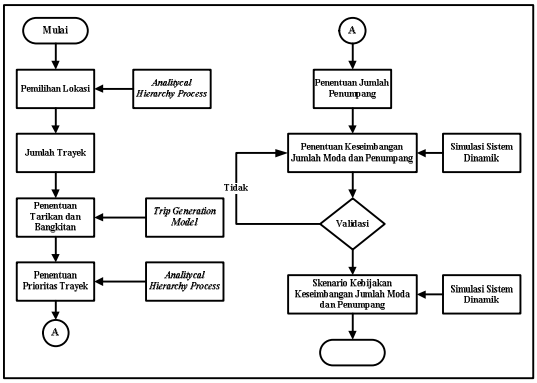
1.2 Research Purpose

This research purpose is to rationalize amount of public transportation vehicles in every public transportation route in Jakarta, so ideal ratio can be gotten between fleets and passengers

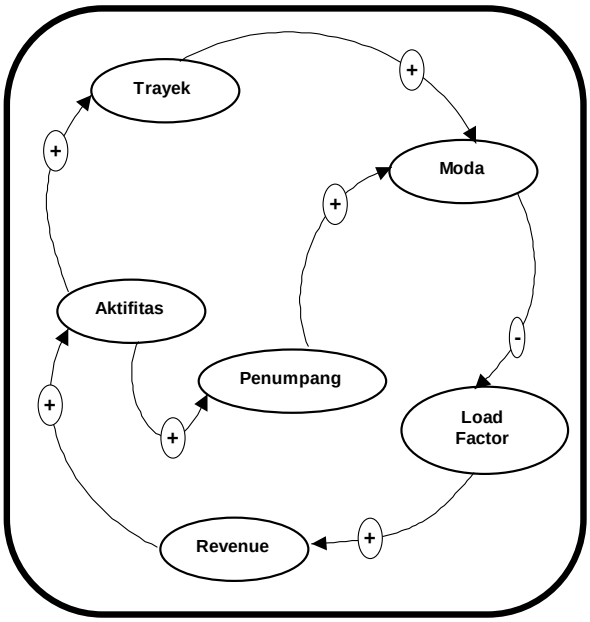
2. DISCUSSION

2.1 Research Methodology

Approach in these activities is system approach. This approach is chosen because model of policy in determining balance between amount of mode and passengers is influenced by many interrelated elements between one and another and dynamics in nature.



Picture 1. Mind frame flow diagram



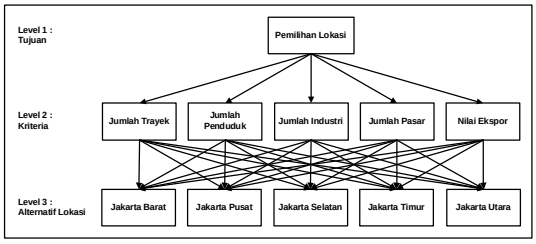
Picture 2 : Causal Loop Diagram model mental

2.2 Research Result

Discussion in this research will be carried out in phases, firstly by determining research location by choosing alternatives of research location, namely Central Jakarta, West Jakarta, East Jakarta, North Jakarta, and South Jakarta. Then after location is chosen, project priorities should be determined as object in this transportation research. Then, calculation of passengers and total fleet determining model are carried out to determine balance between total mode or fleet needed with total passengers. Then, scenario of policy is made to determine balance between total mode and total passengers.

2.3 Determine Research Location

Determine research location is carried out by using AHP Method. Hierarchy Structure of Problems in this selection can be seen in Picture 3.



Picture 3. Hierarchy Structure research location determination

Selection process is carried out by holding discussion with experts; consist of academicians, namely, Mr. Ir. Edi Santoso Msc, Lecturer of Industrial Engineering, University of Bina Nusantara, and also constitutes researcher from BPPT. The second and third experts are practitioners, namely, staff from Jakarta Transportation Agency and Planning Bureau, Transportation Department.

Result from software expert choice is that load criteria of total route is 0,398, load criteria of total population is 0,245; load criteria of total industries is 0,156; load criteria of total market is 0,136, and load criteria of total export is 0,064. Based on load values, the highest load criterion is for total route. So in order to choose location as research object based on location with the highest total route is North Jakarta with total route is 37 routes.

2.4 Determine total passenger on 5 routes in North Jakarta

From 37 routes in North Jakarta, 5 routes are chosen as the highest amount of passengers by considering that the highest amount of passengers indicate route with the more need of public transportation amount. Based on selection result, 5 routes with highest amount of total passengers are Tanjung Priok – Blok M, Tanjung Priok – Embrio, Tanjung Priok – Kota, Tanjung Priok – Cililitan, Tanjung Priok – Cilincing.

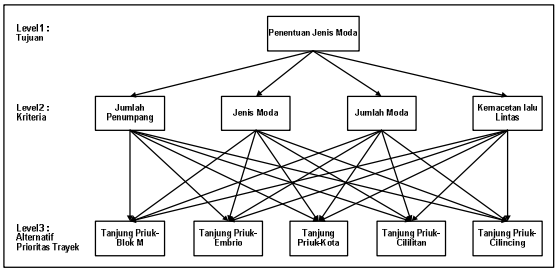
Determine total passengers in these routes are carried out by making Origin Destination (O-D) Matrix, to find how many the highest amount of total passengers is determined. Reference to total passengers, research priority is Tanjung Priok – Blok M.

Tabel 1: Amount of passengers from origin to destination 5 selection trajec

Origin	Destination						Oi
	Tj. Priok	Blok M	Embrio	Kota	Cililitan	Cilincing	
Tj. Priok	-	1.376	1.112	1.088	992	952	**5.520**
Blok M	1.186	-	217	2.030	1.987	270	**5.690**
Embrio	1.150	220	-	276	150	234	**2.030**
Kota	1.123	2.023	245	-	1.089	350	**4.830**
Cililitan	1.023	1.856	174	1.134	-	347	**4.534**
Cilincing	983	254	270	332	365	-	**2.204**
Dj	**5.465**	**5.729**	**2.018**	**4.860**	**4.583**	**2.153**	-

2.5 Determine Route Priority in North Jakarta

From 5 routes chosen, there are other route priorities that should be chosen as research objects because of time limitation in research. Selection process is carried out by using AHP method. Hierarchy structure of problems in route alternative chosen can be seen in Picture 4.



Picture 4. Hierarchy structure of moda selection

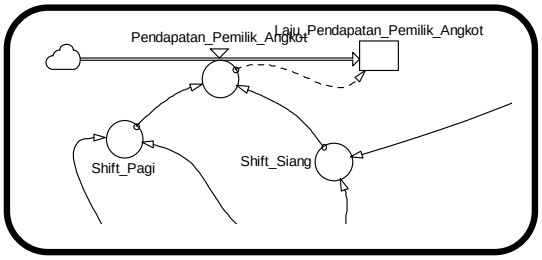
Criteria in choosing this route are type of mode, total mode, total passengers and traffic jam. As a result of software, load criteria of mode type is 0,338; load criteria of total mode is 0,220; load criteria of total passengers is 0,083; load criteria of traffic jam is 0,359.
Based on those load values, the highest criterion is traffic jam. So in order to choose route as research object based on route, the highest potential traffic jam is route of Tanjung Priok – Cilincing, passed by *Mikrolet M-14*.
From O-D Matrix, it can be known that Dj value is 2,153 passengers and total Oi is 2.204 passengers. So total passengers in route Tanjung Priok – Cilincing will be an input in the model for the further step; namely, to choose between both values as the highest value, and total passengers in this route is 2.204 passengers per day.

2.6 Determine Balance Model of Total Mode and Passengers

In order to determine balance of total mode and passengers, modeling and simulation is carried out by using dynamic system simulation.

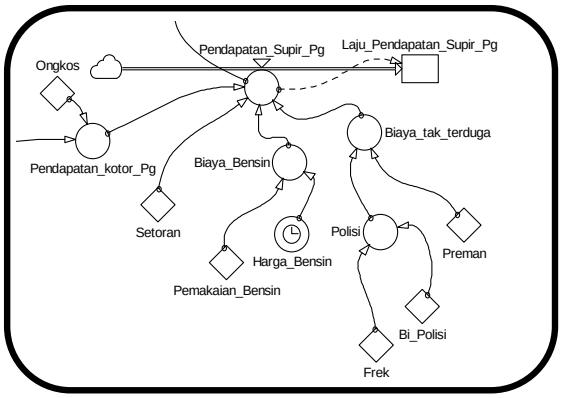
2.7 Balance Model Simulation on Total Mode and Passengers by Using Dynamic System Simulation

Simulation made in route transportation model of mode M14 is to generate 3 big systems, namely income for vehicles' owners, income for drivers, and income for drivers based on ratio.



Picture 6 : Drivers' income system

System in Picture 6 is formed based on drivers' income for morning and noon shift. An assumption used in system served in Picture 7 is for vehicles' owners who as mode fleet M14, not vehicles' owners individually.



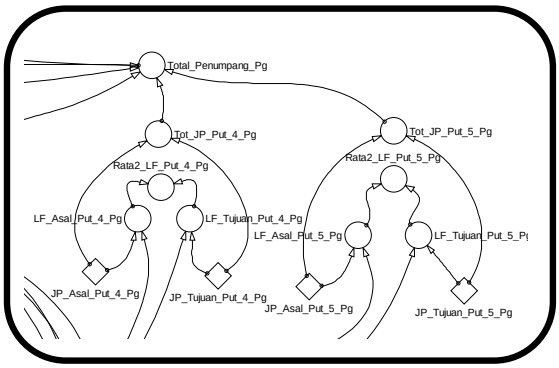
Picture 7. for vehicles' owners income system

Drivers' income is net income of drivers after being deducted with other expenses. Discussion and analysis carried out then is for morning income of drivers, and this condition is also valid for noon income of drivers, but dynamic system simulation model used in both existing conditions are morning and noon shift. Assumed that on morning and noon shift, total drivers drive mode M14 is one person. Net income is gotten by deducting net income with combination of variable and deposit constant, gasoline expense and undetermined expense. Other expenses in this system are deposit, gasoline expense and undetermined expense. Total deposit constant constitutes obligatory deposit data given by public transportation vehicle to the owners, namely Rp 100.000,- Gasoline is gotten from variable of gasoline price and constant of total gasoline consumption. Constant average of gasoline consumption based on interview result with public vehicles' driver is 19,2 liters for each shift.
Gasoline price is become variable because as it is known, gasoline price is not stable and always experience fluctuation, so gasoline variable uses step function, namely on 31st period, there is addition for 500. Variable of gasoline expenses is gotten by multiplying constant of gasoline consumption with variable of gasoline price. Based on simulation, expenses paid by public vehicle's driver starting from 31st period will decrease Rp 500,-
Undetermined expense comes from police variable (pay police because of traffic trespassing carried out) and constant of street kids. In one day, any drivers get traffic ticket in route M14

from police because of any reasons. The most reason is waiting passengers or stop more than 5 minutes not in the usual place. In addition, passengers motor and go down not in the usual place in the location of Cilincing Street and Yos Sudarso Street.

Total traffic ticket averagely is Rp 15.000,- based on interview with several public vehicles' drivers. While frequency is determined in constant informed is that one week or 5 monitoring days, there is possibility to get traffic ticket 3 times, so its value is 0,6.

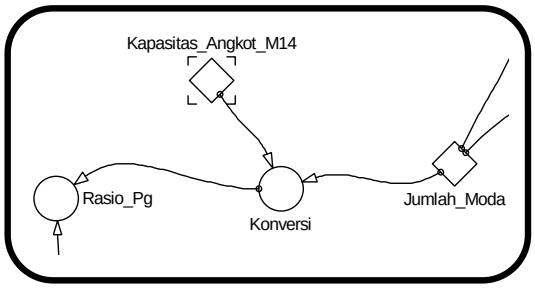
The final variable is morning gross income. This income constitutes combination between constant of expenses with variable of total morning passengers. Constant of expenses is gotten based on average expenses paid by passengers, namely Rp 2.500,-. Variable of total morning passengers is described in model served in Picture 8.



Picture 8. Variable of total morning passengers

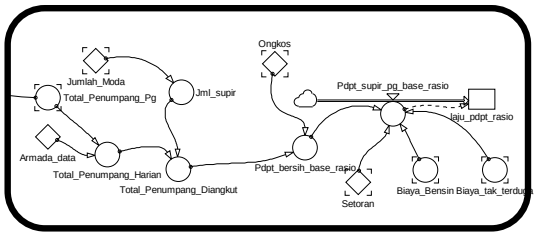
Variable of total morning passengers means total passengers who motor M14 in the morning shift, namely from 5 o'clock in the morning up to 12 o'clock at noon. It means that there are 5 times passengers' rotations by using this mode from Tanjung Priok Terminal to Cilincing Terminal.

The abovementioned model only represents 4th and 5th morning shifts. The following explanation will only describe total passengers in morning shift for the 4th rotation. Total passengers in 4th rotation are gotten by adding constant of total passengers from origin and destination. Total passengers from origin and destination are determined as constant in this model. Because passengers motor are assumed in the fixed amount.



Picture 9. Load Factor model determination

Determining risk is carried out separately for morning and noon shifts. The following ratio constitutes load factor happen in the morning shift. This statement is same with served in Picture 10



Picture 10. Total passengers and mode comparison

The abovementioned model constitutes determination of total drivers' income influenced by ratio; in this matter is load factor. If it is influenced by ratio, so variable, of course, should be known, is total drivers. Because there are many fleet together with total vehicles' drivers. So variable of total drivers is added by entering constant of total mode.

2.8 Analysis of Simulation Result

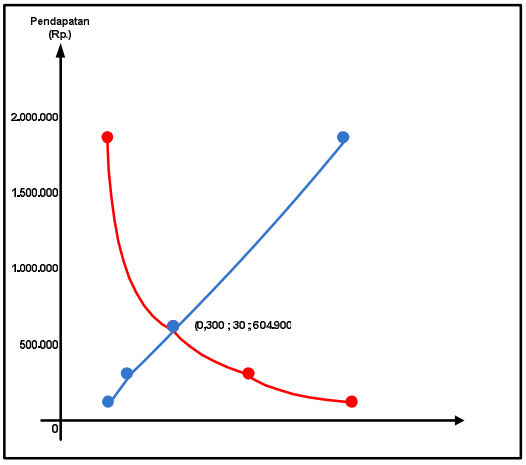
Based on simulation result between total mode, ratio and drivers' income described in Table 2, it is known that more available mode is lower load factor ratio, as a result of more drivers' income, and otherwise.

Tabel 2: Simulation Result

Total Mode	Load Factor Ratio	Net driver's income (Rp.)
79	0,114	90.400
50	0,180	273.100
30	0,300	604.900
12	0,750	1.849.150

Based on modeling result to determine balance between total mode and total passengers by using dynamic system simulation, it is known that total mode optimally is 30 modes, and ratio between total passengers and transportation capacity is 0,3000 and driver's income per day is Rp

604.900,- Based on simulation result, condition of transportation amount right now is 79 vehicles, and they are not realistic compared with those amounts, because load factor ratio will be low, and as a consequence, driver's income will also low.



Picture 5.17. Total mode and driver's income relation

2.9 Scenario of Balance Policy between Total Mode with Passengers

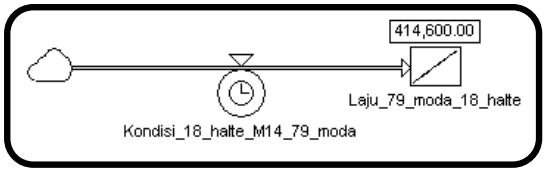
Balance scenario between mode and total passengers is to develop scheduling for mode in route M14. Mode scheduling meant here is to schedule arriving and leaving of mode from one stasion to other stopping place.

Trip carried out by Mode M14 is basically without scheduling. There are 79 vehicles operated to bring passengers from the morning up to noon. Every vehicle does not have exact stopping place. Vehicle will be stopped where passengers want to stop. Based on monitoring result along route of Tanjung Priok – Cilincing, it is known that there are 18 roads passed by this mode. It is also known that every time vehicle stops need averagely one minute or 60 seconds. And length of trip from one stopping place to other stopping place is at least 1,6 minutes or 96 seconds. So average time needed from on stopping place to another stopping place is 2,6 minutes or 156 seconds. If mode M14 leaves in the morning at 5.00 o'clock from Tanjung Priok Terminal, so this mode will arrive in Cilincing at 5.23 o'clock.

Basically, scheduling may not be carried out by operating 79 vehicles all at once. If so, of course, traffic jam cannot be avoided, and load factor is very small, as proven in the previous model.

2.10 Mode Scheduling Policy without Adding Stopping Place

This policy will be carried out in the scenario of total mode of 79, 30 and 20. This scenario will not be carried out by adding stopping places. First scenario will be valid for total mode of 79 with traffic jam condition. So length of time needed to pass with this traffic jam is 300 seconds. Stopping time does not change, namely 60 seconds, but length of running mode is 240 seconds, because there are several traffic jam points. Picture below serves SFD in accordance with actual condition.



Picture 11. System 79 Mode with 18 Halte

From abovementioned simulation, it is known that it is impossible to schedule 79 modes in one day, because time needed for 79 modes operated are around 116 hours after 5 o'clock.

Therefore, there is mode accumulation along Tanjung Priok – Cilincing route. And there is unfair competition among public vehicles' drivers. Based on simulation result, if fleet operated is 79 vehicles, to driver' s income is very low, that is Rp 90.400,- It is if driver drives in the morning shift. Actually, there are 4 up to 5 drivers drive fleet.

Second scenario will be valid for total modes as amount of 79 vehicles if there is no traffic jam. It means that trip period should be passed from one stopping place to another stopping place is 156 seconds. Third scenario is to operate 30 vehicles in 18 stopping places, and conditions are traffic jams. There are 30 vehicles chosen because they are fitted with harmony between load factor and best driver's income.

From simulation result, it is known that the 30th vehicle actually finishes its trip 43,67 hours. The following will be carried forth scenario if there is no traffic jam, assumed that length of time needed to pass from one stopping place to another is 156 seconds. The fifth and sixth scenarios are to operate 20 modes in 18 stopping places in traffic jam and non traffic jam conditions. If traffic jam happens, so the following is its simulation result. From those conditions, it is known that the 20th mode will arrive in Cilincing around 29,08 hours from the first mode leaving time at 5 o'clock in the morning. The 6th scenario is if for 20 modes in fluently traffic, and there are 18 stopping places. From those condition that the 20th mode will

arrive in Cilincing around 15,12 hours from the first mode leaving time at 5 o'clock in the morning. It is meant that the 20th mode can finish its trip at 22.12 o'clock.

Tabel 3: Scenario recapitulation

Scenario	Moda (unit)	Head Way (second)	Time Cycle last (hour)	Condition
I	79	300	115,00	Macet
II		156	59,89	Tidak Macet
III	30	300	43,67	Macet
IV		156	22,71	Tidak Macet
V	20	300	29,08	Macet
VI		156	15,12	Tidak Macet

2.11 Mode Scheduling Scenario By Adding Stopping Places

The second big scenario constitutes scenario to implement stopping place development as amount of 10 places along M14 mode route from Tanjung Priok – Cilincing. Total modes simulated are 70, 30 and 20. Conditions are if there is traffic jam and there is no traffic jam.

If the second scenario is chosen, so of course, there is consequence should be gotten by government, there are 10 stopping places should be developed as public service facilities. In this matter, stopping places are not to arrange M14 mode scheduling, in order that drivers do not stop to motor and go down passengers, as well as to decrease traffic jam along those routes.

The first scenario carried out for M14 mode is 79 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed that several traffic jams happen along those routes. So length of time to pass those routes from one to another stopping place is 300 seconds.

From simulation, it is known that first mode leaves Tanjung Priok is at 5 o'clock, and arrives in Cilincing at 5.45 o'clock. So length of time to pass from Tanjung Priok to Cilincing is 45 minutes. The last mode is the 79th arrive in Cilincing on 62,5 hours.

The second scenario is carried out for M14 mode of 79 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed that there is no traffic jam along routes. So trip time needed from one to another stopping place is 156 seconds.

From simulation, it is known that first mode will leave Tanjung Priok at 5 o'clock, and arrive in Cilincing at 5.23 o'clock, so average trip time passed from Tanjung Priok to Cilincing is 23 minutes. Last time the 79th mode arrive in Cilincing is at the 32,5 hours.

Third scenario is carried out for M14 mode is 30 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed there are several traffic jam along routes. So trip time needed from one to another stopping place is 300 seconds.

From simulation, it is known that first mode leaves Tanjung Priok at 5 o'clock, and arrives in Cilincing at 5.23 o'clock, so average trip time passed from Tanjung Priok to Cilincing is 23 minutes. Last time the 30th mode arrives in Cilincing is at the 23,67 hours.

The forth scenario is carried out for M14 mode is 30 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed there is no traffic jam along routes. So trip time needed from one to another stopping place is 156 seconds.

From simulation, it is known that first mode leaves Tanjung Priok at 5 o'clock, and arrives in Cilincing at 5.23 o'clock, so average trip time passed from Tanjung Priok to Cilincing is 23 minutes. Last time the 30th mode arrives in Cilincing is at the 12,31 hours.

The fifth scenario is carried out for M14 mode is 20 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed there are several traffic jams along routes. So trip time needed from one to another stopping place is 300 seconds.

From simulation, it is known that first mode leaves Tanjung Priok at 5 o'clock, and arrives in Cilincing at 5.23 o'clock, so average trip time passed from Tanjung Priok to Cilincing is 23 minutes. Last time the 30th mode arrives in Cilincing is at the 15,75 hours.

The sixth scenario is carried out for M14 mode is 20 vehicles, and operated based on schedule by using 10 stopping places, as well as assumed there is no traffic jam along routes. So trip time needed from one to another stopping place is 156 seconds.

From simulation, it is known that first mode leaves Tanjung Priok at 5 o'clock, and arrives in Cilincing at 5.23 o'clock, so average trip time passed from Tanjung Priok to Cilincing is 23 minutes. Last time the 30th mode arrives in Cilincing is at the 8,19 hours.

From abovementioned sixth scenario of simulation result, the following Table 4 will provide its recapitulation.

Table 4:. Sixth scenario recapitulation

Scenario	Moda (unit)	Head Way (second)	Time Cycle Last Moda (hour)	Condition
I	79	300	62,50	Macet
II		156	32,50	Tidak Macet
III	30	300	23,67	Macet
IV		156	12,31	Tidak Macet
V	20	300	15,75	Macet
VI		156	8,19	Tidak Macet

Based on calculation result of harmony for amount of mode, ratio and total driver's income, so best ratio or load factor is 0,30. This value is become indicator to develop scenario in line with two abovementioned big scenarios. Simulation result to operate M14 route is 30 modes provided in the following table.

Table 5: 30 Moda schedulling with halte adddition

Cyclus	Starting Time	Finishing Time	Cycle Time (Hour)
I	05.00	06.18	1,30
II	06.18	07.36	
III	07.36	08.54	
IV	08.54	09.12	
V	09.12	10.30	
VI	10.30	11.48	
VII	11.48	13.06	

By applying scenario to operate 30 modes and additional stopping places, so there is one rotation in the morning shift, and driver can carry out 7 rotations, while of there is no schedule, driver only can carry out 5 rotations. So it will influence driver's income significantly. The following is the comparison.

Table 5: Comparison driver's income with policy

Policy	Moda	Rasio (Load Factor)	Number of Cyclus in 1 Shift	Drivers' Revenue (Rp./day)
Without adding shelter	30	0,300	5	604.900
With adding shelter	30	0,421	7	940.650

From abovementioned table, it is known that additional stopping places for 30 vehicles will generate ratio lower than additional stopping places for additional stopping places, namely 0,421. Refer to this policy, driver's income increase from Rp 604.000,- to become Rp 940.650,- because rotation will increase also, namely from 5 rotations to become 7 rotations. The following SFD simulation result indicates the increase in driver's income.

3. CONCLUSION AND SUGGESTIONS

3.1 Conclusion

1. Based on developed model result, total public transportation vehicles for Tanjung Priok – Cilincing (M-14) rationally are 30 vehicles. Those amounts will give the highest load factor if they are integrated with innovation as public transportation scheduling system, so they can increase driver's income and will decrease traffic jams.
2. Based on policy and scenario made, suggested policy is to schedule 30 vehicles by adding 10 stopping places. Additional stopping places will increase government's fund as amount of Rp 100.000.000,- and they will increase driver's income become Rp 940.650,-

3.2 Suggestions

In view of conditions, there are 79 M-14 vehicles with average trip feasibility are for 60 vehicles. System evaluation of licenses for M-14 routes may be carried out.

ABSTRACT

The City of Depok produces solid waste up to 3,000-3,400 m^3/day. The amount of solid waste transportable to landfill is only 1,200m^3/day, approximately 35% of total amount produced. Solid waste is transported to Cipayung Landfill, an area of 11.1 hectares, which is predicted to be packed by 2010. The objective of this research is to implement the 3Rs (Reuse, Reduce & Recycle) concept in providing inputs and feedback for the Government City of Depok in order to minimize the amount of solid waste and prolonging landfill operational period. There are 3 activities in this research which are observing a location already implementing 3Rs concept, outlining an integrated solid waste management (ISWM-3Rs) concept model and developing solid waste pilot plant. The ISWM-3Rs concept model can be successfully implemented through community socialization activities, with the assist during the implementation process. The ISWM-3Rs concept model is proven to reduce amount of solid waste transported to landfill. This program will generate revenue to the RW (Rukun Warga). ISWM-3Rs Cadres and agents play an important role to successfully the ISWM-3Rs concept.

Keywords

Solid waste, ISWM-3Rs, pilot plant, Neighborhood Organization (RW)

1. INTRODUCTION

The City of Depok is located in West Java with an area of 200,9km^2 and population reaching 1,503 million people [1]. The city is constantly growing and producing solid waste up to 3,000-3,400m^3/day [1]. However, the amount of solid waste transportable to landfill is only 1,200m^3/day, approximately 35% of total amount produced. The source of solid waste originates from residential (62%), traditional market (21%) and others (17%). Solid waste transported to Cipayung Landfill, the 11.1 hectares final disposal area, predicted to be packed by 2010 [1].

Waste management is managed by the Office of Cleanliness and Landscaping (OCL) City of Depok. OCL has a strategy which used in solid waste management as follow: a) implementing a new 3Rs (reduce, reuse and recycle) concept basis paradigm with the community's involvement; b) optimizing the waste treatment in every sub-district through developing Waste Treatment Unit (WTU); c) reducing the amount of solid waste sent to landfill (TPA) through proper treatment at WTU; d) increasing the community's involvement in producing compost at their home site; and e) composing and implementing Local Government Decree (Perda) on cleanliness management and in line with Law no. 18 (2008) on Solid Waste Management [1].

OCL has built 5 WTU's in 2007 and at this moment is still operational. In 2008, an additional 18 WTU's were built where 5 have been operational. By 2011, OCL is planning to have added an additional 40 WTU's thus totalling 60 WTU's in Depok. Each WTU has a capacity of 30 m^3/day except the one located at landfill (90 m^3/day) [1].

The obstacle faced by OCL , amongst, are the low level of community's awareness on clean and healthy living and the implementation of 3Rs [1]. The limitation of infrastructure, human resources and funding is also part of the obstacles that needs to be addressed, along with the community's refusal of having WTU built in their neighbourhood. An example of community refusal is seen at Taman Cipayung Residence and Bukit Rivaria Residence. These refusal cause a delay in delivering WTU and thus not able to meet the target set in the early stages.

The obstacle in solid waste management faced by the Government of Depok addreses the needs to develop a waste management model that reflects the community's involvement. The model that will be developed is aimed to reduce the amount of solid waste directly from its main source, which is residential. This, in turn, will also reduce the amount of waste send to the landfill.

ISSN 114-1284

2. OBJECTIVES

The objective of this research is to implement the 3Rs (*Reuse, Reduce* & *Recycle*) concept in providing inputs and feedback for the Government City of Depok in order to develop an Integrated Solid Waste Management System (ISWM-3Rs). These inputs and feedback could minimize the amount of solid waste send to landfill, thus prolonging its operational period.

3. METHODOLOGY

There are 3 activities in conducting this research: 1) Observation at location which already implementing 3Rs concept for its solid waste management; 2) outlining an integrated solid waste management concept model with 3Rs basis; and 3) developing solid waste pilot plant with 3Rs basis.

3.1. Observation

Observation conducted as input and comparator in developing integrated solid waste management base on 3Rs (ISWM-3Rs) at pilot plant. Observation will be conducted at location which are already implementing 3Rs concept in their solid waste management. The object of this observation, amongst, is socialization process which have been conducted, implementing 3Rs concept process, solid waste separation, supplying the facilities, composting and recycle process, organization, funding aspect and obstacles.

Observation in the field conducted at house as source of solid waste and the activity of composting and separating took place. Hereinafter, result of observation noted and became materials to analyze the outlining ISWM-3Rs concept model and it's implementing process.

3.2. Outlining an Integrated Solid Waste Management Concept Model with 3Rs Basis

The concept model is developed based on the community's needs and requirement, which is then utilized to facilitate during try-out phase.

3.3. Developing Solid Waste Pilot Plant with 3Rs Basis

The practice of ISWM-3Rs does not conduct in wide area but only in one RW. RW 04, which resides at Mekarjaya Sub-district, was chosen as pilot plant location base on their good response during socialization process.

The ISWM-3Rs model that will be conducted should be appropriate with the local community requirement. The selection of model will be discussed with the entire community member, thus, the chosen model is a collective decision within the community.

The practice of ISWM-3Rs model includes the following three activity phase which are preparation phase, implementing phase and improvement phase as shown in Table 1.

Table 1: Phase of ISWM-3Rs practice

PREPARATION	IMPLEMENTATION	IMPROVEMENT
Exploring potential location and solid waste composition	Model building	Monitoring
Program briefing and explanation	Discussing	Evaluating
Survey of community needs	Organization building	
Planning to fulfill community needs	Implementing

4. RESULTS AND DISCUSSIONS

4.1. Observation Results

Observation was conducted at the Griya Pancoran Mas Residence within Rangkapan Jaya Sub-District, Pancoran Mas District. This residence is located in one RW that consists of 7 RT's, comprise of 360 middle-income housing units and is seen in Figure 1 below.

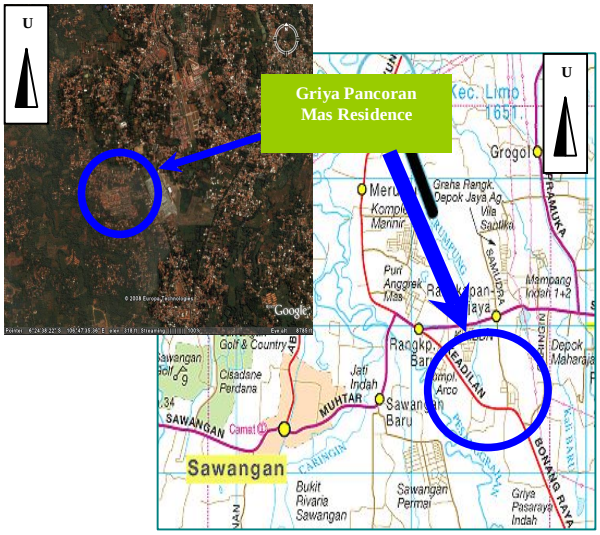

Figure 1: Observation location at Griya Pancoran Mas Residence, Rangkapan Jaya Sub-district [2, 3]

Waste management at Griya Pancoran Mas Residence was first socialized in October 2007 through participating in various residence activities such as neighborhood meetings. Work Groups (WG) and Environmental Cadres (EC) were formalized, where WG would be the person in charge, proctor and enforcement whenever EC face challenges. EC were chosen based on their ability and willingness to implement ISWM-3Rs. EC is responsible for briefing, monitoring, coordinating with housing units within their supervising area, managing recycled materials such as selling these materials to recycle agent and sales bookkeeping.

The ISWM-3Rs model was implemented starting in May 2008. Each RT had 4 EC, totalling 28 for the entire residence area. Each EC recieves Rp 30.000/day from OCL for the first 3 months. This funding is provided since it is an OCL work program, and in addition, OCL also provides bins for individual composter for seperating inorganic waste, drill to create bio-pore and poster and banner for campaigning.

Observation was conducted on each EC and houses as the main subject of waste management, where the observation is required to see how EC performs their duties with consistency. The observation items for EC include whatever actions taken when dealing with recycled material, ability to motivate the housing unit within their supervising area in order to seperate waste and composting, along with level of consistency shown in implementing the model in their own home. The observation in each housing include level of awareness and consistency in dealing with waste seperation, making compost, usage of recycled material, and their views toward WG and EC.

The observation period lasted for approximately 2 months, and the ISWM-3Rs model implemented at Griya Pancoran Mas is as follow:

a. Each house conducted waste separation for organic and inorganic waste
b. Organic waste consist of three types, which are yard waste, unprocessed food waste and processed food waste
c. Yard waste is converted to compost by forming a rounded wire mesh and the waste is inserted into the rounded area
d. Unprocessed food waste is converted to compost via takakura method
e. Processed food waste is converted to compost via bio-pore
f. Inorganic waste recyclable is collected in the bins provided, collected every 7-10 days by EC, sold to recycle agent and bookkeeped the amount sold
g. Waste that cannot be converted to compost or as recycled material will be collected by waste collector and taken to temporary station

Figure 2: Solid waste separation, bio-pore and composting with Takakura method in Griya Pancoran Mas Residence

In the early stages of implementation, it is observed that the EC are still active in controlling and briefing the houses under their supervision. But later in the program, inconsistancy begins to grow. Some EC in RT 05 and 07 shows sign of boredome and demotivated, EC in RT 04 shows inconsistency in compost processing especially shredding the waste. But on the other hand, EC in RT 02 and 03 still shows consistency in motivating their resident as well as within their homes for waste separating and composting.

Based on house observation, it is seen that waste seperating went well with the exception some houses were inconsistent in performing this act. Composting via takakura method also went well at the early implementation stage, but reaching the end of observation period it is seen that the community's motivation started to wear out especially during the shredding process. The common reasoning being the fact that this process is time consuming, where the bulk of their time is allocated towards their family or full-time job. In addition, some resident complain that the takakura method is difficult to perform. The roles and responsibility of WG and EC were shown positive, with the exception that some thought WG didn't provide sufficient support to implement ISWM-3Rs.

There were several difficulties that the resident felt in implementing this system, which are:

a. Shredding takes too much time, thus demotivating resident to perform this task
b. Minimum knowledge on composting via takakura method resulting compost produced being too wet, too dry or containing maggot, thus causing lack of interest from resident
c. Composting via bio-pore attracts mouse and rodent, thus causing lack of interest from resident
d. Duration between recyled material collection is too long, thus creating a sense that the resident's house is filled with garbage

These feedbacks from Griya Pancoran Mas residence will be utilized in the model development at pilot plant.

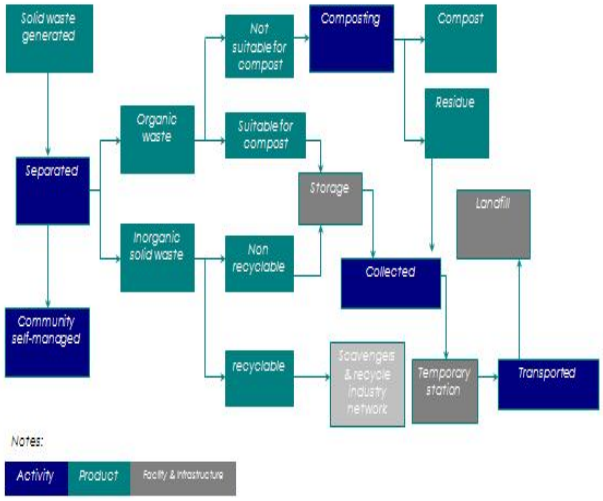
4.2. An Integrated Solid Waste Management Concept Model with 3Rs Basis Results

The 3Rs concept has very important role in an integrated solid waste management system. One of its benefits is to reduce solid waste volume that enters into landfill, thus prolonging the landfill operational period. The 3Rs concept related with solid waste management hierarchy resides on top of hierarchy. This concept can be developed based on solid waste type to separate, garbage bin type and location, and composting methods used. The ISWM-3Rs concept could be seen in Figure 3 below.

Solid waste separation was conducted to dissociate waste deemed for reused, recycled or composted based on its originate being organic or inorganic waste. Inorganic waste will be further separated into paper, plastic, glass, textile and metal.

Solid waste that has been separated will not be mixed when transferred to temporary station (TPS). Bins and transportation system are needed to dissociate the waste types. The bins could be individually or communally provided.

Figure 3: Integrated solid waste management concept model



with 3Rs basis in general

The bins to be utilized must be strong enough, waterproof, inexpensive, easily made or obtained, and easily emptied. The suitable materials that could be used include plastic, fiberglass, metal, wood, cane or bamboo. Indonesian National Standard (SNI) No.19-2454-2002 could be followed for waste bin material and size. The amount of bins utilize is exactly the same amount of waste separated. The waste bins are placed in front of each residence or house and accessible to waste collector and owner. The alternatives of waste bins location can be seen at Figure 4.

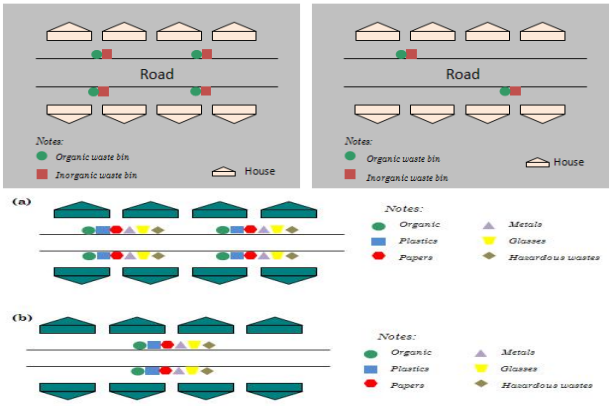


Figure 4: Alternatives of waste bins location at residence area

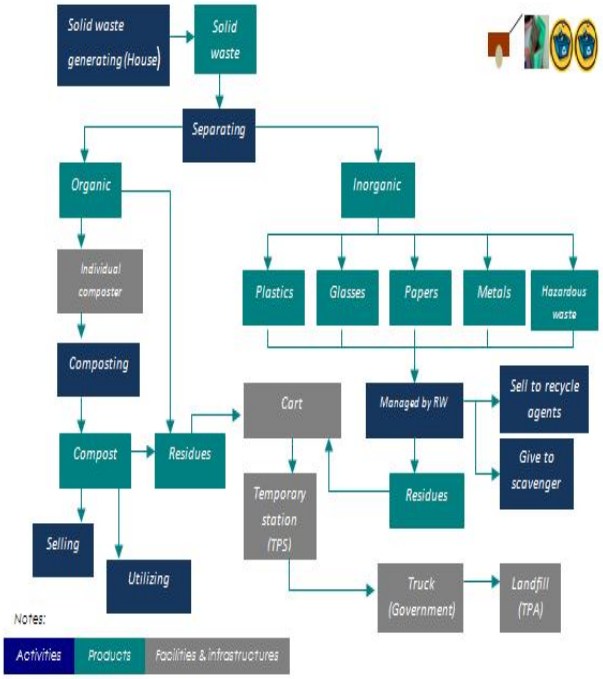
Transportation type and period that will be performed refers to ISWM-3Rs model. Waste transportation will be divided into two transportation types, each for organic and inorganic waste. Organic waste will be carried away to temporary station daily or every two days. Should organic waste will composted communally, it should be carried away daily. But the other hand, the waste doesn't have to be carried away daily if individually composted since it is not economical.

Organic waste will be composted and becomes fertilizer. There are several methods in composting depending if individual or communal. Takakura method is performed for individual composting, whereas open windrow method is performed for communal composting. Bio-pore, both individually and communally, could be useful to make compost for yard waste.

According to the explanation above, therefore a models has



been developed as shown at Figure 5 below.

Figure 5: The ISWM-3R model of integrated solid waste management that implemented at RW 04 Mekarjaya Sub-District

The ISWM-3Rs model has been developed base on:

a. Composting methods: individually or communally
b. Type of waste separated which consist of two waste types (organic and inorganic waste) or six waste types (organic, plastic, paper, glass, metal, and hazardous waste)
c. Management of inorganic recycled materials conducted by waste owners or local organization (RW/PKK)

4.3. Solid Waste Management Pilot Plant Results

The Pilot Plant was conducted at RW 04 in Mekarjaya Sub-District, started with initial phase of socializing the model. Socialization were done during several meetings with local

organization (RW/RW Siaga/Ketua RT/PKK), where in the meetings formal organization was formed and in line with the already local RW/RW Siaga/Ketua RT/PKK organization. In addition, Environmental Cadres were appointed to assist the community during ISWM-3Rs practice.

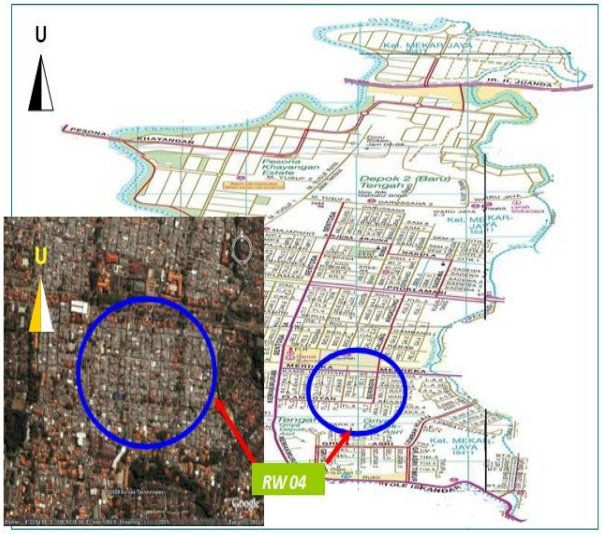


Figure 8: Pilot plant location at RW 04 Mekarjaya Sub-District [3, 4]

The materials needed to implement this model consist of plastic bag utilized as temporary storage of inorganic recycled material and plastic bin utilized as individual composter. This initial try out will be conducted only on 75 houses, with the hope that other residents will be inspired to emulate this program and provide their own materials.

The ISWM-3Rs model chosen for RW 04 is using model 4 with some minor alterations to accomodate the community's current condition. Model 4 is based on seperating the waste into 2 categories, which are organic and inorganic waste. Organic waste deemed for composting is immediately fed into the composter and utilized in the try-out, whereas the ones undeemed are trashed and taken to temporary station at Merdeka Road.

Figure 9: The practice of ISWM-3Rs at RW 04 Mekarjaya Sub-District

Inorganic waste is delivered by its owner weekly to RW office, and then sold off to recycle agent. The alteration performed on model 4 accomodates recycled material managed by RW and PKK organization and not by owner/source of waste.

5. CONCLUSIONS

The ISWM-3Rs concept model is applied successfully through socialization and supervision during implementation process at all time and consistently. Socialization activities were performed during community's monthly meeting, thus eliminating the need for additional meetings. Socialization was necessitated to conduct in order to enhance and shift the community's paradigm on solid waste so they can better understand waste treatment and management correctly. The other successful key of socialization is community's awareness towards the importance of solid waste management.

At the starting period of ISWM-3Rs practice, local organization which includes RW, PKK and EC should be formed. This organization and EC will implement the model and maintain ISWM-3Rs consistenly and sustainably.

The implementation of ISWM-3Rs is able to reduce the amount of waste tranported to temporary station and landfill while simultaneously converting organic waste into compost as value added material and also recycling inorganic waste.

Other succesful ISWM-3Rs factor includes the presence of recycle agents to support the inorganic recycled material chain, connecting the owner/source to recycle factory. Collaborating with these agents is an additional source of income for RW/PKK organization.

ABSTRACT

This study is concerned with the solution approach of Minimum Concave cost Multicommodity Flow (MCMF) problem. The proposed MCMF makes use of transportation and production cost as well as revenue as its component and it takes form of multisource multidestination system. Concave cost function of our model is associated with transportation and production cost. The objective function of the model is minimization of negative profit.

The particular issue considered in our MCMF model is the use of network representation (NR) in order to solve the model. All the components of the model are represented in link cost functions of links of NR and Flow Requirement of nodes of it. This paper will be focused on the heuristic solution of the problem.

Due to the complexity of the model, the solution approach takes form of bi-level model. The objective of first level is to cluster NR into some sub networks in order to modify multisource network problem into some single source network problem. The objective of second level is to solve the NR, but at this level the NR is already clustered into some sub networks that takes form of single source.

Keywords

Minimum Concave-cost Multicommodity Flow problem, multi sources, network representation.

1. INTRODUCTION

The problem of Minimum Concave-cost Multicommodity Flow (MCMF) arises in many application areas. One of them is its application in the optimization of freight distribution system. Its task is how to assign some amount of products to particular plant to satisfy demand at some points in order to minimize cost of the system.

Concave-cost function arises usually due to the encountered economies of scale in considering some components of cost, such as transportation and production cost. In practice, the unit cost of transporting (or producing) freight usually decreases as the amount of freight increases. Hence, in economies of scale, the marginal cost of transporting (or producing) products is presumed as a decreasing function over the usual operating range. Consequently, in actual operations the transportation (or production) cost can usually be formulated as a concave cost function.

A key mathematical difficulty in analyzing the minimum concave cost network problem is the optimal flow x^* may be a relative minimum and not a global minimum. That is, x^* may minimize the objective function over the intersection of the feasible region and a neighborhood of x^*, but may not minimize the objective function over the entire feasible region.

The MCMF problem proposed in this work is characterized by particular issue regarding the approach used in model solution. We are employing Network Representation (NR) in order to solve the problem. Our NR is originally formed by associated physical network which represents production and demand points, as well as intermediate points (e.g. warehouses). Links between those points denote transportation facilities between those points, such as roads, waterways, railways and airways. Furthermore, we add dummy links and nodes to such physical network, if it is needed, to represent all of the cost components of the model. By using this NR, we solve the problem of MCMF of such NR through the algorithm that is developed in this work.

Due to the complexity of the problem of minimization of concave cost function, especially due to the multisource network and multicommodity problem, we try to approach our MCMF solution by bi-level model. Bi-level model stratify MCMF problem into 2 (two) levels. The objective of first level is to cluster NR into some sub networks in order to modify (original) multisource network problem into some single source networks. The objective of the second level is to solve the original MCMF problem,

but at this level the NR is already clustered into some sub networks. Each of sub network takes form of single source multidestination network.

The organization of the paper is as follows. Section 2 provides an overview of current literature on MCMF problem; section 3 presents our model and discusses its formulation; section 4 proposes algorithm to solve our model, and finally section 5 summarizes the research undertaken and propose some recommendation.

2. LITERATURE REVIEW

Traditionally, minimum concave cost network flow problems have usually been solved in the following 3 ways [7]:

1. By solving a series of Linear Programming approximations to the original problem
2. By local search methods designed to send an extreme flow by searching among candidate solutions
3. By metaheuristic methods, such as Tabu Search, Genetic Algorithm, Simulated Anealling.

Zangwill [8] argue that although concave functions can be minimized by an exhaustive search of all the extreme points of the convex feasible region, such an approach is impractical for all but the simplest of problems. He proposes some theorems which explicitly characterize the extreme points for certain single commodity networks. Algorithms are developed to determine the solution for networks with single source multiple destination networks and single destination multiple source.

Gallo [3] proposes that there is a one-to-one correspondence between the set of extreme flows and Destination Spanning Tree, where the root is source node , each terminal node is a destination, and the remaining destinations (if any) appear as intermediate nodes. Solving the problem of minimum concave cost network flow is based on an implicit enumeration of the elements of Destination Spanning Tree, using a Branch and Bound method. He employs uncapacitated and single source multidestination network.

Guisewite and Pardalos [4] discuss a wide range of results for minimum concave-cost network flow problem, including related applications , complexity issues, and solution techniques. They show that that problem is NP-hard for cases with cost functions other than fixed charge. Algorithms for the general problem are exact or approximate. Exact techniques are efficient only for specific subclasses of problems, and are usually based on branch-and-bound or dynamic programming techniques. Approximation algorithms are based on local search or solving a related linear or convex problem.

Larsson, Migdalas and Rönnqvist [5] propose a heuristic solution technique for the capacitated concave minimum cost network flow problem based on a Lagrangean dualization of the problem. The Lagrangean dual is solved by a subgradient search procedure.

Yan and Luo [7] employ the techniques of simulated annealing and threshold accepting to develop several heuristic that would efficiently solve the concave cost transportation network problems, which take form of . single stage and capacitated network.

Fontess and Gon□alves [2] address the single source uncapacitated minimum concave cost network flow problem. They present a hybrid approach combining a genetic algorithm with a local search.

Yan, Juang, Chen and Lai [7] propose utilization of Genetic Algorithm to develop a global search algorithm for solving concave cost transshipment problems. Efficient encoding, initial population generation, as well as cross over and mutation strategies have been developed to deal with characteristic of the model as single commodity and multisource multidestination problem.

3. MODEL FORMULATION

Our MCMF problem employs transportation cost, production cost as well as "negative revenue" as its cost components. The formulation is set up as cost minimization problem with quantity of products distributed on each link of NR as decision variable. As the transportation and production cost are designed as concave cost function, hence our proposed model follows the nature of MCMF problem. MCMF is aimed to minimize cost in order to deliver some amounts of products from origin to destination, whereas it is limited by some constraints in capacity. The formula of our MCMF problem is as follows :

$$\min Z(x_{ijm}) = \sum_{i \in I} \sum_{j \in J} \sum_{m \in M} \varphi_{ijm}(x_{ijm}) \qquad (1)$$

subject to :

$$\sum_i x_{ilm} - \sum_j x_{ljm} = q_{lm} \quad \forall\, l \in N,\ \forall\, m \in M \qquad (2)$$

$$x_{ijm} \geq 0 \quad \forall (i,j) \in A,\ \forall\, m \in M \qquad (3)$$

where :

x_{ijm} : is aggregate flow on link $i - j$ of product - m

$\varphi_{ijm}(.)\ \forall i \in I, j \in J, \forall m \in M$: is link cost function of link $i - j$ of product-m

q_i : is flow requirement of node-i

N : is set of nodes of network representation

A : is set of links of network reprsentation

M : is set of products

Equation 1 shows the objective function of minimizing total cost of all links on the network which associated to all types of products. The optimization is limited by Flow Requirement on each node, that is total inflow minus total outflow of the node (equation 2). Finally, non negative flow is guaranteed in this optimization.

ISSN 114-1284

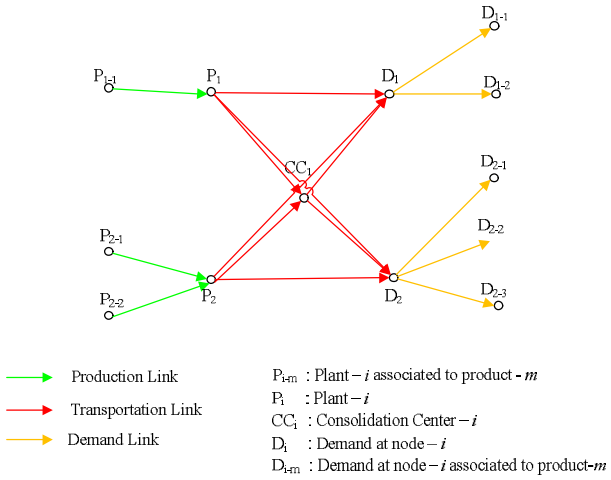

Figure 1. Example of Network Representation

NR associated to our proposed model is denoted in figure 1. Our NR consists of 3 types of links, those are production links which represent production cost, transportation links which represent transportation cost and demand links which represent revenue. Each of production links is associated to production cost of certain type of product, while each of demand links is associated to revenue obtained from selling certain type of product on that node. Both production and demand links are product-exclusive. Furthermore, transportation link is assigned to deal with all types of products aggregately since it is assumed that unit cost to transport any type of products in certain transportation link is similar.

Solving MCMF problem of such NR is similar to solving minimization model of equation 1. All of the constraints of equation 2 are satisfied by the Flow Requirements determined to all of nodes of NR.

4. HEURISTIC SOLUTION OF MCMF PROBLEM

Due to the complexity of solution of MCMF problem, particularly caused by multisource as well as multicommodity problem of the model, we approach the solution by bi-level model. Figure 2 shows the step-wise of our bi-level model.

At the first level, we focus on clustering the destination nodes, based on the associated production point which is the best-suited to be assigned to. At this level, we consider our model as a linear model. It implies that the cost to transport (or produce, or sell) one unit of product from one point to another point is constant, not depend on the quantity of product it deals with. Such unit cost is defined through the associated link cost function, that is by corresponding one unit of flow to its associated cost function.

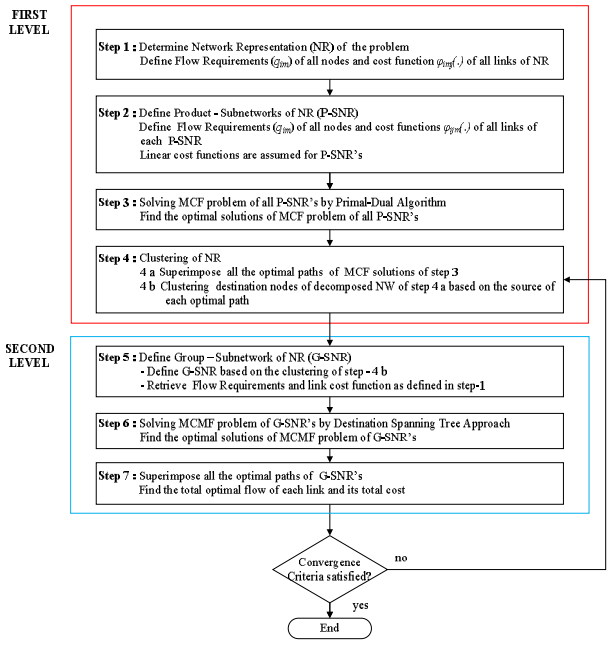

Figure 2. Step-wise of Bi-Level Model

At this level, NR is decomposed into M – Product Sub Network Representation (P-SNR) , where M is the number of types of products. Each of P-SNR represents all the possible links and nodes to be assigned to serve distribution of certain product from origin to destination. P-SNR of product-*x* (for example) consists only of links and nodes of NR in which product *x* can pass through them.

Figure 3a shows the example of one NR that consists of 2 production points (P_1 and P_2) , 7 demand points (D_1~D_7) and it deals with 2 types of products (product 1 and 2). P_1 produces both types of product, whereas P_2 only produces product 1. P-SNR's of such NR are shown in figure 3b and 3c. Figure 3b denotes P-SNR of product 1 and figure 3c denotes that of product 2. Due to product-exclusivity of production links (or demand links) , it is shown that in P-SNR 1 there are no link $P_{2-2} – P_2$ and D_1-D_{1-2} as well as other links associated to product 2. Whereas, there are no link $P_{1-1} – P_1$, $D_1 – D_{1-1}$ and other links associated to product 1 in P-SNR 2.

Due to the linear assumption, the first level concerns to Minimum Cost Flow (MCF) problem. MCF problem of P-SNR's are solved by Primal-dual algorithm. The algoritmic strategy of the Primal-dual is at every iteration it solves a shortest path problem and then solves a maximum flow problem that sends flow along all shortest path [1]. The Primal-dual also maintains a pseudoflow that satisfies the reduced cost optimality conditions and gradually converts it into a flow by augmenting flows along shortest path.

Furthermore, at the end of first level, MCF solutions of all P-SNR's are superimposed to find total optimal flow of first level. The superimposing is allowed to find total flow due to 2 (two) reasons :

1. Unit cost of transportation link of any type of products in certain transportation link is similar.

2. Eventhough the unit cost of production and demand link of all product may not be similar, there exists independency between production link (or demand link) of certain product and the others (due to product-exclusivity of production or demand links) .

D_{i-m} : Demand at node – *i* associated to product-*m*

Justified by the optimal solutions of first level, we proceed to cluster the destination nodes into S - Group Sub Network Representation (G-SNR), where S is the number of source nodes. Figure 4a and 4b show one possible clustering of NR discussed in figure 3a. Figure 4a represents G-SNR 1 which consists of links that are originated in node P_1, whereas figure 4b shows that of node P_2. Production links of G-SNR are not employed directly in the structure of G-SNR, hence each of G-SNR's forms single source multidestination system, where node P_i is designed as a source. Production links just functioned at the algorithm to assign production cost of certain product that consumed at node D_{i-m} and supplied by associated production point.

At second level, all or some of link cost functions are taken into account as concave functions.. Hence, the second level is dealing with Single Source Multidestination MCMF problem. The problem of each G-SNR is solved by heuristic algorithm related to Destination Spanning Tree solutions [3].

The following description will explain the step-wise more clearly.

Step 1 is aimed to define the NR of MCMF problem. NR is composed of links and nodes which represent all of the cost components of the mathematical model. In step 1, all link cost functions are defined, as well as flow requirements of all nodes. Special assignment is carried out to the production and demand links. To each of production links (and demand links), we assign cost function associated to certain product. Whereas, each of transportation links is assigned to cover all types of product, hence its link cost function is defined in aggregate form, no matter the type of product transported.

In association to the production link cost function assignment described above, flow requirement of production point (P_{i-m}) is numbered as production capacity of node-*i* on product-*m* , where *m* is the-*m* of associated production link. The similar treatment is carried out to the demand point (D_{i-m}), where the flow requirement of demand point denotes the quantity of product consumed at node-*i* on product-*m* and *m* is the-*m* of associated demand link. Flow requirement of intermediate nodes should be assigned as zero, since the inflow and outflow at such nodes are always designed in balance.

Step 2 is aimed to define Product – Subnetwork (P-SNR), included Flow Requirement of all nodes as well as link cost function of all links. P-SNR is originally formed by NR. Each of P-SNR is associated to certain type of product. P-SNR of certain product is distinguished to the other P-SNR only in the amount of Flow Requirement of both production point and demand point. When we assign flow requirement of production points of P-SNR of product-*x* (for example), we just number the flow requirement of production points that related to production links which are associated to product-*x*.

The similar assignment is carried out to Flow Requirement of Demand Points. When we assign Flow Requirement of demand points of P-SNR of product-*x*, we just number the Flow Requirement of demand points that related to demand links which are associated to product-*x*.

Flow Requirement of the remaining nodes of Production Points and Demand Points are set as zero. This zero value is due to no product is considered in P-SNR of *x* except product-*x* itself.

At step 3, we solve Minimum Cost Flow problem of each P-SNR of step 2 by Primal-dual Algorithm. In general, Prima-dual algorithm employs shortest path and maximum flow algorithm to optimize the assignment of distribution in order to minimize total cost.

Having the optimal paths of all P-SNR's, at step 4 we superimpose optimal paths of all P-SNR's and find total optimal flow of NR in the first level. From such path pattern of total optimal flow of NR, we heuristically cluster the destination nodes into some groups, depend on the number of origin nodes of NR. Therefore, clustering makes NR grouped into *S* Group – Sub Network (G-SNR), where *S* is the number of origin nodes. Accordingly, each G-SNR takes form of single source multidestination network.

Using G-SNR's of step 4, we proceed to second level to solve MCMF problem of G-SNR's. At step 5, Flow Requirements and Link Cost Functions of G-SNR are defined by retrieving all information of step 1. Thus, link cost function of G-SNR takes form of concave function.

At step 6, we solve the MCMF problem of each G-SNR by Destination Spanning Tree algorithm. DST algorithm developed by Gallo [3] is employed at this step.

Step 7 is aimed to superimpose all the optimal paths of G-SNR's and find the associated optimal flows of NR.

Due to the heuristic approach of clustering destination nodes (step 4), in which it may produce more than one possible set of clustering, step 7 could be continued by rearrangement the clustering of step 4 and carry out step 5 to step 7 in similar ways to the first iteration. The process will be ended when the convergence criteria is satisfied.

5. CONCLUSION

Due to the complexity of problem of Minimum Concave-cost Multicommodity Flow, particularly of multisource network, this research work proposes one heuristic solution which takes form of bi-level model. The principle of that approach is the assumption of linear cost function of first level and concave cost one of second level. Those are assumed in order to change the problem of multi source into single source one. It is realized that the proposed step-wise is merely an attempt to come close to the global optimum solution. This research work is essentially intended to make contribution to research field of freight distribution. Further works may be carried out in order to make comparation between some approaches that have been developed by previous researchers with this work.

ABSTRACT

In its long-term effort to revitalize Indonesia railway, government is also looking at the possibility to develop a high speed passenger railway transport system in Jawa. The Jawa High Speed Train (JHST) will form an important element of multimodal transport system in the region and in the same time is expected to reduce over-congestion and over-saturation of Jawa's road network in many years to come. But Indonesia has no experience on high speed train and its implementation will have to be based on studies and experiences of many different aspects and perspectives in other countries. While high speed train technology is now available in Japan and some European countries and can be imported and borrowed, the socio-economic and political conditions of contemporary Indonesia are somewhat distinct and deserve investigation.

This paper reports the literature reviews of studies and practical experiences about high speed rail transport that had been done elsewhere in the world and that had been widely published in the international journals. The paper will also identify the various factors that can lead to the successful implementation of the system as well as its shortcomings, once it is decided the system will be built in Indonesia. Special focus is given to Jawa island, where economic and population consideration matters and political support could be influential in building up policy consensus and determination in national scale. The paper also takes a look at the possibility of financing scheme to search for the best option available. Public-private partnership and its corresponding project financing would be examined accordingly. Early findings of the study will serve as basic and background information to the policy makers in transport sector and will serve as both basic academic and practical guidance for the future rail-based transport development in Indonesia.

High-speed train, Jawa's rail, public-private partnership, project financing

1. INTRODUCTION

1.1. The People Movement

There are at least two academic rationales for implementing a high speed train in Jawa island. First, is the steady increase of population and its consequences for high demand of traveling in the island. Second, is the heavy reliance of Jawa's economic mobility on road system which had been oversaturated, overcongested, and consistently deteriorated. A long-term perspective of Jawa's economy reveals the unchallenged trend of the dominance of the region in the national economy. This strongly indicates that economic mobility in Jawa will still be growing steadily in the future. The road system in Jawa, however, cannot be continuously burdened as the major transport mode to carry the additional future passenger urban and inter-urban traveling, without reasonable modal shares from other modes, especially railway. With 151 million people in 2025, passenger trips in Jawa would be growing tremendously high and it is believed that only the combination of road, rail, air, and coastal sea transport as an integrated system would be able to ease the burden of intra- and inter island people traveling.

Indonesia is now embarking on the railway revitalization programs to put the rail transport in the economic perspectives and to make rail as the backbone of national transport, especially for national distribution and logistic system. It is perceived that the high speed rail system would significantly contribute to more efficient passenger movements in Jawa and would be instrumental to the

revitalization efforts in the longer term, and in the same time also the economic efficiency of the country. A high speed rail transport in Jawa would also be a significant step toward a multimodal transport system, which is now lacking from national transport configuration.

1.2. Population Growth

One of many outstanding political economic issue of contemporary Indonesia is its population growth and dispersion. Indonesia population grew by 1.36 percent between 2000-2005, leading to total number of population of 220 million in 2005. Although growth rate is projected to decline to an average of 1.25 percent between 2005-2015 and 1.05 percent between 2015-2025, total population will still reach more than 234 million in 2010, 248 million in 2015, 261.5 million in 2020, and 273.6 million in 2025 [1]. Figure 1 shows the population imbalance in which Jawa island with only 7 percent of Indonesia total land area will be inhabited by 151.5 million people in 2025. In contrast, Papua with 17 percent of land area and with all the relatively unexploited wealth and treasures of its land, sea, and forest will only be inhabited by 3.7 million people, 20 years from now.

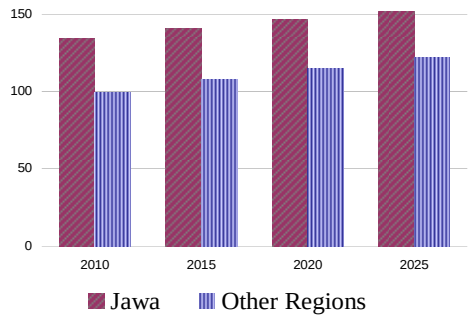

Figure 1 : Projection of Jawa Population
Source : Bappenas, BPS, UNFPA, 2005

Another demographic issue in Indonesia is the massive urbanization that has long been occurring in a rather alarming rate, as shown in Figure 2. In Jawa, around 82 percent of its population on the average is projected to live in urban areas by 2025, increase significantly from 57 percent in 2000. Bali is the second largest region in term of urbanization rate with 79.6 percent followed by Kalimantan 59.8 percent, Sumatera with 57.3 percent, and Sulawesi by 46.2 percent [2]. Figures 1 and 2 clearly show a very-skewed population distribution between regions that has been occurring for so many years in the past and that is still persistently prevailing until 2025, and probably longer. Population growth, *per se*, is probably not really the main issue here as well as its distribution over regions could be made more evenly and regional economy is growing well to absorb

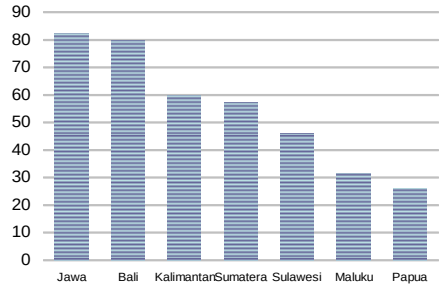

Figure 2 : Projection of 2025 Urbanization Rate
Source : Bappenas, BPS, UNFPA, 2005

increasing labor forces from every region in the country. But in Indonesia dispersed population and more even economic development have never been the case. Since Jawa's population is growing rapidly and its corresponding people mobility is also increasing significantly, it is imperative for Jawa to have a modern rail-based transport system that is capable to carry millions of person-trips in a much faster mode and more efficient manner.

As the sustainable carrying capacity of Jawa has declined steadily, it is not an exaggeration to put Jawa as the main focus of national efforts to ease the burden of population pressures and its following social, economic, and mobility problems. But population policy measures cannot be effectively implemented without other policy measures, including the transportation measures, a rather total solution for long suffering of Jawa's over-crowdedness, over-saturated, and transport inefficiencies . Table 1 shows the population figures of the provinces in Jawa for 2005 and 2025 and its corresponding percentages of urban population in provincial levels. Table 1 clearly shows the increasing numbers of provincial population in Jawa and its corresponding urbanization rates. West Jawa is the province that will be experiencing the highest population rise and 81.4 percent of the population will inhabit urban areas in 2025.

With only 7 percent of total national land area, Jawa island will be the home for more than 151 million people in 2025. But this most populous island in the country has been for many years contributing almost 60 percent to the national economy and will most likely stay that way for the unforeseeable future. The combination of demographic and economic advancement has placed Jawa as the central of national economic development. As such, the regional transport system must also be put in the economic perspective and cannot be singled out from economic policy stream. Overall, urbanization rate in Jawa will go well over 80 percent and will put about 120 million people in its urban areas.

Table 1: Jawa Population Configuration

	2005	2025
Banten	9,309.0 (60.2%)	15,343.5 (81.5%)
DKI Jakarta	8,699.6 (100.0%)	9,259.9 (100.0%)
West Jawa	39,066.7 (58.8%)	52,740.8 (81.4%)
DI Yogyakarta	3,280.2 (64.3%)	3,776.5 (82.8%)
Central Jawa	31,887.2 (48.6%)	33,152.8 (73.8%)
East Jawa	35,550.4 (48.9%)	37,194.5 (73.7%)
Total	127,793.1 (63.5%)	151,468.0 (82.2%)

1.3. Regional Economic Disparity

Regional economic disparity in Indonesia is a latent phenomenon, as latent as the population imbalance. Although regions have their own regional budgets assembled from regional taxes and central government grants, nevertheless, sector budgets were so predominantly larger that regions had frequently been depending upon to build large scale projects in the regions. As a result, gaps between regional and sector and gaps among regions rapidly escalated and the lack of sector-regional linkages had somehow contributed to the regional economic disparity. For many years, sector priorities and their budget allocation tend to focus on more developed regions where economic benefits are more obvious while less developed and remote regions tend to be left behind. This explains why the regional economic disparity in Indonesia is so persistent and its record can be traced back to 1980 and 1990 decades to look at the share of each region in national economy.

This phenomenal fact about economic gap can be seen from Figure 3 which shows extremely skewed share of regional GDP between Western and Eastern Indonesia and between Jawa and off-Jawa in the period of 1975-2006. Assembled from regional economic data collected by Bappenas in the pre-decentralization years and the latest data from BPS, the figures clearly depict the facts that imbalance was so persistent that for many decades Western Indonesia- Jawa, Sumatera, and Bali- had been contributing around 80 percent to national GDP, and Eastern Indonesia, the rest of the archipelago which in fact are very rich in natural, marine, and mineral resources, contribute only about 20 percent [3].

Out of 80 percent of western Indonesia contribution to the national GDP, 58 percent on the average was created from Jawa economy alone. According to BPS report on September 2007, the 2006 GDP at current market price was Rp.3,338 trillion, out of which Jawa economy contributed Rp.1,855 trillion, Sumatera shared Rp.697.9 trillion, and Bali shared Rp.37.4 trillion [4]. Jawa with almost 60 percent share to the economy was becoming increasingly dominant as the origin of export, while the role of Sumatera was decreasing, and the role of other regions were relatively the same. More than that, these figures also confirm the fact that economic disparity will presumably prevail far beyond 2006 as there was no major policy effort whatsoever has ever been done recently to address the issue.

1.4. Lack of Transport Intermodalism

Export, investment, and consumption by both public sector for capital goods and by public at large for consumables will continue to drive the economic growth of the country. For the past several years following the crisis, growth had been primarily driven by consumption and not by investment. These economic activities had been served reasonably well by transport system when economy grew by an average of 7 percent during two decades before the 1997 crisis. In this sense, the role of transportation is absolutely important in supporting the social and economic development of the country. But following the crisis, transport infrastructure was deteriorated rapidly to the extent that transport has failed to support the efficient mobility of the nation.

Economic movement in Indonesia, especially in Jawa has long been heavily dependent on road system. Although railway transport had been operating in Jawa since the colonial time, its role in transporting people had been consistently declining from time to time due primarily to rapid development of road networks and the declining rail networks. The national modal share for both passenger and freight transports can be seen from Figures 4 and 5. In 2005, total passenger trips reached 2.38 billion people and total cargo 2.76 million tons. But shares of rail transport in national mobility constitute only 7.32 percent for passenger movement and a negligible 0.67 percent for freight. Figures 4 and 5 also reveal the dominance of road transport in Indonesia with 84.13 and 91.25 percent

respectively for passenger and freight [5]. This modal share situation does not
seem to change much in 2009 due mainly to the lack of major infrastructure investment and no enhancement in public sector spending in the railway sector.

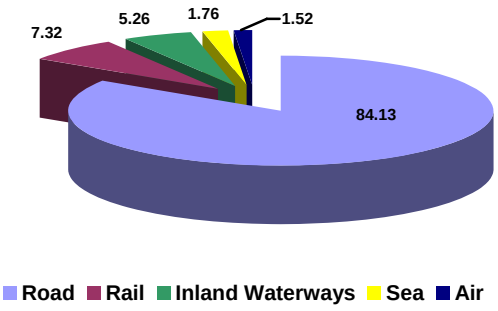

Figure 4: National Modal Share of People Movement (%, 2005)
Source : Dept. of Transport, 2005

For the past fifteen years, railway sector in Indonesia had been governed by Law Number 13/1992 which authorized public monopoly and extremely sector oriented. Public sector is the owner, the provider, the financier, and the operator of the national railway system and services. Monopoly by the state and its delegation to the state-owned enterprise (SOE) had been the core of all the railway business and services, whose financing had long been relying on the state budget. Government regulations and other operating regulations had not given enough rooms for private partnership, and if any, only in a small scale business. Despite of its comparative advantages of being energy efficient, congestion free, and mass transport, railway sector in the past had been under tight regulation, socially oriented, and had never been put in the center of economic activities

The fact that the majority of economic mobility in Jawa is carried out by road reveals the policy shortcomings where transport intermodalism has never existed and transport development has long been focussed on road. Unfortunately, this road-heavy policy had been there for a long time and Indonesia had come to the situation where road network has been under heavy burdens and other modes such as rail and coastal shipping had been kept insignificant.

2. LITERATURE REVIEW

2.1. Early Research

The very first emerging idea of high speed train can probably be traced back to 1904 when Robert Goddard, who was a college freshman at the time, wrote a paper proposing a form of frictionless travel by raising train cars off the rails by using electromagnetic repulsion roadbeds [6]. In the early 1920s, a German scientist named Hermann Kemper pioneered a work in attractive-mode magnetic levitation levitating (Maglev) trains. Kemper continued to research and pursue his concept through the 1930s and 1940s and established the basic design for practical Maglev in a 1953 paper [7]. Since then, research on high speed train continued to be developed and the system started to be implemented. At the beginning of 2008, there were about 10,000 kilometers of new high speed lines in operation around the world and, in total more than 20,000 kilometers of the worldwide rail network was devoted to high speed services [8].

Early study on high speed rail in Jawa was started in 1996 when HSR-200 Management with Halcrow Fox undertook a study of Jawa's rail and its possibility to build a 200 to 300 km/h speed train to shorten a travel time of Jakarta-Surabaya to around 3 to 4 hours. For speed and procurement reasons the

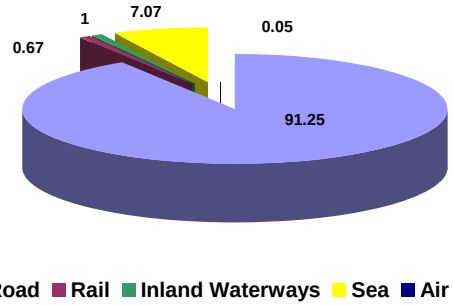

Figure 5: National Modal Share of Freight Movement (%, 2005)
Source : Dept of Transport, 2005

study indicated the need for a standard gauge and will therefore be entirely new track and require total separation from all cross traffic. The north corridor length, the size of the population served, and the continuing economic growth of the region all indicate that at some time in the future, the high sped train with 300 km/h speed will become both economically and financially viable in Jawa [9].

At about the same time, a feasibility study on High Speed Train on Java North Line was also conducted by SYSTRA-SOFRETU-SOFRERAIL (SSS Study) in March 1996. The study investigated three scenarios for the corridor: (1) S-160M, a system with 160 km/h commercial speed for both passengers and cargo on the existing 1,067 mm narrow gauge track; (2) S-200M with a 200 km/h commercial speed on a standard gauge of 1,435 mm track for both passengers and cargo; and (3) S-300P a passenger only train with a commercial speed of 300 km/h, possibly up to 360 km/h, on a standard gauge track.

Table 1 shows the configuration of the scenarios.

Table 1 : The Scenarios' Configuration

Scenarios	Track length (km)	Travel time (hours)	Projected traffic in 2022 (mill. pax)	Estimated Costs (1996 mill. US$)
S-160M	722	5.4	14.6	1,800
S-200M	687	4.0	17.8	8,900
S-300P	687	2.5	21.5	10,600
Option at 360 km/h	687	2.2	26.0	10,600

Source : The SSS Study, 1996

shortened to only about 2.2 to 5.5 hours only, compared, for example, by using the Argo Bromo express line with 9 hour travel time. Each of the scenarios had its own advantages and disadvantages, viewed from different aspects: generated traffic, total costs, sociology, environment, and strategic perspectives. The government at that time selected the S-300P alternative although still expressing the desire to improve the existing narrow gauge network. Using a multi-criteria analysis, the study recommended the S-300P as the ultimate system for future Jawa rail transport system. With 300 km/h train speed, the service will be very competitive compared to airplanes. In France, Japan, and Spain, the 300 km/h speed has demonstrated to be technically, commercially, and financially successful based on the latest and proven technology. In staging, the existing system must be enhanced by some elements of S-160M for improving the quality of current passengers and cargo regional rail transport. The study had also indicated the need for building the 683 km line between Jakarta-Surabaya with a commercial speed up to 360 km/h using a standard gauge [10].

A more recent study on JHST was done by a consortium of Japanese consultant firms (JJJA Study) in 2008 which coined the system as "Argo Cahaya", a system with 300 km/h commercial speed on 1,435 mm standard gauge with the estimated total costs of more than 2 trillion Japanese Yen [11]. The technical specification is displayed in Table 2 below. The study has also identified four scenarios of financing schemes of using public-private partnership and the study went further by setting the technical modern project financing techniques.

It appears that railway in the world has gained new momentum. In Spain, the first HSR was inaugurated in April 1992 on the Madrid-Seville route with great success. In the paper published in 2007 on the network economies, Coto, Inglada, and Rey [12] concluded that high speed rail implies a significant reduction of generalized cost in the rail mode. This reduction produces two clearly differentiated effects, known as induction and substitution, which correspond to those trips which would not have been made if this new service did not exist and those which would have been made in another mode of transport. Further, they concluded that the introduction of high speed rail produces a dramatic change in demand patterns for different modes of transport. Modal split will change dramatically in the affected corridor as the generalized cost of the railway is lower than the generalized cost of air transport. Table 3 shows this modal split changes. The HSR market share is correlated with rail commercial speed. In those lines where the average speed of rail is around 200 km the market share of the HSR is higher than 80 percent.

With the three scenarios, Jakarta-Surabaya could be

In the US, a high speed train has been envisioned to be constructed in the 168 km Richmond-South Hampton Corridor, Virginia. The HSR is determined to operate in 2025 with maximum allowed speed between 130 and 180 km/h speed [13]. But RSH Corridor was only the beginning; it was a small stretch in the massive development plan of US HST determined in 2008 and 2009. The nationwide HST network would include the Northeast Corridor, California Corridor, Empire (NY) Corridor, Pacific Northwest Corridor, South Central Corridor, Chicago Hub Network, Florida Corridor, Keystone (PA) Corridor, Northern New England Corridor, Southeast Corridor, and Gulf Coast Corridor. With the allocated federal funding of around US$ 9.5 billion in 2008 and 2009 and future additional funding anticipated due to national importance placed by Obama Administration, HST development was really on the national agenda of the US [14].

Table 2 : Technical Specification of JHST

Train length	8 cars @ 25 meters = 200 meters
Body width	3,380 mm
Maximum speed	300 km/h
Total weight	About 400 tons at 100% passenger volume
Maximum axle loads	< 14 tons at 100% passenger volumes
Capacity	Executives : 50 seats, economy class 580 seats, total 630 seats
Gauge	Standard 1,435 mm
Power	AC 25 kV, 50 Hz
Control system	Digital ATC with onboard braking patterns

Morocco is moving forward with plans to expand its rail network by building a high-speed rail service linking Tangier to Casablanca. A new TGV line will cut travel times between the two cities from more than five hours to a bit more than two hours. Some 8 million passengers per year are expected to use the new train by 2016. These agreements relate to the

design, construction, commissioning, use of rolling stock, the commercial services to be offered by the high-speed rail link, and the maintenance of a 200 km stretch of track allowing a running speed of 320 km/hour [15].

Table 3 : Travel Time and Market Share of HSR in Europe

	Length (km)	Travel time (h)	Speed (km/h)	Market Share (%)	
				Rail	Air
Madrid-Barcelona	630	2.75	229	50	50
Madrid-Seville	471	2.42	195	83	17

In China, it is determined that the Beijing-Shanghai high-speed railway will be put into operation in 2010. The new rail line will allow passenger trains to run at the speed of 350 km/h, meaning the whole trip will take only five hours, or nine hours less than that at current speed. The 1,464 km Beijing-Shanghai main railway line is one of the most important in China, connecting two of the country's most prominent economic areas and forming the busiest railway route. The new line, upon its completion in five years, will have a one-way line capacity to 80 million passengers and more than 100 million tons of cargo annually.

With an investment of US$ 31.6 billions, the railway was the most expensive construction project in one lump sum China had started since 1949. About 50 percent of the investment came from the state-owned Beijing-Shanghai High-Speed Railway Co. Ltd. The remainder would be raised through share offerings, bank loans and foreign investment. Indigenous and foreign strategic investors would have a chance to invest in the railway as the government intended to diversify the investors. [16].

The study on the economic impacts of high speed rail investment was done by Gines de Rus [17] who studied the costs and benefits of a new high speed line. Rus found out that while the engineering aspect of high speed train is complicated, its economic analysis is very simple. The lack of private sector participation, however, increases the risk of losing the net benefits in the best alternative use of public money. Rus pointed out that the construction of a new line of HSR of a length within the range of 400-600 km has a significant impact on air transport.

High speed rail track is a civil engineering infrastructure. As such the construction of such system will have to undergo strength of material and other structural analyses on the strength, durability, and safety of the system. Studies on these matters have also been conducted elsewhere. The main challenges for civil engineers are to select the corridor, develop an economical drawing for it, construct it and finally do the inspection and maintenance works of it. Engineers have to study the design and operational requirement of high-speed track, effect of high speed on track and vehicle, and salient features of high-speed track. Mechanical and electrical engineers will also to get involve in the construction of a HST project. The new corridor will usually be of double electrified lines for high-speed passenger traffic. The signaling system shall have cab signaling with automatic train control, solid state interlocking device, centralized traffic control, and non insulated track circuits. The telecommunication shall be with latest technology consisting of fibre optic system, train radio control and tele-printer and facsimile arrangement. For electrification, the power supply system will have auto transformer system of 2x25 kV with OHE system of maximum span of 60 m and current carrying capacity of 920 Amperes [18], [19].

2.2. High Speed Train in Operation

2.2.1. Japanese System

The early high speed train line operating in Japan was the Tokaido-Shinkansen line which started operation in 1964 and since then has expanded considerably. Its success also prompted the development of high speed trains in the west. But the Japanese public demanded an even faster form of high speed rail travel. The Shinkansen used a conventional train design, with motors and other equipment mounted on the rolling stock, electric power gathered from overhead wires, and wheels running on rails.

It was impossible to increase the speeds much more. Some of the limitations included: greater size and weight of on board equipment, difficulty in collecting electric power, and reduced adhesion between wheels and rails at higher speeds that may cause wheel slipping. There had to be some new sort of technology that could create faster trains that were

just as safe as or even safer than the trains running on the Shinkansen lines [20].

The former Japanese National Railways (JNR) began conducting Maglev research and development in 1970. The Miyazaki Test Track was built in southern Japan and test runs were being conducted on the tracks. In 1979, the prototype ML-500 test train reached an unmanned speed of 517 km/hour on the 7 km track, which proved that Maglev had a great potential for reaching higher speeds than any other train built before that. At this stage of development, the government started funding the project. The MLU001 was the first Maglev developed with government financial aid. Other models were built and continued to be tested and experimented on the Miyazaki test track. But there was a problem with the track. It was too short and only had a single guide way with no tunnels and no gradients. The experimental data gathered on the Miyazaki test track would be too limited to verify trains commercial potential and use [21].

Maglev stands for Magnetically Levitated and could be regarded as the latest technology of high speed train. Maglev trains will not have to touch the tracks in order to move, i.e. they will travel frictionless. That creates the potential for speeds faster than all the conventional rail travel used today. Maglev vehicles are designed for operating speeds up to 500 km/hour, a tremendous speed advantage over conventional rail travel. Since Maglev trains do not actually touch the rails when they travel, there is no mechanical contact and wear, so that Maglev guide-ways could last up to 50 years or more with very little maintenance at all. Maglev vehicles will have longer lifetimes than conventional rail travel for this reason. They will also have longer lifetimes than automobiles, trucks, and airplanes.

After the JNR was split and privatized in 1987, the Tokaido Shinkansen experienced an increase in passengers which led to more calls to build a commercial Maglev line as soon as possible. As a result, the Yamanashi Test Line was constructed in Tamanashi Prefecture, approximately 100 km west of Tokyo. The Yamanashi test line was 18.4 km long and supported a wide range of tests to determine the commercial feasibility of the Maglev train. The track was made up 16 km of tunnels and an open section that was 1.5 km long in the middle of the track. A substation for power conversion and other facilities were located in the 1.5 km stretch of open section. Part of the line was double tracked to simulate trains going in opposite directions at super high speeds.

Trial runs began on the Yamanashi Test line in April 1997. The cars were not levitated but instead were driven at low speeds on rubber tires. Once tests confirmed that there were no defects in the vehicles or the guideway itself, levitation runs began at the end of May 1997. The speeds were increased incrementally to monitor car movement and verify braking performance. On December 12 1997, a new world record of 531 km/hour was set for manned train travel. A maximum speed of 550 km/h was set for unmanned travel 12 days later [22].

2.2.2. The TGV System

From the first service with fare-paying passengers in September 1981, the French train *à grande vitesse* (TGV) has set the pace in European high-speed (initially above 200 km/h) rail operations. The *lignes à grande vitesse* (LGV) network remains perceived as environmentally sound compared to short and medium-haul air travel or mass use of private cars. Not only has the TGV developed with successive fleet orders, the dedicated high-speed network on which they are primarily designed to run, the LGV, continue to expand within France and across borders. By mid-2008, the French government had made a new commitment to high-speed rail that, if carried through, will see the format break out from the main Paris-centered radial routes, well on the way to being a true national network. The TGV/LGV system evolved from several projects aimed at cutting rail travel times, with hover and magnetic levitation systems and gas turbine propulsion being discarded along the way.

With reduced point-to-point travel times and attractive pricing policies, domestic air traffic has fallen or air routes have ceased completely. Unlike the Japanese Shinkansen counterpart that largely evolved due to the limitations of narrow gauge lines and thus became an entirely separate network, LGV were created and developed within the context of the wider SNCF operation. To prolong the life of track formations, strict 17-ton axle weight limits are imposed where TGVs run. While many communities lobbied to be included in the LGV network, mindful of the noise and visual intrusion of high-speed rail operations, SNCF adopted a range of measures aimed at reducing noise disturbance in adjoining new lines. The majority of TGV operate at a maximum service speed of 300 km/h to 320 km/h

2.2.3. The Korea High Speed Train

Korea's first high-speed line, the 300 km/h KTX trains, based on the French TGV, complete the Seoul-Busan journey in 2 hours 40 minutes compared to 4 hours 10 minutes by conventional train. In 2008, a further 120 km is completed (total 412 km), to further reduce travel time The project was developed over 12 years with total cost of $ 15.3 billion. There are 46 trains, 12 made in France by Alstom, and the rest in Korea by Rotem. They are

388 meter long with 18 coaches, 935 passenger seats, and weigh 771 tons. Korea's first high-speed railway will open April 1st. French TGV trains reaching 300 km/h will cover the 409 km between Seoul and Pusan in just 2 hours 40 minutes, against 4 hours 10 minutes with current trains and track. When the second phase, Taegu - Pusan, is complete in 2008, trip time will be 2.17 hours. Fares set by the construction and transportation ministry have been set at 124-148 % of the existing high-speed train service, and 63-72 % of airline tickets. Korea will start running domestically designed and built 300 km/h trains, known as G7, in 2007

2.2.4. The Taiwan High Speed Train

The first four cars of the 700T Shinkansen trains destined for Taiwan have been unveiled. They will be formed as 12-car sets and have a maximum operating speed of 300 km/h. Services on the Taiwan High Speed Line are scheduled to start in 2005. East Japan Railway will build two prototype bullet trains capable of a top speed of 400 km/h and test them from 2005 to 2008 in northeastern Japan. It aims to launch the trains by 2013 and run them at a maximum speed of 360 km/h, which could be the fastest in the world for commercial trains [23]

3. JAWA RAIL TRANSPORT

The Indonesia Railway

In spite of massive studies that had been undertaken in the past and the issuance of formal planning documents such as mid-term development planning, transport blue-prints, the National Transport System (Sistranas), and their corresponding legal and regulation frameworks, rail transport in Indonesia has been stagnant for decades. Public monopoly, dualism in government agencies between Department of Transport and State Ministry of State Owned Enterprises (SOE), and heavy reliance on state funding had made the SOE, PT KAI behaved like public organization and had been in a difficult position to run the rail business in an efficient and effective fashion.

The transport system in Jawa, however, has been far from sufficient to transport future passenger trips in the region, especially when population has reached more than 150 million in 2025. Jawa rail system, therefore, must be modernize and revitalized as to be able to gain much more share in passenger transport which is currently very small in the national level. Table 4 shows the existing rail network in Indonesia in which 1,610 km out of 6,797 km (23.7 percent) is not in operation. Indonesia had been experiencing the decline of its railway network and services for long. The rail network had decline from 6,797 km in 1939 to 6,096 km in 1955 and only 4,675 km in 2006. The decline was due to the closing of some railroad links resulted from less demand or infrastructure damages. Number of stations and shelter also declined from the 1.516 units in 1939 to only 571 units in 2001. The number of locomotives was also sharply declining from 1.314 units in 1939 to 530 units in 2000.

It is legitimate to assume that public monopoly of Indonesia railway has to be regarded as to come to an end due to declining services, safety, and maintenance budget where government is no longer able to provide sufficient public service obligation (PSO) and infrastructure maintenance. Therefore railway reforms must be undertaken to establish a new railway industry and services which is modern, safe, professional, effective, efficient, and reliable. The path to railway reforms has been opened by the issuance of the new Railway Law (Number 23/2007) which dismantles the public monopoly of railway provision in Indonesia and opens the door for railway provision by private sectors and local governments [24]. This new law marks the beginning of new era in Indonesia railway where private investors are now allowed to invest in railway infrastructure, industry, and services without the obligation to cooperate with the SOE. Railway industry and services are considered vital to the economy. Under the forthcoming new law, railway sector will be freed from natural monopoly and will embark on a more liberalized market structure.

With 3,327 km network in service, Jawa rail is the biggest rail transport in the country for passenger trips. Table 5 demonstrates the number of 2005 passenger volumes for six major corridors in Jawa. Therefore, market restructuring and unbundling for Indonesia railway are urgently necessary to revitalize the sector which is now declining over time. Opportunity will soon be widely opened to invest in different market segment of rail industry, including an extensive system of high-speed passenger and freight rails in Jawa and other big islands. Preparation works to the railway revitalization programs has been undertaken by the Technical Team of the railway revitalization coordination team and has been outlined in its interim report [25]. In the report, revitalization programs will include revitalization of the railway sector, its institutions, corporate restructuring, and human resources development of railway sector.

The main objectives of the railway revitalization program are twofold. First is to increase the railway shares in the national passenger and freight movements. Second is to make railway as the backbone for the national transport, logistic, and distribution systems. As such, railway will closely interact with the economy. Government is now

working on the national railway revitalization programs but many things on what direction and how much government will take on the reform programs are remained to be seen in the near future.

Table 4 : Indonesia Rail Network, 2006

The current rail network in Jawa, Sumatera, and Madura 6,797 km	In operation 4,675 km;	Sumatera 1,348 km	Main Line 1,329 km	North Sumatera 516 km
			Secondary Line 19 km	West Sumatera 169 km South Sumatera 663 km
		Jawa 3,327 km	Main Line 2,966 km	West Jawa 1,125 km
			Secondary Line 361 km	Central Jawa 1,130 km East Jawa 1,072 km
	Non operation 2,122 km;	Sumatera 512 km; Jawa and Madura 1,610 km	North Sumatera 428 km	West Jawa 410 km
			West Sumatera 80 km	Central Jawa 585 km
			South Sumatera 4 km	East Jawa & Madura 615 km

4. PRELIMINARY FINDINGS

4.1. The Benefits of High Speed Train

High Speed Train (HST) is a new technology that allows the train moving at a very high speed between 300 to 350 kilometers per hour. In Japan as well as in European countries, HST had been implemented as a transport mode with the objective to change the modal split of passenger transport with the aim to reduce travel time, congestion, traffic accidents, and environmental damage. But besides of modal choice changes, a HST would have other economic and environmental benefits. The ultimate implementation of high speed train in Jawa would reduce air and highway congestion, air pollution, and inefficient energy use, the transport parameters that have becoming worse over time. Although the investment would be tremendously high in the beginning, long-term economic benefits to the society would outweigh the costs.

4.2. Jawa HST Early Findings

Table 7 lists a summary of the characteristics of JHST that can be concluded so far from the previous studies. A further study needs to be undertaken to refine these characteristics and to investigate the real economic and technical feasibility of such a system. The proposed JHST Line passing through Jakarta – Cirebon – Semarang – Surabaya, for example, will serve for the predicted demand of about 20 million passengers per year in 2023.

5. MANAGEMENT AND FINANCING SCHEMES

Investing in JHST system is on the frontline of government effort to revitalize the Indonesia railway. The ultimate objective is to change the modal split in passenger transport from road to rail with the aim of reducing congestion, accidents, and environmental externalities. But the system requires high quality infrastructure, meaning that new dedicated track has to be built at a cost substantially higher than the conventional rail line. Consequently, a very large infrastructure project such as the JHST cannot be solely financed by the government. It is envisaged that some sort of public-private partnership (PPP) must be employed with a non- or partial recourse modern project financing as the means to fund the project.

It is difficult at this time to formulate the management organization and project financing arrangement for the JHST project. Although it is clear that a careful PPP scheme must be established from the beginning. But for the interest of an academic satisfaction, this study proposes project management and its corresponding financing schemes as shown in Figure 6 as a preliminary arrangement. Figure 6 llustrates a typical PPP project structure involving many parties united in a vertical chain from suppliers, contractors, advisors, to insurers through many contractual agreements. This structure can be adopted with some modifications along the line to the JHST project. To develop an IPP, a developer or the special purpose vehicle (SPV) of the JHST project typically needed to sign four primary contracts: (1) a construction or equipment contract usually on a fixed-price, turnkey basis with an experienced contractor; (2) a long-term operation & maintenance contract; (3) a long-term power

purchase agreement with a creditworthy public utility; and (4) a long-term contract for track and stations management and supervision. Project financing of JHST project can be constructed from both debt and equity financings.

Table 7 : Summary of JHST Characteristics

Maximum Speed	300 km/h
Reduce travel time	JHST with cruise speed up to 300 km per hour would be able to traverse Jakarta-Surabaya (684 km) within just 2 hour and 45 minutes, comparable favorably with air transport and the current conventional train. Access time to Jakarta and Surabaya airports are getting longer from time to time due to heavily congested roads. JHST offers the advantage of railways by getting rid of access time to the airports, waiting times in the airports for check-in, boarding, baggage claim, etc., thereby reducing the total time for point to point traveling.
Low energy consumption	JHST would be powered by electricity supply and no fossil-based energy would be consumed. As such, the system would be very energy efficient and environmentally friendly. The system does not burn oil but instead uses electricity, which can be produced from coal, nuclear, hydro, wind, or solar power plants.
Axle loads	< 14 tons
Gauge width	1435 mm standard gauge and UIC 60 rail
Alignment & Tracks	New double track, built as far as possible within the railway right of way with. Sleepers are made from concrete twin block.
Signaling System	The latest technology, computer based, radio links, and satellite system, engineered to the highest international high speed standards. The entire system will be controlled from a single control center.
Overhead Power	Electric power transmitted from the grid to the trains via an overhead line system. The 25 kV AC modern system to be installed and should be capable of 300 km/h train operation.
Rolling Stocks	Initial train fleet of 25 sets, each set consists of 8-12 cars with power car at one end and a driving trailer car at the other. Made from lightweight construction using monocoque design in which the entire vehicle body is a structural element. Axle load should not exceed 17 tons.. The power car will be energized from the overhead catenary system at 25 kV.
Estimated Costs	In the range of US$ 10-20 billion

6. THE NEED FOR FURTHER STUDY

In Indonesia, the idea of building a high speed train seems to be far away from realization. But the completion of 5.4 km Suramadu bridge between Jawa and Madura Islands might prove it otherwise. The country is also considering to link up Jawa and Sumatera islands by building a more than 30 km long span bridge that utilizes a rail passage. Imagine a high grade economic linkage between Madura, Jawa, and Sumatera with high speed traveling for both people and cargo. So, high speed railways are probably on the horizon already.

Technology for high speed rail had been well developed in France, Japan, and Germany. The common characteristics can now be concluded that a high speed rail with more than 300 km/h speed would need a very special purpose infrastructure and rolling stock combined with specific operating conditions. In dense populated areas such as urban and suburban, it is necessary to install 2 metre-high fencing to provide a secure environment for high-speed lines and to minimize the risks of collision with people, animals and road vehicles; at grade road crossings are not allowed so that the lines must be built on a separate grade.

Despite of the construction costs, it is preferable to build double tracks workable in both directions, allowing trains to operate at full speed, irrespective of the direction, on either track. Each high-speed train should have an axle load not exceeding 17 tons, with a power car at each end of the rake of articulated trailers. The driver receives the speed limit indications on his cab-signal display. These are fed in as coded frequencies or digital messages carried in the current flowing in the rail strings. The driver's role is not limited to watching automatic controls operate; human beings remain “in the driving seat” and are therefore still able to react, if the situation suddenly deteriorates. On the other hand, driving aids make the driver's task easier and the continuous speed control system trips emergency braking if the train's speed becomes incompatible with safety. It takes three kilometer stopping distance to stop a high sped train running at full speed. Accordingly, when it must be slowed, decrementing speed limit indications are transmitted to the driver in the form of a restrictive sequence.

After the railway renaissance in Japan and European countries, many other countries including China and America have revived their railways by building a Maglev high speed rail system. They have proven to

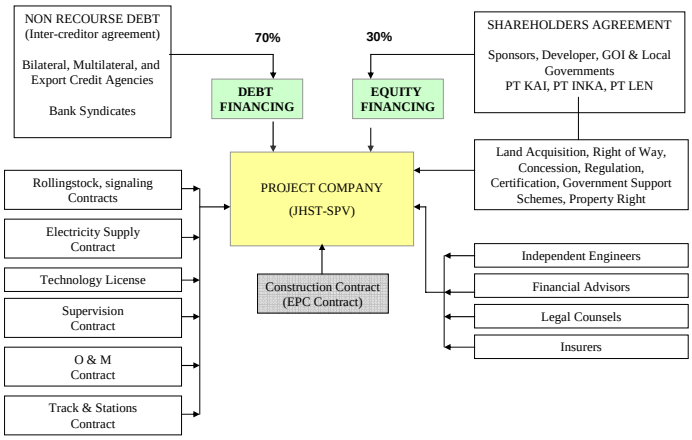

Figure 6: Typical Proposed JHST Project Financing

be faster than traditional railway systems that use metal wheels and rails and are slowed by friction. The low maintenance of the Maglev is an advantage that should not be taken lightly. When you don't have to deal with the wear and tear of contact friction you gain greater longevity of the vehicle. Energy saved by not using motors running on fossil fuels allows more energy efficiency and environmental friendliness. Maglev will have a positive impact on sustainability. Using superconducting magnets instead of fossil fuels, it will not emit greenhouse gases into the atmosphere. Energy created by magnetic fields can be easily replenished. The track of a Maglev train is small compared to those of a conventional train and are elevated above the ground so the track itself will not have a large effect on the topography of a region. Since a Maglev train levitates above the track, it will experience no mechanical wear and thus will require very little maintenance. Overall, the sustainability of Maglev is very positive. Although the relative costs of constructing Maglev trains are still expensive, there are many other positive factors that overshadow this..

Indonesia, however, is still in the beginning. Research and studies need to be undertaken to investigate further what would be the best option for high speed rail in terms of technology, environment, investment, and financing. This paper only provides a slight insight and creates more awareness to the transport planners in this country of the necessity of more efficient, reliable, and modern way of traveling. Such research is collaborative in nature involving many disciplines and requires government support in both political and funding matters.

Abstract

By the year 2025 Jakarta population will reach 9.26 million people, while the day population is believed to be much more than that due to commuting people to and from its supporting cities of Bodetabek. By now the total population of Jabodetabek is believed to be more than 20 million. This situation is of course getting worse when road infrastructures and other means of public transport cannot keep up with the increasing population and its travel demand.

The provision of safe. convenient and reliable rail-based public transportation services is a must to solve the problem of urban transportation in the Jabodetabek region and to help increase its economic sustainability. As the share of urban railway services in the Jabodetabek transportation system is only of a small portion. it is rather imperative for the region to have an efficient rail-based urban public transport system. Currently, rail transport contributes only around 7 percent of national people mobility. Government is now revitalizing the railway sector following the issuance of Law Number 23/2007 in which public monopoly is abolished and market for rail industry and services is open for competition.

Government through the Railway Revitalization Team is now working on enhancing Jabodetabek rail system and services as a means to increase the share of rail transport on the national public transport and hence on the regional economy of Jabodetabek. The study will function as a background study on the implementation of enhanced Jabodetabek Rail-Based public transport system.

This paper presents various factors that can lead to the improvement of economic and people movements in the Jabodetabek area by means of rail-based public transport. The factors include the level of service of the Jabodetabek Rail, the access to the system, the improvement in infrastructure and rolling-stock performances, and the quality and capability levels of management and human resources needed to operate such a system. The performance indicators of such system to better serve the demand would be the quality of people movement using the rail system (comfort, access, affordability, safety, security) and the efficiency of the people movement (access time, travel time, egress time, and speed). The study will preliminarily look at the possible modal shift that could happen as a result of the system. The paper will also take a look at the possibility of private participation and financing scheme to search for the best option available.

1. INTRODUCTION

1.1. The Complexity

Jakarta expanded from 180 square kilometers in 1960 to a fully urbanized metropolis in the 1970s. At about the same period of time, Jakarta and its neighbor cities-Bogor, Depok, Tangerang, and Bekasi-(Bodetabek) agglomerated into one greater Jakarta area called Jabodetabek (Figure 1). Since then. Jabodetabek becomes the largest urban agglomeration in Indonesia. But the expansion of the city and the acceleration of the development of its physical economic and business facilities have not been accompanied by the enhancement of transport infrastructure and services that can serve the city's mobility accordingly. The result is that the urban

transport problems in the greater urban region have been accumulated and becoming more complex from time to time. The traffic congestion is so massive that the region is now under constant threat of total urban gridlock.

Traffic congestion problem is so severe that it will need a dynamic, significant, brave, fast, and smart solution. Ordinary and conventional approach simply is not going to work. The solution must be dynamic to keep up with the uncontrollable growth of population and its increasing vehicle ownership and utilization. It must be significant and brave because the unstoppable growth of population and vehicle ownership is highly influenced by the socio-economic activities of the city which are believed to occupy a significant amount of national productivity. The solution must also be fast because the cities are getting worse from time to time or threatened to head for a total gridlock. Brave and smart solution will be absolutely necessary due to the political complexity of the problems. And one critical solution to the problems would be to establish an integrated rail-based public transportation in the greater area as the backbone to accommodate millions of person trips generated every day in the region.

Figure 1 . Jabodetabek Greater Area

1.2. The Study Area

Table 1 shows that with only 6.580 square kilometers of land area. the population of the agglomeration increased dramatically from 8.34 million people in 1971 to 24.93 million in 2007. The land area of original Jakarta is 656 square kilometers and was inhabited by about 9.0 million people in 2007. The Bodetabek area which is 5.925 square kilometers in size is the house for 15.877 million people. During the working days. Jakarta population is believed to be much more to reach 10 to 12 million people due to commuting people to and from its supporting cities of Bodetabek.

Table 1 : Jabodetabek Propulation Growth

Regions	Area (sq.km)	Population in 1971	Population in 2007
DKI Jakarta	655.7	4.579	9.057
Bogor & Depok	3.380.7	1.863	6.529
Tangerang	1.259.8	1.067	5.076
Bekasi	1.284.2	831	4.268
Jabodetabek	6580.4	8.340	24.930

Source : BPS-2008

Figure 2 depicts the population density of the agglomerated region. The figure shows that with only 656 square km land area. DKI Jakarta has the size of population density of 13.500 people per square kilometer. made it the densest region in Indonesia. The Jakarta city center was the most populated region with the density of 18.618 persons per square kilometer.

As in many other big cities in Indonesia, urbanization is still consistently progressing in the Jabodetabek region. Urban population increased by 1.27 times during the period 1990-2000 from 13.1 millions to 23.0 million people. Urban area expanded by 1.41 times during the same period from 1,660 square kilometer to 2,339.4 square kilometer. The share of urban areas within the region increased from 25 percent to 35 percent in the 1990s. Projections made by BPS, Bappenas,,and UNFPA [1] show an alarming number; that more than 80 percent of Jawa population will reside in urban areas in 2025. This means more than 120 million people in Jawa will be urban inhabitants sixteen years from now.

There are several factors leading to the condition. First, is the marginalization of rural economy where agriculture, the biggest sector absorbing workforce so far, has consistently declined, forcing farmers and peasants to sell their agricultural land and gradually turning them into landless sporadic workers. When they have spent up their money for consumption purposes and finally found that rural economy can no longer provide opportunity for them to survive, they invade urban areas as the last resort to earn money with whatever means they have. Second, the urban-centered economic development in the last several decades had widened the urban-rural gap in such a way that urban areas had generated big employment opportunity for rural people to work. And third, despite excellent development planning this country has had in the past, massive economic and political centralization and the lack of workable regional economy strategy and implementation to strengthen regional economy had left rural development in the sideline.

There are a lot of consequences of the massive urbanization on the economic carrying capacity of the city and the quality, capacity, and efficiency of urban transport. The transport system simply cannot keep up

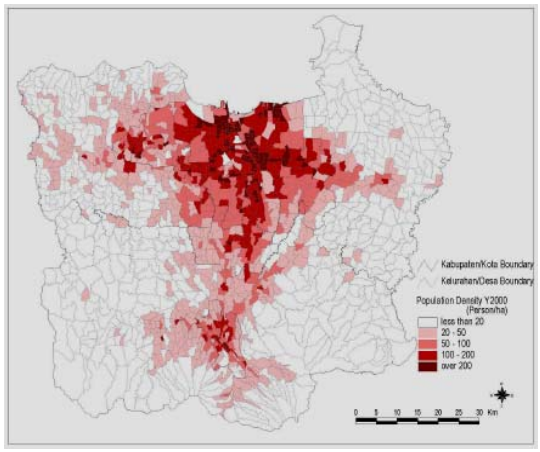

Figure 2 : Population Density

Source : SITRAMP Study 2004

with the increasing demand and keeps deteriorating over time and in some extent becomes a contributing factor to the process of urban decay. These phenomena have been taking place in Jabodetabek greater area where the quality of life of its population had been gradually declining.

1.3. The Traffic Problems

Massive traffic congestion has been taking place day by day in Jakarta's road network for so many years without any significant mitigation measures at sight. The city administration has always blaming the unbalanced growth between road network (only a negligible 0.01 percent per year) and traffic (9 percent per year) as the major cause of congestion. But the imbalance is only one factor of the many contributing factors to the creation of the massive congestion. Another factor is the uncontrollable growth of motorized vehicles. Figure 3 reveals the fact that only in 5 year period between 2002 to 2007. the number of registered vehicles has risen from 4.1 million to 5.8 million. out of which 3.58 millions were the motorcycles. So far city government. including Bodetabek regions do not have any measures to mitigate the increasing number of motorized vehicle on the road, including any traffic demand management strategy to curb the use of vehicular traffic during the working days.

In 2002. there were 7.3 million commuting trips that required public transport services. The numbers is estimated to grow to 9.9 million trips by 2010 and 13 million trips in 2020. Jakarta intra urban trips constitute the largest portion of the total daily trips and the rest are external commuting trips generated from the Bodetabek areas. As many as 3.6 million person trips will commute to inner Jakarta city in 2020. Based on the traffic and road network data, the city government has forecast the total gridlock will happen in 2014 when the number of four-wheeled motorized vehicles (about 3.3 millions) fills the road space totally, if no major actions is undertaken to mitigate the use of private cars [2].

With only 7.650 km road length or 6.3 percent of total land area, Jakarta generated about 17.1 million person trips per day in 2008 and the trips were served by 5.6 million private cars, including motorcycles, and by only 86.435 public transport vehicles, buses in all sizes, paratransit, and rail. The private cars which constitute 98.5 percent of total vehicles in Jakarta carry 44 percent of the total person trips, while public transport with only 1.5 percent fleet carries 56 percent of total person trips. Only about 3 percent of the trips were served by Jabotabek rail. Because there is no policy to curb the rapid growing of car ownership and usage, more than 1.100 new vehicles was added to the city street every single day in Jakarta

Many studies on Jakarta urban transport had been undertaken and recommendation on policy measures and transport infrastructure development had also been made to the government but implementation had so far been so poor. Decisions that had been made, however, rarely followed the policy recommendation of the studies, indicating the missing links between conceptual framework and political decision making process. The uncontrollable traffic growth in Jakarta and the resulted massive traffic congestion can be seen as policy shortcomings that have been around for so many years without any major correction measures on place. The failures of good policy combined with the imbalances between supply and demand of transport facilities had made the traffic situation in Jabodetabek area gets worse from time to time.

Another important policy development in the Jabodetabek traffic problems is the transport demand management (TDM). The complexities of urban transport problems in the area have been contributed also from the inconsistencies of land use implementation. The interaction between transport facility and land use that can result in an efficient

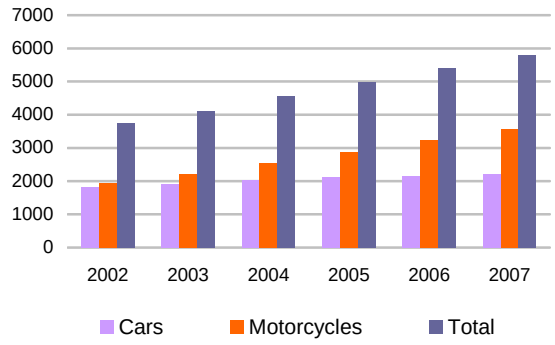

Figure 3 : Number of Registered Vehicles in Jakarta
(1.000) Source : Jakarta City Report, 2008

urban structure and movements simply does not exist. Integration of transport modes and between transport and land use had also been very poor as an integrated institution is also lacking from the policy making process.

1.4. The Economic Lost

Economic lost resulting from heavy congestion is clearly a primary concern of all parties, government. road users, and industry. But everybody seems to get stuck in the middle of congestion and does not seem to understand what to do. SITRAMP study [3] in 2004 had estimated the annual congestion costs which is also the economic lost to amount to Rp. 3.000 billion for vehicle operating costs and Rp. 2.500 billion for the value of travel time. The study further projected that should there be no improvement undertaken in the period up to the year 2020, accumulated economic lost would amount to Rp. 65.000 billion, which consists of Rp. 28.100 billion for additional vehicle operating costs and Rp. 36.900 for longer travel times at the present value discounted by 12 percent. This estimated economic lost, even limited merely to vehicle operating cost and travel time, would be more than the development cost proposed in the master plan.

In accordance with the anticipated growth in population and vehicle ownership in the next 20 years, total number of trips is expected to grow even more rapidly. The total number of trips made in Jabodetabek in 2020 will increase at about 37 percent compared to 2002. A total person trip per day was 36.7 million in 2002. The number will rise to 45.2 million in 2010 and 50.4 million in 2020. Person trips generated from Bodetabek areas constitute a slightly more than a half of the total trips; the other half will be generated from the city of Jakarta, including from and to the central business districts at the central city.

At present, the modal share of public transport in total passenger trips is about 60 percent (excluding non-motorized transport). If no action is taken. modal share of public transport, especially the share of the bus, will fall to less than half of the total motorized share because of the low level of service. and the modal share of the private car, which is more convenient in mobility, will rapidly increase.

2. THE EXISTING JABODETABEK RAIL

2.1. Poor Services

Jabodetabek Rail is currently running an urban commuter system of about 160 km operating length, connecting major cities in Jabodetabek, Bogor in the south, Bekasi in the east, Tangerang in the west, and Serpong in the southeast. Figure 4 shows the existing rail network. Seven lines are in operation, including the new revived line to Tanjung Priok. This system currently carries about 400.000 passengers per day or about 0.2 percent of the total passenger travel demand. The quality of the urban railway, however, is poor with low level of service in almost every aspect such as low train and line capacity, low frequency, delayed schedules, damaged and uncomfortable train cars, poor station facilities, and insufficient station plazas and access roads. Buses, on the other hand, play a dominant role in the region's public transportation; however, the quality and level of bus service at present is also poor in many aspects such as unscheduled departure, unexpected stoppage of operation, long waiting time, sense of insecurity on board by passengers, and dirty condition inside the buses. These urban public transport problems in Jabodetabek can be attributed to lack of effective public transport planning, insufficient maintenance funding, lack of good public policy, and insufficient monitoring on operation.

Jabodetabek Rail, however, has been experiencing some structured problems in train operation. The major problems include shortage of line capacity, poor safety, shortage of electrical spare parts, and signaling problems. Due to the shortage in line capacity. overcrowded passenger on the trains had been a chronic phenomenon. The current level crossing equipment for safety was installed by Japan in 1980's and has been maintained rather improperly. However. collision accident with electric car occurs frequently due to deterioration caused by long year use and damages. Meanwhile, because of the frequent and unexpected strong lightning, signaling system in Jabodetabek has many faults and it may cause train accident.

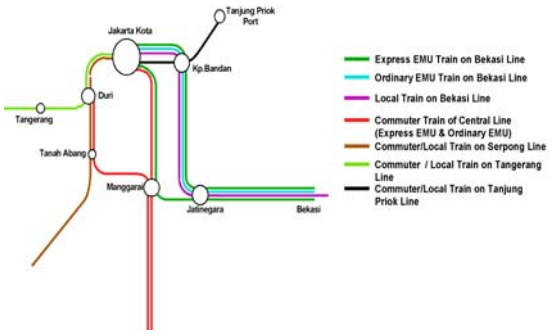

Figure 4 : The Existing Jabodetabek Rail Network
Source : Daop Jabotabek PT KAI

The electrification of the Serpong and Tangerang Lines had been completed in 1995 and 1998 respectively with financed by France Loan. There are four DC traction power substations on each line with 3.000 KW capacities respectively. Meanwhile. electrification of adjacent line as Western Line had been operated since 1986 financed by Japanese Loan.

The different DC outgoing voltage between France and Japan substation systems were confirmed by investigation team on 1997. which is measured of 1.720 V DC nominal on France area and 1.650 V DC nominal on Japan area.

This performance indicates that the existing rail facility have much room to be improved to maximize its potential. In addition to the existing rail network. an independent mass transit system has been planned to operate at around 2015. This new rail system is expected to provide quality rail transportation services for the next generations leading to enhancement of business and commercial activities in the capital region.

2.2. Shortage of Capacity

Table 2 depicts the passenger volumes of Jabodetabek Railway from 2001 to 2007. The volumes declined from 121.5 millions in 2001 to 100.5 in 2004 and picked up a little bit to 108.1 million in 2007. This passenger volumes in Jabodetabek rail constitute about 70 percent of total national rail passenger volumes and had been creating shortage of capacity for the system. Jabodetabek rail is always in short supply against increased demand due to the shortage of rolling stock and poor management. The shortage of capacity in 2002 is shown in Table 3. The table clearly shows that load factors during morning peak hours amounted from 207 percent in the Serpong Line to 340 percent in Bogor Central Line. Bogor-Central Line has the highest passenger volumes.

Table 2 : Jabodetabek Passenger Volumes 2001-2007

Year	Economy Class	Air Conditioned	Total
2001	115.610.243	5.860.925	121.471.168
2002	111.482.152	5.935.313	117.417.465
2003	95.386.433	6.654.454	102.040.887
2004	91.565.130	9.018.413	100.583.543
2005	92.367.502	8.601.896	100.969.398
2006	94.780.400	9.644.320	104.424.720
2007	104.915.164	13.180.533	118.095.697

Source : DG Railway, 2008

2.3. Saturated Stations

Gambir station was so crowded with long distance train passengers and commuter that PT KAI has been forced to cancel using this station for all ordinary commuter trains. In double-double tracking project. Manggarai Station is planned to be the only terminal for long and middle distance trains. The routes of these trains will be arranged and simplified without conflict with the commuter trains. There are extremely shortages of the access roads to the station, which is because of no station plaza on Jabotabek railway station. PT.KA (Persero) have managed valuable and enormous land in Jabotabek area, but these lands have not been used sufficiently, especially as station square can count a little.

2.4. Freight Transport

The freight train in the Jabotabek area is operated on Western line, Eastern line, Tanjungpriok line, and Bekasi line. The coal train is operated on Serpong line, Western line, Eastern line, and Bekasi line. The container train is operated on Tanjungpriok line, Eastern line, and Bekasi line. The share of railway freight transportation, however, is small and diminishing. Jabodetabek rail is probably focusing on passengers while freight transport will be the domain of separate freight rail operator.

2.5. Mixed Land Use

Historically the railway in Jabotabek was developed for cargo transportation connecting Jakarta Kota and Tanjung Priok with the other regions, and also for middle and long distance trains connecting Jakarta to the other regions. In other words, until recently, the railway network had not been developed for passenger travel within urban areas. Currently land use surrounding the railway stations is not appropriate for a railway transport system. In order to attract rail passengers, highly dense urban facilities should ideally be located within walking distance from the stations. However at present there are few high-rise office buildings and commercial facilities. At present. the land near the stations is usually occupied by low-class housing in urban areas. Consequently sufficient passenger demand for the railway cannot be expected from the existing urban land use.

2.6. Lack of Integration between Modes of Transport

Integration between railway and other modes of transport can be made at an interchange transport node. Furthermore integration between railway and road transport is provided by access roads to railway stations. However, these transport facilities for integration between rail and road have not been well developed and integration does not really exist. It is unfortunate that for many years the arrogance and ignorance of both rail operator and city government had kept Jabodetabek rail and busway, for example, separated to each other and passengers have been unable to reap he benefit of inter modal transport. Efforts have been done to integrate these two modes of passenger transport in Jabodetabek but strong leadership seems lacking.

Table 3 : Commuter Transport (Morning Peak 2 Hours). 2002

Line	Number of train	Headway (minutes)	Train Capacity	Passenger Volume	Load Factor
Bogor -Central Line	18	6.7	15.224	51.744	340 %
Bekasi Line	13	9.2	8.448	22.240	263 %
Serpong Line	7	17.1	6.800	14.089	207 %
Tangerang Line	2	60	800	2.275	284 %

Source : DG Railway. 2004

2.7. Lack of Access Roads to Railway Station

Except for big stations such as Gambir and Kota, smaller railway stations at Jabodetabek are suffering from poor access roads. Station squares have not been well developed even though lands for station squares are available at many stations. The available squares in fact have been occupied by vendors and activities not related with railway traveling. The width of access road to Serpong Station is very narrow. Passengers have to walk on the railway along access road from level crossing without walking on access road.

2.8. Safety and Security

In general, the railway transport is the safest mode of transport compared with other modes. But Jabodetabek rail transport is probably the exception. The reasons are obvious; shortage of technical staff, the deferred maintenance of facilities and rolling stock, and poor attitudes of passengers. It is extremely dangerous for a train beyond capacity to operate with no door or opened door. A lot of passengers are still riding the train on top of the railcars. Between 2000-2002, railway accidents record shows 12 accidents and 43 collisions with cars or public transport vehicles occurred.

3. LITERATURE REVIEW

3.1. Past Studies

Many studies on urban transportation in Jakarta and other cities in Indonesia had been undertaken in the past. Reports of the studies had been widely published. All of those studies in general come to the conclusions that cites' transport condition will be greatly improved if the city governments build a mass rapid transit as a backbone of urban transport system. Since cities population grew very rapidly. there is no more land available for road network expansion and if there is any, land acquisition is usually very expensive and socially and politically sensitive. Transportation demand management, therefore, is critically needed. Unfortunately, none of those recommendations has never been implemented seriously by the city administrations.

The lack of integration of modes is partly attributable to the lack of access roads to railway stations and subsequently lack of feeder bus services. At present many access roads to the stations in Jabodetabek are either in a poor condition or simply do not exist. Part of the station space is also frequently occupied for non-rail business purposes.

Cities are now trapped in the middle of heavy congestion as a result of wrong consistent policies and do not really know what to do or being ignorance of the policy recommendations. On the contrary, no full-scale study has so far ever been conducted on the railway transport, especially study on the enhancement of Jabodetabek rail. This paper will not describe the past studies in detail. And instead will focus on the findings and recommendation of SITRAMP Study on the integrated transport master plan for Jabodetabek, finalized in 2004 by JICA and Bappenas [3].

3.2. The Spatial Planning

The future Jabodetabek transport system, including its rail-based transport system must be based on the consolidated spatial plan dedicated for the Jabodetabek region and its upstream areas, the Bopunjur (Bogor-Puncak-Cianjur). The Jabodetabek Bopunjur spatial plan has been prepared by the Department of Public Works and has been approved as the Presidential Regulation. The plan, shown in Figure 5, shall be the principal guidelines for the region's spatial development including transportation system development. The plan maintains the common regional planning issues to provide a guiding principles of population dispersion in the Bodetabek area, to restrict development in southern water catchment areas, and to promote linear

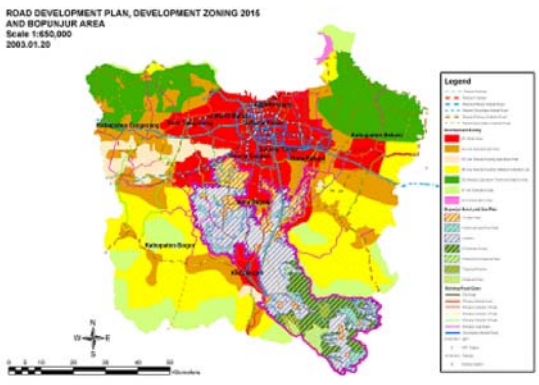

Figure 5 : Jabodetabek Bopunjur Spatial Planning
Source : SITRAMP Study. 2004

development along the East-West axis (Bekasi-Tangerang).

Figure 6 shows major destinations of home-to-work trips in year 2002. The largest attraction center is located in the central area of DKI Jakarta. and its sphere of influence reaches the neighboring cities of Bodetabek. To achieve sustainable urban growth in Bodetabek area, the Master Plan proposes that urban center development should be encouraged to realize balanced residence-employment suburban development. This should be supported by a strict urban development control of the designated land use plan and development zoning. Following this guideline, planning issues in transportation sector should be identified and an efficient trunk transportation system must also be established.

3.3. Transit Based Development

Figure 7 shows the trunk transport network proposed by the study on the ground of rail-based scenario. The scenario was prepared to emphasize the mass transit oriented system because the heavy burden by vehicle traffic is expected in the center of Jakarta due to difficulty in road capacity expansion by road construction including the high mobility highway network and ordinary arterial roads. The scenario

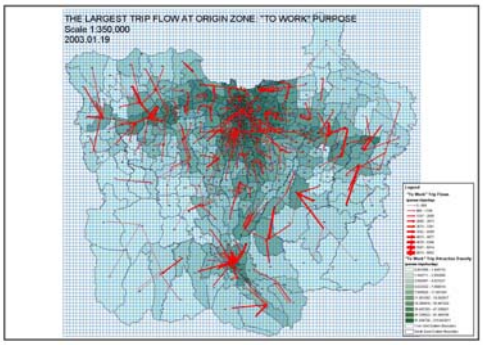

Figure 6 : Major destinations of Home-to-

was constructed based on the development of: (1) Double Double Tracking of the Western Line between Karet and Manggarai; (2) Double Tracking of Tangerang Line between Tangerang and Duri and extension to the Soekarno-Hatta Airport; (3) Construction of New West-East Mass Transit Line between Duri and Cikarang; (4) Double Tracking of Serpong Line between Serpong and Tanah Abang; (5) Jakarta MRT between Kota; Fatamawati/Lebak Bulus; and (6) New Mass Transit Line between Ciledug and Blok M.

3.4. Policy Recommendation

The development of a full-scale Jabodetabek Railway must be supported by the implementation of some policy measures, especially with respect to the management and operational aspects. Among policy measures recommended by SITRAMP was the enhancement of maintenance system for electric traincars, improvement of the quality of management of railway operation, and railway financial reform. Government was also urged to establish multimodal transport system with the provision of extensive public transportation network and with rail as the primary mode. To improve the attractiveness of railway business, it is necessary to serve high intensity land development in the surrounding area of railway stations.

3.5. Transport Demand Management

The Jabodetabek megalopolitan area has no well-structured transport demand management strategies so far. This is understandable, however, due to the lack of an integrated transport planning and integrated transport authority in the area. A small scale traffic improvement programs such as optimization of traffic signal controls, intersection improvement programs, and law enforcement for traffic violation by paratransit (ojek. angkot. and micro buses) had never been undertaken consistently. Travel demand management strategy such as the 3-in-1 scheme seems generally effective in reducing the number of vehicles entering the restricted zone; but the scheme has become ineffective due to the facts that congestion moved to the alternative streets and car users picked a person on the street to fulfill 3- passenger requirement. The current 3-in-1 scheme can actually be transformed to a road pricing scheme with an aim to generating part of funds to develop transportation infrastructures and to improve public transport services. But the strategy has never been implemented so far.

3.6. Integrated Transport Authority

An integrated public transportation in Jabodetabek area would need an integrated transport authority to take care the coordination in planning process and development fund raising between respective government agencies and foreign lending organizations. Indonesia transport sector is now

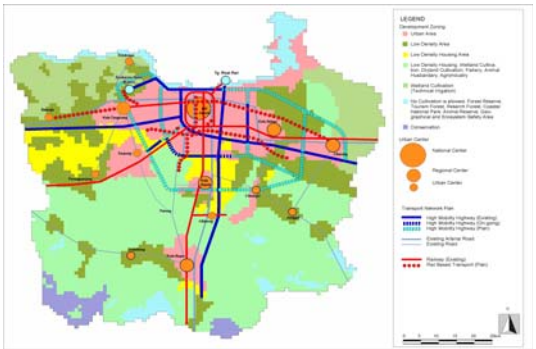

Figure 7 : Rail-Based Jabodetabek master Plan
Source : SITRAMP 2004

lacking of effective coordination in planning between different transportation sub-sectors and between the central and local governments. Furthermore, there is almost no coordination in planning between transportation sector and other development sectors such as housing development and railway system development. These facts suggest it is very necessary to institute an organization with a strong power for authorization of region-wide plans that covers multiple local governments, equipped by solid planning and supported by sufficient technical staff and funds.

4. THE NEW JABODETABEK RAIL

4.1. The Background

As many as 120 million people will reside in urban areas in 2025 in Jawa. It is imperative therefore for government to prepare rail-based urban public transportation which is efficient, reliable, and able to fulfill the demand in a more convenience manner. The development of a full-scale Jabodetabek rail-based transport system is therefore imperative for the agglomeration. The 24.9 million people in 2007 and probably 30 million in the years ahead would not be served adequately by the existing road-base public transport. A full-scale rail transport will not only ease the massive congestion of road traffic and is therefore critical for sustaining the economic mobility of the region, but will also mark the most critical step of the national railway revitalization efforts.

4.2. The Railway Master Plan

Government is now preparing a national level railway master plan projected until 2025 [4]. In the master plan, it was projected that rail passenger trips in Jawa would increase from the current 6 percent of national passenger volumes to 8.49 percent in 2010 and 12.0 percent in 2025. In the national level it was projected that rail passengers would constitute 15 to 17 percent of national passenger volumes. The projected number of rail passengers in 2025 is shown in Table 4. In Jawa Bali alone, there would be almost 245 million passenger volumes by rail, consisting of intra- and inter provincial, including urban rail passengers. Jabodetabek rail is presumably the biggest part of the total national rail passenger. To serve the nationwide projected demand, it was projected that 6.800 km tracks must be available for service, meaning that as long as 3.473 km new track must be built until 2025 in Jawa. This must also be accompanied by 669 locomotives and 6.690 train sets to serve the 2025 demand.

Table 4 : Projection of National Rail Passenger Volumes by Regions (2025)

Regions	2006	2010	2015	2020	2025
Jawa Bali	127.519.723	155.158.347	184.299.294	214.417.082	244.673.991
Sumatera	2.566.924	4.366.143	6.401.799	8.653.562	11.103.851
Kalimantan	-	-	479.468	781.226	1.120.520
Sulawesi	-	-	2.483.369	3.902.371	5.406.375

Source : Draft II. National Railway Master Plan. DG Railway. April 2009

For urban rail, the master plan has laid out a long-term development plan for Jabodetabek Rail until 2025. With 5.790 square kilometer land area, Jabodetabek rail would need around 900 km double track to serve passenger demand in 2025. With the assumption of 18 hours daily operation, 15 minute headway, four major routes, and average speed of 30 km per hour, it was estimated that Jabodetabek would need 128 trains, with flexible number of railcars, to utilize the tracks optimally.

4.3. The On-Going Rail Projects

The works of Jabodetabek rail network enhancement programs have actually been progressing. Figure 8 schematically illustrates this work of network enhancement. Table 5 lists rail projects that have been constructed or on-going. In addition to the list and as a part of the long-term development programs outlined in the Railway Master Plan, the following rail projects can be considered as strategic actions to achieve the objectives.

4.3.1. Track Elevation of Eastern Line

The Eastern line is now passing through the highly populated urban districts of Jakarta with at grade intersections with the crossing roads. This has a severe adverse effect on train operation in terms of safety and punctuality and at the same time causing traffic congestion around the level crossing by obstruction of traffic flow and poor safety. The road congestion will furthermore increase, which leads to compelling the train to reduce speed near the level crossing. The elevation of the line will include 5.4 km track between Pasar Senen and Kampung Bandan, a rehabilitation of Kota Station, and an extension of 2 km elevated railway between Jakarta station and new station at Kali Besar Barat.

4.3.2. Double Tracking and Electrification of Serpong Line

Upgrading of 23.4 km railway line between Tanah Abang-Serpong into a double track electri-fied line has partially been done. With this improvement the Serpong line will be able to transport more passengers as a commuter railway.

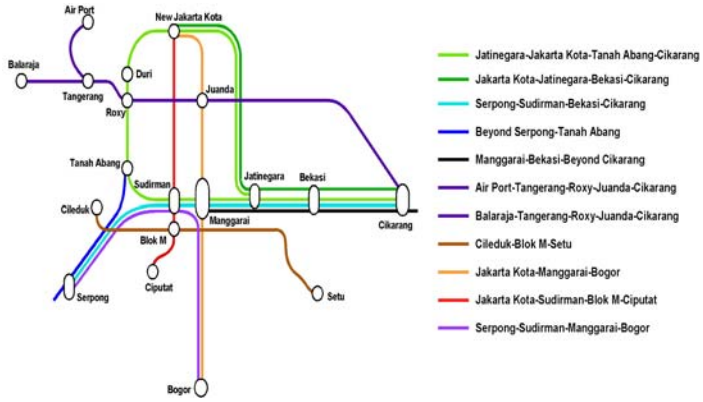

Figure 8 : The Railway Network Enhancement Program
Source: SITRAMP Study 2004

4.3.3. Double Tracking and Electrification of Tangerang Line

Track improvement and the electrification of Tangerang Line's single track were completed in 1999. Since land and other facilities are already available for the double tracking and electrification. the work can be started immediately. There is a plan to extend the Tangerang Line to Soekarno Hatta international airport to provide direct rail access from central Jakarta to the airport.

4.3.4. Tanjung Priok-Citayam-Parung Panjang New Railway Line

This line is planned to transport cargo by connecting Tanjung Priok, Cakung (Bekasi Line), Nambo (Cibinong Cement), Citayam (Bogor Line), and Parung Panjang Merak Line) . The section between Citayam and Nambo has been completed with a single non-electrified track. The rehabilitation and improvement of the line will revive freight rail movement that has been decreasing in recent years.

4.3.5. Grade Separation at Manggarai Central Station

Regional long distance train operation at Gambir and Jakarta Kota stations will be terminated in order to use the semi-loop line as an urban railway. The middle and long distance trains will stop at the Manggarai station and urban rail services will be provided in a semi-loop operation. To provide frequent urban rail service on the semi-loop line, it is necessary to separate the semi-loop line from the middle and long distance line, as well as the central line, by grade separation at the Manggarai station. This project is to be included in the double-double tracking project of the Bekasi line. With that, Manggarai station is prepared for bigger and better station and is projected to play a larger role as central station in the city.

4.4. The New Rail Network

It is necessary to improve the overall performance of services in which the existing network should be expanded to accommodate greater passenger carrying capacity, to increase frequency, and accordingly to increase fleet size by adding more railcars. Figure 8 depicts one alternative of the basic networking concept for future Jabodetabek rail services. In addition to or in replacement of the existing services. several new lines and services were added to the existing network. The coverage of the new network was much larger and included the linkages of major points previously not connected. Among the important lines include the airport link which connects the airport with Cikarang, Ciputat, to Jakarta Kota Line via Sudirman, and a looping line of Jatinegara to Cikarang via Kota. Tanah Abang and Sudirman.

The basic networking concepts applied to new rail system which possibly be developed by other private operators should cover existing and emerging urban centers and should work as part of the distribution system of the existing main commuter system. Its inter-modality, however, must be carefully taken into consideration. More than that quality of the new system should meet the passenger demand of urban middle- and high-income class people in future.

With the new lines and services added to the future rail network, passenger carrying capacity will be increased incrementally in accordance with increases of the demand. To accommodate prospective demand of middle and upper high income people, the express commuter trains will be introduced and will be equipped with air conditioning system; hence, the service is provided with a higher fare than that of the normal rail services in anticipation of higher willingness and affordability to pay of the users. The demand for this type of service seems to be very high at present and it is a promising business opportunity to improve commuter train services when private operators come to the market. It is imperative, however, that the new services will provide convenience of transfer between the north-south operation and east-west operation, minimizing the headways, and maximizing passenger carrying capacity. Attention should also be given to the airport rail access and maintain inter-modality with other rail other systems such as MRT.

The new Jabodetabek will provide extensive services for east-west corridor with three new lines. The first line starts from Cikarang through Bekasi and reaches Serpong. This line has intra-modal transfer points at

Manggarai and Sudirman stations with the MRT north-south line and the Bogor-Central line. The second east-west line also starts from Cikarang. passing the northern area of Kota Bekasi then reaches Balaraja in the west. This line connects new development area in Southern Bekasi and the airport. and will promote the development of Western Tangerang Area. There are several intra-modal points at Juanda and near Harmoni with south-north lines. Bogor-Central Line and MRT. And the third East-West Line starts from Bekasi through the southern area of Cikampek Arterial Road, Blok M, Ciledug and reaches Tangerang. This line has an important role to reduce the congestion of the Cikampek road network and the road between Blok M and Ciledug.

Table 5 : Jabodetabek Rail Enhancement Projects

Projects	Project Cost (US$ million)
Depok Electric Railcar Depot	102.7
Parungpanjang-Citayam New Railway Line	121.6
Tanah Abang-Serpong Double Tracking	83.1
Construction of 50 Electric Railcar Trainset	245.0
Grade Separation at Manggarai	58.38
Railway Electrification of Jawa Main Line	678.0
Engineering Design of Jakarta MRT	30.0
Double Double Tracking Manggarai-Bekasi Line	645.0
Total costs	1,963.78

Other important features of the new Jabodetabek rail network will be the new Jakarta Kota Station that will be constructed on the Loop Line and the first line of Jakarta Mass Rapid Transit (MRT) line. At this new station passengers can transfer to the Loop Line and MRT. It is possible to shorten headway of Central Line to 3 minutes. This line's train operation is undisturbed by the Western Line train operation by grade separation at the Manggarai Station. The MRT is provided along the major arterial roads in the central part of DKI Jakarta, namely, Sudirman-Thamrin corridor, connecting Blok M and Kota. This line has multiple transfer points with other rail systems.

4.5. The Spin-off

The current Jabotabek rail is operating as a regional division of PT KAI, the incumbent operator. In July 2008, the Jabotabek rail was spin-off and transformed into PT KAI Commuter Jabodetabek (PT KCJ) and will be gradually transformed into a separate entity with the main purpose to make rail as the backbone of public transport in Jabodetabek area. The current Jabotabek rail transport carries about 400.000 passengers per day or 70 percent of total rail passengers but constitutes only 4 percent of Jabodetabek total public transport demand. In its railway master plan. it is projected that up to 900 km new tracks will be developed until 2025. adding around 720 km to the existing tracks. This projection would probably fit within the network expansion projected by the SITRAMP Study described above. The expansion of the rail network will be accompanied by 128 unit trains. It is also projected that the full-scale Jabodetabek operation in 2025 will require around 1.4 million Kwh electricity power per day, a demand that could be fulfilled by the future power supply when 20.000 MW new generations have been completely entered the power grid at that time.

4.6. Investment and Financing

Unlike other infrastructure projects such as power generation, toll roads, and telecommunication, rail projects are usually not so attractive for private investors to invest. At least for the first ten years of railway revitalization programs, government investment and public expenditures would be very critical for building the basic infrastructure, providing support, and bearing the risks of investment.

5. CONCLUSION

Jabodetabek greater region is envisioned to have a consolidated rail-based transport system as the backbone for more than 30 million people and probably more than 50 million daily person trips in 2025. As long as 900 km rail network would be developed until 2025 along with its corresponding trains and railcars, energy needs, and management. In terms of organization, steps have been taken to go to that direction by spinning-off the current Jabotabek rail into the a new separate entity, the PT KAI Commuter Jabodetabek. This new urban rail operator is expected to be the embryo for a full-scale modern rail urban operator in the near future.

According to the railway law, new railway infrastructure and services could be provided by local governments and private investors. Enhanced by the decentralization policy, local and city governments are responsible for the provision of its own transport service, including for rail service. The crucial issue is how to ensure that the strategies and policies stipulated based on these individual spatial plans are mutually consistent and well coordinated at the region and city level. It is probably still the responsibility of central government. i.e. Department of Transportation. to integrate the national and regional rail infrastructure and services and to provide technical and management guidance to local governments. It is also necessary for central government to reconcile the disputes that could arise because of the differences in the infrastructure planning at the local level.

ISSN 114-1284

With regard to the institutional aspect of transportation management in the Jabodetabek region, it is urgently needed to clearly define the rationale of the establishment and conceptual structure of a transportation authority to deal with an integrated transportation master plan and management. This could be achieved by either strengthening the existing institution, establishing new metropolitan transportation authority, and by forming a metropolitan transport planning commission. Coverage of such an institution could also be enhanced to include the integration of transportation system and land use, in particular land use and urban development control.

Financial constraint is considered as the major obstacle for rail infrastructure development in the Jabodetabek region. For the next ten years. government would need to invest rather heavily in the railway revitalization program since rail market is probably not sweet enough for private investors to enter. After the extended basic infrastructure accompanied with adequate and conducive regulations have been in place. the market would probably be mature to invite large-scale private investment.

ABSTRACT

The construction industry appears to adopt innovative concepts and protocols from other industries such as lean production, supply chain management, total quality management and value management in targeting improved efficiencies. But the 'culture of manufacturing' is seen to be largely derived from the respective organization culture, whereas 'the culture of construction' is reflected in each 'project culture'. This may be one of the reasons why concepts and protocols from 'manufacturing' cannot be directly transplanted in construction. While some of them may be adapted for one project, the same 'adjusted formats' cannot be used in other projects. This requires separate, if not unique, adjustments of various/ different ideas to suit project specific requirements.

This paper discusses some theoretical issues concerning an ongoing research project which aim to build a knowledge sharing culture that supports successful lessons learned within construction organization in Indonesia. The theories on project learning and the concept of organizational culture are presented and discussed. Furthermore the paper demonstrates links between a culture that influences of project behavior and the perception of team members and how this tie can be used to foster the development of construction process and lessons learned.

Keywords
Organization Culture, Process, Lessons Learned,Contractor

1. INTRODUCTION

Managing knowledge effectively is critical to the survival and advance of a company especially in project-based industries such as construction (Kamara, Anumba, and Carillo, 2002). Effective knowledge management can reduce project time and cost, improve quality and provide a major source of competitive advantage for the construction organizations (Shelbourn, Bouchlaghem, Anumba, Carrillo, Khalfan, and Glass, 2006; Kivrak, Arslan, Dikmen, and Birgonul, 2008). Stoddart (2001) argues that knowledge sharing can only work if the culture of the organization promotes it. Studies by De Long and Liam (2000), shows that culture influence knowledge sharing by as much as 80%.

The construction industry is being viewed as one with poor quality emphasis compared to other sectors like the manufacturing and service sectors (Kubal, 1994; Kanji and Wong, 1998; Wong and Fung, 1999). It not only the final product that is subject to criticisms but the processes, the peoples, the materials etc are under tremendous pressure for better quality in construction. One of the common reasons for the failure of TQM is the cultural position of the company. If the TQM effort is inconsistent with the organizational culture, the effort will be undermined (Dean and Evans,1994 in Adebanjo and Kehoe, 1998). However, addressing culture change has not been easy since most people are unclear about exactly what this means and how it should be approached (Smith, Tranfield, Foster, and Whittle, 1993). Williams et al. (1993) in Adebanjo and Kehoe

(1999) addressed that, despite the growing awareness of cultural issues, comparatively little attention has been paid to the practical, day-to-day processes involved in creating, managing and changing organisational culture. A cultural and behavioral shift in the mind-set of all participants in the construction process especially top or senior management is necessary if the construction industry is to improve its performance (Kanji and Wong, 1998; Love and Heng, 2000; Haupt and Whiteman, 2004).To bring about this change the organization must identify the elements that contribute to the development of knowledge sharing in construction organization.

An Ernst and Young study identified culture as the biggest impediment to knowledge transfer, citing the inability to change people's behaviors as the biggest hindrance to managing knowledge (Watson, 1998). In another study of 453 firms, over half indicated that organizational culture was a major barrier to success in their knowledge management initiatives (Ruggles, 1998). Studies on the role of culture in knowledge management have focused on such issues as the effect of organizational culture on knowledge sharing behaviors (DeLong & Fahey, 2000; Jarvenpaa & Staples, 2001). Similarly, Gold, Malhotra, & Segars (2001) found While studies have shown that culture influences knowledge management and, in particular, knowledge sharing, there is little research on the broader aspects of the nature and means through which organizational culture influences the overall approach taken to knowledge management in a firm.

The construction industry presents particular challenges for the design of lessons-learned systems, as it encompasses multiple contexts - those of business, technology, process and the separation of the design and construction stages, to name a few - and multiple stakeholders with often competing interests. Its processes are idiosyncratic (i.e. different parties improvise different solutions to unique challenges) and contextual (i.e. different types of projects pose different kinds of challenges).

The paper aim to build a conceptual knowledge sharing culture that supports successful lessons learned within construction organization in Indonesia.

2. CULTURE OBSTACLES TO SUCCESSFUL KNOWLEDGE SHARING

Since culture has the potential to impact on business activities of companies, knowledge management practices can also be affected by cultural. Davenport and Prusak (1998), knowledge management is the process of creating value from an organization's intangible assets. Culture are important issues for every organization in every industry. There are many different definitions of culture. The definitions differ greatly according to the research fields. Barthorpe *et al*. (2000) presented an overview of the literature published on the subject of culture and defined it simply as ''what we are and what we do as a society''. A research carried out by Abeysekera (2002) showed that culture in the construction industry is considered to be about the "characteristics of the industry, approaches to construction, competence of craftsmen and people who work in the industry, and the goals, values and strategies of the organizations they work in". Holden (2002) defined culture as varieties of common knowledge. He suggested that cross-cultural management can be viewed as a form of knowledge management, and culture as an organizational knowledge resource which can be managed.

The notion of knowledge sharing has attracted much attention in the knowledge management literature. Themes, such as attitudes to knowledge sharing, actual knowledge sharing behavior, media and means for knowledge sharing, barriers to knowledge sharing have been among the topics discussed both in the published literature and at academic and practitioner-oriented conferences. On the other hand, there have been several studies that showed an impact on knowledge management practices (Voel and Han 2005; Ford and Chan, 2003). Finestone and Snyman (2005) found that cultural diversity in companies result in barriers in knowledge sharing. Similarly, Sackmann and Friesl (2007) assessed the cultural influences on knowledge sharing behavior in project teams. They determined that different cultural backgrounds of team members due to different ethnicities, gender, national culture or functions create a context of cultural complexity, which might affect knowledge sharing in a negative way. Thiessen *et al.* (2007) found that cultural differences increase the difficulties of transferring explicit knowledge whereas the increase is smaller for those associated with the tacit knowledge transfer.
